Aadland, E.; Steene-Johannessen, J. (2012):

The use of individual cut points from treadmill walking to assess free-living moderate to vigorous physical activity in obese subjects by accelerometry: is it useful?

In: *BMC Med.Res Methodol.* 12 (1471-2288 (Linking)), S. 172. DOI: 10.1186/1471-2288-12-172.

Abstract:

ABSTRACT: BACKGROUND: Variation in counts between subjects at a given speed or work rate are the most important source of error in physical activity (PA) measurements with accelerometers. The aim of this study was to explore how the use of individual accelerometer cut points (ICPs) affected the analysis of PA field data. METHODS: We performed a treadmill calibration protocol to determine cut points for moderate to vigorous PA (MVPA) (>/=3 metabolic equivalents) and assessed free-living PA in 44 severely obese subjects using the Actigraph GT1M accelerometer. We obtained cut points in 42 subjects (11 men, mean (standard deviation) of body mass index (BMI) 39.8 (5.7), age 43.2 (9.2) years), of whom 35 had valid measurement of free-living PA (minutes of MVPA/day). Linear regression was used to analyze associations with the ICPs and time in MVPA/day. MVPA/day was also compared with values derived using a group cut point (GCP). RESULTS: Resting oxygen consumption (partial r = 0.74, p < .001), work economy (partial r = -0.76, p < .001) and BMI (partial r = 0.52, p = .001) explained 68.4% of the variation in the ICPs (F = 26.7, p < .001). The ICPs explained 79.1% of the variation in the minutes spent in MVPA/day. Moderate to vigorous PA/day derived from the ICPs vs. the GCP varied substantially (R2 = 14%, p = .023, coefficient of variation = 45.1%). CONCLUSIONS: The results indicate that the use of ICPs had a strong influence on the PA level. Two thirds of the variation in the ICPs could be explained, however, a certain degree of measurement error will be present. Thus, we are not able to conclude with respect to the most appropriate procedure for analyzing time in MVPA

Aan Het Rot, Marije; Moskowitz, D. S.; Young, Simon N. (2014):

Impulsive behaviour in interpersonal encounters: Associations with quarrelsomeness and agreeableness.

In: *Br J Psychol* 106 (1), S. 152–161. DOI: 10.1111/bjop.12070.

Abstract:

Associations between impulsivity and interpersonal behaviours have rarely been examined, even though impulsivity may disrupt the flow of social interactions. For example, it is unknown to what extent the commonly used Barratt Impulsiveness Scale (BIS-11) predicts impulsive behaviour in social situations, and how behaving impulsively during interpersonal encounters might influence levels of quarrelsomeness and agreeableness. In this study, 48 healthy working individuals completed the BIS-11 and recorded their behaviour in social situations using event-contingent recording. Record forms included items representing quarrelsome, agreeable, and impulsive behaviours. BIS-11 motor impulsiveness scores predicted impulsive behaviour in social situations. Impulsive behaviour was associated, in different interactions, with both agreeableness and quarrelsomeness. Behaving impulsively in specific interactions was negatively associated with agreeableness in participants with higher BIS-11 motor impulsiveness and positively associated with agreeableness in participants with lower BIS-11 motor impulsiveness. Impulsive quarrelsome behaviour may cause interpersonal problems. Impulsive agreeable behaviour may have positive effects in individuals with low trait impulsivity. The idea that there are between-person differences in the effects of state impulsivity on the flow of social interaction deserves further study.

Comparing the frequency of hypertension determined by peri-dialysis measurement and ABPM in hemodialysis patients.

In: *Ren Fail* 36 (5), S. 682–686. DOI: 10.3109/0886022X.2014.883933.

Abstract:

Abstract Controlling blood pressure in hemodialysis patients is crucial but not always easy. The most common blood pressure measurement method is peri-dialysis measurement, but due to interdialytic blood pressure fluctuations, we are unsure if it is the proper way for evaluating blood pressure. Some studies have shown the superiority of 24-h ambulatory blood pressure monitoring over peri-dialysis blood pressure measurement. We aimed to compare the consistency of these methods in

determining hypertension among hemodialysis patients. We studied 50 patients (mean age: 55.8 years) on regular hemodialysis in Imam Khomeini University Hospital, Tehran, Iran. Peri-dialysis blood pressure and interdialytic 24-h ambulatory blood pressure monitoring were recorded for each patient. Patients' demographic data and peri-dialysis weight were recorded too. All data were analyzed using the PASW Statistics 18.0, SPSS Inc. (Chicago, IL). There was a significant difference between pre-dialysis mean systolic blood pressure (146.1 +/- 23.3 mmHg) and mean systolic blood pressure recorded by ambulatory blood pressure monitoring (135.3 +/- 19.3 mmHg) (p = 0.001). There was also a significant difference between pre-dialysis mean diastolic blood pressure (83 +/- 14 mmHg) and mean diastolic blood pressure recorded by ambulatory blood pressure monitoring (77.3 +/- 10 mmHg) (p = 0.003). But the frequencies of hypertension measured with both methods were significantly consistent and the Kappa agreement coefficient was 0.525 (p = 0.001). Considering ambulatory blood pressure monitoring as the gold standard for blood pressure measurement, our recommendation for the best cutoff point to diagnose hypertension, with the highest sensitivity and specificity would be 135/80 mmHg for pre-dialysis blood pressure and 115/70 mmHg for post-dialysis blood pressure.

Ecological momentary assessment of fatigue, sleepiness, and exhaustion in ESKD.

In: *BMC Nephrol* 15, S. 29. DOI: 10.1186/1471-2369-15-29.

Abstract:

BACKGROUND: Many patients on maintenance dialysis experience significant sleepiness and fatigue. However, the influence of the hemodialysis (HD) day and circadian rhythms on patients' symptoms have not been well characterized. We sought to use ecological momentary assessment to evaluate day-to-day and diurnal variability of fatigue, sleepiness, exhaustion and related symptoms in thrice-weekly maintenance HD patients. METHODS: Subjects used a modified cellular phone to access an interactive voice response system that administered the Daytime Insomnia Symptom Scale (DISS). The DISS assessed subjective vitality, mood, and alertness through 19 questions using 7- point Likert scales. Subjects completed the DISS 4 times daily for 7 consecutive days. Factor analysis was conducted and a mean composite score of fatigue-sleepiness-exhaustion was created. Linear mixed regression models (LMM) were used to examine the association of time of day, dialysis day and fatigue, sleepiness, and exhaustion composite scores. RESULTS: The 55 participants completed 1,252 of 1,540 (81%) possible assessments over the 7 day period. Multiple symptoms related to mood (e.g., feeling sad, feeling tense), cognition (e.g., difficulty concentrating), and fatigue (e.g., exhaustion, feeling sleepy) demonstrated significant daily and diurnal variation, with higher overall symptom scores noted on hemodialysis days and later in the day. In factor analysis, 4 factors explained the majority of the observed variance for DISS symptoms. Fatigue, sleepiness, and exhaustion loaded onto the same factor and were highly intercorrelated. In LMM, mean composite fatigue-sleepiness-exhaustion scores were associated with dialysis day (coefficient and 95% confidence interval [CI] 0.21 [0.02 - 0.39]) and time of day (coefficient and 95% CI 0.33 [0.25 - 0.41]. Observed associations were minimally affected by adjustment for demographics and common confounders. CONCLUSIONS: Maintenance HD patients experience fatigue-sleepiness-exhaustion symptoms that demonstrate significant daily and diurnal variation. The variability in symptoms may contribute to poor symptom awareness by providers and greater misclassification bias of fatigue related symptoms in clinical studies.

The individual RDH index: a novel vector index for statistical assessment of antihypertensive treatment reduction, duration, and homogeneity.

In: *Blood Press Monit* 11 (2), S. 69–78. DOI: 10.1097/01.mbp.0000209070.07837.45.

Abstract:

We propose a new vector index for the statistical assessment of antihypertensive treatment duration and homogeneity from ambulatory blood pressure monitoring. We termed this approach for evaluating and comparing blood pressure coverage offered by antihypertensive drugs over 24 h as the reduction-duration-homogeneity index. The reduction-duration-homogeneity index is a three-component vector index that incorporates information about the reduction, duration, and homogeneity of antihypertensive treatment, as well as their statistical significance. The advantages of the reduction-duration-homogeneity index are demonstrated by several comparative examples.

Abraham, Lucy; Humphrey, Louise; Arbuckle, Rob; Dennerstein, Lorraine; Simon, James A.; Mirkin, Sebastian et al. (2014):

Qualitative cross-cultural exploration of breast symptoms and impacts associated with hormonal treatments for menopausal symptoms to inform the development of new patient-reported measurement tools.

In: *Maturitas* 80 (3), S. 273–281. DOI: 10.1016/j.maturitas.2014.11.019.

Abstract:

To explore cross-cultural experiences of women taking estrogen plus progestin therapies (EPT) and develop a symptom-based electronic diary and impact questionnaire for EPT-related breast symptoms. (1) Concept elicitation interviews were conducted with women in the US (n=14), Italy (n=15), Mexico (n=15) and China (n=15) to explore breast symptoms associated with EPT. Patients completed the Breast Sensitivity Questionnaire (BSQ) to evaluate understanding and comprehensiveness. (2) Based on concept elicitation, a 6-item eDiary (Breast Pain/Tenderness Daily Diary - BPT-DD) was generated and the BSQ modified forming the 18-item Breast Sensations Impact Questionnaire (BSIQ). (3) The measures were pilot-tested and then cognitively debriefed with US women receiving EPT. All qualitative data was subject to thematic analysis. Concept elicitation identified breast pain/tenderness, swollen breasts and sensitivity to contact as important symptoms, impacting women's emotional well-being, relationships with family/friends, social life, sleep, ability to move freely, contact, clothing and sexual activity. Experiences were relatively consistent across the country samples. Based on pilot testing and cognitive debriefing, the BPT-DD was reduced to 4 items (and renamed the Breast Pain Daily Diary - BP-DD) and the BSIQ was reduced to 13 items due to conceptual redundancy. Women taking EPT in the US, China, Mexico and Italy reported breast sensations that have a detrimental impact on quality of life. Two new measures were developed to assess the severity and impact of breast pain specific to EPT. This work highlights that EPT-related symptoms should be part of treatment decision-making, and treatments with less burdensome side effects are needed.

Abroms, L. C.; Lee, Westmaas J.; Bontemps-Jones, J.; Ramani, R.; Mellerson, J. (2013):

A content analysis of popular smartphone apps for smoking cessation.

In: *Am.J.Prev.Med.* 45 (6), S. 732–736. DOI: 10.1016/j.amepre.2013.07.008.

Abstract:

BACKGROUND: Smartphone applications (apps) are increasingly available for smoking cessation. PURPOSE: This study examined the content of popular apps for smoking cessation for both iPhone and Android operating systems in February 2012. METHODS: A total of 252 smoking-cessation apps were identified for the iPhone and 148 for the Android. Across both operating systems, the most popular apps were identified (n=47 for the iPhone and n=51 for the Android) and analyzed for their (1) approach to smoking cessation and (2) adherence to an index based on the U.S. Public Health Service's Clinical Practice Guidelines for Treating Tobacco Use and Dependence. Where available, apps were coded for frequency of downloads. The analysis took place in 2012. RESULTS: Overall, popular apps have low levels of adherence, with an average score of 12.9 of a possible 42 on the Adherence Index. No apps recommended calling a quitline, and only a handful of apps recommended using approved medications (4.1%). Android apps in the sample were downloaded worldwide between 310,800 and 1,248,000 times per month. For both the iPhone and Android, user ratings were positively associated with scores on the Adherence Index. For the iPhone, display order was also positively associated with scores on the Adherence Index. CONCLUSIONS: Apps could be improved by better integration with the Clinical Practice Guidelines and other evidence-based practices

Abuhamdeh, Sami; Csikszentmihalyi, Mihaly (2012):

Attentional involvement and intrinsic motivation.

In: *Motivation and Emotion* 36 (3), S. 257–267. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-20780-002%26site%3dehost-live;samiabuhamdeh@sehir.edu.tr.

Abstract:

The current study used the Experience Sampling Method to examine attentional involvement-the degree to which one's attention is devoted to moment-to-moment activity-as a potential mediator of two previously identified relationships within the field of intrinsic motivation: (1) the positive relationship between a balance of challenges and skills and enjoyment, and (2) the positive relationship between competence valuation and enjoyment. Multilevel, within-person analyses indicated attentional involvement fully mediated both relationships. Implications of the findings for intrinsic motivation processes are discussed. The Cox-Maze III procedure success rate: comparison by electrocardiogram, 24-hour holter monitoring and long-term monitoring.

In: *The Annals of thoracic surgery* 88 (1), S. 101–105. DOI: 10.1016/j.athoracsur.2009.04.014.

Abstract:

BACKGROUND\r\nThe detection of atrial arrhythmia recurrence is more accurate when using long-term (5 days to 3 weeks) continuous monitoring devices. In this study, we focus on the comparison of the recurrence of atrial arrhythmias in patients after the Cox-Maze III procedure obtained by three modalities: electrocardiography (ECG), 24-hour Holter monitoring, and long-term monitoring (LTM).\r\nMETHODS\r\nPatients with follow-up longer than 6 months who reported sinus rhythm while not taking antiarrhythmic drugs were eligible. Atrial arrhythmias longer than 30 s were considered a recurrence. The ECG, 24-hour Holter monitoring, and LTM (5 days) reports were ascertained and compared at the same time.\r\nRESULTS\r\nPatients (n = 291) underwent the full Cox-Maze III procedure, with 194 eligible for the study and 76 agreeing to participate. The average time to monitoring after surgery was 9.8 (+/- 7.7) months. The ECGs determined 96% of patients in sinus rhythm, Holter monitoring determined 91% in sinus rhythm, and LTM indicated 84% in sinus rhythm. Comparing ECG results and LTM results revealed that 9 patients (12%) had a significant rhythm change. Holter monitoring did not capture all the patients having events lasting longer than 1 hour. No additional information was captured by the use of LTM in patients with paroxysmal atrial fibrillation.\r\nCONCLUSIONS\r\nThis study reconfirmed that ECG overestimated the success rate after the Cox-Maze III operation by 12% compared with LTM. These changes may carry clinical significance when determining the success of the Cox-Maze III procedure and determining the medical management, including antiarrhythmic and anticoagulation therapy, of the patients who were found to have significant events.

Adamo, K. B.; Langlois, K. A.; Brett, K. E.; Colley, R. C. (2012):

Young children and parental physical activity levels: findings from the canadian health measures survey.

In: *Am.J Prev.Med.* 43 (2), S. 168–175. DOI: 10.1016/j.amepre.2012.02.032.

Abstract:

BACKGROUND: Physical inactivity is a global public health concern. The relationship between dependent children in the home and parental physical activity has not been quantified using objective measures, nor has the relative association of the physical activity levels of mothers and fathers been examined. PURPOSE: To investigate the association of children of different ages in the home on two measures of parental physical activity: daily moderate-to-vigorous physical activity (MVPA) and likelihood of meeting the guideline of 150 minutes of MVPA per week accumulated in 10-minute bouts. METHODS: Data were from the 2007-2009 Canadian Health Measures Survey (n=2315), and analyses were conducted between February and December 2011. MVPA was measured directly using accelerometry. Linear (minutes of MVPA) and logistic (meeting physical activity guidelines) regression models were performed to determine if the presence, number of children, or the age of the youngest child at home was associated with parental physical activity. All models were adjusted for parental age, marital status, household income, employment, and BMI. RESULTS: Mothers whose youngest child was aged <6 years and fathers whose youngest was aged 6-11 years engaged in fewer minutes of daily MVPA than those without dependent children. Linear regression results identified that in comparison to those without children, women whose youngest child in the home was aged <6 years participated in 7.7 minutes less activity per day (p=0.007) whereas men engaged in 5.7 fewer minutes per day, or 54 and 40 minutes per week less, respectively. Similarly, logistic regression analyses indicated that both women and men were less likely to meet guidelines if their youngest child in the home was aged <6 years (OR=0.31, 95% CI=0.11, 0.87; OR=0.34, 95% CI=0.13, 0.93). CONCLUSIONS: The physical activity level of parents with young children present in the home was lower than that of those without children. Given the many physiologic, psychological, and social benefits of healthy active living, research efforts should continue to focus on strategies to encourage parents with young children to establish or re-engage in a physically active lifestyle, not only for their own health but to model healthy behavior for the next generation

Self-criticism, dependency, and stress reactivity: an experience sampling approach to testing Blatt and Zuroff's (1992) theory of personality predispositions to depression in high-risk youth.

In: *Pers Soc Psychol Bull* 35 (11), S. 1440–1451. DOI: 10.1177/0146167209343811.

Abstract:

S. J. Blatt and D. C. Zuroff's 1992 theory of personality predispositions to depression posits that individuals who possess high levels of self-criticism and/or dependency are vulnerable to developing depression following negative events. The current study used experience sampling methodology to test this theory in a sample of 49 children ages 7 to 14. Children completed measures of dependency, self-criticism, and depressive symptoms. Subsequently, children were given a handheld computer that signaled them to complete measures of depressive symptoms and negative events at randomly selected times over 2 months. Results of hierarchical linear modeling analyses indicated that higher levels of both self-criticism and dependency were associated with greater elevations in depressive symptoms following negative events. Furthermore, each personality predisposition remained a significant predictor of such elevations after controlling for the interaction between the other personality predisposition and negative events. The results suggest that dependency and self-criticism represent distinct vulnerability factors to depression in youth.

Adams, Marc A.; Johnson, William D.; Tudor-Locke, Catrine (2013):

Steps/day translation of the moderate-to-vigorous physical activity guideline for children and adolescents.

In: *Int J Behav Nutr Phys Act* 10 (49), S. 2–11. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-18159-001%26site%3dehost-live;marc.adams@asu.edu.

Abstract:

Background: An evidence-based steps/day translation of U.S. federal guidelines for youth to engage in ≥60 minutes/day of moderate-to-vigorous physical activity (MVPA) would help health researchers, practitioners, and lay professionals charged with increasing youth's physical activity (PA). The purpose of this study was to determine the number of free-living steps/day (both raw and adjusted to a pedometer scale) that correctly classified children (6–11 years) and adolescents (12–17 years) as meeting the 60-minute MVPA guideline using the 2005–2006 National Health and Nutrition Examination Survey (NHANES) accelerometer data, and to evaluate the 12,000 steps/day recommendation recently adopted by the President's Challenge Physical Activity and Fitness Awards Program. Methods: Analyses were conducted among children (n = 915) and adolescents (n = 1,302) in 2011 and 2012. Receiver Operating Characteristic (ROC) curve plots and classification statistics revealed candidate steps/day cut points that discriminated meeting/not meeting the MVPA threshold by age group, gender and different accelerometer activity cut points. The Evenson and two Freedson age-specific (3 and 4 METs) cut points were used to define minimum MVPA, and optimal steps/day were examined for raw steps and adjusted to a pedometer-scale to facilitate translation to lay populations. Results: For boys and girls (6–11 years) with ≥ 60 minutes/day of MVPA, a range of 11,500–13,500 uncensored steps/day for children was the optimal range that balanced classification errors. For adolescent boys and girls (12–17) with ≥60 minutes/day of MVPA, 11,500–14,000 uncensored steps/day was optimal. Translation to a pedometer-scaling reduced these minimum values by 2,500 step/day to 9,000 steps/day. Area under the curve was ≥84% in all analyses. Conclusions: No single study has definitively identified a precise and unyielding steps/day value for youth. Considering the other evidence to date, we propose a reasonable 'rule of thumb' value of ≥ 11,500 accelerometer-determined steps/day for both children and adolescents (and both genders), accepting that more is better. For practical applications, 9,000 steps/day appears to be a more pedometer-friendly value. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Addy, C. L.; Trilk, J. L.; Dowda, M.; Byun, W.; Pate, R. R. (2013):

Assessing Preschool Children's Physical Activity: How Many Days of Accelerometry Measurement.

In: *Pediatr.Exerc.Sci.* 26 (1), S. 103–109.

Abstract:

The purpose of this study was to determine the minimum number of days of accelerometry required to estimate accurately MVPA and total PA in 3- to 5-year-old children. The study examined these metrics for all days, weekdays, and in-school activities. Study participants were 204 children attending 22 preschools who wore accelerometers for at least six hour per day for up to 12 days during most waking hours. The primary analysis considered the intraclass correlation coefficient (ICC) for each metric to estimate the number of days required to attain a specified reliability. The ICC estimates are 0.81 for MVPA-all days, 0.78 for total PA-all days, 0.83 for MVPA-weekdays, 0.80 for total PA-weekdays, 0.81 for in-school MVPA, and 0.84 for in-school total PA. We recommend a full seven days of measurement whenever possible, but researchers can achieve acceptable reliability with fewer days as indicated by the Spearman-Brown prophecy: 3-4 days for any weekday measure and 5-6 days for the all-days measures

Adibi, Sasan (2014):

Biomedical sensing analyzer (BSA) for mobile-health (mHealth)-LTE.

In: *IEEE J Biomed Health Inform* 18 (1), S. 345–351. DOI: 10.1109/JBHI.2013.2262076.

Abstract:

The rapid expansion of mobile-based systems, the capabilities of smartphone devices, as well as the radio access and cellular network technologies are the wind beneath the wing of mobile health (mHealth). In this paper, the concept of biomedical sensing analyzer (BSA) is presented, which is a novel framework, devised for sensor-based mHealth applications. The BSA is capable of formulating the Quality of Service (QoS) measurements in an end-to-end sense, covering the entire communication path (wearable sensors, link-technology, smartphone, cell-towers, mobile-cloud, and the end-users). The characterization and formulation of BSA depend on a number of factors, including the deployment of application-specific biomedical sensors, generic link-technologies, collection, aggregation, and prioritization of mHealth data, cellular network based on the Long-Term Evolution (LTE) access technology, and extensive multidimensional delay analyses. The results are studied and analyzed in a LabView 8.5 programming environment.

Adiyaman, Ahmet; Dechering, Dirk G.; Boggia, José; Li, Yan; Hansen, Tine W.; Kikuya, Masahiro et al. (2008):

Determinants of the ambulatory arterial stiffness index in 7604 subjects from 6 populations.

In: *Hypertension* 52 (6), S. 1038–1044. DOI: 10.1161/HYPERTENSIONAHA.108.119511.

Abstract:

The ambulatory arterial stiffness index (AASI) is derived from 24-hour ambulatory blood pressure recordings. We investigated whether the goodness-of-fit of the AASI regression line in individual subjects (r(2)) impacts on the association of AASI with established determinants of the relation between diastolic and systolic blood pressures. We constructed the International Database on the Ambulatory Blood Pressure in Relation to Cardiovascular Outcomes (7604 participants from 6 countries). AASI was unity minus the regression slope of diastolic on systolic blood pressure in individual 24-hour ambulatory recordings. AASI correlated positively with age and 24-hour mean arterial pressure and negatively with body height and 24-hour heart rate. The single correlation coefficients and the mutually adjusted partial regression coefficients of AASI with age, height, 24-hour mean pressure, and 24-hour heart rate increased from the lowest to the highest quartile of r(2). These findings were consistent in dippers and nondippers (night:day ratio of systolic pressure >or=0.90), women and men, and in Europeans, Asians, and South Americans. The cumulative z score for the association of AASI with these determinants of the relation between diastolic and systolic blood pressures increased curvilinearly with r(2), with most of the improvement in the association occurring above the 20th percentile of r(2) (0.36). In conclusion, a better fit of the AASI regression line enhances the statistical power of analyses involving AASI as marker of arterial stiffness. An r(2) value of 0.36 might be a threshold in sensitivity analyses to improve the stratification of cardiovascular risk.

Affuso, Olivia; Stevens, June; Catellier, Diane; McMurray, Robert G.; Ward, Dianne S.; Lytle, Leslie et al. (2011):

Validity of self-reported leisure-time sedentary behavior in adolescents.

In: *J Negat Results Biomed* 10 (2), S. 1–9.

Abstract:

BACKGROUND:

To evaluate the concordance between leisure-time sedentary behavior in adolescents assessed by an activity-based questionnaire and accelerometry. A convenience sample of 128 girls and 73 boys, 11-15 years of age (12.6 ± 1.1 years) from six states across the United States examined as part of the feasibility studies for the Trial of Activity in Adolescent Girls (TAAG). Three days of self-reported time spent watching TV/videos, using computers, playing video/computer games, and talking on the phone was assessed using a modified version of the Self-Administered Physical Activity Checklist (SAPAC). Criterion measure of sedentary behavior was via accelerometry over three days using a cut point of < 50 counts · 30 sec^{-1} epoch. Comparisons between sedentary behavior by the two instruments were made.

RESULTS:

Adolescents generally underestimated minutes of sedentary behavior compared to accelerometry-measured minutes. The overall correlation between minutes of sedentary behavior by self-report and accelerometry was weak (Spearman r = 0.14; 95% CI 0.05, 0.23). Adjustment of sedentary minutes of behavior for total minutes assessed using either percentages or the residuals

method tended to increase correlations slightly. However, regression analyses showed no significant association between self-reported sedentary behavior and minutes of sedentary behavior captured via accelerometry.

DISCUSSION:

These findings suggest that the modified 3-day Self-Administered Physical Activity Checklist is not a reliable method for assessing sedentary behavior. It is recommended that until validation studies for self-report instruments of sedentary behavior demonstrate validity, objective measures should be used.

Afsar, Baris (2013):

The impact of different anthropometric measures on sustained normotension, white coat hypertension, masked hypertension, and sustained hypertension in patients with type 2 diabetes.

In: *Endocrinol Metab (Seoul)* 28 (3), S. 199–206. DOI: 10.3803/EnM.2013.28.3.199.

Abstract:

BACKGROUND: Many studies have aimed to determine whether body mass index (BMI), waist circumference (WC), or waist to hip ratio (WHR) best predicts hypertension in diabetic patients, with conflicting results. However, no study has examined the specific relationship between these anthropometric parameters with sustained normotension (SNT), white coat hypertension (WCHT), masked hypertension (MHT), and sustained hypertension (SHT) based on office and ambulatory blood pressure (BP) measurements in these patients. METHODS: Patients with newly diagnosed type 2 diabetes underwent the following procedures: history taking, measurements of anthropometric parameters, office and ambulatory BP measurements, physical examination, laboratory analysis, and random and 24-hour urine analysis. RESULTS: In total, there were 65 dippers and 37 nondipper patients. None of the anthropometric parameters were different between the dippers and the nondippers. There were 25 patients with SNT, 32 with WCHT, seven with MHT, and 38 with SHT. A comparison of anthropometric parameters between these four groups of patients showed that WC (P=0.016) and WHR (P=0.015) were different among all groups. According to regression analysis, only BMI was independently related with MHT (odds ratio [OR], 1.373, P=0.022), whereas only WC has been associated with SHT (OR, 1.321, P=0.041). CONCLUSION: Among anthropometric parameters, only WC and WHR were different in SNT, WCHT, MHT, and SHT in newly diagnosed patients with type 2 diabetes.

Afsar, Baris; Elsurer, Rengin (2014):

The relationship between magnesium and ambulatory blood pressure, augmentation index, pulse wave velocity, total peripheral resistance, and cardiac output in essential hypertensive patients.

In: *J Am Soc Hypertens* 8 (1), S. 28–35. DOI: 10.1016/j.jash.2013.10.006.

Abstract:

Magnesium levels have been shown to be associated with elevated blood pressure (BP), endothelial dysfunction, insulin resistance, vascular calcification, inflammation, and atherosclerosis. It was also demonstrated that patients with hypertension have increased inflammation, insulin resistance, and endothelial dysfunction. However, the relationship between magnesium, ambulatory BPs, and central hemodynamic parameters were not evaluated extensively. Serum magnesium levels, ambulatory blood pressures, augmentation index (Aix), pulse wave velocity, total peripheral resistances, and cardiac output were measured for all patients. In total, 184 essential hypertension patients were enrolled. In univariate analysis, magnesium levels were correlated with hemoglobin (r = +0.155; P = .037), albumin (r = +0.180; P = .018), pulse pressure (daytime; r = -0.170; P = .021), pulse pressure (24-hour; r = -0.156; P = .035), Aix (daytime; r = -0.223; P = .002), Aix (nighttime; r = -0.169; P = .022), and Aix (24-hour; r = -0.247; P = .001). In regression analysis, magnesium levels were independently and conversely associated with daytime Aix (P < .0001), nighttime Aix (P = .019), and 24-hour Aix (P < .0001). We suggest that magnesium levels were associated with Aix but not with total peripheral resistances, pulse wave velocity, cardiac output, and central BPs. The unique mechanisms related with magnesium and Aix but not shared by other central parameters needs to be determined.

Agarwal, Rajiv (2009):

Volume-associated ambulatory blood pressure patterns in hemodialysis patients.

In: *Hypertension* 54 (2), S. 241–247. DOI: 10.1161/HYPERTENSIONAHA.109.136366.

Abstract:

Although volume excess causes hypertension, whether it also affects circadian patterns of arterial pressures among hemodialysis patients remains unknown. To test the notion of whether volume overload is associated with a unique blood pressure (BP) \"signature,\" a posthoc analysis was performed among 145 patients participating in the Dry-Weight Reduction in Hypertensive Hemodialysis Patients randomized, controlled trial. Using 400 ambulatory BP recordings over 8 weeks composed of 35 302 measurements, the trended cosinor model was found to be the best descriptor of BP chronobiology. The trended cosinor model may be described as a pattern of sinusoidal oscillation around a straight line with an upward trend during the interdialytic period that has an intercept at the postdialysis time. Augmented volume removal therapy reduced the intercept systolic BP and increased the rate of rise in systolic BP over the interdialytic interval but had no effect on the systolic BP fluctuation (amplitude). Thus, an elevated intercept and blunted slope pattern characterize the \"volume-overload BP pattern\" on ambulatory BP monitoring. Similar changes were seen for diastolic BP. Augmented volume removal therapy neither restored dipping nor was associated with a lag phenomenon for either the wake or the sleep systolic BP. Lowering of systolic BP was greater than diastolic BP such that pulse pressure was reduced. An observational cohort of 37 patients followed for 6 months confirmed these findings. Randomized trials are now needed to evaluate the clinical impact of augmented volume removal therapy on hard outcomes, because reduction of pulse pressure with this simple expedient has the potential to improve survival in hemodialysis patients.

Agarwal, Rajiv; Light, Robert P. (2008):

Physical activity and hemodynamic reactivity in chronic kidney disease.

In: *Clinical journal of the American Society of Nephrology : CJASN* 3 (6), S. 1660–1668. DOI: 10.2215/CJN.02920608.

Abstract:

BACKGROUND AND OBJECTIVES\r\nPatients with chronic kidney disease (CKD) have an elevated cardiovascular risk. This study was designed to understand better the presence and strength of the relationship between physical activity and BP and to explore determinants of hemodynamic reactivity.\r\nDESIGN, SETTING, PARTICIPANTS, & MEASUREMENTS\r\nTwenty-four patients with CKD (mean age 69.5 yr; 3.1 antihypertensive drugs; estimated GFR 47 ml/min per 1.73 m(2), albumin/creatinine ratio 403 mg/g) were studied on three occasions during a 6-wk period with 24-h ambulatory BP monitoring and simultaneous activity monitoring with wrist actigraphy.\r\nRESULTS\r\nNondippers were found have a greater level of sleep activity compared with dippers, although the awake activity level was similar (7.06 versus 6.73) between groups (P = 0.042 for interaction). In 3587 BP activity pairs, hemodynamic reactivity was variable between individuals (systolic BP reactivity 1.06 [SD 10.50]; diastolic BP reactivity 0.89 [SD 7.80] heart rate reactivity 1.18 [SD 11.00]); those who were more sedentary had a greater increment in systolic BP compared with those who were less sedentary. Antihypertensive drugs blunted hemodynamic reactivity. Hemodynamic reactivity was greatest between 12 a.m. and 8 a.m., making this a vulnerable period for cardiovascular events.\r\nCONCLUSIONS\r\nGreater hemodynamic reactivity in sedentary people with CKD offers a possible and thus far unrecognized mechanism of cardiovascular damage. Besides reducing BP, antihypertensive drugs reduce hemodynamic reactivity, which offers another plausible mechanism of cardiovascular protection with their use.

Agarwal, Rajiv; Light, Robert P. (2010):

Physical activity is a determinant of circadian blood pressure variation in chronic kidney disease.

In: *American journal of nephrology* 31 (1), S. 15–23. DOI: 10.1159/000252878.

Abstract:

BACKGROUND\r\nCircadian variation in blood pressure (BP), which is commonly blunted among patients with chronic kidney disease (CKD), has been associated with increased cardiovascular risk. The causes of this blunted circadian variation remain incompletely understood.\r\nMETHODS\r\nWe hypothesized that physical activity is a determinant of circadian BP variation. Accordingly, we studied 101 patients with CKD (mean age 69 years, mostly men) with 24-hour ambulatory BP monitoring and simultaneous monitoring of physical activity on 2 occasions 4 weeks apart.\r\nRESULTS\r\nMeasured by wrist actigraphy, a higher level of physical activity was associated with lower overall mean BP. A higher level of activity also altered the circadian systolic BP rhythm; this alteration was characterized by both a higher amplitude of variation (and thus greater dipping) and restoration of acrophase (time at peak BP) to a less vulnerable period for cardiovascular events. Among the most sedentary

participants, both systolic and pulse pressure acrophases were seen in the early hours of the morning which is also the most vulnerable period for cardiovascular events.\r\nCONCLUSION\r\nPhysical activity is an independent determinant of circadian variation in BP. We speculate that among patients with CKD, a sedentary lifestyle, rather than non-dipping, mediates increased cardiovascular risk.

Agarwal, Rajiv; Light, Robert P. (2010):

The effect of measuring ambulatory blood pressure on nighttime sleep and daytime activity--implications for dipping.

In: *Clinical journal of the American Society of Nephrology : CJASN* 5 (2), S. 281–285. DOI: 10.2215/CJN.07011009.

Abstract:

BACKGROUND AND OBJECTIVES\r\nAmbulatory blood pressure (BP) monitoring is commonly used to assess the circadian pattern of BP. Circadian BP pattern is influenced by physical activity and sleep cycle. The effect of BP monitoring itself on the level of physical activity and sleep remains unknown. If BP monitoring affects these parameters, then monitoring itself may influence the circadian BP pattern.\r\nDESIGN, SETTING, PARTICIPANTS, & MEASUREMENTS\r\nTo assess the effect of ambulatory BP monitoring on sleep duration, sleep efficiency, and daytime activity, we measured physical activity using wrist actigraphy in 103 veterans with chronic kidney disease. After 6 to 7 days of continuous activity monitoring, participants underwent ambulatory BP monitoring with simultaneous actigraphy. The above experiment was repeated after 1 mo.\r\nRESULTS\r\nAmong the top tertile of patients (most sleep), when wearing ambulatory BP patients spent less time in bed at night (-92 min, P < 0.0001), were less asleep during those hours (-98 min, P < 0.0001), and had reduced sleep efficiency (82% versus 77%, -5% P = 0.02). On the day of ambulatory BP monitoring, patients were more sedentary during waking hours (+27 minutes, P = 0.002). During ambulatory BP monitoring, waking after sleep onset more than median was associated with greater odds for nondipping (odds ratio 10.5, P = 0.008).\r\nCONCLUSIONS\r\nAmbulatory BP monitoring is associated with disturbed sleep and reduced physical activity, characteristics that influence dipping. Ambulatory BP monitoring may itself induce nondipping and may thus mitigate the prognostic significance of the dipping phenomenon.

Out-of-office blood pressure monitoring in chronic kidney disease.

In: *Blood Press Monit* 14 (1), S. 2–11. DOI: 10.1097/MBP.0b013e3283262f58.

Abstract:

Blood pressure (BP) control is vital to the management of patients with chronic kidney disease (CKD) yet most treatment decisions use BPs obtained in the clinic. The purpose of this report is to review the importance of self-measured and automatic ambulatory BPs in the management of patients with CKD. Compared with clinic-obtained BPs, self-measured BP more accurately defines hypertension in CKD. Masked hypertension seems to be associated with higher risk of end-stage renal disease in CKD patients. Conversely, white-coat hypertension seems to be associated with better renal outcomes than those who have persistent hypertension. Ambulatory BP monitoring is the only tool to monitor BP during sleep, diagnose nondipping, and, as self-measured BPs, have greater prognostic power in CKD compared with clinic BP. In hemodialysis patients, self-measured BP, but not pre/post-dialysis BP, shares the combination of high sensitivity and high specificity of greater than 80% to make a diagnosis of hypertension with the reference standard of ambulatory BP monitoring. In addition, self-measured and ambulatory BPs seem to be better correlates of left-ventricular hypertrophy and mortality in hemodialysis patients compared with pre/post-dialysis BP. Emerging data suggest that out-of-office BP monitoring is superior to BP obtained in the clinic when predicting target-organ damage and prognosis. Out-of-office BP monitoring is recommended for the management of hypertension in all stages of CKD.

Prediction of energy expenditure from wrist accelerometry in people with and without Down syndrome.

In: *Adapt.Phys.Activ.Q.* 29 (2), S. 179–190. Online verfügbar unter PM:22467836.

Abstract:

This study examined the relationship between energy expenditure and wrist accelerometer output during walking in persons with and without Down syndrome (DS). Energy expenditure in metabolic equivalent units (METs) and activity-count rate were respectively measured with portable spirometry and a uniaxial wrist accelerometer in 17 persons with DS (age: 24.7+/-6.9 years; 9 women) and 21 persons without DS (age: 26.3+/-5.2 years; 12 women) during six over-ground walking trials. Combined groups regression showed that the relationship between METs and activity-count rate differed between groups (p<.001). Separate models for each group included activity-count rate and squared activity-count rate as significant predictors of METs (p</=.005). Prediction of METs appeared accurate based on Bland-Altman plots and the lack of between-group difference in mean absolute prediction error (DS: 17.07%; Non-DS: 18.74%). Although persons with DS show altered METs to activity-count rate relationship during walking, prediction of their energy expenditure from wrist accelerometry appears feasible

Occupational burnout and severe injuries: An eight-year prospective cohort study among Finnish forest industry workers.

In: *Journal of occupational health* 55 (6), S. 450–457.

Abstract:

OBJECTIVES:

Burnout is a psychological consequence of prolonged work stress. Studies have shown that it is related to physical and mental disorders. The safety outcomes of burnout have been studied to a lesser extent and only in the work context. This study explored the effect of burnout on future severe injuries regardless of their context.

METHODS:

A total of 10,062 forest industry employees (77% men, 63% manual workers) without previous injuries participated in 1996 or 2000 in the "Still Working" study examining the work-related antecedents of health and mortality. Burnout was assessed using the Maslach Burnout Inventory-General Survey. Injuries leading to death or hospitalization were regarded as severe. We extracted such injuries from independent national registers. The relationship between burnout and new injuries was analyzed using Cox proportional regression. The analyses were adjusted for age, sex, marital status, and occupational status.

RESULTS:

There were 788 new injuries over eight years. Injuries were more common among male and manual workers. After adjustments, each one-unit increase in the burnout score was related to a 9% increase in the risk of injury (95% confidence interval: 1.2-1.17). Experiencing symptoms at least monthly was related to a 1.18-fold adjusted injury risk (95% CI: 1.2-1.36). Of the subscales of burnout, exhaustion and cynicism but not lack of professional efficacy predicted injuries after adjustments.

CONCLUSIONS:

In addition to mental and physical disorders, burnout predicts severe injuries. Developing work conditions and optimizing workload may enhance safety and decrease health expenses related to all injuries.

Ainsworth, J.; Palmier-Claus, J. E.; MacHin, M.; Barrowclough, C.; Dunn, G.; Rogers, A. et al. (2013):

A Comparison of two delivery modalities of a mobile phone-based assessment for serious mental illness: native smartphone application vs text-messaging only implementations.

In: *J Med Internet Res* 15 (4), S. e60. DOI: 10.2196/jmir.2328.

Abstract:

BACKGROUND: Mobile phone-based assessment may represent a cost-effective and clinically effective method of monitoring psychotic symptoms in real-time. There are several software options, including the use of native smartphone applications and text messages (short message service, SMS). Little is known about the strengths and limitations of these two approaches in monitoring symptoms in individuals with serious mental illness. OBJECTIVE: The objective of this study was to compare two different delivery modalities of the same diagnostic assessment for individuals with non-affective psychosis-a native smartphone application employing a graphical, touch user interface against an SMS text-only implementation. The overall hypothesis of the study was that patient participants with sewrious mental illness would find both delivery modalities feasible and acceptable to use, measured by the quantitative post-assessment feedback questionnaire scores, the number of data points completed, and the time taken to complete the assessment. It was also predicted that a native smartphone application would (1) yield a greater

number of data points, (2) take less time, and (3) be more positively appraised by patient participant users than the text-based system. METHODS: A randomized repeated measures crossover design was employed. Participants with currently treated Diagnostic and Statistical Manual (Fourth Edition) schizophrenia or related disorders (n=24) were randomly allocated to completing 6 days of assessment (four sets of questions per day) with a native smartphone application or the SMS text-only implementation. There was then a 1-week break before completing a further 6 days with the alternative delivery modality. Quantitative feedback questionnaires were administered at the end of each period of sampling. RESULTS: A greater proportion of data points were completed with the native smartphone application in comparison to the SMS text-only implementation (beta = -.25, SE=.11, P=.02), which also took significantly less time to complete (beta =.78, SE= .09, P<.001). Although there were no significant differences in participants' quantitative feedback for the two delivery modalities, most participants reported preferring the native smartphone application (67%; n=16) and found it easier to use (71%; n=16). 33% of participants reported that they would be willing to complete mobile phone assessment for 5 weeks or longer. CONCLUSIONS: Native smartphone applications and SMS text are both valuable methods of delivering real-time assessment in individuals with schizophrenia. However, a more streamlined graphical user interface may lead to better compliance and shorter entry times. Further research is needed to test the efficacy of this technology within clinical services, to assess validity over longer periods of time and when delivered on patients' own phones

Comparative Study of the Routine Daily Usability of FoodLog: A Smartphone-based Food Recording Tool Assisted by Image Retrieval.

In: *J Diabetes Sci Technol* 8 (2), S. 203–208. DOI: 10.1177/1932296814522745.

Abstract:

The health care field is focusing considerable attention on dietary control, which requires that individuals record what they eat. We have developed a novel smartphone application called FoodLog, a multimedia food recording tool that allows users to take photos of their meals and to produce textual food records. Unlike conventional smartphone-based food recording tools, FoodLog allows users to employ meal photos to help them to input textual descriptions based on image retrieval. In this study, we conducted usability experiments to evaluate the routine daily use of FoodLog systems with and without image-based assistance. We produced 2 food recording tools: FoodLog with image-based assistance (FL-I) and FoodLog with text input only (FL-T). We recruited 18 university students (age = 18-24 years), all of whom performed food recording for the first time. The participants used FoodLog on a daily basis for 1 month. In the subjective evaluation, FL-I had higher average scores for questions related to ease of use, fun, frequency of browsing, and intention to continue. In particular, the latter 3 factors received significantly higher scores with FL-I than with FL-T. In the quantitative evaluation, the daily average number of meal events and food records did not differ significantly between FL-I and FL-T. A detailed analysis of the individual records showed that 1 participant produced 3 times as many records using FL-I compared with FL-T. The subjective assessment showed that our new tool, which fully exploits the use of images, is a promising method for food recording.

Are implantable loop recorders useful in detecting arrhythmias in children with unexplained syncope?

In: *Pacing and clinical electrophysiology : PACE* 32 (11), S. 1422–1427. DOI: 10.1111/j.1540-8159.2009.02486.x.

Abstract:

INTRODUCTION\r\nSyncope and presyncope are symptoms that occur infrequently in children, are unpredictable, and represent a diagnostic challenge to the physician. Conventional diagnostic investigations are often unable to establish a diagnosis, making it difficult to determine patient risk and direct appropriate therapy. The implantable loop recorder (ILR) is a medical device that was created for prolonged monitoring of heart rate and rhythm and has been used in a limited number of pediatric studies in which the cause of the syncope is unknown.\r\nMETHODS\r\nThis is a retrospective review of the clinical, surgical, and follow-up data of patients who had ILR devices implanted after conventional testing failed to identify a cause for their symptoms.\r\nRESULTS\r\nThe diagnostic yield of the ILR device in unmasking the cause for symptoms in our patient cohort was 64%. In our study, manually activated events accounted for 71% of all documented episodes and 68% of the cases involving hemodynamically important arrhythmias or transient rhythm changes. The ILR device can be safely implanted and explanted in children without significant morbidity, in most cases. None of our patients experienced any long-term adverse events associated with placement of the device and all were alive at last follow-up.\r\nCONCLUSIONS\r\nThe use of the ILR device is a useful tool to help unmask arrhythmias as a cause of unexplained syncope in children. Patient selection for who should and should not have an ILR device implanted will continue to influence its diagnostic utility and generate controversy among stakeholders.

Effects of chronic khat use on cardiovascular, adrenocortical, and psychological responses to stress in men and women.

In: *The American Journal on Addictions* 22 (2), S. 99–107.

Abstract:

Background: Khat is a psychostimulant plant widely used in Africa and its use has been growing rapidly in Europe and North America. Objectives:We investigated effects of chronic khat (Catha edulis) use on cardiovascular, adrenocortical, and psychological responses to acute stress. Methods: Chronic khat users and nonusers were compared on physiological measures and mood reports in a cross-sectional, mixed design. Measurements were conducted during 24-hour ambulatory monitoring and during a laboratory session. A total of 152 participants (58 women) were recruited by flyers posted around Sana'a University campus and the surrounding community in Sana'a, Yemen. Salivary cortisol and self-report measures were collected during a 24-hour ambulatory period prior to a lab testing session. In addition, blood pressures (BP), salivary cortisol, and mood measures were assessed during rest and in response to acute mental stress. Results: Khat users exhibited enhanced evening and attenuated morning cortisol levels, reflecting a blunted diurnal pattern of adrenocortical activity compared to nonusers. Khat users reported greater negative affect during the ambulatory period and during the laboratory session. In addition, they exhibited attenuated BP responses to stress. Conclusions and Scientific Significance: These novel results demonstrate altered adrenocortical activity and increased dysphoric mood among khat users. The extent to which these associations are due to effects of chronic khat use per se or instead reflect predisposing risk factors for khat use is yet to be determined. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Among overweight middle-aged men, first-borns have lower insulin sensitivity than second-borns.

In: *Sci Rep* 4, S. 3906. DOI: 10.1038/srep03906.

Abstract:

We aimed to assess whether birth order affects metabolism and body composition in overweight middle-aged men. We studied 50 men aged 45.6 +/- 5.5 years, who were overweight (BMI 27.5 +/- 1.7 kg/m(2)) but otherwise healthy in Auckland, New Zealand. These included 26 first-borns and 24 second-borns. Insulin sensitivity was assessed by the Matsuda method from an oral glucose tolerance test. Other assessments included DXA-derived body composition, lipid profiles, 24-hour ambulatory blood pressure, and carotid intima-media thickness. First-born men were 6.9 kg heavier ($p = 0.013$) and had greater BMI (29.1 vs 27.5 kg/m(2); $p = 0.004$) than second-borns. Insulin sensitivity in first-born men was 33% lower than in second-borns (4.38 vs

6.51; p = 0.014), despite adjustment for fat mass. There were no significant differences in ambulatory blood pressure, lipid profile or carotid intima-media thickness between first- and second-borns. Thus, first-born adults may be at a greater risk of metabolic and cardiovascular diseases.

Monitoring Functional Capability of Individuals with Lower Limb Amputations Using Mobile Phones.

In: *PLoS One* 8 (6), S. e65340. DOI: 10.1371/journal.pone.0065340.

Abstract:

To be effective, a prescribed prosthetic device must match the functional requirements and capabilities of each patient. These capabilities are usually assessed by a clinician and reported by the Medicare K-level designation of mobility. However, it is not clear how the K-level designation objectively relates to the use of prostheses outside of a clinical environment. Here, we quantify participant activity using mobile phones and relate activity measured during real world activity to the assigned K-levels. We observe a correlation between K-level and the proportion of moderate to high activity over the course of a week. This relationship suggests that accelerometry-based technologies such as mobile phones can be used to evaluate real world activity for mobility assessment. Quantifying everyday activity promises to improve assessment of real world prosthesis use, leading to a better matching of prostheses to individuals and enabling better evaluations of future prosthetic devices

Neuroticism developmental courses - implications for depression, anxiety and everyday emotional experience; a prospective study from adolescence to young adulthood.

In: *BMC Psychiatry* 14 (1), S. 210. DOI: 10.1186/s12888-014-0210-2.

Abstract:

BACKGROUND: Neuroticism is frequently discussed as a risk factor for psychopathology. According to the maturity principle, neuroticism decreases over the course of life, but not uniformly across individuals. However, the implications of differences in personality maturation on mental health have not been well studied so far. Hence, we hypothesized that different forms of neuroticism development from adolescence to young adulthood are associated with differences in depression, anxiety and everyday emotional experience at the age of 25. METHODS: A sample of 266 adolescents from the general population was examined three times over ten years (age at T0: 15, T1: 20 and T2: 25) using questionnaires, interviews and ecological momentary assessment (EMA). At all measurement points, neuroticism was assessed with the NEO inventory. At T2, diagnoses of major depression and anxiety disorders were captured with a structured clinical interview (M-CIDI). Phone-based EMA was used to assess emotional experience and affective instability over a two-week period at T2. RESULTS: The best fitting model was a latent class growth analysis with two groups of neuroticism development. Most individuals (n = 205) showed moderate values whereas 61 participants were clustered into a group with elevated neuroticism levels. In both groups neuroticism significantly changed during the ten year period with a peak at the age of 20. Individuals with a higher absolute level were at 14-fold increased risk for depression and 7-fold risk for anxiety disorders at the age of 25. In EMA, increased negative affect and arousal as well as decreased positive emotions were found in this high group. CONCLUSIONS: Other than expected, personality did not mature in our sample. However, there was a significant change of neuroticism values from adolescence to young adulthood. Further, over 20% of our participants showed a neuroticism development which was associated with adverse outcomes such as negatively toned emotional experience and a heightened risk to suffer from depressive and anxiety disorders in young adulthood. These high-risk persons need to be identified early to provide interventions supporting continuous personality maturation.

Alexander, Gerianne M.; Saenz, Janet (2012):

Early androgens, activity levels and toy choices of children in the second year of life.

In: *Hormones and Behavior* 62 (4), S. 500–504. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-26107-001%26site%3dehost-live;galexander@tamu.edu.

Abstract:

The hypothesis that stronger preferences for active play styles contribute to stronger preferences for male-typical toys was examined in 47 boys and 37 girls at 19-months of age using ambulatory monitoring technology (i.e., actigraphy) to measure activity levels during contact with male-typical, female-typical, and gender-neutral toys. Digit ratios and salivary testosterone levels were measured earlier in children at 3-4 months of age. There were no significant sex differences in digit ratios, salivary testosterone levels, or overall activity levels during toy play. In contrast, contact times showed large sex differences in infants' toy preferences. The within-sex comparisons showed that infant girls had significant preferences for female-typical toys over male-typical toys, whereas infant boys showed only a small preference for male-typical toys over female-typical toys. More male-typical digit ratios in early infancy predicted higher activity counts during toy play and less female-typical toy preferences in girls. However, in both sexes, activity levels were unrelated to toy preferences suggesting that factors other than activity level preferences contribute to the early emergence of gender-linked toy preferences. Using smartphone applications as hand therapy interventions.

In: *J Hand Ther*, S. 254–256. DOI: 10.1016/j.jht.2013.12.009.

Abstract:

In the hand therapy clinic, smartphones can be used as an educational resource, to view a photo or video of a home exercise program, or as a method of electronically documenting progress related to healing from an injury. Smartphone applications may also serve as appropriate therapy interventions to address deficits often presenting with common hand injuries. For individuals with trapeziometacarpal arthrosis, gaming can encourage radial abduction range of motion and neuromuscular control required for joint stability. People with distal radius fractures may benefit from smartphone applications for range of motion and proprioceptive training. These treatments may assist with addressing client-centered goals and be motivating in the current technology driven times.

Accuracy of accelerometer regression models in predicting energy expenditure and METs in children and youth.

In: *Pediatr.Exerc.Sci.* 24 (4), S. 519–536. Online verfügbar unter PM:23196761.

Abstract:

This study examined the validity of commonly used regression equations for the Actigraph and Actical accelerometers in predicting energy expenditure (EE) in children and adolescents. Sixty healthy (8-16 yrs) participants completed four treadmill (TM) and five self-paced activities of daily living (ADL). Four Actigraph (AG) and three Actical (AC) regression equations were used to estimate EE. Bias (+/- 95% CI) and root mean squared errors were used to assess the validity of the regression equations compared with indirect calorimetry. For children, the Freedson (AG) model accurately predicted EE for all activities combined and the Treuth (AG) model accurately predicted EE for TM activities. For adolescents, the Freedson model accurately predicted EE for TM activities and the Treuth model accurately predicted EE for all activities and for TM activities. No other equation accurately estimated EE. The percent agreement for the AG and AC equations were better for light and vigorous compared with moderate intensity activities. The Trost (AG) equation most accurately classified all activity intensity categories. Overall, equations yield inconsistent point estimates of EE

Mobile technologies in the early detection of cognitive decline.

In: *PLoS One* 9 (12), S. e112197. DOI: 10.1371/journal.pone.0112197.

Abstract:

The identification of biological and pathophysiological processes implicated in different forms of dementia is itself dependent on reliable descriptions of cognitive performance and capacities. However, traditional instruments are often unable to detect subtle declines in cognitive functions due to natural variation at the time of testing. Mobile technologies permit the repeated assessment of cognitive functions and may thereby provide more reliable descriptions of early cognitive difficulties that are

inaccessible to clinic or hospital-based instruments. This assessment strategy is also able to characterize in real-time the dynamic associations between cognitive performance and specific daily life behaviors or activities. In a cohort of elderly rural residents, 60 individuals were administered neuropsychological and neuroimaging exams as well as a one-week period of electronic ambulatory monitoring of behavior, semantic memory performance, and daily life experiences. Whereas imaging markers were unrelated to traditional neuropsychological test scores, they were significantly associated with mobile assessments of semantic memory performance. Moreover, certain daily life activities such as reading or completing crossword puzzles were associated with increases in semantic memory performance over the subsequent hours of the same day. The revolution in mobile technologies provides unprecedented opportunities to overcome the barriers of time and context that characterize traditional hospital and clinical-based assessments. The combination of both novel and traditional methods should provide the best opportunity for identifying the earliest risk factors and biomarkers for Alzheimer's disease and other forms of dementia.

Allen, Kelli D.; Golightly, Yvonne M.; Olsen, Maren K. (2006):

Pilot study of pain and coping among patients with osteoarthritis: a daily diary analysis.

In: *Journal of clinical rheumatology : practical reports on rheumatic & musculoskeletal diseases* 12 (3), S. 118–123. DOI: 10.1097/01.rhu.0000221801.63880.3f.

Abstract:

BACKGROUND AND OBJECTIVES\r\nFew studies have examined patterns of pain and coping among patients with osteoarthritis (OA). This pilot study used a daily diary approach to examine pain and coping strategy use among white and nonwhite veterans with OA.\r\nMETHODS\r\nParticipants (23 white, 13 nonwhite; 89% male; mean age = 63 years) completed diaries of pain (10-cm visual analog scale) and coping (total, problem-focused, and emotion-focused) for 30 days. Analyses examined relationships of mean self-reported pain severity and variability with coping strategy use as well as racial differences in these associations.\r\nRESULTS\r\nThe mean pain level (4.46 [scale of 0-10], standard deviation [SD] = 2.12) and mean within-subject pain variance (1.94, SD = 1.79) were similar between white and nonwhite participants. With respect to pain variability, 2 distinct subgroups were observed, with approximately half of participants reporting high variability and half reporting low variability. The mean total coping score (on a scale of 0-7) was 2.62 (SD = 1.77), with problem-focused strategies being used more often than emotion-focused. There were no significant associations between coping (total, problem-focused, and emotion-focused) and mean pain severity, but the direction of these relationships differed according to race.\r\nCONCLUSION\r\nResults of this pilot study showed considerable between-subject variability in pain and coping strategy use as well as some racial differences. Medical treatment and self-management approaches may be improved if they can be tailored according to patients' pain patterns and preferred coping strategies.

Randomized controlled pilot study testing use of smartphone technology for obesity treatment.

In: *J Obes* 2013, S. 151597. DOI: 10.1155/2013/151597.

Abstract:

BACKGROUND: The established interventions for weight loss are resource intensive which can create barriers for full participation and ultimate translation. The major goal of this pilot study was to evaluate the feasibility, acceptability, and preliminary efficacy of theoretically based behavioral interventions delivered by smartphone technology. METHODS: The study randomized 68 obese adults to receive one of four interventions for six months: (1) intensive counseling intervention, (2) intensive counseling plus smartphone intervention, (3) a less intensive counseling plus smartphone intervention, and (4) smartphone intervention only. The outcome measures of weight, BMI, waist circumference, and self-reported dietary intake and physical activity were assessed at baseline and six months. RESULTS: The sample was 78% female and 49% African American, with an average age of 45 years, and average BMI of 34.3 kg/m(2). There were trends for differences in weight loss among the four intervention groups. Participants in the intensive counseling plus self-monitoring smartphone group and less intensive counseling plus self-monitoring smartphone group tended to lose more weight than other groups (5.4 kg and 3.3 kg, resp.). CONCLUSIONS: The results of this pilot trial of a weight loss intervention provide preliminary support for using a smartphone application for self-monitoring as an adjunct to behavioral counseling.

Tissue Doppler imaging in the evaluation of left ventricular function in young adults with autosomal dominant polycystic kidney disease.

In: *American journal of kidney diseases : the official journal of the National Kidney Foundation* 47 (4), S. 587–592. DOI: 10.1053/j.ajkd.2005.12.023.

Abstract:

BACKGROUND\r\nHypertension and increased left ventricular mass index (LVMI) have been reported in patients with early stages of autosomal dominant polycystic kidney disease (ADPKD). Whether these abnormalities are associated with diastolic dysfunction in this stage remains to be established. The aim of the study is to evaluate diastolic function in young normotensive patients with ADPKD by using tissue Doppler imaging (TDI), the most sensitive method available to date.\r\nMETHODS\r\nThirty-two young clinically normotensive patients aged 21 to 30 years were compared with 23 controls with similar ages. Ambulatory blood pressure measurement (ABPM) was performed to confirm normal blood pressure. Subsequently, patients and controls underwent echocardiography using transmitral Doppler and TDI.\r\nRESULTS\r\nLVMI was greater in patients with ADPKD than controls (89.3 +/- 17.7 versus 77.6 +/- 15.9 g/m2; P < 0.02). No significant differences were found in transmitral Doppler and TDI results. When ABPMs were taken into account, 11 patients had mild hypertension and showed increased LVMI and decreased early diastolic peak velocity (E wave: 67.0 +/- 12.0 cm/s in hypertensive patients with ADPKD versus 81.4 +/- 3.3 cm/s in normotensive patients with ADPKD versus 79.3 +/- 2.9 cm/s in controls; P < 0.04) and decreased TDI peak early diastolic annular velocity (11.6 +/- 2.8 cm/s in hypertensive patients with ADPKD versus 13.2 +/- 1.6 cm/s in normotensive patients with ADPKD versus 13.4 +/- 1.6 in controls; P < 0.05).\r\nCONCLUSION\r\nDiastolic dysfunction is not a prominent sign in young normotensive patients with ADPKD.

Decreased physical activity predicts cognitive dysfunction and reduced cerebral blood flow in heart failure.

In: *J Neurol Sci* 339 (1-2), S. 169–175. DOI: 10.1016/j.jns.2014.02.008.

Abstract:

OBJECTIVE: Cognitive impairment in heart failure (HF) is believed to result from brain hypoperfusion subsequent to cardiac dysfunction. Physical inactivity is prevalent in HF and correlated with reduced cardiac and cognitive function. Yet, no longitudinal studies have examined the neurocognitive effects of physical inactivity in HF. The current study examined whether reduced physical activity increases risk for cognitive impairment and brain hypoperfusion over time in HF. METHODS: At baseline and 12months later, 65 HF patients underwent neuropsychological testing, transcranial Doppler ultrasonography, and were asked to wear an accelerometer for seven days. RESULTS: Lower baseline step count and less time spent in moderate free-living activity best predicted worse attention/executive function and decreased cerebral perfusion at the 12-month follow-up. Decreased baseline cerebral perfusion also emerged as a strong predictor of poorer 12-month attention/executive function. CONCLUSIONS: Lower physical activity predicted worse cognition and cerebral perfusion 12months later in HF. Physical inactivity in HF may contribute to cognitive impairment and exacerbate risk for conditions such as Alzheimer's disease. Larger studies are needed to elucidate the mechanisms by which physical inactivity leads to cognitive dysfunction in HF, including clarification of the role of cerebral hypoperfusion.

Alpers, Georg W. (2009):

Ambulatory assessment in panic disorder and specific phobia.

In: *Psychological Assessment* 21 (4), S. 476–485. DOI: 10.1037/a0017489.

Abstract:

Anxiety disorders are among the most prevalent mental disorders. In panic disorder, panic attacks often occur at unpredictable times, making it difficult to study these episodes in the laboratory. In specific phobias, symptoms occur in very circumscribed situations and specific triggers are sometimes difficult to reproduce in the laboratory. Ambulatory assessment, or ecological momentary assessment, can further the understanding of the natural course and scope of symptoms under ecologically valid circumstances. Because bodily symptoms are integral to the diagnosis of anxiety disorders, the objective assessment of physiological responses in the patients' natural environment is particularly important. On the one hand, research has highlighted intriguing discrepancies between the experience of symptoms and physiology during panic attacks. On the other hand, it has validated symptom reporting during therapeutic exposure to phobic situations. Therefore, ambulatory assessment can yield

useful information about the psychopathology of anxiety disorders, and it can be used to monitor change during clinical interventions.

Alschuler, Kevin N.; Hoodin, Flora; Murphy, Susan L.; Geisser, Michael E. (2011):

Ambulatory monitoring as a measure of disability in chronic low back pain populations.

In: *Clin J Pain* 27 (8), S. 707–715. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-20610-008&site=ehost-live;kalschul@uw.edu.

Abstract:

Purpose: The link between chronic back pain and disability is well established. Despite this, the literature also reflects an inconsistency in methods of assessing disability, as studies interchangeably use self-report measures, clinical tests, and electronic monitoring. The purpose of this study was to conduct a multimethod comparison of disability measures to identify similarities and differences in the constructs measured by each. Method: Twenty chronic back pain patients participated in a clinic visit to complete questionnaires and clinical tests, followed by 5 days of wearing a wrist-worn electronic ambulatory monitoring device to measure activity. Results: Multiple regression analyses were conducted to identify the significant predictors of each disability assessment. Results showed that operant variables were predictive of physical activity, cognitive-behavioral variables were predictive of perceived disability, and no variables were predictive of physical ability. Discussion: The results indicate substantial differences in the types of variables that predict disability when measured through 3 different methods. This is suggestive of differences in the constructs measured by each type of disability assessment. The implications for researchers who assess predictors of disability and clinicians who use disability measures in their assessment of patients are that the measures of disability they select should be carefully matched to the proposed purposes. Strong theoretical and practical considerations support using electronic ambulatory monitoring in future research and clinical service. A comparative study of an ambulatory blood pressure measuring device and a wrist blood pressure monitor with a position sensor versus a mercury sphygmomanometer.

In: *European journal of internal medicine* 18 (2), S. 118–123.

Abstract:

Background

Self-measurements of blood pressure (BP) and 24-hour BP measurements are better predictors of cardiovascular mortality and morbidity than office BP measurements. The objective of this study was to compare the accuracy and precision of a wrist BP monitor with a position sensor (Omron 637IT) and of an ambulatory BP measuring monitor (ABPM; Nissei DS-250) with a mercury sphygmomanometer.

Methods

A total of 139 patients (69 women and 70 men) were included in the study. The BP of each subject was first measured with a mercury device using the same (left) arm. After this, the wrist monitor was used for BP measurement. Upon completion of the BP readings, 24-hour BP monitoring was performed using Nissei DS-250 monitors. Mean and standard deviations were calculated for all devices. In order to assess the agreement between the measurement methods, the Bland–Altman method and graphics were utilized.

Results

The mean systolic BP measured by the mercury device was 133.2 ± 18.4 mmHg and the diastolic BP was 85.4 ± 12.5 mmHg, whereas the digital device measured systolic BP as 135.7 ± 17.2 mmHg and diastolic BP as 87.0 ± 12.5 mmHg. The 24-hour BP measurement was 134.6 ± 16.6 mmHg for systolic BP and 85.6 ± 11.1 mmHg for diastolic BP. The difference with regard to systolic BP between the mercury and the Omron devices was − 2.5 ± 5.3 mmHg, which is within the AAMI standard. However, while the mean values of the differences between the mercury and ABPM devices remained under 5 mmHg, their standard deviation was above ± 8 mmHg. For diastolic BP, the difference between all of the devices was below 5 ± 8 mmHg.

Conclusions

The wrist BP monitor produced results consistent with those of the mercury sphygmomanometer when both were compared with the results of the ABPM. As BP measurement with these devices is a practical and repeatable method, they can be used instead of ABPM in the diagnosis and monitoring of hypertension. However, there is a need for further comparative studies.

Epidemiology of Masked and White-Coat Hypertension: The Family-Based SKIPOGH Study.

In: *PLoS One* 9 (3), S. e92522. DOI: 10.1371/journal.pone.0092522.

Abstract:

OBJECTIVE: We investigated factors associated with masked and white-coat hypertension in a Swiss population-based sample. METHODS: The Swiss Kidney Project on Genes in Hypertension is a family-based cross-sectional study. Office and 24-hour ambulatory blood pressure were measured using validated devices. Masked hypertension was defined as office blood pressure<140/90 mmHg and daytime ambulatory blood pressure>/=135/85 mmHg. White-coat hypertension was defined as office blood pressure>/=140/90 mmHg and daytime ambulatory blood pressure<135/85 mmHg. Mixed-effect logistic regression was used to examine the relationship of masked and white-coat hypertension with associated factors, while taking familial correlations into account. High-normal office blood pressure was defined as systolic/diastolic blood pressure within the 130-139/85-89 mmHg range. RESULTS: Among the 652 participants included in this analysis, 51% were female. Mean age (+/-SD) was 48 (+/-18) years. The proportion of participants with masked and white coat hypertension was respectively 15.8% and 2.6%. Masked hypertension was associated with age (odds ratio (OR) = 1.02, p = 0.012), high-normal office blood pressure (OR = 6.68, p<0.001), and obesity (OR = 3.63, p = 0.001). White-coat hypertension was significantly associated with age (OR = 1.07, p<0.001) but not with education, family history of hypertension, or physical activity. CONCLUSIONS: Our findings suggest that physicians should consider ambulatory blood pressure monitoring for older individuals with high-normal office blood pressure and/or who are obese.

Ambrosi, Pierre; Kreitmann, Bernard; Habib, Gilbert (2014):

Home blood pressure monitoring in heart transplant recipients: comparison with ambulatory blood pressure monitoring.

In: *Transplantation* 97 (3), S. 363–367. DOI: 10.1097/01.TP.0000435704.55805.f9.

Abstract:

BACKGROUND: How reliable is home blood pressure monitoring (HBPM) in heart transplant recipients is not known. Possibly, it may underestimate hypertensive burden, because blood pressure (BP) nondipper profile is frequent among these patients. This prospective study has been designed to determine whether HBPM adequately identifies hypertension in heart transplant recipients. METHOD: We compared HBPM with ambulatory blood pressure monitoring (ABPM) for the diagnosis of uncontrolled hypertension in 74 patients 13.5+/-6.7 years after heart transplantation. HBPM was measured with a validated semiautomatic device twice every morning and twice every evening on 7 consecutive days, within 15 days of ABPM. We also measured the relationship between HBPM, ABPM, and organ damage as measured by albuminuria and left ventricular mass. RESULTS: A nondipper profile was found in 53 (72%) patients. HBPM and ABPM were close according to Pearson bivariate correlations. There was no significant correlation between left ventricular mass and BP either at HBPM or ABPM. Proteinuria significantly correlated with systolic BP either at HBPM (R=0.42; P=0.0002) or ABPM (R=0.25; P=0.03). HBPM adequately classified 61 of 74 (82%) patients as hypertensives or as nonhypertensives or controlled hypertensives. CONCLUSION: Despite a high prevalence of nondipper profile, HBPM gives a reliable estimate of BP burden in most heart transplant recipients. Thus, our results strongly suggest that HBPM is useful for the long-term follow-up of heart transplant recipients.

Amici, A.; Cicconetti, P.; Sagrafoli, C.; Baratta, A.; Passador, P.; Pecci, T. et al. (2009):

Exaggerated morning blood pressure surge and cardiovascular events. A 5-year longitudinal study in normotensive and well-controlled hypertensive elderly.

In: *Archives of gerontology and geriatrics* 49 (2), S. e105-9. DOI: 10.1016/j.archger.2008.10.003.

Abstract:

Cardiovascular events (CE) occur most frequently in the morning hours in hypertensive subjects. We studied the association between the morning blood pressure (BP) surge and CE in prognosis of 10 normotensive and 32 well-controlled hypertensive elderly, in whom ambulatory BP monitoring was performed and who were followed prospectively for 5 years. The morning surge (MS) of BP was calculated as mean systolic BP during 2h after awakening--mean systolic BP during 1h that included the lowest sleep BP. During an average of 60 months, five CE occurred. When the patients were divided into two groups according to MS, those in the top terzile (MS group; MS> or =34 mmHg, n=14) had a higher prevalence of CE (5 versus 0, p=0.001) during the follow-up period, than the others (non-MS group; MS<34 mmHg, n=28). The logistic regression analysis showed the MS sleep-trough surge as predictive variable of CE (odds ratio, OR=0.794, p=0.022). In conclusion, in older normotensives and well-controlled hypertensives, a higher BP MS is associated with vascular risk independently of clinical and ambulatory BP. Reduction of the MS could thus be a therapeutic target for preventing vascular events also in non-hypertensive patients.

Aminian, S.; Hinckson, E. A. (2012):

Examining the validity of the ActivPAL monitor in measuring posture and ambulatory movement in children.

In: *Int.J.Behav.Nutr.Phys.Act.* 9 (1479-5868 (Linking)), S. 119. DOI: 10.1186/1479-5868-9-119.

Abstract:

BACKGROUND: Decreasing sedentary activities that involve prolonged sitting may be an important strategy to reduce obesity and other physical and psychosocial health problems in children. The first step to understanding the effect of sedentary activities on children's health is to objectively assess these activities with a valid measurement tool. PURPOSE: To examine the validity of the ActivPAL monitor in measuring sitting/lying, standing, and walking time, transition counts and step counts in children in a laboratory setting. METHODS: Twenty five healthy elementary school children (age 9.9 +/- 0.3 years; BMI 18.2 +/- 1.9; mean +/- SD) were randomly recruited across the Auckland region, New Zealand. Children were fitted with ActivPAL monitors and observed during simulated free-living activities involving sitting/lying, standing and walking, followed by treadmill and over-ground activities at various speeds (slow, normal, fast) against video observation (criterion measure). The ActivPAL sit-to-stand and stand-to-sit transition counts and steps were also compared with video data. The accuracy of step counts measured by the ActivPAL was also compared against the New Lifestyles NL-2000 and the Yamax Digi-Walker SW-200 pedometers. RESULTS: We observed a perfect correlation between the ActivPAL monitor in time spent sitting/lying, standing, and walking in simulated free-living activities with direct observation. Correlations between the ActivPAL and video observation in total numbers of sit-to-stand and stand-to-sit transitions were high (r = 0.99 +/- 0.01). Unlike pedometers, the ActivPAL did not misclassify fidgeting as steps taken. Strong correlations (r = 0.88-1.00) between ActivPAL step counts and video observation in both treadmill and over-ground slow and normal walking were also observed. During treadmill and over-ground fast walking and running, the correlations were low (r = 0.21-0.46). CONCLUSION: The ActivPAL monitor is a valid measurement tool for assessing time spent sitting/lying, standing, and walking, sit-to-stand and stand-to-sit transition counts and step counts in slow and normal walking. The device did not measure accurately steps taken during treadmill and over-ground fast walking and running in children

Hyperhomocysteinemia is a significant risk factor for silent cerebral infarction in patients with chronic renal failure undergoing hemodialysis.

In: *Metabolism: clinical and experimental* 55 (5), S. 656–661. DOI: 10.1016/j.metabol.2005.12.007.

Abstract:

In patients with chronic renal failure undergoing hemodialysis (HD), the presence of silent cerebral infarction (SCI) is associated with high mortality. Plasma total homocysteine (tHcy), which increases with renal dysfunction, has been flagged as a novel predictor for cerebrovascular events. We tested the hypothesis that the presence of SCI correlates with tHcy in HD patients. Based on brain magnetic resonance imaging findings, 44 patients undergoing HD were divided into a with-SCI group (61+/-9 years [mean+/-SD]; n=24) and a without-SCI group (60+/-8 years, n=20), in whom 24-hour ambulatory blood pressure monitoring was performed. The number of patients with diabetes or hypertension was not different between the 2 groups. We made the following observations: (1) the percentage of smokers was higher in the with-SCI group than in the without-SCI group (P<.05); (2) plasma levels of high-density lipoprotein cholesterol were lower and tHcy was higher in the with-SCI group than in the without-SCI group (P<.05 and P<.0001, respectively); (3) and systolic ambulatory blood pressure and mean heart rate during nighttime were higher in the with-SCI group than in the without-SCI group (P<.05). Multivariate logistic analysis identified hyperhomocysteinemia as an independent and significant risk factor for SCI (odds ratio, 1.22; 95% CI, 1.10-1.36; P<.01). Our findings indicate that plasma tHcy may be a novel useful predictor for SCI in patients with chronic renal failure undergoing HD.

Anastasopoulou, P.; Tansella, M.; Stumpp, J.; Shammas, L.; Hey, S. (2012):

Classification of human physical activity and energy expenditure estimation by accelerometry and barometry.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 6451–6454. DOI: 10.1109/EMBC.2012.6347471.

Abstract:

Regular exercise and physical activity are among the most important factors influencing the quality of life and make a significant contribution to the maintenance of health and well-being. The assessment of physical activity via accelerometry has become a promising technique often used as means to objectively measure physical activity. This work proposes a simple and reliable method to assess human physical activity and calculate the energy expenditure (EE) by using an acceleration and an air pressure sensor. Our proposed algorithm differentiates between 7 activities with an average accuracy of 98.2% and estimates the second by second EE with an average percent error of 1.59 +/- 8.20% using a single measurement unit attached to the subject's hip

Anastasopoulou, Panagiota; Tubic, Mirnes; Schmidt, Steffen; Neumann, Rainer; Woll, Alexander; Hartel, Sascha (2014):

Validation and Comparison of Two Methods to Assess Human Energy Expenditure during Free-Living Activities.

In: *PLoS One* 9 (2), S. e90606. DOI: 10.1371/journal.pone.0090606.

Abstract:

BACKGROUND: The measurement of activity energy expenditure (AEE) via accelerometry is the most commonly used objective method for assessing human daily physical activity and has gained increasing importance in the medical, sports and psychological science research in recent years. OBJECTIVE: The purpose of this study was to determine which of the following procedures is more accurate to determine the energy cost during the most common everyday life activities; a single regression or an activity based approach. For this we used a device that utilizes single regression models (GT3X, ActiGraph Manufacturing Technology Inc., FL., USA) and a device using activity-dependent calculation models (move II, movisens GmbH, Karlsruhe, Germany). MATERIAL AND METHODS: Nineteen adults (11 male, 8 female; 30.4+/-9.0 years) wore the activity monitors attached to the waist and a portable indirect calorimeter (IC) as reference measure for AEE while performing several typical daily activities. The accuracy of the two devices for estimating AEE was assessed as the mean differences between their output and the reference and evaluated using Bland-Altman analysis. RESULTS: The GT3X overestimated the AEE of walking (GT3X minus reference, 1.26 kcal/min), walking fast (1.72 kcal/min), walking up-/downhill (1.45 kcal/min) and walking upstairs (1.92 kcal/min) and underestimated the AEE of jogging (-1.30 kcal/min) and walking upstairs (-2.46 kcal/min). The errors for move II were smaller than those for GT3X for all activities. The move II overestimated AEE of walking (move II minus reference, 0.21 kcal/min), walking up-/downhill (0.06 kcal/min) and stair walking (upstairs: 0.13 kcal/min; downstairs: 0.29 kcal/min) and underestimated AEE of walking fast (-0.11 kcal/min) and jogging (-0.93 kcal/min). CONCLUSIONS: Our data suggest that the activity monitor using activity-dependent calculation models is more appropriate for predicting AEE in daily life than the activity monitor using a single regression model.

Anderson, Rachel J.; Goddard, Lorna; Powell, Jane H. (2011):

Social Problem-Solving and Depressive Symptom Vulnerability: The Importance of Real-Life Problem-Solving Performance.

In: *Cogn Ther Res* 35 (1), S. 48–56. DOI: 10.1007/s10608-009-9286-2.

Abstract:

Previous research suggests poor social problem-solving may function as a vulnerability factor for depressive symptoms. However, the ecological validity of previous findings is questionable, with recent research using real-life performance based approaches to ascertain how solutions are implemented in the 'real world'. The current study employed a longitudinal design to examine the role of real-life problem-solving as a predictor of future depressive symptoms. Participants completed a diary of the interpersonal problems they encountered, and their attempts to solve them. They also completed traditional measures of social problem-solving (SPSI-R and MEPS task). Real-life problem-solving performance predicted depressive symptoms 3 months after the initial testing session, beyond the variance accounted for by traditional measures of social problem-solving. This suggests that the ability to hypothetically problem-solve is distinct from the ability to generate and implement problem-solving strategies in real-life, and that it is the latter which is most important in predicting depressive symptoms.

Anderson, David E.; McNeely, Jessica D.; Chesney, Margaret A.; Windham, Beverly G. (2008):

Breathing variability at rest is positively associated with 24-h blood pressure level.

In: *Am J Hypertens* 21 (12), S. 1324–1329. DOI: 10.1038/ajh.2008.292.

Abstract:

BACKGROUND\r\nPrevious research has reported that inhibition of breathing can be observed in hypertensive patients at rest during the daytime, as well as in sleep at night. The present study hypothesized that the variability of breathing and end-tidal CO(2) (PetCO(2)) in seated women at rest is positively associated with their 24-h blood pressure level.\r\nMETHODS\r\nBreath-to-breath measures of breathing rate and tidal volume were recorded via inductive plethysmography in each of 54 women during two 20-min sessions of seated rest, and in 32 women during night time sleep. PetCO(2) was also recorded during these sessions via a respiratory gas monitor. Ambulatory blood pressure was recorded for 24 h between the two clinic sessions via oscillometry.\r\nRESULTS\r\nBreath pauses >10 s were observed significantly more often in women in the upper than the lower tertile of 24-h systolic blood pressure. Breath-to-breath variability in breathing rate, tidal volume, and minute ventilation were greater in the higher blood pressure tertile women. Variability in PetCO(2) was also greater in high blood pressure tertile. These associations were independent of age, weight, and body surface area (BSA). Breathing variability was inversely correlated with heart rate variability (HRV).\r\nCONCLUSION\r\nGreater variability in breathing at rest that is independent of metabolic activity characterizes women with elevated blood pressure. The linear association of breathing variability with 24-h blood pressure level is consistent with the hypothesis that intermittent breathing inhibition may predispose to the development of some forms of hypertension.

Andreadis, E. A.; Angelopoulos, E. T.; Kolyvas, G. N.; Agaliotis, G. D.; Mousoulis, C. G.; Mousoulis, G. P. (2014):

The effect of aliskiren versus ramipril-based treatment on the Ambulatory Arterial Stiffness Index in hypertensive patients.

In: *Int Angiol* 33 (1), S. 78–83.

Abstract:

AIM: Aim of the present study was to compare the effectiveness of two renin-angiotensin-aldosterone system inhibitors in arterial stiffness reduction in previously untreated hypertensive patients. METHODS: In this open label study, 154 naive, or not treated in the last six months hypertensive patients were randomly assigned to receive aliskiren 300 mg or ramipril 5 mg daily. Six weeks after the initiation of treatment, patients were evaluated for blood pressure (BP) control. Patients with SBP >/=140 and/or DBP >/=90 mmHg were assigned to an adjunct of 25 mg hydrochlorothiazide as combination treatment. A re-evaluation of BP control was done after another 6 weeks. Individuals with BP >/=140/90 mmHg were further administered amlodipine 5 mg. The final evaluation was performed six months after the start of the study. Twenty four-hour ambulatory blood pressure monitoring was carried out and the ambulatory arterial stiffness index (AASI) was calculated at baseline and after 6 months of treatment. RESULTS: Aliskiren-based therapy, as compared with ramipril-based therapy reduced BP to a similar degree: 13+/-11 vs. 12+/-11 mmHg reduction in systolic (P=0.34) and 8+/-7 vs. 7+/-7 mmHg reduction in diastolic BP (P=0.44). AASI was reduced by 0.04+/-0.1 in the aliskiren group and by 0.02+/-0.2 in the ramipril group. AASI reduction did not differ significantly in the two groups (P=0.13). CONCLUSION: In hypertensive patients, aliskiren-based treatment as well as ramipril-based treatment appears to have a beneficial effect on arterial stiffness. As arterial stiffness is an important modifiable risk factor, our findings highlight the value of aliskiren beyond BP lowering properties.

Andrews, N. E.; Strong, J.; Meredith, P. J.; D'Arrigo, R. G. (2013):

Association Between Physical Activity and Sleep in Adults With Chronic Pain: A Momentary, Within-Persons Perspective.

In: *Phys.Ther.* (0031-9023 (Linking)). DOI: 10.2522/ptj.20130302.

Abstract:

BACKGROUND: Individuals with chronic pain consider improved sleep as one of the most important outcomes of treatment. Physical activity has been shown to have beneficial effects on sleep in the general population. Despite this, the physical activity-sleep relationship has not been directly examined in a chronic pain sample. OBJECTIVE: This study aimed to examine the association between objective daytime physical activity and subsequent objective sleep for individuals with chronic pain while controlling for pain and psychosocial variables. DESIGN: An observational prospective within-persons study design was employed. METHODS: A clinical sample of fifty adults with chronic pain was recruited. Participation involved completing a demographic questionnaire followed by five days of data collection. Over this period participants wore a tri-axial accelerometer to monitor their daytime activity and sleep. Participants also carried a Palm Hand Held Computer that administered a

questionnaire measuring pain, mood, catastrophizing, and stress, six times throughout the day. RESULTS: Results demonstrated that higher fluctuations in daytime activity significantly predicted shorter sleep duration. Furthermore, higher mean daytime activity levels and a greater number of pain sites contributed significantly to the prediction of longer periods of wakefulness at night. LIMITATIONS: The small sample size used in this study limits the generalizability of findings. Missing data may have led to over- or under-estimations of effect sizes, and additional factors that may be associated with sleep (such as medication usage and environmental factors) were not measured. CONCLUSIONS: Results of this study suggest engagement in high intensity activity and high fluctuations in activity are associated with poorer sleep at night; hence, activity modulation may be a key treatment strategy to address sleep complaints in individuals with chronic pain

How stress management improves quality of life after treatment for breast cancer.

In: *Journal of Consulting and Clinical Psychology* 74 (6), S. 1143–1152. DOI: 10.1037/0022-006X.74.6.1143.

Abstract:

The range of effects of psychosocial interventions on quality of life among women with breast cancer remains uncertain. Furthermore, it is unclear which components of multimodal interventions account for such effects. To address these issues, the authors tested a 10-week group cognitive-behavioral stress management intervention among 199 women newly treated for nonmetastatic breast cancer, following them for 1 year after recruitment. The intervention reduced reports of social disruption and increased emotional well-being, positive states of mind, benefit finding, positive lifestyle change, and positive affect for up to 12 months (indeed, some effects strengthened over time). With respect to mechanisms tested, the intervention increased confidence in being able to relax at will. There was also evidence that effects of the intervention on the various outcomes examined were mediated by change in confidence about being able to relax. Thus, this intervention had beneficial effects on diverse aspects of quality of life after treatment for breast cancer, which appear linked to a specific stress management skill taught in the intervention. Impact of home patient telemonitoring on use of β-blockers in congestive heart failure.

In: *Drugs & aging* 27 (10), S. 801–805.

Abstract:

Introduction Congestive heart failure (CHF), which typically affects older people, is characterized by high short- and mid-term mortality rates. However, despite accumulating evidence showing that administration of β-blockers (β-adrenoceptor antagonists) can improve the clinical status of CHF patients, use of these agents in adequate dosages in this setting is not routine. One reason for this appears to be a concern about a possible risk of bradyarrhythmia associated with use of β-blockers. Telecardiology has recently been investigated as a means of constantly monitoring the heart rate of CHF patients in their homes. Its use may allay concerns about the risk of bradyarrhythmia and facilitate a more widespread use of β-blockers in this context.

Objectives The primary objectives of this study were to assess the impact of telemonitoring on patients' adherence to prescribed therapeutic regimens, particularly β-blockers, and to explore whether use of home telemonitoring reduces mortality and rate of re-admission to hospital in elderly CHF patients compared with normal specialized CHF team care.

Methods A total of 57 patients with CHF (31 New York Heart Association [NYHA] class II, 23 NYHA class III and 3 NYHA class IV), with a mean ±SD age of 78.2±7.3 years, were randomized to a control group who received standard care, based on routinely scheduled clinic visits, from a team specialized in CHF patient management, or to a home telemonitoring group (TM group), managed by the same specialized CHF team. Patients were followed up over 12 months.

Results Compared with the control group, the TM group had a significant increase in the use of β-blockers, HMG-CoA reductase inhibitors (statins) and aldosterone receptor antagonists. A reduction in nitrate administration compared with baseline was also seen in the TM group. The 12-month occurrence of the primary combined endpoint of mortality and hospital re-admission for CHF was significantly lower in the TM group than in the control group ($p < 0.01$).

Conclusions This study showed that a home-care model including telemonitoring of relevant clinical parameters may provide useful support in the management of patients with CHF. Home telemonitoring in CHF patients was associated with increased use of β-blockers at appropriate doses, suggesting that this strategy reassured physicians regarding the safety of careful use of these agents in this setting. However, larger studies are required to confirm these findings. Our findings indicate that there is a need to investigate relevant parameters in CHF patients at the point of care (i.e. in patients' daily lives), which can in turn optimize β-blocker and other drug therapy.

A prognostic index for risk stratification for acute heart failure and death in subjects with ischemic cardiomyopathy and cardiac defibrillator.

In: *Heart Vessels. DOI:* 10.1007/s00380-014-0494-7.

Abstract:

To propose a clinical prognostic index for death and heart failure in patients with ischemic cardiomyopathy implanted with an ICD. This prospective study included 192 consecutive patients (age 68 +/- 10) recruited from 2004 to 2009 and implanted with an ICD for MADIT II criteria. All patients performed 24-h ambulatory blood pressure monitoring after discharge and common haematological samples. The prognostic index (PI) was built according to the formula: 120 - age + mean 24 h systolic blood pressure - (creatinine x 10). Other variables were assessed: EF, haemoglobin concentration, mean 24 h heart rate and diastolic blood pressure, sodium level, pacing mode and diabetes. Non-arrhythmic cardiac death and new hospitalizations for heart failure during 1-year follow-up were the combined end point. A total of 48 events (25 %) occurred during the follow-up: 7 cardiac deaths and 41 hospitalizations for acute heart failure. Cox proportional-hazards model showed that PI was the only predictor of events (HR = 0.96; CI 95 % 0.944-0.976, p < 0.0001). ROC curve showed that PI best cut-off was 144, with AUC 0.79, p < 0.0001; sensitivity 77 %, specificity 74 %, positive predictive value 50 %, negative predictive value 90 %. PI was predictive of events in a clinical setting where EF had no predictive value. PI works according to the rule "the lower the worse". The high negative predictive value (90 %) of PI allows to identify subjects at lower risk for death and heart failure. PI can be a practical tool to stratify risk in ischemic cardiomyopathy.

Antos, S. A.; Albert, M. V.; Kording, K. P. (2013):

Hand, belt, pocket or bag: Practical activity tracking with mobile phones.

In: *J.Neurosci.Methods* (0165-0270 (Linking)). DOI: 10.1016/j.jneumeth.2013.09.015.

Abstract:

For rehabilitation and diagnoses, an understanding of patient activities and movements is important. Modern smartphones have built in accelerometers which promise to enable quantifying minute-by-minute what patients do (e.g. walk or sit). Such a capability could inform recommendations of physical activities and improve medical diagnostics. However, a major problem is that during everyday life, we carry our phone in different ways, e.g. on our belt, in our pocket, in our hand, or in a bag. The recorded accelerations are not only affected by our activities but also by the phone's location. Here we develop a method to solve this kind of problem, based on the intuition that activities change rarely, and phone locations change even less often. A hidden Markov model (HMM) tracks changes across both activities and locations, enabled by a static support vector machine (SVM) classifier that probabilistically identifies activity-location pairs. We find that this approach improves tracking accuracy on healthy subjects as compared to a static classifier alone. The obtained method can be readily applied to patient populations. Our research enables the use of phones as activity tracking devices, without the need of previous approaches to instruct subjects to always carry the phone in the same location

Antypas, Konstantinos; Wangberg, Silje C. (2014):

An internet- and mobile-based tailored intervention to enhance maintenance of physical activity after cardiac rehabilitation: short-term results of a randomized controlled trial.

In: *J Med Internet Res* 16 (3), S. e77. DOI: 10.2196/jmir.3132.

Abstract:

BACKGROUND: An increase in physical activity for secondary prevention of cardiovascular disease and cardiac rehabilitation has multiple therapeutic benefits, including decreased mortality. Internet- and mobile-based interventions for physical activity have shown promising results in helping users increase or maintain their level of physical activity in general and specifically in secondary prevention of cardiovascular diseases and cardiac rehabilitation. One component related to the efficacy of these interventions is tailoring of the content to the individual. OBJECTIVE: Our trial assessed the effect of a longitudinally tailored Internet- and mobile-based intervention for physical activity as an extension of a face-to-face cardiac rehabilitation stay. We hypothesized that users of the tailored intervention would maintain their physical activity level better than users of the nontailored version. METHODS: The study population included adult participants of a cardiac rehabilitation program in Norway with home Internet access and a mobile phone. The participants were randomized in monthly clusters to a tailored or nontailored (control) intervention group. All participants had access to a website with information regarding cardiac rehabilitation, an online discussion forum, and an online activity calendar. Those using the tailored intervention received tailored

content based on models of health behavior via the website and mobile fully automated text messages. The main outcome was self-reported level of physical activity, which was obtained using an online international physical activity questionnaire at baseline, at discharge, and at 1 month and 3 months after discharge from the cardiac rehabilitation program. RESULTS: Included in the study were 69 participants. One month after discharge, the tailored intervention group (n=10) had a higher median level of overall physical activity (median 2737.5, IQR 4200.2) than the control group (n=14, median 1650.0, IQR 2443.5), but the difference was not significant (Kolmogorov-Smirnov Z=0.823, P=.38, r=.17). At 3 months after discharge, the tailored intervention group (n=7) had a significantly higher median level of overall physical activity (median 5613.0, IQR 2828.0) than the control group (n=12, median 1356.0, IQR 2937.0; Kolmogorov-Smirnov Z=1.397, P=.02, r=.33). The median adherence was 45.0 (95% CI 0.0-169.8) days for the tailored group and 111.0 (95% CI 45.1-176.9) days for the control group; however, the difference was not significant (P=.39). There were no statistically significant differences between the 2 groups in stage of change, self-efficacy, social support, perceived tailoring, anxiety, or depression. CONCLUSIONS: Because of the small sample size and the high attrition rate at the follow-up visits, we cannot make conclusions regarding the efficacy of our approach, but the results indicate that the tailored version of the intervention may have contributed to the long-term higher physical activity maintained after cardiac rehabilitation by participants receiving the tailored intervention compared with those receiving the nontailored intervention. Appel, Hoa B.; Huang, Bu; Cole, Allison; James, Rosalina; Ai, Amy L. (2014):

Starting the Conversation - A Childhood Obesity Knowledge Project Using an App.

In: *Br J Med Med Res* 4 (7), S. 1526–1538.

Abstract:

PURPOSE: Starting the Conversation was a pilot project to test an intervention for childhood obesity, a major public health epidemic, using a free smartphone application (app). The primary aim was to assess students' knowledge of nutritional indicators, physical exercise and use of screen time before and after the intervention. METHODS: The study was conducted in 2011-2012. The sample, recruited from seven high schools in Snohomish County, Washington, was 65.3% minority participants. Of the 118 participants in the sample (n=118), 79 handwrote their responses (n=78) and 36 responded via the app (n=39). We compared the frequency and types of physical exercise, frequency of screen time, and nutritional variables of high school students. Participants used the cell phone app or a handwritten log to record their daily entries for 20 days. RESULTS: Both males (n=43) and females (n=75) grades 9-12 used the app or handwritten entries. Participants who used the app ate less fast food and exercised more, as compared with those who recorded their entries by hand. Screen time usage decreased over the course of the study, based on a comparison of the post-survey level and the pre-survey level. Knowledge of recommended daily consumption of vegetables increased post-test in the app group and knowledge of water consumption increased significantly in both groups. There was no significant difference in BMI pre and post-test. CONCLUSIONS: Patterns of nutritional intake, physical exercise and knowledge of these issues varied pre and post-test. It is critical to further examine factors associated with lack of physical activity and food intake patterns of youth using social media to further address the childhood obesity epidemic. Future research should focus on specific ethnic subgroups and an intervention at the school level aimed at the students with BMI >/= 95th percentile.

Better physical activity classification using smartphone acceleration sensor.

In: *J Med Syst* 38 (9), S. 95. DOI: 10.1007/s10916-014-0095-0.

Abstract:

Obesity is becoming one of the serious problems for the health of worldwide population. Social interactions on mobile phones and computers via internet through social e-networks are one of the major causes of lack of physical activities. For the health specialist, it is important to track the record of physical activities of the obese or overweight patients to supervise weight loss control. In this study, acceleration sensor present in the smartphone is used to monitor the physical activity of the user. Physical activities including Walking, Jogging, Sitting, Standing, Walking upstairs and Walking downstairs are classified. Time domain features are extracted from the acceleration data recorded by smartphone during different physical activities. Time and space complexity of the whole framework is done by optimal feature subset selection and pruning of instances. Classification results of six physical activities are reported in this paper. Using simple time domain features, 99 % classification accuracy is achieved. Furthermore, attributes subset selection is used to remove the redundant features and to minimize the time complexity of the algorithm. A subset of 30 features produced more than 98 % classification accuracy for the six physical activities.

Arterial stiffness and dipper/nondipper blood pressure status in women with preeclampsia.

In: *Adv Ther* 25 (9), S. 925–934.

Abstract:

Introduction

The aim of this study was to investigate the clinical relevance of dipper status in women with preeclampsia by comparing arterial stiffness index (SI) values, and dipper and nondipper status.

Methods

A total of 60 pregnant women in their third trimester were enrolled in the study. SI values were measured using a digital photoplethysmographic method (Pulse Trace System, Micro Medical Ltd., Gillingham, Kent, UK). Twenty-four-hour ambulatory blood pressure was measured by a SpaceLabs 90217 oscillometric device (SpaceLabs Inc., Redmond, WA, USA). Systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), and pulse pressure (PP) were recorded. Those preeclamptic women whose mean nighttime blood pressure measurements were at least 10% lower compared with mean daytime measurements were classified as dipper status, and those with a decrease of less than 10% were classified as nondipper status.

Results

Seventeen women were preeclamptic with a dipper status, 13 women had nondipper status preeclampsia, and 30 women were normotensive. SI values were significantly higher in preeclamptic women compared with normotensive women (8.8±1.2 m/s vs. 5.9±0.8 m/s, P<0.001), but SI values of preeclamptic women with dipper status and preeclamptic women with nondipper status did not differ significantly from each other (P=0.485).

Conclusion

There was no significant difference in SI values between the dipper and nondipper preeclamptic groups. These results indicate that dipper and nondipper measurements may not be suitable for clinical follow-up of preeclamptic women.

Renal Denervation Using an Irrigated Catheter in Patients with Resistant Hypertension: A Promising Strategy?

In: *Arq. Bras. Cardiol.* 0, S. 0. DOI: 10.5935/abc.20140034.

Abstract:

Background: Systemic hypertension is an important public health problem and a significant cause of cardiovascular mortality. Its high prevalence and the low rates of blood pressure control have resulted in the search for alternative therapeutic strategies. Percutaneous renal sympathetic denervation emerged as a perspective in the treatment of patients with resistant hypertension. Objective: To evaluate the feasibility and safety of renal denervation using an irrigated catheter. Methods: Ten patients with resistant hypertension underwent the procedure. The primary endpoint was safety, as assessed by periprocedural adverse events, renal function and renal vascular abnormalities at 6 months. The secondary endpoints were changes in blood pressure levels (office and ambulatory monitoring) and in the number of antihypertensive drugs at 6 months. Results: The mean age was 47.3 (+/- 12) years, and 90% of patients were women. In the first case, renal artery dissection occurred as a result of trauma due to the long sheath; no further cases were observed after technical adjustments, thus showing an effect of the learning curve. No cases of thrombosis/renal infarction or death were reported. Elevation of serum creatinine levels was not observed during follow-up. At 6 months, one case of significant renal artery stenosis with no clinical consequences was diagnosed. Renal denervation reduced office blood pressure levels by 14.6/6.6 mmHg, on average (p = 0.4 both for systolic and diastolic blood pressure). Blood pressure levels on ambulatory monitoring decreased by 28/17.6 mmHg (p = 0.02 and p = 0.07 for systolic and diastolic blood pressure, respectively). A mean reduction of 2.1 antihypertensive drugs was observed. Conclusion: Renal denervation is feasible and safe in the treatment of resistant systemic arterial hypertension. Larger studies are required to confirm our findings.

Armeli, Stephen; Dehart, Tracy; Tennen, Howard; Todd, Michael; Affleck, Glenn (2007):

Daily interpersonal stress and the stressor-vulnerability model of alcohol use.

In: *Journal of Social and Clinical Psychology* 26 (8), S. 896–921.

Abstract:

We used an experience sampling design to examine the within–person, within–day associations among interpersonal stress, negative affect, and alcohol use, and how these associations varied as a function of alcohol–outcome expectancies (AOEs), avoidance coping style, sex, and neuroticism. Ninety–eight community adult drinkers who wanted to reduce their alcohol consumption (49 women) reported for 21 days on their interpersonal stress and affect (three times per day), and alcohol use (as it occurred) using hand–held computers. Several individual difference factors interacted with daytime interpersonal stress and afternoon negative affect in predicting nighttime alcohol use, with individuals high in careless unconcern AOEs or low in impairment AOEs demonstrating stronger positive associations between daytime stress and negative affect and nighttime drinking. Daytime drinking and individual difference factors also interacted in predicting nighttime interpersonal stress, with individuals high in careless unconcern AOEs or those low in impairment AOEs or avoidance coping style demonstrating the strongest positive associations between daytime drinking and nighttime stress. The interactive effects in predicting drinking outcomes were generally limited to days on which some interpersonal stress occurred.

Armeli, Stephen; Feinn, Richard; Tennen, Howard; Kranzler, Henry R. (2006):

The effects of naltrexone on alcohol consumption and affect reactivity to daily interpersonal events among heavy drinkers.

In: *Experimental and Clinical Psychopharmacology* 14 (2), S. 199–208. DOI: 10.1037/1064-1297.14.2.199.

Abstract:

The authors examined whether the associations among daily positive and negative interpersonal events, alcohol consumption, and affect varied as a function of naltrexone or placebo administered in a targeted (in anticipation of or in response to high-risk drinking situations) or daily fashion. Heavy drinkers (N = 149) received 4 sessions of brief coping skills counseling in addition to 8 weeks of naltrexone treatment. They recorded for 8 weeks in structured nightly diaries their interpersonal interactions, affect, and alcohol consumption. The authors predicted that participants receiving naltrexone, compared with those taking placebo, would drink less in response to interpersonal encounters and that naltrexone administration would attenuate the link between positive interpersonal events and positive affective states. Results indicated that both positive and negative interpersonal interactions were associated with an increased probability of engaging in any drinking and that positive daily social celebratory events were associated with an increased probability of engaging in heavy drinking. Participants taking naltrexone in a targeted fashion showed the strongest positive association between the number of positive social celebratory events and drinking. Although this finding was inconsistent with the overall reduction in drinking that has been generally reported for those treated with naltrexone, positive social celebratory events occurred on only a minority of days. Participants taking naltrexone, compared with those taking placebo, showed weaker associations between positive social celebratory events and positive and negative affective states. Findings are discussed in terms of naltrexone's dampening effects on the rewarding properties of alcohol use and certain positively valenced stimuli.

Armey, Michael F. (2012):

Ecological momentary assessment and intervention in nonsuicidal self-injury: A novel approach to treatment.

In: *Journal of Cognitive Psychotherapy* 26 (4), S. 299–317. DOI: 10.1037/t04534-000;

Abstract:

This study provides an introduction to ecological momentary assessment (EMA) methods and the potential use of ecological momentary intervention (EMI) for nonsuicidal self-injury (NSSI). The novel use of EMA and EMI are discussed within the context of the emotion regulation function of NSSI, the ability of these approaches to complement established treatments (i.e., cognitive behavior therapy & dialectical behavior therapy), and the specific areas in which an EMI treatment approach can augment traditional treatment. Based on established EMA findings in general and specific applications of EMA to the NSSI, a model EMI for NSSI is proposed (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Armey, Michael F.; Crowther, Janis H.; Miller, Ivan W. (2011):

Changes in Ecological Momentary Assessment reported affect associated with episodes of nonsuicidal self-injury.

In: *Behav Ther* 42 (4), S. 579–588. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-25130-003&site=ehost-live;michaelarmey@gmail.com.

Abstract:

Although emotion regulation deficits have been frequently implicated in the incidence of nonsuicidal self-injurious behavior (NSSI), no research to date has examined in vivo change of affect associated with real-world NSSI behavior. The present study employed Ecological Momentary Assessment (EMA) to assess change in affect associated with episodes of experienced NSSI in a sample of 36 college students with a self-reported history of NSSI. Results indicated that individuals who reported NSSI behavior over the course of the study experienced increases in negative affect prior to an episode of NSSI that peaked during the episode and faded gradually in the hours following the episode, with affect change roughly approximating a quadratic curve. These changes in affect were detected only at times in which individuals engaged in NSSI and were absent for individuals who did not report NSSI over the course of the study. Moreover, changes in negative affect associated with NSSI were, on average, detectable hours prior to the NSSI event. These findings suggest that episodes of NSSI may be predicted through a careful examination of affect change long before actual NSSI behavior occurs. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Arnold, Suzanne V.; Kosiborod, Mikhail; Li, Yan; Jones, Philip G.; Yue, Patrick; Belardinelli, Luiz; Spertus, John A. (2014):

Comparison of the Seattle Angina Questionnaire With Daily Angina Diary in the TERISA Clinical Trial.

In: *Circ Cardiovasc Qual Outcomes. DOI:* 10.1161/CIRCOUTCOMES.113.000752.

Abstract:

BACKGROUND: As new techniques emerge to quantify patients' health status, new opportunities are created to validate patient-reported outcome questionnaires. The Seattle Angina Questionnaire (SAQ), a widely used coronary artery disease-specific health status tool, has not been validated against daily records of angina frequency and sublingual nitroglycerin (SL NTG) use. Additional evidence supporting the validity of the SAQ could justify its broader use as an outcome for clinical studies designed to evaluate treatments that may improve patients' symptoms, function, and quality of life. METHODS AND RESULTS: We used data from 917 patients with type 2 diabetes mellitus, coronary artery disease, and stable angina from the multinational Type 2 Diabetes Evaluation of Ranolazine in Subjects With Chronic Stable Angina (TERISA) trial. The number of angina episodes and SL NTG used were recorded and transmitted daily using an electronic diary. In cross-sectional analyses, there was a strong relationship between the 2 SAQ angina frequency questions (ie, frequency of angina and SL NTG use) and the corresponding diary responses, with correlation coefficients of -0.64 for angina frequency (95% confidence interval,-0.68 to -0.60) and -0.69 for SL NTG use (95% confidence interval, -0.73 to -0.66). Longitudinally, changes in SAQ angina frequency scores from day 1 to week 8 also correlated with changes in angina frequency (-0.42; 95% confidence interval, -0.48 to -0.30) and SL NTG use by diary (-0.38; 95% confidence interval, -0.43 to -0.32) over the corresponding time period. Correlations were similar when stratified by age, sex, or geography. CONCLUSIONS: In a multinational cohort of patients with stable angina, the SAQ angina frequency domain was significantly correlated, both cross sectionally and longitudinally, with daily diary entries of angina frequency and SL NTG use. These data further support the validity of the SAQ angina frequency domain across a broad spectrum of patients with stable angina. CLINICAL TRIAL REGISTRATION: URL: http://www.clinicaltrials.gov. Unique identifier: NCT01425359.

Arnold, Suzanne V.; McGuire, Darren K.; Spertus, John A.; Li, Yan; Yue, Patrick; Ben-Yehuda, Ori et al. (2014):

Effectiveness of ranolazine in patients with type 2 diabetes mellitus and chronic stable angina according to baseline hemoglobin A1c.

In: *Am Heart J* 168 (4), S. 457-465.e2. DOI: 10.1016/j.ahj.2014.06.020.

Abstract:

BACKGROUND: Ranolazine reduces the frequency of angina and use of sublingual nitroglycerin (SL NTG) in stable angina patients with type 2 diabetes (T2DM). Because pre-clinical data suggest that myocardial late sodium current (INaL), the target of ranolazine, is increased by hyperglycemia, we investigated whether the efficacy of ranolazine was influenced by glycemic control. METHODS: TERISA was a multinational, randomized, double-blind trial of ranolazine vs. placebo in patients with T2DM and

stable angina. Anginal episodes and SL NTG use were recorded daily in an electronic diary. Health status was evaluated at baseline and 8weeks post-randomization using the Seattle Angina Questionnaire (SAQ). The interaction between baseline HbA1c and treatment effect was tested across endpoints using analysis of covariance models, with HbA1c as a continuous variable with restricted cubic splines. RESULTS: The study included 913 patients, with mean age 63.6years, 39% women, mean T2DM duration 7.4years, and mean HbA1c of 7.3%. Heterogeneity of efficacy by HbA1c was observed for the primary endpoint of angina frequency (Pinteraction = .027), the key secondary endpoint of SL NTG use (Pinteraction = .030), SAQ angina frequency (Pinteraction = .001), and SAQ treatment satisfaction (Pinteraction = .025) with greater efficacy of ranolazine in those with higher HbA1c values, increasing continuously from HbA1c levels >6.5%. CONCLUSION: Among patients with T2DM and stable angina, the therapeutic benefits of ranolazine were greater in those with higher HbA1c values. These data suggest that ranolazine is particularly beneficial in patients with stable angina who have suboptimally controlled T2DM.

Arora, Vineet (2006):

The Effects of On-Duty Napping on Intern Sleep Time and Fatigue.

In: *Ann Intern Med* 144 (11), S. 792. DOI: 10.7326/0003-4819-144-11-200606060-00005.

Abstract:

Background:

Naps during extended work shifts are effective in reducing fatigue in other industries, but the use of a nap as a countermeasure to prevent fatigue in residents is uncertain.

Objective:

To assess the effects of a call-night nap on resident sleep and fatigue.

Design:

1-year, within-participant, paired trial with crossover at midmonth.

Setting:

Academic teaching hospital. Participants: 38 of 40 internal medicine interns.

Measurements:

Sleep was measured by using wristwatch actigra-phy. By using the experience sampling method on a personal digital assistant, random alerts prompted interns to rate fatigue on the 7-point Stanford Sleepiness Scale (7 is most tired). Hospital paging logs and structured interviews provided information on use of cov- erage.

Intervention:

For 2 weeks of every month, interns were assigned to the nap schedule, which provided coverage to on-duty interns from midnight to 7:00 a.m. so that they could finish their work and take a nap. The other 2 weeks of the month constituted a standard schedule.

Results:

Interns received 41 more minutes of sleep while on call with the nap schedule (185 minutes vs. 144 minutes; P 0.001). When interns with the nap schedule used coverage, they received 68 more minutes of sleep (210 minutes vs. 142 minutes; P0.001). Despite these small increases in sleep, interns reported less overall fatigue while on the nap schedule than while on the stan- dard schedule (1.74 vs. 2.26; P10.017). Postcall fatigue with the nap schedule was lower by nearly 1 point (2.23 vs 3.16; P2 0.036), which is almost equivalent to the difference between on- call and postcall fatigue with the standard schedule (2.06 vs. 3.16). However, use of coverage by interns on the nap schedule was impaired by their desire to care for their patients and concerns about discontinuity of care.

Limitations: This was a single-institution study that did not have the power to examine outcomes related to intern or patient well-being.

Conclusions: Coverage to allow a nap during an extended duty-hour shift can increase sleep and decrease fatigue for residents

Arora, Sanjay (2014):

Text message program improves outcomes, decreases ED utilization among ED patients with poorly controlled diabetes.

In: *ED Manag* 26 (2), S. 20–23.

Abstract:

Diabetic patients who lack access to primary care tend to frequent the ED, often with complications from their disease that could have been prevented with proper management and education. To get around the problem of access, researchers tested an automated program that continuously delivered educational messaging via text to a group of patients who presented to the ED with poorly controlled diabetes. After six months, researchers noted improvements in Hb A1c levels, self-reported medication adherence, and ED utilization when compared with a control group. And the impact was particularly noteworthy among Latinos, according to the researchers. The text messaging program, dubbed TExT-Med, was developed by four physicians and two diabetes educators. The messages were delivered daily, and contained educational as well motivational content derived from the National Diabetes Education Program.There were also medication reminders, healthy living challenges, and trivia questions about diabetes. At six months, Hb A1c levels decreased by 1.05% in the intervention group, compared to 0.60% in the control group, and self-reported medication adherence improved from 4.5 to 5.4 (as measured on an 8 point scale) in the intervention group versus a decrease of 0.1 in the control group. During the six-month study period, 35.9% of patients in the intervention group presented to the ED for care, as compared to 51.6% of patients in the control group.

Arora, Vineet M.; Georgitis, Emily; Siddique, Juned; Vekhter, Ben; Woodruff, James N.; Humphrey, Holly J.; Meltzer, David O. (2008):

Association of workload of on-call medical interns with on-call sleep duration, shift duration, and participation in educational activities.

In: *JAMA* 300 (10), S. 1146–1153.

Abstract:

CONTEXT:

Further restrictions in resident duty hours are being considered, and it is important to understand the association between workload, sleep loss, shift duration, and the educational time of on-call medical interns.

OBJECTIVE:

To assess whether increased on-call intern workload, as measured by the number of new admissions on-call and the number of previously admitted patients remaining on the service, was associated with reductions in on-call sleep, increased total shift duration, and lower likelihood of participation in educational activities.

DESIGN, SETTING, AND PARTICIPANTS:

Prospective cohort study of medical interns at a single US academic medical center from July 1, 2003, through June 24, 2005. Of the 81 interns, 56 participated (69%), for a total of 165 general medicine inpatient months resulting in 1100 call nights.

MAIN OUTCOME MEASURES:

On-call sleep duration, estimated by wrist watch actigraphy; total shift duration, measured from paging logs; and participation in educational activities (didactic lectures or bedside teaching), measured by experience sampling method via a personal digital assistant.

RESULTS:

Mean (SD) sleep duration on-call was 2.8 (1.5) hours and mean (SD) shift duration was 29.9 (1.7) hours. Interns reported spending 11% of their time in educational activities. Early in the academic year (July to October), each new on-call admission was associated with less sleep (-10.5 minutes [95% confidence interval {CI}, -16.8 to -4.2 minutes]; P < .001) and a longer shift duration (13.2 minutes [95% CI, 3.2-23.3 minutes]; P = .01). A higher number of previously admitted patients remaining on the service was associated with a lower odds of participation in educational activities (odds ratio, 0.82 [95% CI, 0.70-0.96]; P = .01]. Call nights during the week and early in the academic year were associated with the most sleep loss and longest shift durations.

CONCLUSION:

In this study population, increased on-call workload was associated with more sleep loss, longer shift duration, and a lower likelihood of participation in educational activities.

Arundell, Lauren; Ridgers, Nicola D.; Veitch, Jenny; Salmon, Jo; Hinkley, Trina; Timperio, Anna (2013):

5-year changes in afterschool physical activity and sedentary behavior.

In: *Am J Prev Med* 44 (6), S. 605–611. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-17361-009%26site%3dehost-live;nicky.ridgers@deakin.edu.au.

Abstract:

Background: The afterschool period holds promise for the promotion of physical activity, yet little is known about the importance of this period as children age. Purpose: To examine changes in physical activity of children aged 5–6 years and 10–12 years and their sedentary time in the afterschool period over 3 and 5 years, and to determine the contribution of this period to daily physical activity and sedentary behavior over time. Methods: Data from two longitudinal studies conducted in Melbourne, Australia, were used. Accelerometer data were provided for 2053 children at baseline (Children Living in Active Neighbourhoods Study [CLAN]: 2001; Health, Eating and Play Study [HEAPS]: 2002/2003); 756 at 3-year follow-up (time point 2 [T2]); and 622 at 5-year follow-up (T3). Light (LPA), moderate (MPA) and vigorous (VPA) physical activity were determined using age-adjusted cut-points. Sedentary time was defined as ≤ 100 counts/minute. Multilevel analyses, conducted in April 2012, assessed change in physical activity and sedentary time and the contributions of the afterschool period to overall levels. Results: Afterschool MPA and VPA decreased among both cohorts, particularly in the younger cohort, who performed less than half of their baseline levels at T3 (MPA: T1 = 24 minutes; T3 = 11 minutes; VPA: T1 = 12 minutes; T3 = 4 minutes). LPA also declined in the older cohort. Afterschool sedentary time increased among the younger (T1 = 42 minutes; T3 = 64 minutes) and older cohorts (T1 = 57 minutes; T3 = 84 minutes). The contribution of the afterschool period to overall MPA and VPA increased in the older cohort from 23% to 33% over 5 years. In the younger cohort, the contribution of the afterschool period to daily MPA and VPA decreased by 3% over 5 years. Conclusions: The importance of the afterschool period for children's physical activity increases with age, particularly as children enter adolescence. Arvidsson, D.; Eriksson, U.; Lonn, S. L.; Sundquist, K. (2012):

Neighborhood Walkability, Income, and Hour-by-Hour Physical Activity Patterns.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e31827a1d05.

Abstract:

PURPOSE: To investigate both the mean daily physical activity and the hour by hour physical activity pattern across the day using accelerometry, and how they are associated with neighborhood walkability and individual income. METHODS: Moderate physical activity (MPA) was assessed by accelerometry in 2,252 adults in the City of Stockholm, Sweden. Neighborhood walkability (residential density, street connectivity, land use mix) was objectively assessed within 1,000m network buffers around the participants' residence and individual income was self-reported. RESULTS: Living in a high walkability neighborhood was associated with more mean daily MPA compared with living in a low walkability neighborhood on weekdays and weekend days. Hour by hour analyses showed that this association appeared mainly in the afternoon/early evening during weekdays, while it appeared across the middle of the day during weekend days. Individual income was associated with mean daily MPA on weekend days. On weekdays, the hour by hour analyses showed that high income was associated with more MPA around noon and in late afternoon/early evening, while low income was associated with more MPA at the hours before noon and in the early afternoon. During the weekend, high income was more consistently associated with higher MPA. CONCLUSIONS: Hour by hour accelerometry physical activity patterns provides a more comprehensive picture of the associations between neighborhood walkability and individual income and physical activity and the variability of these associations across the day

Arzbaecher, Robert; Hampton, David R.; Burke, Martin C.; Garrett, Michael C. (2010):

Subcutaneous electrocardiogram monitors and their field of view.

In: *J Electrocardiol* 43 (6), S. 601–605.

Abstract:

Continuous electrocardiogram (ECG) monitoring of cardiac patients on a long-term, even permanent, basis has become possible. Postsurgical cases, those with significant risk factors, or patients with chronic conditions are candidates for these procedures to assess evolving risk factors and detect life-threatening events. A small sensing device can be implanted subcutaneously to assess the ECG, transmitting status and alerts to local caregivers or a remote monitoring service. We and others have shown that a differential electrode pair with only 2- to 3-cm spacing can produce QRS amplitudes greater than 1 mV, sufficient to accurately identify asystole, tachyarrhythmias, and ST-segment changes. Medtronic's REVEAL and St Jude Medical's CONFIRM are implantable look recorders (ILRs) with a single pair of subcutaneous electrodes mounted on the surface of the case (6 × 2 × 0.7 cm). They store representative rhythm strips when the heart rate exceeds preset limits or when the patient presses a button on the accompanying actuator. These records may be transferred for physician review during a subsequent office visit. Transoma's SLEUTH is a similar ILR, except that one of the electrodes is at the end of a 6-cm lead tunneled under the skin and the wider separation may result in a larger ECG amplitude. Instead of storing the records, SLEUTH transmits them through the skin to a home base unit, which sends them via telephone to a monitoring service. Angel Medical's ALERT system also has a tunneled lead, but one that is introduced pervenously into the right ventricle hoping to detect ST changes in addition to rhythm abnormalities. Advanced multivector ILR devices with integrated event alerting are rapidly approaching commercialization. AJ Medical Devices' CARDIOALARM (4 × 4 × 0.6 cm) has 4 electrodes at the corners of the square package, arranged as 2

orthogonal recording pairs that can produce a robust signal that is relatively immune to signal fluctuations caused by changes in the direction of cardiac activation and patient's body position. This permits accurate identification of dramatic changes in the ECG pattern, such as those occurring in ventricular fibrillation and polymorphic tachycardia. Because of this feature, CARDIOALARM can detect cardiac arrest, and its external receiver can alert bystanders to begin cardiopulmonary resuscitation and can automatically summon Emergency Medical Services. In the future, addition of other sensors, integration of data streams via body surface wireless networks, and real-time interpretive algorithms will allow enhanced monitoring systems to more generally assess evolving risks, the impacts of therapeutic interventions, and patient compliance with rehabilitative programs. When coupled to remote medical monitoring services, these devices have the potential to dramatically impact patient outcomes by lessening the diagnostic dependence on symptom recognition and decreasing event response times. Significant cost savings may also be realized through more efficient use of specialist resources, reduction in the number of office visits to physicians, and long-term improvements in patient health. Structural and behavior barriers to adoption need to be addressed for these methods to reach their full potential, addressing patient privacy concerns, adequate reimbursement, and integration into standard care protocols.

Asaka, Yoko; Takada, Satoshi (2011):

Comparing sleep measures of infants derived from parental reports in sleep diaries and acceleration sensors.

In: *Acta Paediatr* 100 (8), S. 1158–1163. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-14007-035&site=ehost-live;asaka@konan-wu.ac.jp.

Abstract:

Aim: Comparing sleep measures of infants derived from two data collection methods, acceleration sensors and sleep diaries, and identify the clinical application for each data collection method. Methods: The participants were 52 pairs of infants and mothers. Infant sleep measures were obtained through the actigraphs (Micro-mini RC, Ambulatory Monitoring Inc., Ardsley, NY, USA) and sleep diaries for over a period of 7 days. Results: The results showed that the concordance in sleep measures derived from two methods showed decreases in the following order: sleep offset time [r = 0.91 (p = 0.00)], sleep onset time r = 0.89 (p = 0.00), nocturnal sleep duration [r = 0.75 (p = 0.00)], the number of night wakings [r = 0.46 (p < 0.01)] and WASO [r = 0.34 (p < 0.05)]. It was revealed that the accuracy of sleep diary records was affected by the sleeping place and varied throughout the study period. Conclusion: It was confirmed that the sleep measures indicating sleep schedule reported from the sleep diaries had high concordances compared with the data from the actigraphs. Using the sleep diary was recommended to understand behaviours when focusing on infant's daily rhythms. In terms of accuracy and stability of recording throughout the study period, understanding sleep quality and independence of sleeping places, the choice of actigraph was recommended. Asferg, C. L.; Andersen, U. B.; Linneberg, A.; Goetze, J. P.; Jeppesen, J. L. (2014):

Copeptin, a surrogate marker for arginine vasopressin secretion, is associated with higher glucose and insulin concentrations but not higher blood pressure in obese men.

In: *Diabet Med. DOI:* 10.1111/dme.12411.

Abstract:

AIM: To explore the putative associations of plasma copeptin, the C-terminal portion of provasopressin and a surrogate marker for arginine vasopressin secretion, with obesity-related health problems, such as hyperlipidaemia, hyperinsulinaemia, hyperglycaemia, high blood pressure and an android fat distribution. METHODS: In 103 obese men (mean age +/- standard deviation: 49.4 +/- 10.2 years) and 27 normal weight control men (mean age: 51.5 +/- 8.4 years), taking no medication, we measured 24-h ambulatory blood pressure, fasting blood concentrations of copeptin, lipids, glucose and insulin, and determined body composition by dual energy X-ray absorptiometry scanning. RESULTS: The obese men had higher [median (interquartile range)] plasma copeptin concentrations [6.6 (4.6-9.5) vs. 4.9 (3.5-6.8) pmol/l, P = 0.040] compared with the normal weight men. In the obese men, plasma copeptin was not related to 24-h systolic blood pressure (r = 0.11, P = 0.29), 24-h diastolic blood pressure (r = 0.11, P = 0.28), BMI (r = 0.09, P = 0.37), total body fatness percentage (r = 0.10, P = 0.33), android fat mass percentage (r = 0.04, P = 0.66) or serum triglyceride concentrations (r = 0.04; P = 0.68). In contrast, plasma copeptin was associated with higher serum insulin concentrations (r = 0.26, P = 0.0085) and insulin resistance as assessed by the homeostasis assessment model (r = 0.28, P = 0.0051). CONCLUSIONS: Plasma copeptin, a surrogate marker for arginine vasopressin secretion, is higher in obese men compared with normal weight men, and is associated with abnormalities in glucose and insulin metabolism, but not with higher blood pressure or an android fat distribution in obese men.

Asferg, Camilla L.; Andersen, Ulrik B.; Linneberg, Allan; Moller, Daniel V.; Hedley, Paula L.; Christiansen, Michael; Jeppesen, Jorgen L. (2014):

Obese Hypertensive Men Have Plasma Concentrations of C-Reactive Protein Similar to That of Obese Normotensive Men.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu029.

Abstract:

BACKGROUND: Low-grade chronic inflammation is a characteristic feature of obesity, the most important lifestyle risk factor for hypertension. Elevated plasma concentrations of the inflammatory biomarker C-reactive protein (CRP) are associated with an increased risk of hypertension, but elevated plasma CRP concentrations are also closely associated with obesity. It is uncertain whether CRP is directly involved in the pathogenesis of hypertension or is only a marker of other pathogenic processes closely related to obesity. METHODS: We studied 103 obese men (body mass index (BMI) >/=30.0kg/m2); 63 of these men had 24-hour ambulatory blood pressure (ABP) >/=130/80mm Hg and comprised the obese hypertensive (OHT) group. The 40 remaining obese men had 24-hour ABP <130/80mm Hg and comprised the obese normotensive (ONT) group. Our control group comprised 27 lean normotensive (LNT) men. All participants were medication-free. We measured plasma CRP concentrations with a high-sensitivity assay and determined body composition by dual energy x-ray absorptiometry scanning. RESULTS: There were no differences in anthropometric measures (BMI, waist circumference, or total fat mass percentage) between OHT and ONT groups (P >/= 0.08). The obese groups had higher CRP concentrations than the LNT group (OHT: median = 2.30, interquartile range (IQR) = 1.10-4.10mg/L; ONT: median = 2.55, IQR = 1.25-4.80mg/L; LNT: median = 0.60, IQR = 0.30-1.00mg/L; P < 0.001), but there was no difference in CRP concentrations between OHT and ONT groups (P = 1.00). In the obese men, CRP was not correlated with either 24-hour systolic (r = 0.04; P = 0.71) or 24-hour diastolic ABP (r = -0.03; P = 0.78). CONCLUSIONS: Obese hypertensive men, matched for anthropometric measurements, have plasma CRP concentrations similar to those of obese normotensive men.

Ash, Garrett I.; Walker, Timothy J.; Olson, Kayla M.; Stratton, Jeffrey H.; Gomez, Ana L.; Kraemer, William J. et al. (2013):

Reproducibility of ambulatory blood pressure changes from the initial values on two different days.

In: *Clinics (Sao Paulo)* 68 (12), S. 1509–1515. DOI: 10.6061/clinics/2013(12)06.

Abstract:

OBJECTIVE: We tested the reproducibility of changes in the ambulatory blood pressure (BP) from the initial values, an indicator of BP reactivity and cardiovascular health outcomes, in young, healthy adults. METHOD: The subjects wore an ambulatory BP monitor attached by the same investigator at the same time of day until the next morning on two different days (day 1 and day 2) separated by a week. We compared the ambulatory BP change from the initial values at hourly intervals over 24 waking and sleeping hours on days 1 and 2 using linear regression and repeated measures analysis of covariance. RESULTS: The subjects comprised 88 men and 57 women (mean age+/-SE 22.4+/-0.3 years) with normal BP (118.3+/-0.9/69.7+/-0.6 mmHg). For the total sample, the correlation between the ambulatory BP change on day 1 vs. day 2 over 24, waking, and sleeping hours ranged from 0.37-0.61; among women, the correlation was 0.38-0.71, and among men, it was 0.24-0.52. Among women, the ambulatory systolic/diastolic BP change was greater by 3.1+/-1.0/2.4+/-0.8 mmHg over 24 hours and by 3.0+/-1.1/2.4+/-0.8 mmHg over waking hours on day 1 than on day 2. The diastolic ambulatory BP change during sleeping hours was greater by 2.2+/-0.9 mmHg on day 1 than on day 2, but the systolic ambulatory BP change during sleeping hours on days 1 and 2 did not differ. Among men, the ambulatory BP change on days 1 and 2 did not differ. CONCLUSION: Our primary findings were that the ambulatory BP change from the initial values was moderately reproducible; however, it was more reproducible in men than in women. These results suggest that women, but not men, may experience an alerting reaction to initially wearing the ambulatory BP monitor.

Atienza, Audie A.; King, Abby C.; Oliveira, Brian M.; Ahn, David K.; Gardner, Christopher D. (2008):

Using hand-held computer technologies to improve dietary intake.

In: *Am J Prev Med* 34 (6), S. 514–518.

Abstract:

Background

Portable hand-held information technology offers much promise not only in assessing dietary intake in the real world, but also in providing dietary feedback to individuals. However, stringent research designs have not been employed to examine whether it

can be effective in modifying dietary behaviors. The purpose of this pilot study was to evaluate the efficacy of a hand-held computer (i.e., personal digital assistant [PDA]) for increasing vegetable and whole-grain intake over 8 weeks in mid-life and older adults, using a randomized study design.

Methods

Twenty-seven healthy adults aged ≥50 were randomized and completed the 8-week study. Intervention participants received an instructional session and a PDA programmed to monitor their vegetable and whole-grain intake levels twice per day and to provide daily individualized feedback, goal-setting, and support. Controls received standard, age-appropriate, written nutritional education materials. Dietary intake was assessed via the Block Food Frequency Questionnaire at baseline and 8 weeks.

Results

Relative to controls, intervention participants reported significantly greater increases in vegetable servings (1.5–2.5 servings/day; p=0.02), as well as a trend toward greater intake of dietary fiber from grains (3.7–4.5 servings/day; p=0.10).

Conclusions

This study's findings provide preliminary evidence that using portable hand-held technology to provide daily individualized feedback on dietary behavior in the real world can increase the dietary intake of healthy food groups.

Atkin, A. J.; Gorely, T.; Clemes, S. A.; Yates, T.; Edwardson, C.; Brage, S. et al. (2012):

Methods of Measurement in epidemiology: sedentary Behaviour.

In: *Int.J Epidemiol.* 41 (5), S. 1460–1471. DOI: 10.1093/ije/dys118.

Abstract:

BACKGROUND: Research examining sedentary behaviour as a potentially independent risk factor for chronic disease morbidity and mortality has expanded rapidly in recent years. METHODS: We present a narrative overview of the sedentary behaviour measurement literature. Subjective and objective methods of measuring sedentary behaviour suitable for use in population-based research with children and adults are examined. The validity and reliability of each method is considered, gaps in the literature specific to each method identified and potential future directions discussed. RESULTS: To date, subjective approaches to sedentary behaviour measurement, e.g. questionnaires, have focused predominantly on TV viewing or other screen-based behaviours. Typically, such measures demonstrate moderate reliability but slight to moderate validity. Accelerometry is increasingly being used for sedentary behaviour assessments; this approach overcomes some of the limitations of subjective methods, but detection of specific postures and postural changes by this method is somewhat limited. Instruments developed specifically for the assessment of body posture have demonstrated good reliability and validity in the limited research conducted to date. Miniaturization of monitoring devices, interoperability between measurement and communication technologies and advanced analytical approaches are potential avenues for future developments in this field. CONCLUSIONS: High-quality measurement is essential in all elements of sedentary behaviour epidemiology, from determining associations with health outcomes to the development and evaluation of behaviour change interventions. Sedentary behaviour measurement remains relatively under-developed, although new instruments, both objective and subjective, show considerable promise and warrant further testing

Atkin, Andrew J.; Sharp, Stephen J.; Corder, Kirsten; van Sluijs, Esther M F (2014):

Prevalence and Correlates of Screen time in Youth: An International Perspective.

In: *Am J Prev Med. DOI:* 10.1016/j.amepre.2014.07.043.

Abstract:

BACKGROUND: Screen time (including TV viewing/computer use) may be adversely associated with metabolic and mental health in children. PURPOSE: To describe the prevalence and sociodemographic correlates of screen time in an international sample of children aged 4-17 years. METHODS: Data from the International Children's Accelerometry Database were collected between 1997-2009 and analyzed in 2013. Participants were 11,434 children (48.9% boys; mean [SD] age at first assessment, 11.7 [3.2] years). Exposures were sex, age, weight status, maternal education, and ethnicity. The outcome was self- or proxy-reported screen time <2 or >2 hours/day. Analyses were conducted initially at study level and then combined using random-effects meta-analysis. RESULTS: Within each contributing study, at least two thirds of participants exceeded 2 hours/day of screen time. In meta-analytic models, overweight or obese children were more likely to exceed 2 hours/day of screen time than those who were non-overweight (OR=1.58, 95% CI=1.33,1.88). Girls (vs boys: 0.65; 0.54, 0.78) and participants with more highly educated mothers (vs <university level: 0.53; 0.42, 0.68) were less likely to exceed 2 hours/day of screen time. Associations of age and ethnicity with screen time were inconsistent at study level and non-significant in pooled analyses. CONCLUSIONS: Screen time in excess of public health guidelines was highly prevalent, particularly among boys, those who were overweight or obese, and

those with mothers of lower educational attainment. The population-attributable risk associated with this exposure is potentially high; further efforts to understand the determinants of within- and between-country variation in these behaviors and inform the development of effective behavior change intervention programs is warranted.

Attu, S. D.; Rhebergen, D.; Comijs, H. C.; Parker, G.; Stek, M. L. (2012):

Psychomotor symptoms in depressed elderly patients: assessment of the construct validity of the Dutch CORE by accelerometry.

In: *J.Affect.Disord.* 137 (1-3), S. 146–150. DOI: 10.1016/j.jad.2011.12.035.

Abstract:

BACKGROUND: Psychomotor symptoms are putative distinguishing features of melancholia that may guide treatment decisions. Hence, there is a need for valid instruments to assess psychomotor symptoms. The objective of this study is to examine the construct validity of the CORE, an observational instrument designed to quantify psychomotor symptoms in depression. METHODS: Associations between CORE scores and levels of motor activity measured by accelerometry were examined in a sample of 25 elderly depressed in-patients, for various time intervals, during 24h of follow-up. RESULTS: Total CORE scores (as well as CORE retardation and agitation sub-scale scores) were negatively correlated with activity scores, with depression severity increasing the correlational strength substantively. For total CORE scores and retardation sub-scale scores, the highest associations were quantified across morning intervals. LIMITATIONS: Given the nature of the study mild levels of depression were overrepresented, monitoring of motor activity lasted only 24h and non-motor activity items in the CORE were not measured. CONCLUSION: Associations between CORE total scores and retardation sub-scale scores support the validity of the CORE as well as quantifying associations between severity of psychomotor disturbance and clinical depression severity. Study results also support the application of accelerometry tools in quantifying components of clinical depression

Audrain-McGovern, Janet; Wileyto, E. Paul; Ashare, Rebecca; Cuevas, Jocelyn; Strasser, Andrew A. (2014):

Reward and affective regulation in depression-prone smokers.

In: *Biological Psychiatry* 76 (9), S. 689–697. DOI: 10.1037/t03774-000;

Abstract:

Background: There is a disproportionately high smoking prevalence among individuals who are prone to depression. While depression has been conceptualized as a disorder of dysregulated positive affect and disrupted reward processing, little research has been conducted to determine the role of smoking in these processes among depression-prone smokers. Methods: Depression-prone smokers (DP+; n = 34) and smokers not depression-prone (DP−; n = 49) underwent two laboratory sessions, one while smoking abstinent and one while smoking ad libitum, to assess the relative reinforcing value of smoking and reward sensitivity. Using experience sampling methods, participants completed self-report measures of subjective reward, positive affect, and negative affect across 3 days while smoking as usual and 3 days while smoking abstinent. Results: DP+ were two times more likely to work for cigarette puffs versus money in a progressive ratio, choice task (odds ratio 2.05; 95% confidence interval 1.04 to 4.06, p = .039) compared with DP−. Reward sensitivity as measured by the signal detection task did not yield any significant findings. Mixed models regressions revealed a three-way interaction (depression group, smoking phase, and time) for subjective reward, negative affect, and positive affect. For all three of these outcomes, the slopes for DP− and DP+ differed significantly from each other (ps < .05) and the effect of smoking (versus abstinence) over time was greater for DP+ than DP− smokers (ps < .05). Conclusions: These findings indicate that the effects of smoking on reward and positive affect regulation are specific to DP+ smokers and highlight novel targets for smoking cessation treatment in this population. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Avet, John; Pichot, Vincent; Barthelemy, Jean-Claude; Laurent, Bernard; Garcin, Arnauld; Roche, Frederic; Celle, Sebastien (2014):

Leukoaraiosis and ambulatory blood pressure load in a healthy elderly cohort study: the PROOF study.

In: *Int J Cardiol* 172 (1), S. 59–63. DOI: 10.1016/j.ijcard.2013.11.052.

Abstract:

BACKGROUND: Old age and hypertension are consistently reported to be the main risk factors of leukoaraiosis. The association between white matter lesions (WMLs) and other cardiovascular risk factors (CVRF) remains controversial. We evaluated the

association between CVRF and WMLs in a cohort study and determined the blood pressure variables that could predict WML severity. METHODS: 830 subjects (65+/-1 years of age, 60% women) from the PROOF study, with a reliable ABPM and brain MRI, were included. The exclusion criteria included prior myocardial infarction, stroke, heart failure, atrial fibrillation, type 1 diabetes mellitus, and pacing. White matter changes on MRI were defined as hyperintensities >5mm on FLAIR images. We used the total degree of WML (range: 0-30) by adding the region-specific scores of both hemispheres. RESULTS: Linear regression analyses demonstrated a significant relationship between total leukoaraiosis score and 24h systolic blood pressure (SBP), 24h diastolic BP, daytime SBP and DBP and nighttime SBP. No significant relationship was found between leukoaraiosis score and clinical SBP, clinical DBP, or nocturnal DIP. There was also no significant relationship between leukoaraiosis and other recognized cardiovascular risk factors. Based on a ROC curve analysis, we identified the optimal threshold separating high-risk WML patients for a mean 24h SBP above 123 mmHg (p<0.05). CONCLUSIONS: Even moderate increases in 24h SBP promote arteriolar fragility of the cerebral white matter in a population aged 65. The prognostic implications of such abnormalities in asymptomatic and moderate cardiovascular risk populations remain to be evaluated.

Axelsson, Johan; Reinprecht, Faina; Siennicki-Lantz, Arkadiusz; Elmståhl, Sölve (2008):

Low ambulatory blood pressure is associated with lower cognitive function in healthy elderly men.

In: *Blood Press Monit* 13 (5), S. 269–275. DOI: 10.1097/MBP.0b013e32830d4be6.

Abstract:

INTRODUCTION\r\nLow blood pressure (BP) has been found to be associated with cerebrovascular damage in the elderly. Studies of the relation of ambulatory BP to cognitive function in elderly persons aged 80 years or above is lacking, however.\r\nMETHODS\r\nNinety-seven 81-year-old men from the population study 'Men born in 1914' underwent ambulatory BP monitoring and were given a cognitive test battery, 79 subjects completing all six tests. Low ambulatory systolic blood pressure (SBP) was defined as <130 mmHg and low ambulatory diastolic blood pressure (DBP) as <80 mmHg (corresponding in terms of office BP to approximately <140 and <90 mmHg, respectively). Odds ratios (OR) for lower cognitive function were calculated using a forward stepwise logistic regression model, controlling for confounding factors.\r\nRESULTS\r\nSubjects with ambulatory SBP <130 mmHg had higher OR values for daytime (OR 2.6; P=0.037), nighttime (OR 3.6; P=0.032) and 24h (OR 2.6; P=0.038) BP measurements. A lower cognitive function was associated with lower nighttime SBP and DBP levels and lower 24-h mean SBP compared to subjects with higher cognitive function. OR values connected to low nocturnal SBP, had a tendency to be particularly high among subjects on anti-hypertensive drugs (OR 9.1; P=0.067, n.s.).\r\nCONCLUSION\r\nAmbulatory SBP levels <130 mmHg and lower nighttime SBP and DBP were associated with lower cognitive function in healthy elderly men. Further investigation is needed to ascertain the effects of the presently recommended treatment goal of <140 mmHg for office SBP also on elderly over 80 years of age.

Age-related differences in daily physical activity divided by bout duration: Preliminary findings in female convenience samples.

In: *Journal of Sports Sciences* 30 (7), S. 709–713. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-08444-011&site=ehost-live;ayabemakoto@mac.com.

Abstract:

The purpose of the present investigation was to clarify the relationship between age and bout duration of physical activity (PA) under free-living conditions in female adults. Forty-three females wore an accelerometer (Lifecorder) for seven consecutive days in order to determine the time spent in PA at light intensity (LPA), at moderate intensity (MPA), and at vigorous intensity (VPA). The PA was divided according to the bout duration, such as PA lasting longer than 16 s, 32 s, 60 s, 3 min, >5 min, and >10 min (PA16s, PA32s, PA1m, PA3m, PA5m, PA10m). The time for LPA32s, LPA1m, MPA16s, VPA16s, and the total time for MPA and VPA were significantly associated with age (P < 0.05). There were no significant associations between age and PA lasting >60 s, regardless of intensity category. The results of the present pilot study suggest that the age-associated differences in PA occur mainly in PA lasting 1 min or shorter duration. Ayabe, M.; Kumahara, H.; Morimura, K.; Tanaka, H. (2013):

Epoch length and the physical activity bout analysis: an accelerometry research issue.

In: *BMC Res Notes* 6 (1756-0500 (Linking)), S. 20. DOI: 10.1186/1756-0500-6-20.

Abstract:

BACKGROUND: The purpose of the present investigation was to compare the bouts of daily physical activity (PA) determined by three different accelerometer epoch lengths under free-living conditions. METHODS: One hundred thirty-four adults (50 +/- 7 years) wore an accelerometer (Lifecorder) for 7 consecutive days under free-living conditions in order to determine the time spent in physical activity of light intensity (LPA), moderate intensity (MPA), vigorous intensity (VPA), moderate to vigorous intensity (MVPA), and the total physical activity (TPA; sum of LPA, MPA and VPA). Additionally, all PA was divided according to the bout durations (sporadic, > 3 min, > 5 min, and > 10 min). These indices of PA were analyzed using three different epoch lengths (4 sec, 20 sec and 60 sec) derived from the accelerometer. RESULTS: The LPA significantly increased in association with increases in the epoch length (48.7 +/- 15.9 to 178.7 +/- 62.6 min/day, $p < 0.05$). The amount of sporadic VPA determined by the shortest epoch length (2.9 +/- 5.2 min/day) was significantly longer than the two remaining epoch lengths (1.1 +/- 2.4 to 0.9 +/- 2.5 min/day, $p < 0.05$). The times of the MVPA bouts lasting longer than 3 minutes determined using the 4-second epoch length (2.6 +/- 5.4 to 7.7 +/- 10.0 min/day) were significantly shorter than those determined using the other two settings (6.5 +/- 10.5 to 13.8 +/- 13.8 min/day, $p < 0.05$). The frequencies of the MVPA bouts lasting longer than 10 minutes determined using the 4-second epoch length (0.2 +/- 0.3 bouts/day) were significantly lower than those determined using the other two settings (0.3 +/- 0.4 bouts/day, $p < 0.05$). CONCLUSION: The epoch length setting of the accelerometer affects the estimation of the PA bouts under free-living conditions in middle-aged to older adults

Ayabe, Makoto; Kumahara, Hideaki; Morimura, Kazuhiro; Tanaka, Hiroaki (2014):

Interruption in physical activity bout analysis: an accelerometry research issue.

In: *BMC Res Notes* 7, S. 284. DOI: 10.1186/1756-0500-7-284.

Abstract:

BACKGROUND: The purpose of the present investigation was to clarify the impact of the treatment of interruptions on the durations and the frequency of the physical activity (PA) bouts under free-living conditions. METHODS: One hundred and forty adults (50 +/- 7 years) wore an accelerometer (Lifecorder) for seven consecutive days under free-living conditions. According to the minutes by minutes metabolic equivalents (METs) value, the PA was divided into one of three intensity categories: light intensity PA (LPA, < 3 METs), moderate intensity PA (MPA, 3 to 6 METs), vigorous intensity PA (VPA, > 6 METs), and the sum of the MPA and VPA was defined as moderate to vigorous intensity PA (MVPA, > 3 METs). Thereafter, based on the time series data, we defined MVPA bouts as PA that was maintained at no less than 3 METs completely for 10 minutes or longer with or without allowing for a one-minute or a two-minute break (<3METs). RESULTS: The frequency and duration of the continuous MVPA bouts lasting longer than 10-min were significantly lower and shorter compared with that in the non-continuous MVPA bouts allowing a one- or two-minute interruption (4.11 +/- 1.65, 6.58 +/- 2.72 and 8.97 +/- 3.55 bouts/day, 71.62 +/- 33.66, 119.03 +/- 49.35 and 169.75 +/- 65.87 min/day, $P < 0.05$). The number of days with a total time of MVPA bouts of 30-min was significantly lower in the continuous MVPA bouts compared with that in the non-continuous MVPA bouts allowing a 1-min or 2-min interruption (5.36 +/- 1.65, 6.39 +/- 1.07 and 6.65 +/- 0.85 days/week). CONCLUSION: The treatment of interruptions for the setting of the accelerometer affects the estimation of the MVPA bouts under free-living conditions in middle-aged to older adults. The best analysis process with regard to the accelerometer quantifying the break to reflect the real behavioral pattern and the physiological stress in such subjects remains unclear.

Ayazi, Shahin; Leers, Jessica M.; Oezcelik, Arzu; Abate, Emmanuele; Peyre, Christian G.; Hagen, Jeffrey A. et al. (2009):

Measurement of gastric pH in ambulatory esophageal pH monitoring.

In: *Surgical endoscopy* 23 (9), S. 1968–1973.

Abstract:

Background

Ambulatory esophageal pH monitoring is the method used most widely to quantify gastroesophageal reflux. The degree of gastroesophageal reflux may potentially be underestimated if the resting gastric pH is high. Normal subjects and symptomatic patients undergoing 24-h pH monitoring were studied to determine whether a relationship exists between resting gastric pH and the degree of esophageal acid exposure.

Methods

Normal volunteers (n = 54) and symptomatic patients without prior gastric surgery and off medication (n = 1,582) were studied. Gastric pH was measured by advancing the pH catheter into the stomach before positioning the electrode in the esophagus. The normal range of gastric pH was defined from the normal subjects, and the patients then were classified as having either normal gastric pH or hypochlorhydria. Esophageal acid exposure was compared between the two groups.

Results

The normal range for gastric pH was 0.3–2.9. The median age of the 1,582 patients was 51 years, and their median gastric pH was 1.7. Abnormal esophageal acid exposure was found in 797 patients (50.3%). Hypochlorhydria (resting gastric pH >2.9) was detected in 176 patients (11%). There was an inverse relationship between gastric pH and esophageal acid exposure (r = −0.13). For the patients with positive 24-h pH test results, the major effect of gastric pH was that the hypochlorhydric patients tended to have more reflux in the supine position than those with normal gastric pH.

Conclusion

There is an inverse, dose-dependent relationship between gastric pH and esophageal acid exposure. Negative 24-h esophageal pH test results for a patient with hypochlorhydria may prompt a search for nonacid reflux as the explanation for the patient's symptoms.

Ayubi, S. U.; Parmanto, B. (2012):

PersonA: Persuasive social network for physical Activity.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 2153–2157. DOI: 10.1109/EMBC.2012.6346387.

Abstract:

Advances in physical activity (PA) monitoring devices provide ample opportunities for innovations in the way the information produced by these devices is used to encourage people to have more active lifestyles. One such innovation is expanding the current use of the information from self-management to social support. We developed a Persuasive social network for physical Activity (PersonA) that combines automatic input of physical activity data, a smartphone, and a social networking system (SNS). This paper describes the motivation for and overarching design of the PersonA and its functional and non-functional features. PersonA is designed to intelligently and automatically receive raw PA data from the sensors in the smartphone, calculate the data into meaningful PA information, store the information on a secure server, and show the information to the users as persuasive and real-time feedbacks or publish the information to the SNS to generate social support. The implementation of self-monitoring, social support, and persuasive concepts using currently available technologies has the potential for promoting healthy lifestyle, greater community participation, and higher quality of life. We also expect that PersonA will enable health professionals to collect in situ data related to physical activity. The platform is currently being used and tested to improve PA level of three groups of users in Pittsburgh, PA, USA

Ayyavoo, A.; Derraik, J. G.; Hofman, P. L.; Mathai, S.; Biggs, J.; Stone, P. et al. (2013):

Pre-pubertal children born post-term have reduced insulin sensitivity and other markers of the metabolic syndrome.

In: *PLoS One* 8 (7), S. e67966. DOI: 10.1371/journal.pone.0067966.

Abstract:

BACKGROUND: There are no data on the metabolic consequences of post-term birth (>/=42 weeks gestation). We hypothesized that post-term birth would adversely affect insulin sensitivity, as well as other metabolic parameters and body composition in childhood. METHODS: 77 healthy pre-pubertal children, born appropriate-for-gestational-age were studied in Auckland, New Zealand: 36 born post-term (18 boys) and 41 (27 boys) born at term (38-40 weeks gestation). Primary outcome was insulin sensitivity measured using intravenous glucose tolerance tests and Bergman's minimal model. Other assessments included fasting hormone concentrations and lipid profiles, body composition from whole-body dual-energy X-ray absorptiometry, 24-hour ambulatory blood pressure monitoring, and inflammatory markers. RESULTS: Insulin sensitivity was 34% lower in post-term than in term children (7.7 vs. 11.6 x10(-)(4).min(-)(1).(mU/l); p<0.0001). There was a compensatory increase in acute insulin response among post-term children (418 vs 304 mU/l; p=0.037), who also displayed lower glucose effectiveness than those born at term (2.25 vs 3.11 x10(-)(2).min(-)(1); p=0.047). Post-term children not only had more body fat (p=0.014) and less fat-free mass (p=0.014), but also had increased central adiposity with more truncal fat (p=0.017) and greater android to gynoid fat ratio (p=0.007) compared to term controls. Further, post-term children displayed other markers of the metabolic syndrome: lower normal nocturnal systolic blood pressure dipping (p=0.027), lower adiponectin concentrations (p=0.005), as well as higher leptin (p=0.008) and uric acid (p=0.033) concentrations. Post-term boys (but not girls) also displayed a less favourable lipid profile, with higher total cholesterol (p=0.018) and LDL-C (p=0.006) concentrations, and total cholesterol to HDL-C ratio (p=0.048). CONCLUSIONS: Post-term children have reduced insulin sensitivity and display a number of early markers of the metabolic

syndrome. These findings could have important implications for the management of prolonged pregnancies. Future studies need to examine potential impacts later in life, as well as possible underlying mechanisms

Ayyavoo, Ahila; Derraik, Jose G. B.; Hofman, Paul L.; Biggs, Janene; Cutfield, Wayne S. (2014):

Metabolic, cardiovascular and anthropometric differences between prepubertal girls and boys.

In: *Clin Endocrinol (Oxf). DOI:* 10.1111/cen.12436.

Abstract:

OBJECTIVE: We aimed to assess possible differences in insulin sensitivity and other metabolic, anthropometric and cardiovascular parameters between boys and girls prior to puberty. METHODS: We studied 85 healthy prepubertal children (33 girls and 52 boys) aged 8.7 +/- 1.9 years (range 4.0-11.9 years), born 38-40 weeks gestation, and of birth weight appropriate-for-gestational-age. Insulin sensitivity was measured using frequently sampled intravenous glucose tests and Bergman's minimal model. Other clinical assessments included anthropometric measures, fasting lipid and hormonal profiles, body composition from whole-body dual-energy X-ray absorptiometry and 24-h ambulatory blood pressure monitoring. RESULTS: Prepubertal girls and boys were of similar parent-adjusted height SDS (P = 0.26), but girls had considerably more body fat (P < 0.0001), less fat-free mass (P = 0.0002) and greater abdominal adiposity (P < 0.0001). These differences in body composition were independent of adrenal androgens. Insulin sensitivity was 18% lower in girls (11.0 vs 13.4 x 10-4 /min (mU/l); P = 0.028), but this difference disappeared with adjustment for adiposity and DHEAS concentrations. There were, however, some apparent sex differences in cardiovascular parameters, with girls displaying increased heart rate and reduced blood pressure dipping. Girls also had higher triglyceride concentrations (+23%; P = 0.036). CONCLUSION: There are a number of anthropometric, metabolic and cardiovascular differences between sexes prior to the appearance of external signs of puberty. Although differences in insulin sensitivity were eliminated when adiposity and DHEAS concentrations were accounted for, there were independent differences in body composition and cardiovascular parameters. Thus, gender, adrenarche and adiposity should be accounted for in studies examining metabolic and cardiovascular outcomes prior to puberty.

Azar, K. M.; Lesser, L. I.; Laing, B. Y.; Stephens, J.; Aurora, M. S.; Burke, L. E.; Palaniappan, L. P. (2013):

Mobile applications for weight management: theory-based content analysis.

In: *Am.J.Prev.Med.* 45 (5), S. 583–589. DOI: 10.1016/j.amepre.2013.07.005.

Abstract:

BACKGROUND: The use of smartphone applications (apps) to assist with weight management is increasingly prevalent, but the quality of these apps is not well characterized. PURPOSE: The goal of the study was to evaluate diet/nutrition and anthropometric tracking apps based on incorporation of features consistent with theories of behavior change. METHODS: A comparative, descriptive assessment was conducted of the top-rated free apps in the Health and Fitness category available in the iTunes App Store. Health and Fitness apps (N=200) were evaluated using predetermined inclusion/exclusion criteria and categorized based on commonality in functionality, features, and developer description. Four researchers then evaluated the two most popular apps in each category using two instruments: one based on traditional behavioral theory (score range: 0-100) and the other on the Fogg Behavioral Model (score range: 0-6). Data collection and analysis occurred in November 2012. RESULTS: Eligible apps (n=23) were divided into five categories: (1) diet tracking; (2) healthy cooking; (3) weight/anthropometric tracking; (4) grocery decision making; and (5) restaurant decision making. The mean behavioral theory score was 8.1 (SD=4.2); the mean persuasive technology score was 1.9 (SD=1.7). The top-rated app on both scales was Lose It! by Fitnow Inc. CONCLUSIONS: All apps received low overall scores for inclusion of behavioral theory-based strategies

Future perspectives of Smartphone applications for rheumatic diseases self-management.

In: *Rheumatol Int. DOI:* 10.1007/s00296-014-3117-9.

Abstract:

Rheumatic diseases (RD) self-management interventions are designed to improve health-related quality of life, health care utilization, and perceived self-efficacy. Despite these demonstrated good results, there are several issues that hinder or render less appealing these interventions. One economically and socially viable solution is exploiting the potential of Smartphone technology. This potential comes from Smartphones pervasive presence in actual society, combined with the advantages of being personal, intuitive, and computationally powerful, with capability to support applications and assist its user throughout different activities of daily living and environments persistently. With their global acceptance increasing quickly, there is a great opportunity for mobile health in using Smartphone applications for RD self-management. Besides the potential of such applications, research on the development and evaluation of such applications is in the early stages. Therefore, it is important to foresee its future applicability in order to meet the needs of the twenty-first century.

Aziz, Omer; Lo, Benny; Pansiot, Julien; Atallah, Louis; Yang, Guang-Zhong; Darzi, Ara (2008):

From computers to ubiquitous computing by 2010: health care.

In: *Philosophical Transactions of the Royal Society of London A: Mathematical, Physical and Engineering Sciences* 366 (1881), S. 3805–3811.

Abstract:

Over the past decade, miniaturization and cost reduction in semiconductors have led to computers smaller in size than a pinhead with powerful processing abilities that are affordable enough to be disposable. Similar advances in wireless communication, sensor design and energy storage have meant that the concept of a truly pervasive 'wireless sensor network', used to monitor environments and objects within them, has become a reality. The need for a wireless sensor network designed specifically for human body monitoring has led to the development of wireless 'body sensor network' (BSN) platforms composed of tiny integrated microsensors with on-board processing and wireless data transfer capability. The ubiquitous computing abilities of BSNs offer the prospect of continuous monitoring of human health in any environment, be it home, hospital, outdoors or the workplace. This pervasive technology comes at a time when Western world health care costs have sharply risen, reflected by increasing expenditure on health care as a proportion of gross domestic product over the last 20 years. Drivers of this rise include an ageing post 'baby boom' population, higher incidence of chronic disease and the need for earlier diagnosis. This paper outlines the role of pervasive health care technologies in providing more efficient health care.

Mood states associated with transitory physical symptoms among breast and ovarian cancer survivors.

In: *Journal of Behavioral Medicine* 29 (5), S. 461–475.

Abstract:

This study used electronic diaries to examine patterns of mood and physical symptoms within and across days in two independent samples of cancer patients. Twenty-three breast cancer survivors (post-treatment) and 33 ovarian cancer survivors (on chemotherapy) recorded mood and physical symptoms 4 times daily for 7 consecutive days. A series of repeated-measures multilevel models using SAS Proc Mixed were calculated to estimate the degree to which physical symptoms (e.g., pain, fatigue, and nausea) were associated with participants' moods. Across days, mood vectors with a pleasantness component (i.e., happy-sad and calm-anxious) and mood vectors with an arousal component (i.e., active-passive and peppy-tired) were significantly associated with physical symptom severity. Specifically, breast cancer survivors with greater fatigue and pain reported more negative moods ($\eta^2 \leq 0.33$). Ovarian cancer survivors with greater fatigue ($\eta^2 \leq 0.35$), pain ($\eta^2 \leq 0.04$), and nausea ($\eta^2 \leq 0.04$) also reported more negative moods. Diurnal analyses showed that happy-sad ($\eta^2 \leq 0.16$), active-passive ($\eta^2 \leq 0.27$), and peppy-tired moods ($\eta^2 \leq 0.33$) were significantly negatively associated with fatigue at each of the four daily assessment times in both samples. Although correlational, our findings are consistent with previous studies suggesting that variations in both pleasant and aroused mood covary with changes in real-time physical symptom reports.

An Electronic Diary Study of the Effects of Patient Avoidance and Partner Social Constraints on Patient Momentary Affect in Metastatic Breast Cancer.

In: *Ann.Behav.Med.* (0883-6612 (Linking)). DOI: 10.1007/s12160-012-9436-8.

Abstract:

BACKGROUND: Metastatic breast cancer patients experience significance distress. Although talking with close others about cancer-related concerns may help to alleviate distress, patients often avoid such discussions, and their partners can engage in social constraints that may limit subsequent patient disclosures and exacerbate distress. PURPOSE: We examined how partner constraints unfold, how they influence patient affect, and whether they exacerbate patient avoidance of cancer-related disclosures. METHODS: Fifty-four patients and 48 of their partners completed electronic diary assessments for 14 days. RESULTS: Partners' social constraints carried over from one day to the next, but patients' avoidance of discussing cancer-related concerns did not. When partners engaged in more social constraints one day, patients reported greater negative affect the following day ($p < 0.05$). CONCLUSION: Findings suggest a temporal link between partner constraints and patient momentary affect. Helping partners to become aware of their constraining behaviors and teaching them skills to overcome this may facilitate patient adjustment to metastatic breast cancer

Time-lapse microscopy using smartphone with augmented reality markers.

In: *Microsc Res Tech* 77 (4), S. 243–249. DOI: 10.1002/jemt.22335.

Abstract:

A prototype system that replaces the conventional time-lapse imaging in microscopic inspection for use with smartphones is presented. Existing time-lapse imaging requires a video data feed between a microscope and a computer that varies depending on the type of image grabber. Even with proper hardware setups, a series of tedious and repetitive tasks is still required to relocate to the region-of-interest (ROI) of the specimens. In order to simplify the system and improve the efficiency of time-lapse imaging tasks, a smartphone-based platform utilizing microscopic augmented reality (mu-AR) markers is proposed. To evaluate the feasibility and efficiency of the proposed system, a user test was designed and performed, measuring the elapse time for a trial of the task starting from the execution of the application software to the completion of restoring and imaging of an ROI saved in advance. The results of the user test showed that the average elapse time was 65.3 +/- 15.2 s with 6.86 +/- 3.61 mum of position error and 0.08 +/- 0.40 degrees of angle error. This indicates that the time-lapse imaging task was accomplished rapidly with a high level of accuracy. Thus, simplification of both the system and the task was achieved via our proposed system. Microsc. Res. Tech. 77:243-249, 2014. (c) 2014 Wiley Periodicals, Inc.

Evaluating physical activity using accelerometry in children at risk of developmental coordination disorder in the presence of attention deficit hyperactivity disorder.

In: *Res Dev Disabil* 32 (4), S. 1343–1350. DOI: 10.1016/j.ridd.2011.02.009.

Abstract:

Physical activity (PA) is compromised in children and adolescents with developmental coordination disorder (DCD). Approximately half of all children with DCD suffer from attention-deficit hyperactive disorder (ADHD); a cohort often considered more physically active than typically developing youth. Accelerometry is an effective method of assessing physical activity patterns; although estimates of PA in children with DCD using this quantifiable method have not been attempted. We hypothesize that children with co-morbid DCD/ADHD will be more physically active than children with DCD and healthy peers. Therefore, the purpose of this study was to contrast physical activity (step count and activity energy expenditure using accelerometry [AEE]) between children with DCD, co-morbid DCD and ADHD (DCD/ADHD), and healthy controls. A sample of 110 children with DCD (N=32), DCD/ADHD (N=30) and controls (N=48) age 12-13 years agreed to participate. Co-morbid DCD/ADHD was present in nearly half of the children with DCD (48.4%). Analysis of covariance demonstrated a positive interaction for females step count ($F[1,92]=4.92$, $p=0.009$). A significant group difference for step count ($F[1,92]=4.43$, $p=.04$) was identified in females. Post hoc comparison tests identified significantly lower step count between males with DCD and controls ($p=.004$) and males with DCD/ADHD and controls ($p=0.003$). Conversely, females with DCD/ADHD had significantly more step counts than their controls ($p=.01$). Hyperactivity in females with DCD/ADHD appears to contribute to more physical activity, whereas DCD may contribute to decreased activity in males with DCD and DCD/ADHD. Hyperactivity expressed among girls with DCD/ADHD appears to override the hypoactive behavior associated with females with DCD. Conversely, the expression of hyperactivity among boys with DCD/ADHD does not translate as hypothesized. The contrasting expression of physical activity (i.e., step count and AEE) evaluated using accelerometry in boys and girls with DCD, co-morbid DCD/ADHD and healthy peers are intriguing and constitute further investigation in a larger investigation.

Baggett, Chris D.; Stevens, June; McMurray, Robert G.; Evenson, Kelly R.; Murray, David M.; Catellier, Diane J.; He, Ka (2008):

Tracking of physical activity and inactivity in middle school girls.

In: *Med Sci Sports Exerc* 40 (11), S. 1916.

Abstract:

PURPOSE:

The purpose of this study was to describe and compare the levels of tracking of physical activity and inactivity as assessed by self-report and accelerometry in middle school girls during a 2-yr period.

METHODS:

Participants (n = 951) were from the Trial of Activity for Adolescent Girls (TAAG). The TAAG intervention had minimal effect on physical activity; therefore, both intervention and control participants were included. Inactivity and physical activity were measured by accelerometry (MTI ActiGraph) and self-report (3-d physical activity recall).

RESULTS:

Weighted kappa statistics ranged from 0.14 to 0.17 across inactivity, moderate-to-vigorous physical activity (MVPA), and vigorous physical activity (VPA) for self-report, from 0.13 to 0.20 for 3-d accelerometry, and from 0.22 to 0.29 for a 6-d accelerometry. Intraclass correlations ranged from 0.17 to 0.22 for self-report, 0.06 to 0.23 for 3-d accelerometry, and 0.16 to 0.33 for a 6-d accelerometry. In general, the estimates from the 6-d accelerometry tended to be higher than those from self-report, whereas few differences were observed between 3-d accelerometry and self-report. Odds ratios (OR) for being in the highest quintile at eighth grade for those in the highest quintile at sixth grade compared with those in any other quintile at sixth grade were 3.26 (95% confidence interval = 2.28-4.67), 3.64 (2.55-5.20), and 3.45 (2.42-4.93) for the 6-d accelerometry-measured inactivity, MVPA, and VPA. Corresponding OR from self-report were 2.44 (1.66-3.58) for inactivity, 2.63 (1.83-3.79) for MVPA, and 2.23 (1.54-3.23) for VPA.

CONCLUSION:

Tracking of inactivity and physical activity in middle school girls was fair to moderate. Our results suggest that physical activity and inactivity habits are dynamic for most girls during early adolescence. Population-based efforts should be made in this age group to promote physical activity and offer alternatives to inactivity for all girls.

Baggett, Chris D.; Stevens, June; Catellier, Diane J.; Evenson, Kelly R.; McMurray, Robert G.; He, Ka; Treuth, Margarita S. (2010):

Compensation or displacement of physical activity in middle-school girls: the Trial of Activity for Adolescent Girls.

In: *International Journal of Obesity* 34 (7), S. 1193–1199.

Abstract:

OBJECTIVE:

The 'activitystat' hypothesis suggests that increases in moderate-to-vigorous physical activity (MVPA) are accompanied by a compensatory reduction in light physical activity (LPA) and/or an increase in inactivity to maintain a consistent total physical activity level (TPA). The purpose of this study was to identify the evidence of compensation in middle-school girls.

SUBJECTS:

Participants were 6916, 8th grade girls from the Trial of Activity for Adolescent Girls (TAAG).

DESIGN:

Inactivity and physical activity were measured over 6- consecutive days using accelerometry (MTI Actigraph). A within-girl, repeated measures design was used to assess associations between physical activity and inactivity using general linear mixed models.

RESULTS:

Within a given day, for every one MET-minute more of inactivity, there was 3.18 MET-minutes (95% confidence interval (CI): -3.19, -3.17) less of TPA (activity >2 METS) on the same day. Daily inactivity was also negatively associated with TPA on the following day. Each additional minute of MVPA was associated with 1.85 min less of inactivity on the same day (95% CI: -1.89, -1.82). Daily MVPA was also negatively associated with inactivity the following day.

CONCLUSION:

Our results, based on 6 days of observational data, were not consistent with the 'activitystat' hypothesis, and instead indicated that physical activity displaced inactivity, at least in the short term. Longer intervention trials are needed, nevertheless our findings support the use of interventions to increase physical activity over discrete periods of time in middle-school girls.

Baguet, Jean Philippe; Minville, Caroline; Tamisier, Renaud; Roche, Frederic; Barone-Rochette, Gilles; Ormezzano, Olivier et al. (2011):

Increased aortic root size is associated with nocturnal hypoxia and diastolic blood pressure in obstructive sleep apnea.

In: *Sleep: Journal of Sleep and Sleep Disorders Research* 34 (11), S. 1605–1607. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-13702-021&site=ehost-live;JPBaguet@chu-grenoble.fr.

Abstract:

Study Objectives: Obstructive sleep apnea (OSA) is known as a major cardiovascular risk factor, and high prevalence of OSA has been reported in patients with thoracic aortic dissection. The aim of our study was to assess the relationship between OSA, its vascular consequences, and aortic root size. Design/Patients: 156 newly diagnosed apneic patients free of cardiovascular disease and medication were included. Patients underwent cardiac ultrasound for measuring aortic root diameter, polysomnography, office and 24-h ambulatory blood pressure (BP) measurements, baroreflex sensitivity (BRS), and arterial stiffness evaluation by carotid-to-femoral pulse wave velocity (PWV). Measurements and Results: In univariate analysis, greater aortic root size was associated with older age (P = 0.03) and severity of OSA as expressed by mean nocturnal oxygen saturation (SpO_2) (P = 0.015). Moreover, greater aortic root size was associated with higher diastolic BP, measured both clinically (P = 0.0005) or by 24-h ambulatory BP monitoring (P = 0.02), and PWV (P = 0.03). Mean nocturnal SpO_2 was correlated with BRS (P = 0.0008), thus potentially influencing BP values and arterial stiffness. In multivariate stepwise regression analysis, diastolic BP was the only significant factor for aortic root size (P = 0.0003). Conclusions: In OSA patients, nocturnal hypoxemia decreased BRS and increased diastolic BP, which was the main factor influencing aortic root size. Normalization and extraction of interpretable metrics from raw accelerometry data.

In: *Biostatistics* (1465-4644 (Linking)). DOI: 10.1093/biostatistics/kxt029.

Abstract:

We introduce an explicit set of metrics for human activity based on high-density acceleration recordings from a hip-worn tri-axial accelerometer. These metrics are based on two concepts: (i) Time Active, a measure of the length of time when activity is distinguishable from rest and (ii) AI, a measure of the relative amplitude of activity relative to rest. All measurements are

normalized (have the same interpretation across subjects and days), easy to explain and implement, and reproducible across platforms and software implementations. Metrics were validated by visual inspection of results and quantitative in-lab replication studies, and by an association study with health outcomes

Mobile healthcare applications: system design review, critical issues and challenges.

In: *Australas Phys Eng Sci Med. DOI:* 10.1007/s13246-014-0315-4.

Abstract:

Mobile phones are becoming increasingly important in monitoring and delivery of healthcare interventions. They are often considered as pocket computers, due to their advanced computing features, enhanced preferences and diverse capabilities. Their sophisticated sensors and complex software applications make the mobile healthcare (m-health) based applications more feasible and innovative. In a number of scenarios user-friendliness, convenience and effectiveness of these systems have been acknowledged by both patients as well as healthcare providers. M-health technology employs advanced concepts and techniques from multidisciplinary fields of electrical engineering, computer science, biomedical engineering and medicine which benefit the innovations of these fields towards healthcare systems. This paper deals with two important aspects of current mobile phone based sensor applications in healthcare. Firstly, critical review of advanced applications such as; vital sign monitoring, blood glucose monitoring and in-built camera based smartphone sensor applications. Secondly, investigating challenges and critical issues related to the use of smartphones in healthcare including; reliability, efficiency, mobile phone platform variability, cost effectiveness, energy usage, user interface, quality of medical data, and security and privacy. It was found that the mobile based applications have been widely developed in recent years with fast growing deployment by healthcare professionals and patients. However, despite the advantages of smartphones in patient monitoring, education, and management there are some critical issues and challenges related to security and privacy of data, acceptability, reliability and cost that need to be addressed.

Bailes, Freya (2007):

The prevalence and nature of imagined music in the everyday lives of music students.

In: *Psychology of Music*.

Abstract:

The study of spontaneous and everyday cognitions is an area of rapidly growing interest. One of the most ubiquitous forms of spontaneous cognition is involuntary musical imagery (INMI), the involuntarily retrieved and repetitive mental replay of music. The present study introduced a novel method for capturing temporal features of INMI within a naturalistic setting. This method allowed for the investigation of two questions of interest to INMI researchers in a more objective way than previously possible, concerning (1) the precision of memory representations within INMI and (2) the interactions between INMI and concurrent affective state. Over the course of 4 days, INMI tempo was measured by asking participants to tap to the beat of their INMI with a wrist-worn accelerometer. Participants documented additional details regarding their INMI in a diary. Overall, the tempo of music within INMI was recalled from long-term memory in a highly veridical form, although with a regression to the mean for recalled tempo that parallels previous findings on voluntary musical imagery. A significant positive relationship was found between INMI tempo and subjective arousal, suggesting that INMI interacts with concurrent mood in a similar manner to perceived music. The results suggest several parallels between INMI and voluntary imagery, music perceptual processes, and other types of involuntary memories.

Bailey, D. P.; Fairclough, S. J.; Savory, L. A.; Denton, S. J.; Pang, D.; Deane, C. S.; Kerr, C. J. (2012):

Accelerometry-assessed sedentary behaviour and physical activity levels during the segmented school day in 10-14-year-old children: the HAPPY study.

In: *Eur.J Pediatr.* (0340-6199 (Linking)). DOI: 10.1007/s00431-012-1827-0.

Abstract:

The school day offers several different time periods that provide varying opportunities for sedentary time (SED) and engagement in physical activity (PA), yet little is known about the PA and sedentary behaviour patterns of boys and girls during these times. The volume, intensity and temporal distributions of SED and PA undertaken by 135 schoolchildren aged 10-14 years, during different segments of the school day: (a) school transport, (b) morning recess, (c) lunch break, (d) class time and (e) after school,

were explored using triaxial accelerometry. PA was categorised into SED, light PA (LPA), moderate PA (MPA) and vigorous PA (VPA). Girls engaged in significantly more SED and LPA than boys during recess and lunch break ($p < 0.05$), while boys engaged in significantly higher levels of VPA during recess ($p < 0.001$) and MPA and VPA during lunch break ($p < 0.001$). PA engagement was similar between sexes during other segments of the day. Conclusion: PA patterns appear more beneficial for health in boys during less structured school-based time periods and interventions may therefore target opportunities for girls to be physically active during these times to overcome this observed sex deficit

Bailey, Ryan R.; Klaesner, Joseph W.; Lang, Catherine E. (2014):

An accelerometry-based methodology for assessment of real-world bilateral upper extremity activity.

In: *PLoS One* 9 (7), S. e103135. DOI: 10.1371/journal.pone.0103135.

Abstract:

BACKGROUND: The use of both upper extremities (UE) is necessary for the completion of many everyday tasks. Few clinical assessments measure the abilities of the UEs to work together; rather, they assess unilateral function and compare it between affected and unaffected UEs. Furthermore, clinical assessments are unable to measure function that occurs in the real-world, outside the clinic. This study examines the validity of an innovative approach to assess real-world bilateral UE activity using accelerometry. METHODS: Seventy-four neurologically intact adults completed ten tasks (donning/doffing shoes, grooming, stacking boxes, cutting playdough, folding towels, writing, unilateral sorting, bilateral sorting, unilateral typing, and bilateral typing) while wearing accelerometers on both wrists. Two variables, the Bilateral Magnitude and Magnitude Ratio, were derived from accelerometry data to distinguish between high- and low-intensity tasks, and between bilateral and unilateral tasks. Estimated energy expenditure and time spent in simultaneous UE activity for each task were also calculated. RESULTS: The Bilateral Magnitude distinguished between high- and low-intensity tasks, and the Magnitude Ratio distinguished between unilateral and bilateral UE tasks. The Bilateral Magnitude was strongly correlated with estimated energy expenditure ($rho = 0.74$, $p<0.02$), and the Magnitude Ratio was strongly correlated with time spent in simultaneous UE activity ($rho = 0.93$, $p<0.01$) across tasks. CONCLUSIONS: These results demonstrate face validity and construct validity of this methodology to quantify bilateral UE activity during the performance of everyday tasks performed in a laboratory setting, and can now be used to assess bilateral UE activity in real-world environments.

Bailey, Ryan R.; Lang, Catherine E. (2013):

Upper-limb activity in adults: referent values using accelerometry.

In: *J Rehabil Res Dev* 50 (9), S. 1213–1222. DOI: 10.1682/JRRD.2012.12.0222.

Abstract:

The goal of physical rehabilitation following upper-limb (UL) impairment is functional restoration of the UL for use in daily activities. Because capacity for UL function may not translate into real-world activity, it is important that assessment of real-world UL activity be used in conjunction with clinical measures of capacity. Accelerometry can be used to quantify duration of UL activity outside of the clinic. The purpose of this study was to characterize hours of UL activity and potential modifying factors of UL activity (sedentary activity, cognitive impairment, depressive symptomatology, additive effects of comorbidities, cohabitation status, and age). Seventy-four community-dwelling adults wore accelerometers on bilateral wrists for 25 h and provided information on modifying factors. Mean time of dominant UL activity was 9.1 +/- 1.9 h, and the ratio of activity between the nondominant and dominant ULs was 0.95 +/- 0.06 h. Decreased hours of dominant UL activity was associated with increased time spent in sedentary activity. No other factors were associated with hours of dominant UL activity. These data can be used to help clinicians establish outcome goals for patients given preimpairment level of sedentary activity and to track progress during rehabilitation of the ULs.

Baird, B.; Smallwood, J.; Fishman, D. J.; Mrazek, M. D.; Schooler, J. W. (2013):

Unnoticed intrusions: Dissociations of meta-consciousness in thought suppression.

In: *Conscious.Cogn* 22 (3), S. 1003–1012. DOI: 10.1016/j.concog.2013.06.009.

Abstract:

The current research investigates the interaction between thought suppression and individuals' explicit awareness of their thoughts. Participants in three experiments attempted to suppress thoughts of a prior romantic relationship and their success at

doing so was measured using a combination of self-catching and experience-sampling. In addition to thoughts that individuals spontaneously noticed, individuals were frequently caught engaging in thoughts of their previous partner at experience-sampling probes. Furthermore, probe-caught thoughts were: (i) associated with stronger decoupling of attention from the environment, (ii) more likely to occur under cognitive load, (iii) more frequent for individuals with a desire to reconcile, and (iv) associated with individual differences in the tendency to suppress thoughts. Together, these data suggest that individuals can lack meta-awareness that they have begun to think about a topic they are attempting to suppress, providing novel insight into the cognitive processes that are involved in attempting to control undesired mental states

Baird, Benjamin; Smallwood, Jonathan; Lutz, Antoine; Schooler, Jonathan W. (2014):

The Decoupled Mind: Mind-wandering Disrupts Cortical Phase-locking to Perceptual Events.

In: *J Cogn Neurosci. DOI:* 10.1162/jocn_a_00656.

Abstract:

The mind flows in a "stream of consciousness," which often neglects immediate sensory input in favor of focusing on intrinsic, self-generated thoughts or images. Although considerable research has documented the disruptive influences of task-unrelated thought for perceptual processing and task performance, the brain dynamics associated with these phenomena are not well understood. Here we investigate the possibility, suggested by several convergent lines of research, that task-unrelated thought is associated with a reduction in the trial-to-trial phase consistency of the oscillatory neural signal in response to perceptual input. Using an experience sampling paradigm coupled with continuous high-density electroencephalography, we observed that task-unrelated thought was associated with a reduction of the P1 ERP, replicating prior observations that mind-wandering is accompanied by a reduction of the brain-evoked response to sensory input. Time-frequency analysis of the oscillatory neural response revealed a decrease in theta-band cortical phase-locking, which peaked over parietal scalp regions. Furthermore, we observed that task-unrelated thought impacted the oscillatory mode of the brain during the initiation of a task-relevant action, such that more cortical processing was required to meet task demands. Together, these findings document that the attenuation of perceptual processing that occurs during task-unrelated thought is associated with a reduction in the temporal fidelity with which the brain responds to a stimulus and suggest that increased neural processing may be required to recouple attention to a task. More generally, these data provide novel confirmatory evidence for the mechanisms through which attentional states facilitate the neural processing of sensory input.

Bak, Maarten; Drukker, Marjan; van Os, Jim; Delespaul, Philippe; Myin-Germeys, Inez (2012):

Daily life moment-to-moment variation in coping in people with a diagnosis of schizophrenia: State within trait psychosis.

In: *Psychosis: Psychological, Social and Integrative Approaches* 4 (2), S. 115–125. DOI: 10.1037/t01554-000;

Abstract:

Introduction: Coping is a dynamic concept, associated with variability in stress and the individual's response. It was hypothesized that coping responses vary from moment to moment in daily life in individuals diagnosed with schizophrenia. Methods: Patients diagnosed with schizophrenia (n = 25) were studied using the Experience Sampling Method to assess ongoing coping. Three subcategories of coping, social (interaction with environment), activity (behaviour to relief stress) and abuse (use of substances to deal with stress) were combined in a single coping variable expressed both dichotomously (present or not, representing frequency) and dimensionally (representing intensity). Results: The frequency of coping did not vary over the day with exception of abuse coping variance: 0.48; 95% CI 0.02-10.5). In contrast, the intensity of coping did vary during the day, except for abuse coping (coping combined variance = 0.05, 95% CI 0.01-0.20; social coping variance = 0.13, 95% CI 0.04–0.39; and activity coping variance = 0.10, 95% CI 0.02–0.51). Conclusion: In patients with schizophrenia, coping is stable from moment to moment, indicating a trait mechanism. However, coping varies in intensity, which refers to state properties of coping. Validity problems may arise if studies do not consider the partial variability of coping. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Baker, Sarah R. (2006):

Towards an idiothetic understanding of the role of social problem solving in daily event, mood and health experiences: a prospective daily diary approach.

In: *British Journal of Health Psychology* 11 (Pt 3), S. 513–531. DOI: 10.1348/135910705X57647.

Abstract:

OBJECTIVES\r\nUtilising D'Zurilla's (1986, 1990) transactional social problem solving model as the theoretical framework, the present study sought to examine the dynamics of the social problem solving process in relation to intraindividual experiences of events, mood, and physical health in daily life.\r\nDESIGN\r\nThe study incorporated both idiographic and nomothetic strategies, combining a daily diary approach within a prospective design. As such, each individual's experience of events, mood, and health were assessed on a daily basis, and the prospective relations between social problem solving and these day-to-day experiences examined.\r\nMETHODS\r\nParticipants' (university students) completed a measure of social problem solving at baseline followed, approximately 5 weeks later, by daily self-reports of mood (positive & negative), events (hassles & uplifts), and physical health (health status & URI symptoms) for a period of 14 days. The data were analysed using multilevel hierarchical modelling.\r\nRESULTS\r\nDays on which individuals had greater than their average hassles were associated with higher negative and lower positive mood (i.e. domain specific & cross-over effects), whilst greater uplifts were linked to positive mood only. With regard to health, individuals reported worse status and more URI symptoms on days with greater than their average negative (hassles, negative mood) but not positive influences (uplifts, positive mood). Both social problem solving orientations and skills dimensions were associated prospectively with daily health outcomes, and these relationships were not moderated by day-to-day experiences of mood or events.\r\nCONCLUSIONS\r\nThe data clarify the importance of social problem solving to within-person daily event, mood, and health experiences. The implications of these findings for contemporary transactional social problem solving models are discussed.

Bakker, Arnold B.; Daniels, Kevin (2013):

A day in the life of a happy worker.

Hg. v. Arnold B. Bakker und Kevin Daniels. New York, NY US: Psychology Press (Current issues in work and organizational psychology). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-02788-000%26site%3dehost-live.

Abstract:

(from the cover) This edited collection brings together some of the leading researchers in the study of the daily experience of work and well-being. The book covers both theoretical and methodological issues involved in studying workers' well-being as it evolves on an everyday basis. Interest in the topic of daily fluctuations in worker well-being has grown rapidly over the past ten years. This is partly because of advances in research methods and statistical interests, but also because researchers have found that the psychological processes that influence well-being play out from moment to moment, and from day to day. Topics covered in this book include: (1) the theoretical basis of studying work as a series of daily episodes; (2) assessment of different components of daily well-being; (3) factors involved in the regulation of well-being at work; (4) qualitative and quantitative diary experience sampling and event reconstruction methods; and (5) latent growth curve modeling of diary data. The final chapter of the book includes a preview of how daily methods may evolve in the future. Intended as a guide for researchers with good knowledge of field research methods, the book will be particularly useful to researchers of work-related phenomena that seek to expand their knowledge of dynamic methods in field contexts, and those that want to start using these methods. It will also be of interest to students of work psychology and organizational behavior, and related disciplines. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (cover)

Bakker, J. M.; Lieverse, R.; Menne-Lothmann, C.; Viechtbauer, W.; Pishva, E.; Kenis, G. et al. (2014):

Therapygenetics in mindfulness-based cognitive therapy: do genes have an impact on therapy-induced change in real-life positive affective experiences?

In: *Transl Psychiatry* 4, S. e384. DOI: 10.1038/tp.2014.23.

Abstract:

Positive affect (PA) has an important role in resilience against depression and has been shown to increase with mindfulness-based cognitive therapy (MBCT). To elucidate the underlying mechanisms of change in PA as well as develop insights that may benefit personalized medicine, the current study examined the contribution of genetic variation to individual differences in change in PA in response to MBCT. Individuals (n=126) with residual depressive symptoms were randomized to either an MBCT

group or treatment as usual. PA was assessed using experience sampling methodology (ESM). Single-nucleotide polymorphisms (SNPs) in genes known to be involved in reward functioning were selected. SNPs in the genes for brain-derived neurotrophic factor (BDNF), the muscarinic acetylcholine receptor M2 (CHRM2), the dopamine receptor D4 (DRD4) and the mu1 opioid receptor (OPRM1) significantly moderated the impact of treatment condition over time on PA. Genetic variation in the genes for CHRM2 and OPRM1 specifically had an impact on the level of PA following MBCT. The current study shows that variation in response to MBCT may be contingent on genetic factors associated with the regulation of PA. These findings contribute to our understanding of the processes moderating response to treatment and prediction of treatment outcome.

Bakker, Arnold B.; Xanthopoulou, Despoina (2009):

The crossover of daily work engagement: test of an actor-partner interdependence model.

In: *J Appl Psychol* 94 (6), S. 1562–1571. DOI: 10.1037/a0017525.

Abstract:

This study of 62 dyads of employees (N = 124) examined the crossover of work engagement-a positive, fulfilling, work-related state of mind that is characterized by vigor, dedication, and absorption. We hypothesized that work engagement crosses over from an employee (the actor) to his or her colleague (the partner) on a daily basis. The frequency of daily communication was expected to moderate the crossover of daily work engagement, which in turn would relate to colleagues' daily performance. Participants first filled in a general questionnaire and then completed a diary study over 5 consecutive workdays. The hypotheses were tested with multilevel analyses, using an actor-partner interdependence model. Results confirmed the crossover of daily work engagement, but only on days when employees within a dyad interacted more frequently than usual. Moreover, we found that actor's work engagement (particularly vigor), when frequently communicated, had a positive indirect relationship with partner's performance through partner's work engagement. Finally, results showed that actor's vigor was negatively related to partner's performance when communication was low. However, this negative effect was counteracted when mediated by the vigor of the partner.

Physical activity and insulin sensitivity the RISC study.

In: *Diabetes* 57 (10), S. 2613–2618.

Abstract:

OBJECTIVE— Physical activity is a modifiable risk factor for type 2 diabetes, partly through its action on insulin sensitivity. We report the relation between insulin sensitivity and physical activity measured by accelerometry.

RESEARCH DESIGN AND METHODS— This is a cross-sectional study of 346 men and 455 women, aged 30–60 years, without cardiovascular disease and not treated by drugs for diabetes, hypertension, dyslipidemia, or obesity. Participants were recruited in 18 clinical centers from 13 European countries. Insulin sensitivity was measured by hyperinsulinemic-euglycemic clamp. Physical activity was recorded by accelerometry for a median of 6 days. We studied the relationship of insulin sensitivity with total activity (in counts per minute), percent of time spent sedentary, percent of time in light activity, and activity intensity (whether the participant recorded some vigorous or some moderate activity).

RESULTS— In both men and women, total activity was associated with insulin sensitivity ($P < 0.0001$). Time spent sedentary, in light activity, and activity intensity was also associated with insulin sensitivity ($P < 0.0004/0.01$, $0.002/0.03$, and $0.02/0.004$, respectively, for men/women) but lost significance once adjusted for total activity. Adjustment for confounders such as adiposity attenuated the relationship with total activity; there were no interactions with confounders. Even in the 25% most sedentary individuals, total activity was significantly associated with better insulin sensitivity ($P < 0.0001$).

CONCLUSIONS— Accumulated daily physical activity is a major determinant of insulin sensitivity. Time spent sedentary, time spent in light-activity, and bouts of moderate or vigorous activity did not impact insulin sensitivity independently of total activity.

Ball, Kylie; Cleland, Verity J.; Timperio, Anna F.; Salmon, Jo; Crawford, David A. (2009):

Socioeconomic position and children's physical activity and sedentary behaviors: longitudinal findings from the CLAN study.

In: *J Phys Act Health* 6 (3), S. 289–298.

Abstract:

Background: This study aimed to examine cross-sectional and longitudinal associations between socioeconomic position (SEP) and physical activity and sedentary behaviors amongst children and adolescents.

Methods: Maternal education was reported by parents of 184 5-6 year-old and 358 10-12 year-old children in 2001. In 2001 and 2004, physical activity was assessed by accelerometry. Older children self-reported and parents of younger children proxy-reported physical activity and television (TV) viewing behaviors. Linear regression was used to predict physical activity and sedentary behaviors, and changes in these behaviors, from maternal education.

Results: Among all children, accelerometer-determined and self/parent-reported moderate and vigorous physical activity declined over three years. Girls of higher SEP demonstrated greater decreases in TV viewing behaviours than those of low SEP. In general, no prospective associations were evident between SEP and objectively-assessed physical activity. A small number of prospective associations were noted between SEP and self-reported physical activity, but these were generally weak and inconsistent in direction.

Conclusions: This study did not find strong evidence that maternal education was cross-sectionally or longitudinally predictive of children's physical activity or sedentary behaviors. Given the well-documented inverse relationship of SEP with physical activity levels in adult samples, findings suggest that such disparities may emerge after adolescence.

Ball, Trever J.; Joy, Elizabeth A.; Goh, Tan L.; Hannon, James C.; Gren, Lisa H.; Shaw, Janet M. (2014):

Validity of two brief primary care physical activity questionnaires with accelerometry in clinic staff.

In: *Prim Health Care Res Dev*, S. 1–9. DOI: 10.1017/S1463423613000479.

Abstract:

Background: To date, no physical activity (PA) questionnaires intended for primary care have been compared against a criterion measure of PA and current (2008) aerobic PA recommendations of the American College of Sports Medicine/American Heart Association (ACSM/AHA). Aim: This study evaluated preliminary evidence for criterion validity of two brief (<1 min) PA questionnaires with accelerometry, and their ability to identify if individuals meet ACSM/AHA PA recommendations. Methods: 45 health clinic staff wore an accelerometer for seven consecutive days and afterwards completed two brief PA questionnaires, the Physical Activity Vital Sign (PAVS), and the Speedy Nutrition and Physical Activity Assessment (SNAP). Agreement and descriptive statistics were calculated between the PAVS or SNAP and accelerometry in order to measure each questionnaire's ability to quantify the number of days participants achieved 30 min of moderate-vigorous PA (MVPA) performed in bouts of 10 continuous minutes. Participants with <5 days of 30 bout-min of MVPA were considered insufficiently active according to PA recommendations. Findings: There was a significant positive correlation between number of days with 30 bout-min MVPA and the PAVS (r=0.52, P<0.001), and SNAP (r=0.31, P<0.05). The PAVS had moderate agreement with accelerometry for identifying if individuals met or did not meet PA recommendations (kappa=0.46, P<0.001), whereas SNAP had poor agreement (kappa=0.12, P<0.05). Conclusions: This study provides preliminary evidence of criterion validity of the PAVS and SNAP with accelerometry and agreement identifying if respondents meet current (2008) ACSM/AHA aerobic PA recommendations. The PAVS and SNAP should be evaluated further for repeatability, and in populations varying in PA levels, age, gender, and ethnicity.

Bandini, L. G.; Gleason, J.; Curtin, C.; Lividini, K.; Anderson, S. E.; Cermak, S. A. et al. (2012):

Comparison of physical activity between children with autism spectrum disorders and typically developing children.

In: *Autism* (1362-3613 (Linking)). DOI: 10.1177/1362361312437416.

Abstract:

Regular physical activity is important for promoting health and well-being; however, physical activity behaviors in children with autism spectrum disorders (ASD) have received little attention. We compared physical activity levels among 53 children with ASD and 58 typically developing children aged 3-11 years who participated in the Children's Activity and Meal Patterns Study (CHAMPS). After adjustment for age and sex the amount of time spent daily in moderate and vigorous activity was similar in children with ASD (50.0 minutes/day and typically developing children 57.1 minutes/day). However, parents reported that children with ASD participated in significantly fewer types of physical activities than did typically developing children (6.9 vs. 9.6, p <.0001) and spent less time annually participating in these activities than typically developing children (158 vs. 225 hours per year, p < 0.0001) after adjusting for age and sex. Although both groups of children engaged in similar levels of moderate and vigorous activity as measured by accelerometry, children with ASD engaged in fewer physical activities and for less time

according to parental report, suggesting that some of the activity in children with ASD is not captured by standard questionnaire-based measures

Banegas, José R.; Messerli, Franz H.; Waeber, Bernard; Rodríguez-Artalejo, Fernando; La Sierra, Alex; Segura, Julián et al. (2009):

Discrepancies between office and ambulatory blood pressure: clinical implications.

In: *The American journal of medicine* 122 (12), S. 1136–1141. DOI: 10.1016/j.amjmed.2009.05.020.

Abstract:

BACKGROUND\r\nRecent trials have documented no benefit from small reductions in blood pressure measured in the clinical office. However, ambulatory blood pressure is a better predictor of cardiovascular events than office-based blood pressure. We assessed control of ambulatory blood pressure in treated hypertensive patients at high cardiovascular risk.\r\nMETHODS\r\nWe selected 4729 patients from the Spanish Ambulatory Blood Pressure Monitoring Registry. Patients were aged >/=55 years and presented with at least one of the following co-morbidities: coronary heart disease, stroke, and diabetes with end-organ damage. An average of 2 measures of blood pressure in the office was used for analyses. Also, 24-hour ambulatory blood pressure was recorded at 20-minute intervals with a SpaceLabs 90207 device.\r\nRESULTS\r\nPatients had a mean age of 69.6 (+/-8.2) years, and 60.8% of them were male. Average time from the diagnosis of hypertension to recruitment into the Registry was 10.9 (+/-8.4) years. Mean blood pressure in the office was 152.3/82.3 mm Hg, and mean 24-hour ambulatory blood pressure was 133.3/72.4 mm Hg. About 60% of patients with an office-pressure of 130-139/85-89 mm Hg, 42.4% with office-pressure of 140-159/90-99 mm Hg, and 23.3% with office-pressure > or =160/100 mm Hg were actually normotensive, according to 24-hour ambulatory blood pressure criteria (<130/80 mm Hg).\r\nCONCLUSION\r\nWe suggest that the lack of benefit of antihypertensive therapy in some trials may partly be due to some patients having normal pressure at trial baseline. Ambulatory monitoring of blood pressure may allow for a better assessment of trial eligibility.

High prevalence of masked uncontrolled hypertension in people with treated hypertension.

In: *Eur Heart J. DOI:* 10.1093/eurheartj/ehu016.

Abstract:

AIM: There are limited data on the quality of treated blood pressure (BP) control during normal daily life, and in particular, the prevalence of 'masked uncontrolled hypertension' (MUCH) in people with treated and seemingly well-controlled BP is unknown. This is important because masked hypertension in 'treatment naive' patients is associated with a high risk of cardiovascular events. We therefore conducted the first study to define the prevalence and characteristics of MUCH among a large sample of hypertensive patients in routine clinical practice in whom BP was treated and controlled to recommended clinic BP goals. METHODS AND RESULTS: We analysed data from the Spanish Society of Hypertension ambulatory blood pressure monitoring (ABPM) Registry and identified patients with treated and controlled BP according to current international guidelines (clinic BP <140/90 mmHg). Masked uncontrolled hypertension was diagnosed in these patients if despite controlled clinic BP, the mean 24-h ABPM average remained elevated (24-h systolic BP >/=130 mmHg and/or 24-h diastolic BP >/=80 mmHg). From 62 788 patients with treated BP in the Spanish registry, we identified 14 840 with treated and controlled clinic BP, of whom 4608 patients (31.1%) had MUCH according to 24-h ABPM criteria (mean age 59.4 years, 59.7% men). The prevalence of MUCH was significantly higher in males, patients with borderline clinic BP (130-9/80-9 mmHg), and patients at high cardiovascular risk (smokers, diabetes, obesity). Masked uncontrolled hypertension was most often because of poor control of nocturnal BP, with the proportion of patients in whom MUCH was solely attributable to an elevated nocturnal BP almost double that solely attributable to daytime BP elevation (24.3 vs. 12.9%, P < 0.001). CONCLUSION: The prevalence of masked suboptimal BP control in patients with treated and well-controlled clinic BP is high. Clinic BP monitoring alone is thus inadequate to optimize BP control because many patients have an elevated nocturnal BP. These findings suggest that ABPM should become more routine to confirm BP control, especially in higher risk groups and/or those with borderline control of clinic BP.

Banegas, José R.; Segura, Julián; La Sierra, Alejandro; Gorostidi, Manuel; Rodríguez-Artalejo, Fernando; Sobrino, Javier et al. (2008):

Gender differences in office and ambulatory control of hypertension.

In: *The American journal of medicine* 121 (12), S. 1078–1084.

Abstract:

BACKGROUND:

Gender differences in hypertension control have not been explored fully.

METHODS:

We studied 15,212 white men and 13,936 white women with treated hypertension who were drawn from the Spanish Ambulatory Blood Pressure Registry. For each participant, we obtained office blood pressure (BP) (average of 2 readings) and 24-hour ambulatory BP (average of measurements performed every 20 minutes during day and night).

RESULTS:

Only 16.4% of women and 14.7% of men had both office (<140/90 mm Hg) and ambulatory (<130/80 mm Hg) BP controlled (P<.001). Women had a lower frequency of masked hypertension (office BP<140/90 mm Hg and ambulatory BP> or =130/80 mm Hg) than men (5.9% vs 7.9%, P<.001). Women had a higher frequency of isolated office hypertension (office BP> or =140/90 mm Hg and ambulatory BP<130/80 mm Hg) (32.5% vs 24.2%, P<.001). Although office BP control (office BP<140/90 mm Hg, regardless of ambulatory values) was similar in women and men (22.3% vs 22.6%, P=.542), ambulatory BP control (ambulatory BP<130/80 mm Hg, regardless of office values) was higher in women than in men (48.9% vs 38.9%, P<.001). After adjustment for age, number of antihypertensive drugs, hypertension duration, and risk factors, gender differences in BP control remained practically unchanged.

CONCLUSION:

Ambulatory BP control was higher in women than in men. This may be due to the higher frequency of isolated office hypertension in women, and it is not explained by gender differences in other important clinical characteristics.

Bangash, Farhan; Agarwal, Rajiv (2009):

Masked hypertension and white-coat hypertension in chronic kidney disease: a meta-analysis.

In: *Clinical Journal of the American Society of Nephrology* 4 (3), S. 656–664.

Abstract:

BACKGROUND AND OBJECTIVES:

Poor hypertension control observed in patients with chronic kidney disease (CKD) may in part be due to the suboptimal assessment of BP with clinic BP measurements alone. The goal of this meta-analysis was to estimate the prevalence and determinants of white-coat and masked hypertension in the adult CKD population.

DESIGN, SETTING, PARTICIPANTS, & MEASUREMENTS:

Articles reporting prevalence of masked and white-coat hypertension in patients with CKD were obtained from two major databases. We then performed a meta-analysis to derive pooled estimates of prevalence and determinants of these two conditions.

RESULTS:

Among 980 patients with CKD identified in six studies, the overall prevalence of masked hypertension was 8.3% and of white-coat hypertension was 18.3%. More alarming, 40.4% of patients who had CKD and were thought to have normotension (or adequately treated hypertension) in fact had hypertension at home. Also 30.0% of patients who had CKD and were thought to have hypertension had normotension at home. The thresholds for classification of clinic and ambulatory BP as hypertensive strongly influenced the risk for diagnosis of masked hypertension in favor of white-coat hypertension.

CONCLUSIONS:

Because clinic BP measurements alone lead to substantial misclassification in BP, we estimate that the prevalence of poorly controlled hypertension is likely less than currently estimated. Out-of-office BP monitoring may improve the management of hypertension in patients with CKD. Standardized definitions for the diagnosis of masked and white-coat hypertension would facilitate research.

Bania, Theofani (2014):

Measuring Physical Activity in Young People with Cerebral Palsy: Validity and Reliability of the ActivPAL Monitor.

In: *Physiother Res Int. DOI:* 10.1002/pri.1584.

Abstract:

BACKGROUND AND PURPOSE: We determined the criterion validity and the retest reliability of the ActivPAL monitor in young people with diplegic cerebral palsy (CP). METHODS: Activity monitor data were compared with the criterion of video recording for 10 participants. For the retest reliability, activity monitor data were collected from 24 participants on two occasions. Participants had to have diplegic CP and be between 14 and 22 years of age. They also had to be of Gross Motor Function Classification System level II or III. Outcomes were time spent in standing, number of steps (physical activity) and time spent in sitting (sedentary behaviour). RESULTS: For criterion validity, coefficients of determination were all high (r2 >/= 0.96), and limits of group agreement were relatively narrow, but limits of agreement for individuals were narrow only for number of steps (>/=5.5%). Relative reliability was high for number of steps (intraclass correlation coefficient = 0.87) and moderate for time spent in sitting and lying, and time spent in standing (intraclass correlation coefficients = 0.60-0.66). For groups, changes of up to 7% could be due to measurement error with 95% confidence, but for individuals, changes as high as 68% could be due to measurement error. DISCUSSION: The results support the criterion validity and the retest reliability of the ActivPAL to measure physical activity and sedentary behaviour in groups of young people with diplegic CP but not in individuals. Banks, Laura; Wells, Greg D.; McCrindle, Brian W. (2014):

Cardiac energy metabolism is positively associated with skeletal muscle energy metabolism in physically active adolescents and young adults.

In: *Appl Physiol Nutr Metab* 39 (3), S. 363–368. DOI: 10.1139/apnm-2013-0312.

Abstract:

(31)Phosphorus Magnetic Resonance Spectroscopy ((31)P MRS) is a well-validated, noninvasive magnetic resonance imaging technique that has been used to determine cardiac and skeletal muscle energy metabolism in vivo. Few studies have documented cardiac energy metabolism in adolescents and young adult cohorts. This cross-sectional study sought to explore the association among cardiac energy metabolism, skeletal muscle energy metabolism, moderate-to-vigorous physical activity (MVPA), and age in adolescents and young adults. Ten healthy, active participants (40% male) with a mean +/- SD age of 18.6 +/- 4.9 years, body mass index of 21.1 +/- 2.4 kg.m(-2), and median MVPA level of 83 min per weekday (lower quartile: 45 min per weekday; upper quartile: 114 min per weekday) completed the following study assessments: a (31)P MRS scan to determine cardiac and skeletal muscle energy metabolism, cardiopulmonary exercise testing to determine aerobic power, and accelerometry to determine MVPA over 7 days. Resting cardiac energy metabolism, as measured by the ratio of phosphocreatine to adenosine triphosphate (PCr/ATPbeta, mean +/- SD: 2.76 +/- 0.65), was positively associated with skeletal muscle aerobic oxidative function (Estimate (SE): -0.1(0.01), p < 0.001), as measured by PCr recovery half-time following 60 s of exercise (34 +/- 9 s). This association, which was adjusted for peak aerobic power, MVPA, age, and sex, suggests the development of an association between cardiac and skeletal muscle health at any early age. Larger studies are needed to establish normative data for both physically active and sedentary males and females that may be used for comparison in future studies involving clinical cohorts.

Baquero, Giselle A.; Banchs, Javier E.; Ahmed, Shameer; Naccarelli, Gerald V.; Luck, Jerry C. (2015):

Surface 12 lead electrocardiogram recordings using smart phone technology.

In: *J Electrocardiol* 48 (1), S. 1–7. DOI: 10.1016/j.jelectrocard.2014.09.006.

Abstract:

IMPORTANCE: AliveCor ECG is an FDA approved ambulatory cardiac rhythm monitor that records a single channel (lead I) ECG rhythm strip using an iPhone. In the past few years, the use of smartphones and tablets with health related applications has significantly proliferated. OBJECTIVE: In this initial feasibility trial, we attempted to reproduce the 12 lead ECG using the bipolar arrangement of the AliveCor monitor coupled to smart phone technology. METHODS: We used the AliveCor heart monitor coupled with an iPhone cellular phone and the AliveECG application (APP) in 5 individuals. RESULTS: In our 5 individuals, recordings from both a standard 12 lead ECG and the AliveCor generated 12 lead ECG had the same interpretation. CONCLUSIONS: This study demonstrates the feasibility of creating a 12 lead ECG with a smart phone. The validity of the

recordings would seem to suggest that this technology could become an important useful tool for clinical use. This new hand held smart phone 12 lead ECG recorder needs further development and validation.

Objectively assessed recess physical activity in girls and boys from high and low socioeconomic backgrounds.

In: *BMC Public Health* 14, S. 192. DOI: 10.1186/1471-2458-14-192.

Abstract:

BACKGROUND: The school environment influences children's opportunities for physical activity participation. The aim of the present study was to assess objectively measured school recess physical activity in children from high and low socioeconomic backgrounds. METHODS: Four hundred and seven children (6-11 years old) from 4 primary schools located in high socioeconomic status (high-SES) and low socioeconomic status (low-SES) areas participated in the study. Children's physical activity was measured using accelerometry during morning and afternoon recess during a 4-day school week. The percentage of time spent in light, moderate, vigorous, very high and in moderate- to very high-intensity physical activity were calculated using age-dependent cut-points. Sedentary time was defined as 100 counts per minute. RESULTS: Boys were significantly ($p < 0.001$) more active than girls. No difference in sedentary time between socioeconomic backgrounds was observed. The low-SES group spent significantly more time in light ($p < 0.001$) and very high ($p < 0.05$) intensity physical activity compared to the high-SES group. High-SES boys and girls spent significantly more time in moderate ($p < 0.001$ and $p < 0.05$, respectively) and vigorous ($p < 0.001$) physical activity than low-SES boys. CONCLUSIONS: Differences were observed in recess physical activity levels according to socioeconomic background and sex. These results indicate that recess interventions should target children in low-SES schools.

Compliance with Accelerometry Measurement of Community Ambulation Poststroke.

In: *Phys.Ther.* (0031-9023 (Linking)). DOI: 10.2522/ptj.20120473.

Abstract:

BACKGROUND: The step activity monitor (SAM) quantifies steps taken in the home and community by patient populations. While the SAM has been used to study individuals post-stroke, compliance with SAM has not been addressed. Participants' compliance in wearing the monitor is critical for obtaining accurate assessments. OBJECTIVE: The purpose of this study was to determine the rate of and predictors for inferred compliance with the SAM post-stroke. DESIGN: Cross-sectional. METHODS: 408 community-dwelling individuals two-months post-stroke with moderate-to-severe gait impairment (gait speed of </= 0.8 m/s). Step activity was assessed for two days with the SAM. Inferred compliance was established in three periods: 6:00AM-12:00PM, 12:01PM-6:00PM, and 6:01PM-12:00AM. Compliance was defined as activity recorded in all three periods. The percentage of participant compliance for the first day, second day, both days, and either day was calculated. Demographic and clinical characteristics of compliers and non-compliers were compared. Independent compliance predictors were identified using stepwise logistic regression. RESULTS: Inferred compliance rate in the first day, second day, both days, and either day was 68, 61, 53, and 76%, respectively. Upper and lower extremity impairment, balance control and endurance were significantly different between compliers and non-compliers. On the other hand, older age, greater balance self-efficacy, and better walking endurance were found to be significant predictors of compliance. LIMITATIONS: Participants consisted of individuals with sub-acute stroke. Therefore, our findings may not be generalized to individuals during the acute and chronic phases of stroke recovery. CONCLUSIONS: Strategies to improve compliance are needed, when collecting data for more than one day, and in samples with younger individuals, and persons with low levels of balance self-efficacy and walking endurance

A panel study of air pollution in subjects with heart failure: negative results in treated patients.

In: *Occupational and environmental medicine* 66 (5), S. 325–334.

Abstract:

OBJECTIVES:

To investigate preclinical adverse effects of ambient particulate air pollution and nitrogen oxides in patients with heart failure.

METHODS:

A cohort of 132 non-smoking patients living in Aberdeen, Scotland, with stable chronic heart failure were enrolled in a repeated-measures panel study. Patients with atrial fibrillation or pacemakers were excluded. Participants were studied for 3 days every 2 months for up to 1 year with monitoring of pollutant exposure and concurrent measurements of pathophysiological responses. Measurements included daily area concentration of particulate matter with a median aerodynamic diameter of <10 micrometres (PM(10)), particle number concentration (PNC) and nitrogen oxides; daily estimated personal concentration of particulate matter with a median aerodynamic diameter of <2.5 micrometres (PM(2.5)) and PNC exposures; and 3-day cumulative personal nitrogen dioxide (NO(2)). Concurrent meteorological data were recorded. Blood was taken at the end of each 3-day block for assays of markers of endothelial activation, inflammation and coagulation. Cardiac rhythm was monitored by ambulatory Holter monitor during the final 24 h of each block.

RESULTS:

The average 24 h background ambient PM(10) ranged from 7.4 to 68 microg.m(-3) and PNC from 454 to 11 283 particles.cm(-3). No associations were demonstrated between the incidence of arrhythmias, heart rate variability or haematological/biochemical measures and any variations in pollutant exposures at any lags.

CONCLUSION:

Assuming that low-level pollution affects the parameters measured, these findings may suggest a beneficial effect of modern cardioprotective therapy, which may modify responses to external risk factors. Widespread use of such drugs in susceptible populations may in future reduce the adverse effects of air pollution on the heart.

Barker, Erin T.; Williams, Rebecca L.; Galambos, Nancy L. (2006):

Daily spillover to and from binge eating in first-year university females.

In: *Eating disorders* 14 (3), S. 229–242. DOI: 10.1080/10640260600639079.

Abstract:

Coping models of binge eating propose that stress and/or negative affect trigger binge eating, which serves to shift attention to the binge and its consequences. The current study tested these general assumptions using 14-day daily diary data collected from 66 first-year university females. Hierarchical Generalized Linear Modeling results showed that increased stress, negative affect, and weight concerns were associated with an increased likelihood of reporting symptoms of binge eating within days. Elevated weight concerns predicted next-day binge eating and binge eating predicted greater next-day negative affect. Discussion focuses on implications for coping models of binge eating.

Barkley, Jacob E.; Salvy, Sarah Jeanne; Roemmich, James N. (2012):

The effect of simulated ostracism on physical activity behavior in children.

In: *Pediatrics* 129 (3), S. e659-e666. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-09899-005%26site%3dehost-live;jbarkle1@kent.edu.

Abstract:

OBJECTIVES:

To assess the effects of simulated ostracism on children's physical activity behavior, time allocated to sedentary behavior, and liking of physical activity.

METHODS:

Nineteen children (11 boys, 8 girls; age 11.7 ± 1.3 years) completed 2 experimental sessions. During each session, children played a virtual ball-toss computer game (Cyberball). In one session, children played Cyberball and experienced ostracism; in the other session, they were exposed to the inclusion/control condition. The order of conditions was randomized. After playing Cyberball, children were taken to a gymnasium where they had free-choice access to physical and sedentary activities for 30 minutes. Children could participate in the activities, in any pattern they chose, for the entire period. Physical activity during the free-choice period was assessed via accelerometery and sedentary time via observation. Finally, children reported their liking for the activity session via a visual analog scale.

RESULTS:

Children accumulated 22% fewer (P < .01) accelerometer counts and 41% more (P < .04) minutes of sedentary activity in the ostracized condition (8.9(e+4) ± 4.5(e+4) counts, 11.1 ± 9.3 minutes) relative to the included condition (10.8(e+4) ± 4.7(e+4) counts, 7.9 ± 7.9 minutes). Liking (8.8 ± 1.5 cm included, 8.1 ± 1.9 cm ostracized) of the activity sessions was not significantly different (P > .10) between conditions.

CONCLUSIONS:

Simulated ostracism elicits decreased subsequent physical activity participation in children. Ostracism may contribute to children's lack of physical activity.

Barletta, Gina-Marie; Flynn, Joseph; Mitsnefes, Mark; Samuels, Joshua; Friedman, Lisa Aronson; Ng, Derek et al. (2014):

Heart rate and blood pressure variability in children with chronic kidney disease: a report from the CKiD study.

In: *Pediatr Nephrol. DOI:* 10.1007/s00467-013-2737-8.

Abstract:

BACKGROUND: Autonomic nervous system dysfunction and sympathetic nervous system over-activity play important roles in the development of hypertension associated with chronic kidney disease (CKD). In adults, increased blood pressure variability (BPV) appears to be directly related to sympathetic over-activity with increased risk of end-organ damage and cardiovascular events. Decreased heart rate variability (HRV) has been observed in adults with CKD, and is an independent predictor of mortality. METHODS: The purpose of this study was to evaluate BPV and HRV in pediatric patients enrolled in the Chronic Kidney Disease in Children Study. Ambulatory blood pressure monitoring data were available for analysis of 215 person-visits from 144 children that were not receiving antihypertensive medications. RESULTS: BPV and HRV were determined by standard deviation and coefficient of variation for heart rate and systolic and diastolic blood pressure for each patient averaged for wake/sleep periods during 24-h monitoring. Uniformly lower values were displayed during sleep versus wake periods: BPV was 20 % lower during sleep ($p < 0.001$) and HRV was 30 % lower during sleep ($p < 0.001$). A significant increase in systolic BPV was observed in hypertensive children compared to children with normal blood pressure (6.9 %, $p = 0.009$). Increased diastolic BPV was detected among hypertensive children during sleep period compared to children with normal blood pressure (11.5 %, $p = 0.008$). There was a significant decrease in HRV in hypertensive compared to normotensive children (-8.2 %, $p = 0.006$). CONCLUSIONS: These findings are similar to those in adult patients and may underscore childhood origin and natural progression of adverse cardiovascular outcomes in adults with CKD.

Barmettler, Gabi; Brawn, Jennifer; Maleki, Nasim; Scrivani, Steven; Burstein, Rami; Becerra, Lino; Borsook, David (2014):

A new electronic diary tool for mapping and tracking spatial and temporal head pain patterns in migraine.

In: *Cephalalgia. DOI:* 10.1177/0333102414545892.

Abstract:

AIM: We present an electronic tool for collecting data on the patterns of migraine headache onset and progression. METHODS: A digitized map consisting of 44 color-coded segments was defined based on previous reports of migraine pain and the distribution of nerves in the face, head and neck. The map was overlaid on a schematic map of the face, head and neck nerves. Thirty-six patients (N = 36, 28 female/eight male), who met ICDH-II criteria for episodic migraine and had headaches for at least three years, identified all regions where pain typically started and how pain spread and subsequently progressed. RESULTS: Consistent with previous findings, throbbing was the most prevalent quality of migraine pain, always present in 70% of patients surveyed. For the 70% of the patients with throbbing pain, the temple was the onset site of throbbing pain, with no significant difference in the laterality of onset site (58.3% on the right vs. 55.6% on the left hemisphere). The tool was able to capture patterns of pain distribution for throbbing and pressure headache pain and also may be used to assess the change in the pattern of the pain distribution as the disease progresses. DISCUSSION: The pain map survey may be a useful tool for recording and tracking the temporal pattern of migraine onset both for clinical and research purposes. The tool could be used to create maps of pain locations on a large population scale and thus will be a very useful tool in correlating the temporal nature of headache symptoms with potential mechanisms of disease evolution.

Barnes, Deborah E.; Blackwell, Terri; Stone, Katie L.; Goldman, Suzanne E.; Hillier, Teresa; Yaffe, Kristine (2008):

Cognition in older women: the importance of daytime movement.

In: *J Am Geriatr Soc* 56 (9), S. 1658–1664.

Abstract:

OBJECTIVES: To determine whether an objective measure of daytime movement is associated with better cognitive function in women in their 80s.

DESIGN: Cross-sectional.

SETTING: A study of health and aging.

PARTICIPANTS: Two thousand seven hundred thirty-six older women without evidence of dementia.

MEASUREMENTS:

Daytime movement was assessed using actigraphy, which involved wearing a watch-like device that objectively quantified accelerometer motion over a mean of 3.0+/-0.8 days. Cognitive function was measured using the Trail-Making Test, Part B (Trails B) and the Mini-Mental State Examination (MMSE). Cognitive impairment was defined as performing 1.5 standard deviations (SDs) worse than the mean on a given test.

RESULTS:

Participants had a mean age of 83+/-4; 10% were African American. After adjustment for age, race, and education, women in the highest movement quartiles had better mean cognitive test scores (20+/-0.3 seconds faster on Trails B and 0.3+/-0.2 points higher on MMSE, both P<.001) than those in the lowest quartile and were less likely to be cognitively impaired (odds ratio (OR)=0.61, 95% confidence interval (CI)=0.41-0.92 for Trails B; OR=0.68, 95% CI=0.44-1.07 for MMSE). Associations were similar in different subgroups and were independent of self-reported walking, medical comorbidities, physical function, and other health-related behaviors.

CONCLUSION:

Daytime movement as measured objectively using actigraphy was associated with better cognitive function and lower odds of cognitive impairment in women in their 80s. Additional studies are needed to clarify the direction of the association and to explore potential mechanisms.

Barnes, V. A.; Johnson, M. H.; Williams, R. B.; Williams, V. P. (2012):

IMPACT OF WILLIAMS LIFESKILLS TRAINING ON ANGER, ANXIETY AND AMBULATORY BLOOD PRESSURE IN ADOLESCENTS.

In: *Transl.Behav.Med* 2 (4), S. 401–410. DOI: 10.1007/s13142-012-0162-3.

Abstract:

The Williams LifeSkills(R) (WLS) anger and stress management workshop provides training in strategies to cope with stressful situations and build supportive relationships. The purpose of this study was to determine the impact of school-based Williams LifeSkills training on anger, anxiety and blood pressure in adolescents. 159 adolescents (mean age+/-SD=15.7+/-1.4 years) were randomized to WLS (n=86) or control (CTL, n=73) groups. The WLS group engaged in twelve 50-min WLS training sessions conducted by teachers at school. Anger-in and anxiety scores decreased and anger control scores increased in the WLS group across the six-month follow-up period compared to the CTL group (group x visit, ps<0.05). Daytime diastolic BP was lower across the follow-up in the WLS group (p=0.08). DBP was significantly lower across the follow-up period in the WLS group among those with higher SBP at baseline (p=0.04). These findings demonstrate beneficial impact of WLS upon self-reported anger-in, anger-control, anxiety levels and ambulatory DBP in the natural environment in healthy normotensive youth

Barnes, Christopher M.; Wagner, David T.; Ghumman, Sonia (2012):

Borrowing from sleep to pay work and family: Expanding time-based conflict to the broader nonwork domain.

In: *Personnel Psychology* 65 (4), S. 789–819. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-29592-003%26site%3dehost-live;cmbarnes@vt.edu.

Abstract:

We extend cross-domain research by examining sleep, a domain within the larger nonwork domain that competes for time with work and family domains. We draw from scarcity theory and research on slack resources to contend that, because people cannot increase the amount of time they have, they borrow time from sleep in order to spend more time working and with family. Utilizing a Bureau of Labor Statistics survey of 10,741 participants, we find nonlinear and interactive effects of time spent working and time spent with family on sleep time, suggesting that the negative effects of work and family on sleep time are especially strong when demands for work and family are high. In an experience sampling field study of 122 working adults, we similarly find a nonlinear effect of work time on sleep time as well as an interaction between work time and family time in predicting time spent sleeping. Both studies indicate that as slack time resources become increasingly scarce, time spent working and time spent with family have increasingly powerful negative effects on time spent sleeping. Contrary to our expectations, we found no support for gender as a moderator of these effects. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Barnett, Anthony; Cerin, Ester; Cheung, Man-Chin; Chan, Wai-Man (2014):

An In-Depth Pilot Study on Patterns, Destinations, and Purposes of Walking in Hong Kong Older Adults.

In: *J Aging Phys Act. DOI:* 10.1123/japa.2013-0026.

Abstract:

Walking is a suitable activity for older adults and has physical and mental health benefits. To devise interventions that impact on levels of walking it is necessary to first understand the purposes for which people walk and the destinations to which they walk. Using a 7-day diary and accelerometry, this study investigated destinations and purposes of walking in older adult residents of an ultra-dense Asian city. Participants reported an average of 17.1 walking trips per week and total weekly accelerometer/diary determined trip walking time averaged 735 minutes per week, much higher than reported for older adults in non-Asian settings. The most common destinations were within the neighborhood: parks and streets for recreation walking and shops and eating places for transport-related walking. Errands and eating were the most common purposes for transportation trips. The study results can help inform urban design to encourage walking.

Use of electronic games by young children and fundamental movement skills?

In: *Percept.Mot.Skills* 114 (3), S. 1023–1034. Online verfügbar unter PM:22913038.

Abstract:

This study investigated associations between pre-school children's time spent playing electronic games and their fundamental movement skills. In 2009, 53 children had physical activity (Actigraph accelerometer counts per minute), parent proxy-report of child's time in interactive and non-interactive electronic games (min./week), and movement skill (Test of Gross Motor Development-2) assessed. Hierarchical linear regression, adjusting for age (range = 3-6 years), sex (Step 1), and physical activity (cpm; M=687, SD=175.42; Step 2), examined the relationship between time in (a) non-interactive and (b) interactive electronic games and locomotor and object control skill. More than half (59%, n=31) of the children were female. Adjusted time in interactive game use was associated with object control but not locomotor skill. Adjusted time in non-interactive game use had no association with object control or locomotor skill. Greater time spent playing interactive electronic games is associated with higher object control skill proficiency in these young children. Longitudinal and experimental research is required to determine if playing these games improves object control skills or if children with greater object control skill proficiency prefer and play these games

Barreira, Tiago V.; Harrington, Deirdre M.; Katzmarzyk, Peter T. (2014):

Cardiovascular health metrics and accelerometer-measured physical activity levels: National Health and Nutrition Examination Survey, 2003-2006.

In: *Mayo Clin Proc* 89 (1), S. 81–86. DOI: 10.1016/j.mayocp.2013.10.001.

Abstract:

OBJECTIVE: To determine whether relationships exist between accelerometer-measured moderate-to-vigorous physical activity (MVPA) and other cardiovascular (CV) health metrics in a large sample. PATIENTS AND METHODS: Data from the 2003-2006 National Health and Nutrition Examination Survey (NHANES) collected from January 1, 2003, through December 31, 2006, were used. Overall, 3454 nonpregnant adults 20 years or older who fasted for 6 hours or longer, with valid accelerometer data and with CV health metrics, were included in the study. Blood pressure (BP), body mass index (BMI), smoking status, diet, fasting plasma glucose level, and total cholesterol level were defined as ideal, intermediate, and poor on the basis of American Heart Association criteria. Results were weighted to account for sampling design, oversampling, and nonresponse. RESULTS: Significant increasing linear trends in mean daily MVPA were observed across CV health levels for BMI, BP, and fasting plasma glucose (P<.001). Those with a poor BMI and BP had significantly lower mean daily MVPA than those with intermediate and ideal BMIs and BPs (all P<.001). In addition, individuals with an intermediate fasting plasma glucose level had significantly lower mean daily MVPA than individuals at the ideal levels (P<.001). No significant linear trends were observed for cholesterol, smoking, and diet. A significant linear trend was observed for mean daily MVPA and the overall number of other CV health metrics (P<.001). CONCLUSION: Objectively measured MVPA was related to other CV health metrics in this large sample. These results support the inclusion of physical activity in the overall definition of ideal CV health.

Identifying Children's Nocturnal Sleep Using 24-h Waist Accelerometry.

In: *Med Sci Sports Exerc. DOI:* 10.1249/MSS.0000000000000486.

Abstract:

PURPOSE: The purposes of this study were (1) to add layers and features to a previously published fully automated algorithm designed to identify children's nocturnal sleep and to exclude episodes of nighttime non-wear/wakefulness and potentially misclassified day time sleep episodes, and (2) to validate this refined sleep algorithm (RSA) against sleep logs. METHODS: Forty-five fourth-grade school children (51% female) participants were asked to log evening bedtime and morning wake time and wear an Actigraph GT3X+ accelerometer at their waist for 7 consecutive days. Accelerometers were distributed through a single school participating in the Baton Rouge, USA site of the International Study of Childhood Obesity, Lifestyle, and the Environment (ISCOLE). We compared log-based variables of sleep period time (SPT), bedtime, and wake time to corresponding accelerometer-determined variables of total sleep episode time (TSET), sleep onset, and sleep offset estimated with the RSA. In addition, SPT and sleep onset estimated using standard procedures combining sleep logs and accelerometry (Log+Accel) were compared to the RSA-derived values. RESULTS: RSA TSET (540+/-36 min) was significantly different from Log SPT (560+/-24 min), p=0.003, but not different from Log+Accel SPT (549+/-24 min), p=0.15. Significant and moderately high correlations were apparent between RSA-determined variables and those using the other methods (r=0.61 to 0.74). There were no differences between RSA and Log+Accel estimates of sleep onset (p=0.15) or RSA sleep offset and Log wake time (p=0.16). CONCLUSIONS: The RSA is a refinement of our previous algorithm, allowing researchers who use a 24 h waist-worn accelerometry protocol to distinguish children's nocturnal sleep (including night time wake episodes) from day time activities.

Craving and self-efficacy in the first five weeks of methadone maintenance therapy: a daily process study.

In: *Journal of Studies on Alcohol and Drugs* 70 (5), S. 735–740.

Abstract:

OBJECTIVE:

Among individuals initiating methadone maintenance therapy for heroin addiction, low craving and high self-efficacy are thought to predict treatment response; however, in the case of craving, findings have been inconsistent. This study will test two hypotheses: (1) craving and self-efficacy both predict treatment response and (2) withdrawal symptoms and sleep quality predict greater craving and greater self-efficacy, respectively.

METHOD:

An exploratory study using electronic diary data and multilevel models examined these hypotheses. A sample of 21 heroin users was recruited during the first 1-2 days of methadone maintenance therapy to take part in a 5-week diary study. Comparisons were made between days before participants reached a 70 mg or greater dose and subsequent days. This is in keeping with research showing that this dosage corresponds to optimal opioid receptor blockade.

RESULTS:

Analysis of 449 diary records nested within 21 participants showed a marked decline in heroin use on days subsequent to the 70 mg methadone dosage plateau. Controlling for methadone dosage plateau, the likelihood of heroin use was lower on days in which participants reported both high self-efficacy and low craving, as compared with other days. Support was found for hypothesized direct associations between craving and withdrawal symptoms and between self-efficacy and sleep quality.

CONCLUSIONS:

Consistent with a previously published theory, the effect of low craving on positive response to methadone maintenance therapy is evident on days distinguished by high self-efficacy. Also, improving patients' sleep quality may enhance the benefits of methadone maintenance therapy.

Gait analysis using accelerometry in dystrophin-deficient dogs.

In: *Neuromuscular disorders : NMD* 19 (11), S. 788–796. DOI: 10.1016/j.nmd.2009.07.014.

Abstract:

Dogs affected with Golden Retriever Muscular Dystrophy (GRMD) exhibit striking clinical similarities with patients suffering from Duchenne muscular dystrophy (DMD), particularly gait impairments. The purpose of this study was to describe the use and reliability of accelerometry in gait assessment of dogs with muscular dystrophy. Eight healthy and 11 GRMD adult dogs underwent three gait assessment sessions, using accelerometry. Three-axial recordings of accelerations were performed, and gait variables calculated. Total power, force and regularity of accelerations, stride length and speed, normalized by height at withers, stride frequency, and cranio-caudal power were significantly decreased, whereas medio-lateral power was significantly increased in GRMD dogs. Moreover, these variables were repeatable within and between sessions. Accelerometry provides reliable variables which highlight specific gait patterns of GRMD dogs, describing objectively and quantitatively their slow, short-stepped, and swaying gait. As it is easy to set-up, quick to perform and inexpensive, accelerometry represents a useful tool, to assess locomotion during pre-clinical trials.

Bartlett, Susan J.; Barnes, Teresa; McIvor, R. Andrew (2014):

Integrating patients into meaningful real-world research.

In: *Ann Am Thorac Soc* 11 Suppl 2, S. S112-7. DOI: 10.1513/AnnalsATS.201309-327RM.

Abstract:

Research in respiratory, sleep, and critical care medicine has historically been the domain of scientists and clinicians attempting to understand pathophysiological mechanisms and consequences of disease in an effort to develop effective treatments. This traditional approach of placing scientific rigor before the patient's reality is changing. There is growing recognition of the importance of integrating patient perspectives (e.g., preferences, expectations, and expanded definitions of what constitutes "successful" outcomes) into clinical research to achieve meaningful results for a broader group of stakeholders. This evolution is reflected in the growth of patient-centered organizations and patient advocacy groups that seek to meaningfully integrate patients into the process of prioritizing research needs and creating alliances wherein patients and researchers can partner together to accomplish research goals. In tandem, a growing number of real-world trials (i.e., those with broader, more representative patient populations and routine care pathways) now complement findings from traditional randomized controlled trials and offer new opportunities to design studies that better reflect patients' healthcare preferences and experiences. Patients' perspectives are key determinants of treatment adherence and outcomes, as well as the feasibility and likely value of implementing care pathways. The advent of smartphone and push technologies offer new opportunities for the collection of more patient-centered and ecologically valid patient data, thereby adding new dimensions to meaningfully integrate patients into real-world research.

Basen-Engquist, Karen; Carmack, Cindy L.; Li, Yisheng; Brown, Jubilee; Jhingran, Anuja; Hughes, Daniel C. et al. (2013):

Social-Cognitive Theory Predictors of Exercise Behavior in Endometrial Cancer Survivors.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-05962-001%26site%3dehost-live.

Abstract:

Objective: This study evaluated whether social-cognitive theory (SCT) variables, as measured by questionnaire and ecological momentary assessment (EMA), predicted exercise in endometrial cancer survivors. Method: One hundred posttreatment endometrial cancer survivors received a 6-month home-based exercise intervention. EMAs were conducted by using hand-held computers for 10- to 12-day periods every 2 months. Participants rated morning self-efficacy and positive and negative outcome expectations by using the computer, recorded exercise information in real time and at night, and wore accelerometers. At the midpoint of each assessment period, participants completed SCT questionnaires. Using linear mixed-effects models, the authors tested whether morning SCT variables predicted minutes of exercise that day (Question 1) and whether exercise minutes at time point Tj could be predicted by questionnaire measures of SCT variables from time point Tj-1 (Question 2). Results: Morning self-efficacy significantly predicted that day's exercise minutes ($p < .0001$). Morning positive outcome expectations were also associated with exercise minutes ($p = .0003$), but the relationship was attenuated when self-efficacy was included in the model ($p = .4032$). Morning negative outcome expectations were not associated with exercise minutes. Of the questionnaire measures of SCT variables, only exercise self-efficacy predicted exercise at the next time point ($p = .003$). Conclusions: The consistency of the relationship between self-efficacy and exercise minutes over short (same day) and longer (Tj to Tj-1) time periods provides support for a causal relationship. The strength of the relationship between morning self-efficacy and exercise minutes suggest that real-time interventions that target daily variation in self-efficacy may benefit endometrial cancer survivors' exercise adherence. Bassett Jr, David R.; Wyatt, Holly R.; Thompson, Helen; Peters, John C.; Hill, James O. (2010):

Pedometer-measured physical activity and health behaviors in United States adults.

In: *Med Sci Sports Exerc* 42 (10), S. 1819.

Abstract:

U.S. adults may have lower levels of ambulatory physical activity compared with adults living in other countries.

PURPOSE:

The purpose of this study was to provide descriptive, epidemiological data on the average number of steps per day estimated to be taken by U.S. adults and to identify predictors of pedometer-measured physical activity on the basis of demographic characteristics and self-reported behavioral characteristics.

METHODS:

The America On the Move study was conducted in 2003. Individuals (N = 2522) aged 13 yr and older consented to fill out a survey, including 1921 adults aged 18 yr and older. Valid pedometer data were collected on 1136 adults with Accusplit AE120 pedometers. Data were weighted to reflect the general U.S. population according to several variables (age, gender, race/ethnicity, education, income, level of physical activity, and number of 5- to 17-yr-old children in the household). Differences in steps per day between subgroups were analyzed using unpaired t-tests when only two subgroups were involved or one-way ANOVA if multiple subgroups were involved.

RESULTS:

Adults reported taking an average of 5117 steps per day. Male gender, younger age, higher education level, single marital status, and lower body mass index were all positively associated with steps per day. Steps per day were positively related to other self-reported measures of physical activity and negatively related to self-reported measures on physical inactivity. Living environment (urban, suburban, or rural) and eating habits were not associated with steps per day.

CONCLUSIONS:

In the current study, men and women living in the United States took fewer steps per day than those living in Switzerland, Australia, and Japan. We conclude that low levels of ambulatory physical activity are contributing to the high prevalence of adult obesity in the United States.

Optimal experience among teachers: new insights into the work paradox.

In: *J Psychol* 146 (5), S. 533–557. Online verfügbar unter PM:22931008.

Abstract:

Several studies highlighted that individuals perceive work as an opportunity for flow or optimal experience, but not as desirable and pleasant. This finding was defined as the work paradox. The present study addressed this issue among teachers from the perspective of self-determination theory, investigating work-related intrinsic and extrinsic motivation, as well as autonomous

and controlled behavior regulation. In Study 1, 14 teachers were longitudinally monitored with Experience Sampling Method for one work week. In Study 2, 184 teachers were administered Flow Questionnaire and Work Preference Inventory, respectively investigating opportunities for optimal experience, and motivational orientations at work. Results showed that work-related optimal experiences were associated with both autonomous regulation and with controlled regulation. Moreover, teachers reported both intrinsic and extrinsic motivation at work, with a prevailing intrinsic orientation. Findings provide novel insights on the work paradox, and suggestions for teachers' well-being promotion

Optimal experience and self-determination at school: Joining perspectives.

In: *Motivation and Emotion* 36 (4), S. 425–438. DOI: 10.1037/t06606-000;

Abstract:

This study aimed at investigating optimal experience during schoolwork in relation to SDT concepts of autonomy and locus of causality. Data were gathered from 268 high-school students using Experience Sampling Method for 1 week. Three levels of self-determination were identified: high (corresponding to autonomous regulation), moderate (mixed autonomous and controlled regulation), and low (controlled regulation). Consistently with the literature, the relationship between participants' challenges and skills values was used to recognize occasions for optimal experience, and multilevel modeling was applied in data analysis. Findings showed that during schoolwork as optimal activity (high challenges and high skills) students mostly reported low levels of self-determination. However, the quality of their experience was better in situations of high and moderate self-determination. At the theoretical level, findings allow for a more articulated understanding of the characteristics of optimal experience in academic activities. Practical implications are discussed for enhancing well-being and committed learning at school. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Quality of experience during psychosocial rehabilitation: A real-time investigation with experience sampling method.

In: *Psychiatric Rehabilitation Journal* 35 (6), S. 447–453. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-34112-006%26site%3dehost-live;marta.bassi@unimi.it.

Abstract:

Objective: This study aimed to identify contextual and clinical factors contributing to the quality of experience of people participating in psychosocial rehabilitation activities (RA) and to investigate the association of RA with optimal experience or flow, a state characterized by the perception of high challenges and high skills, deep concentration, positive affect, clear goals, control and autonomous motivation, which contributes to individuals' well-being. Method: Twenty-seven people at an Italian psychiatric rehabilitation center provided real-time information on daily activities and associated experience through experience sampling method. Multilevel models were calculated to assess the factors contributing to participants' quality of experience.

Results: Analyses showed that situation-contingent factors—type of activity and relationship between perceived challenges and skills—predicted participants' quality of experience over and above the clinical factors taken into account in this study: level of global functioning (GAF), rehabilitation duration, and type of setting (residential vs. semiresidential). In addition, RA were prominently associated with optimal experience. Conclusion and Implications for Practice: Results suggest the importance for people involved in rehabilitation programs to engage in challenging tasks, favoring both the onset of positive and complex experiences and skill development. Findings further show the usefulness of real-time assessment methods in monitoring the rehabilitation process. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Bastawrous, A.; Armstrong, M. J. (2013):

Mobile health use in low- and high-income countries: an overview of the peer-reviewed literature.

In: *J R Soc.Med* 106 (4), S. 130–142. DOI: 10.1177/0141076812472620.

Abstract:

The evolution of mobile phone technology has introduced new possibilities to the field of medicine. Combining technological advances with medical expertise has led to the use of mobile phones in all healthcare areas including diagnostics, telemedicine, research, reference libraries and interventions. This article provides an overview of the peer-reviewed literature, published between 1 August 2006 and 1 August 2011, for the application of mobile/cell phones (from basic text-messaging systems to smartphones) in healthcare in both resource-poor and high-income countries. Smartphone use is paving the way in high-income countries, while basic text-messaging systems of standard mobile phones are proving to be of value in low- and middle-income countries. Ranging from infection outbreak reporting, anti-HIV therapy adherence to gait analysis, resuscitation training and radiological imaging, the current uses and future possibilities of mobile phone technology in healthcare are endless. Multiple mobile phone based applications are available for healthcare workers and healthcare consumers; however, the absolute majority lack an evidence base. Therefore, more rigorous research is required to ensure that healthcare is not flooded with non-evidence based applications and is maximized for patient benefit

Surveillance of physical activity in the UK is flawed: validation of the Health Survey for England Physical Activity Questionnaire.

In: *Archives of disease in childhood* 93 (12), S. 1054–1058.

Abstract:

OBJECTIVE:

Public health surveillance of physical activity in children in the UK depends on a parent-reported physical activity questionnaire which has not been validated. We aimed to validate this questionnaire against measurement of physical activity using accelerometry in 6-7-year-old children.

METHODS:

In 130 children aged 6-7 years (64 boys, 66 girls) we estimated habitual moderate-vigorous intensity physical activity (MVPA) using the Health Survey for England parent-report questionnaire for physical activity. For the same time period and the same children, we measured MVPA objectively using 7-day accelerometry with the Actigraph accelerometer.

RESULTS:

The questionnaire over-estimated MVPA significantly (paired t test, $p<0.01$). Mean error (bias) when using the questionnaire was 122 min/day (95% CI 124 to 169). Mean time spent in MVPA was 146 min/day (95% CI 124 to 169) using the questionnaire and 24 min/day (95% CI 22 to 26) using the accelerometer. Rank order correlations between MVPA measured by accelerometer and estimated by the questionnaire were not statistically significant.

CONCLUSIONS:

Public health surveillance of physical activity should not rely on this questionnaire. Levels of habitual physical activity in children are likely to be substantially lower than those reported in UK health surveys

Longitudinal study of physical activity and sedentary behavior in children.

In: *Pediatrics* 127 (1), S. e24-e30. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-14588-002&site=ehost-live;laura.basterfield@ncl.ac.uk.

Abstract:

Objective: Physical activity is thought to decline during childhood, but the extent of the decline is unknown. We made objective measures of 2-year changes in physical activity and sedentary behavior in English children who participated in the Gateshead Millennium Study to explore the nature, timing, and extent of changes in physical activity and sedentary behavior before adolescence. Methods: We conducted a longitudinal study of 405 children (207 girls), aged 7 years, in 2006/2007 and again 24 months later. Physical activity and sedentary behavior were measured with the Actigraph GT1M accelerometer. Data were analyzed in 2010. Changes in total volume of physical activity (accelerometer counts per minute [cpm]), moderate-to-vigorous–intensity physical activity (MVPA), and sedentary behavior were quantified. Factors associated with changes in physical activity and sedentary behavior were tested by using linear regression. Tracking of physical activity and sedentary behavior over the 2-year period was assessed by rank-order correlation. Results: Mean daily volume of physical activity declined by 83 cpm (interquartile range [IQR]: −189 to 31) over 2 years; the percentage of daily time spent in MVPA was low at baseline and declined

by 0.3% (IQR: −1.4 to 0.9). The percentage of daily time in sedentary behavior was high at baseline and increased from 78.0% to 81.1% of the day (change 3.1% [IQR: −0.3 to 6.0]). The decline in MVPA and increase in sedentary behavior were significantly greater in girls and in those with higher BMI z scores at baseline. Physical activity and sedentary behavior showed moderate tracking over the 2-year period. Conclusions: We report here new evidence of low and declining levels of physical activity and MVPA and increasing sedentary behavior before adolescence. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Basterfield, Laura; Pearce, Mark S.; Adamson, Ashley J.; Frary, Jessica K.; Parkinson, Kathryn N.; Wright, Charlotte M.; Reilly, John J. (2012):

Physical activity, sedentary behavior, and adiposity in English children.

In: *Am J Prev Med* 42 (5), S. 445–451. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-10681-005&site=ehost-live;john.j.reilly@strath.ac.uk.

Abstract:

Background: The importance of variation in total volume of physical activity or moderate- to vigorous-intensity physical activity (MVPA) to development of body fatness in childhood is unclear, and it is unclear if physical activity has a greater influence on adiposity in boys than girls. Purpose: To assess relationships between 2-year changes in objectively measured physical activity, sedentary behavior, and adiposity in English children. Methods: Prospective cohort study, set in Northeast England, of a socioeconomically representative sample of 403 children. Measures were change in accelerometer-determined physical activity and sedentary behavior from age 7 to 9 years (data collected 2006/2007 and 2008/2009; analyzed in 2010) and concurrent change in adiposity (fat mass index derived from bioelectric impedance) and change in BMI Z-score. Results: Decline in MVPA was associated with a greater increase in fat mass index in boys but not girls. Declining MVPA was associated with increased BMI Z-score in boys but not girls. Increased sedentary behavior was not associated with increased BMI Z-score in either gender. Conclusions: Avoiding mid–late childhood reductions in MVPA may reduce excessive fat gain, although such strategies may have greater impact on boys than girls. Bauer, S.; Moessner, M. (2012):

Technology-enhanced monitoring in psychotherapy and e-mental health.

In: *J Ment.Health* (0963-8237 (Linking)). DOI: 10.3109/09638237.2012.667886.

Abstract:

Advances in technology increasingly facilitate data collection in the context of psychosocial and psychotherapeutic care. Such technology-enhanced assessments (e.g. via Internet-based systems and mobile devices) open new perspectives for research into processes related to mental health and well-being. The use of this knowledge for the development and refinement of (online and face-to-face) therapeutic interventions promises to contribute to an optimization of care. The aim of this paper is to provide an overview on how information and communication technologies may be used (a) to improve our understanding of illness development and recovery through longitudinal technology-enhanced assessment of symptoms and behaviors (e.g. outcome monitoring and ecological momentary assessment) and (b) to optimize care for mental disorders by integrating such monitoring assessments in specific interventions (e.g. ecological momentary interventions and supportive monitoring) in face-to-face or e-mental health settings

Baumler, D.; Kirschbaum, C.; Kliegel, M.; Alexander, N.; Stalder, T. (2013):

The cortisol awakening response in toddlers and young children.

In: *Psychoneuroendocrinology* (0306-4530 (Linking)). DOI: 10.1016/j.psyneuen.2013.05.008.

Abstract:

The cortisol awakening response (CAR) is frequently assessed in psychoneuroendocrinological research on adult participants. However, knowledge on the development of the CAR during early life is scarce and characterized by inconsistent findings. We have recently shown that a positive CAR is readily observable in young infants under conditions of strict methodological control. However, it still remains unknown whether a significant CAR is maintained consistently throughout toddler- and childhood. Here, we report data from 150 toddlers and young children aged 12-87 months in whom salivary cortisol levels were assessed 0 and 30min post-awakening over three non-consecutive study days. High quality of data was ensured by the use of objective

measures to verify children's awakening times (wrist actigraphy) and sampling times (electronic monitoring containers). Results revealed the presence of a significant CAR (>1.5nmol/L) in 142 (out of 150) children and on a total of 82% of study days. A marked CAR was consistently observed throughout all examined age groups (mean increase: 8.73nmol/L). In addition, the level of cortisol on awakening was found to increase linearly with children's age (r=.17, p=.04). Overall, the current findings strongly suggest that, contrary to previous propositions, the CAR is maintained consistently throughout toddler- and childhood

Baxter, Suzanne D.; Hitchcock, David B.; Guinn, Caroline H.; Vaadi, Kate K.; Puryear, Megan P.; Royer, Julie A. et al. (2014):

A Validation Study Concerning the Effects of Interview Content, Retention Interval, and Grade on Children's Recall Accuracy for Dietary Intake and/or Physical Activity.

In: *J Acad Nutr Diet. DOI:* 10.1016/j.jand.2014.02.017.

Abstract:

BACKGROUND: Practitioners and researchers are interested in assessing children's dietary intake and physical activity together to maximize resources and minimize subject burden. OBJECTIVE: Our aim was to investigate differences in dietary and/or physical activity recall accuracy by content (diet only; physical activity only; diet and physical activity), retention interval (same-day recalls in the afternoon; previous-day recalls in the morning), and grade (third; fifth). DESIGN: Children (n=144; 66% African American, 13% white, 12% Hispanic, 9% other; 50% girls) from four schools were randomly selected for interviews about one of three contents. Each content group was equally divided by retention interval, each equally divided by grade, each equally divided by sex. Information concerning diet and physical activity at school was validated with school-provided breakfast and lunch observations, and accelerometry, respectively. Dietary accuracy measures were food-item omission and intrusion rates, and kilocalorie correspondence rate and inflation ratio. Physical activity accuracy measures were absolute and arithmetic differences for moderate to vigorous physical activity minutes. STATISTICAL ANALYSES PERFORMED: For each accuracy measure, linear models determined effects of content, retention interval, grade, and their two-way and three-way interactions; ethnicity and sex were control variables. RESULTS: Content was significant within four interactions: intrusion rate (contentxretention-intervalxgrade; P=0.0004), correspondence rate (contentxgrade; P=0.0004), inflation ratio (contentxgrade; P=0.0104), and arithmetic difference (contentxretention-intervalxgrade; P=0.0070). Retention interval was significant for correspondence rate (P=0.0004), inflation ratio (P=0.0014), and three interactions: omission rate (retention-intervalxgrade; P=0.0095), intrusion rate, and arithmetic difference (both already mentioned). Grade was significant for absolute difference (P=0.0233) and five interactions mentioned. Content effects depended on other factors. Grade effects were mixed. Dietary accuracy was better with same-day than previous-day retention interval. CONCLUSIONS: Results do not support integrating dietary intake and physical activity in children's recalls, but do support using shorter rather than longer retention intervals to yield more accurate dietary recalls. Additional validation studies need to clarify age effects and identify evidence-based practices to improve children's accuracy for recalling dietary intake and/or physical activity.

Home blood pressure self-monitoring: diagnostic performance in white-coat hypertension.

In: *Blood Press Monit* 11 (2), S. 47–52. DOI: 10.1097/01.mbp.0000200479.19046.94.

Abstract:

OBJECTIVE\r\nTo determine the diagnostic performance of home blood pressure self-monitoring in white-coat hypertension using a 3-day reading program.\r\nMATERIAL AND METHODS\r\nOne hundred and ninety nontreated patients recently diagnosed with mild-moderate hypertension, selected consecutively at four primary healthcare centers in the city of Barcelona, were included. Each patient underwent morning and night home blood pressure self-monitoring with readings in triplicate for three consecutive days, followed by 24-h ambulatory blood pressure monitoring. The normality cut-off point value for home blood pressure self-monitoring and daytime ambulatory blood pressure monitoring was 135/85 mmHg.\r\nRESULTS\r\nSixty-three patients were diagnosed with white-coat hypertension with home blood pressure self-monitoring (34.8%; 95% confidence interval: 27.9-42.2) and 74 with ambulatory blood pressure monitoring (41.6%; 95% confidence interval: 33.7-48.4). No statistically significant differences were observed between home blood pressure self-monitoring values and those of diurnal ambulatory blood pressure monitoring [137.4 (14.3)/82.1 (8.3) mmHg vs. 134.8 (11.3)/81.3 (9.5) mmHg]. Home blood pressure self-monitoring diagnostic performance parameters were sensitivity 50.0% (95% confidence interval: 38.3-61.7), specificity 75.7% (95% confidence interval: 66.3-83.2), positive and negative predictive values 58.7% (95% confidence interval: 45.6-70.8) and 68.6% (95% confidence interval: 59.4-76.7), respectively, and positive and negative probability coefficients 2.05 and 0.66, respectively. Analysis of different normality cut-off points using a receiver operating characteristic curve failed to produce significant improvement in the diagnostic performance of home blood pressure self-monitoring.\r\nCONCLUSIONS\r\nThe

diagnostic accuracy of a 3-day home blood pressure self-monitoring reading program in white-coat hypertension was poor. Ambulatory blood pressure monitoring continues to be the test of choice for this indication.

Industrial/organizational psychology. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 601–619. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-034%26site%3dehost-live.

Abstract:

(from the chapter) Industrial and organizational (I/O) psychology often is thought of as an inherently applied field. A field whose purpose is to study psychological issues within the workplace can and should make contributions to practitioners involved in the design of our work environments and the selection of the individuals who populate that environment. But psychological issues in the workplace reflect a domain broad enough to go beyond the development of practitioner tools. Work makes up a substantial portion of our adult lives, and our experiences at work often are critical to our overall well-being and sense of self. Given this central role of work in one's life, a psychology of work must also explore work experiences irrespective of their potential for practitioners. Indeed, recent calls in the I/O literature have emphasized the study of daily experiences as a primary venue through which work and our behavior at work can be understood (Beal, Weiss, Barros, & MacDermid, 2005; Weiss & Cropanzano, 1996; Weiss & Rupp, 2011). This chapter provides a review of how methods used to examine daily life are used within the discipline of I/O psychology. Various names have been used to describe these methods within I/O psychology, including ecological momentary assessment, experience sampling, ambulatory assessment, and daily diary studies. In this chapter, I refer to these methods collectively as either daily experience research or simply experiential research. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Episodic processes in emotional labor: perceptions of affective delivery and regulation strategies.

In: *J Appl Psychol* 91 (5), S. 1053.

Abstract:

This study examined emotional labor processes from a within-person, episodic framework. The authors hypothesized that the influence of negative emotions on affective delivery would be lessened by regulation strategies for supervisor perceptions but not self-perceptions. In addition, difficulty maintaining display rules was hypothesized to mediate the relation between negative emotions and self-perceptions of affective delivery. Finally, the influence of surface acting strategies on these processes as well as correlations with individual differences was investigated. Hypotheses were tested using ecological momentary assessment of a sample of cheerleading instructors. Results suggest that surface actors can regulate emotions effectively on an episode-to-episode basis but find the episode more difficult. In addition, surface actors exhibit more general tendencies to devalue themselves and experience fewer positive emotions.

Music to the inner ears: Exploring individual differences in musical imagery.

In: *Conscious.Cogn* 22 (4), S. 1163–1173. DOI: 10.1016/j.concog.2013.07.006.

Abstract:

In two studies, we explored the frequency and phenomenology of musical imagery. Study 1 used retrospective reports of musical imagery to assess the contribution of individual differences to imagery characteristics. Study 2 used an experience sampling design to assess the phenomenology of musical imagery over the course of one week in a sample of musicians and non-musicians. Both studies found episodes of musical imagery to be common and positive: people rarely wanted such experiences to end and often heard music that was personally meaningful. Several variables predicted musical imagery, including personality, musical preferences, and positive mood. Musicians tended to hear musical imagery more often, but they reported less frequent episodes of deliberately-generated imagery. Taken together, the present research provides new insights

into individual differences in musical imagery, and it supports the emerging view that such experiences are common, positive, and more voluntary than previously recognized

Blood pressure abnormalities in children with sickle cell anemia.

In: *Pediatr Blood Cancer* 61 (3), S. 518–522. DOI: 10.1002/pbc.24843.

Abstract:

BACKGROUND: Kidney disease is an important cause of morbidity and mortality in patients with sickle cell anemia (SCA). The factors that affect progression of renal disease are unknown, especially in children and adolescents. Alterations in blood pressure, including hypertension and lack of the normal nocturnal dip in blood pressure, are important determinants of diabetic nephropathy and other renal diseases and may play a role in sickle cell nephropathy. Our primary hypothesis was that children with SCA who have microalbuminuria will demonstrate less nocturnal dipping of blood pressure compared to patients without microalbuminuria. We also investigated other potential factors associated with microalbuminuria. PROCEDURE: This prospective study of 52 adolescents with SCA followed in the Children's Medical Center Dallas Comprehensive Sickle Cell Center characterized 24-hour ambulatory blood pressure profiles and presence of microalbuminuria. Stepwise logistic regression was performed to identify significant independent factors that are associated with microalbuminuria. RESULTS: Thirty-five percent of patients were identified as having previously unrecognized hypertension, and 17% had pre-hypertension (blood pressure greater than the 90th percentile but less than the 95th percentile). Fifty-six percent of patients lacked the normal nocturnal dip in blood pressure. In addition, 21% had microalbuminuria, and their percent nocturnal dip was significantly less than those without microalbuminuria (P = 0.01). CONCLUSIONS: Blood pressure abnormalities are common in adolescents with SCA and are a possible modifiable risk factor in the progression of sickle cell nephropathy.

User profiles of a smartphone application to support drug adherence--experiences from the iNephro project.

In: *PLoS.One.* 8 (10), S. e78547. DOI: 10.1371/journal.pone.0078547.

Abstract:

PURPOSE: One of the key problems in the drug therapy of patients with chronic conditions is drug adherence. In 2010 the initiative iNephro was launched (www.inephro.de). A software to support regular and correct drug intake was developed for a smartphone platform (iOS). The study investigated whether and how smartphone users deployed such an application. METHODS: Together with cooperating partners the mobile application "Medikamentenplan" ("Medication Plan") was developed. Users are able to keep and alter a list of their regular medication. A memory function supports regular intake. The application can be downloaded free of charge from the App Store by Apple. After individual consent of users from December 2010 to April 2012 2042338 actions were recorded and analysed from the downloaded applications. Demographic data were collected from 2279 users with a questionnaire. RESULTS: Overall the application was used by 11688 smartphone users. 29% (3406/11688) used it at least once a week for at least four weeks. 27% (3209/11688) used the application for at least 84 days. 68% (1554/2279) of users surveyed were male, the stated age of all users was between 6-87 years (mean 44). 74% of individuals (1697) declared to be suffering from cardiovascular disease, 13% (292) had a previous history of transplantation, 9% (205) were suffering from cancer, 7% (168) reported an impaired renal function and 7% (161) suffered from diabetes mellitus. 69% (1568) of users were on <6 different medications, 9% (201) on 6 - 10 and 1% (26) on more than 10. CONCLUSION: A new smartphone application, which supports drug adherence, was used regularly by chronically ill users with a wide range of diseases over a longer period of time. The majority of users so far were middle-aged and male

Becker, Janine; Schwartz, Carolyn; Saris-Baglama, Renee N.; Kosinski, Mark; Bjorner, Jakob Bue (2007):

Using Item Response Theory (IRT) for Developing and Evaluating the Pain Impact Questionnaire (PIQ-6™).

In: *Pain Medicine* 8 (s3), S. S129-S144.

Abstract:

Objectives. To describe the development and evaluation of the Pain Impact Questionnaire (PIQ-6TM), a six-item measure of pain severity and impact on health-related quality of life (HRQOL) domains.

Participants. Two general US population samples (N = 829 and N = 7,025) and one chronic pain patient sample (N = 350) were included.

Methods. The PIQ-6TM was developed using conventional and item response theory (IRT) methods in four steps: 1) initial selection and development of items based on results from a previously developed Bodily Pain item bank; 2) final item selection based on new data and investigations of unidimensionality, differential item functioning (DIF), and IRT modeling; 3) development of scoring algorithms, population norms, and cross-calibrations; and 4) psychometric evaluation.

Results. Six items on pain intensity and impact satisfied requirements of unidimensionality and lack of DIF and could be scored using IRT methods. The PIQ-6 showed good internal consistency reliability (coefficient alpha = 0.94) and good construct validity. Convergent validity was supported by strong correlations with pain severity scales (visual analog and numerical rating scales; r = 0.81–0.84); discriminant validity was suggested by correlations with the SF-8™ Health Survey Physical and Mental Component Summary measures (r = −0.77; r = −0.32, respectively), significant mean score differences between chronic pain patients and the general population, and between patients differing in self-reported medical conditions (P < 0.001).

Conclusion. The PIQ-6 is a brief, precise questionnaire available in a paper-and-pencil version and a computerized version that includes scoring and feedback software. It may facilitate large-scale, inexpensive, precise, and norm-based pain assessment and monitoring in a wide variety of settings (e.g., homes, clinics, offices).

Beckham, J. C.; Calhoun, P. S.; Dennis, M. F.; Wilson, S. M.; Dedert, E. A. (2012):

Predictors of Lapse in First Week of Smoking Abstinence in PTSD and Non-PTSD Smokers.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/nts252.

Abstract:

INTRODUCTION: Retrospective research suggests smokers with posttraumatic stress disorder (PTSD) lapse more quickly after their quit date. Ecological momentary assessment (EMA) research is needed to confirm the presence of early smoking lapse in PTSD and form conceptualizations that inform intervention. METHODS: Smokers with (n = 55) and without (n = 52) PTSD completed alarm-prompted EMA of situational and psychiatric variables the week before and after a quit date, and self-initiated EMA following smoking lapses. Blood samples at baseline and on the quit date allowed assessment of dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEA(S)). RESULTS: PTSD was related to shorter time to lapse (hazard ratio [HR] = 1.677, 95% CI: 1.106-2.544). Increased smoking abstinence self-efficacy was related to longer time to lapse (HR = 0.608, 95% CI: 0.430-0.860). Analyses of participants' real-time reports revealed that smokers with PTSD were more likely to attribute first-time lapses to negative affect (= 5.412, p = .020), and trauma reminders (Fisher's exact p = .003**). Finally, the quit date decrease in DHEA(S) was related to shorter time to lapse (HR = 1.009, 95% CI: 1.000-1.018, p < .05). CONCLUSIONS: Results provide evidence of shorter time to first smoking lapse in PTSD, and add to evidence that early lapse occasions are more strongly related to trauma reminders, negative affect, and cravings in smokers with PTSD

Beckham, Jean C.; Flood, Amanda M.; Dennis, Michelle F.; Calhoun, Patrick S. (2009):

Ambulatory cardiovascular activity and hostility ratings in women with chronic posttraumatic stress disorder.

In: *Biological Psychiatry* 65 (3), S. 268–272.

Abstract:

The objective of the current study is to evaluate the relationship between hostility and ambulatory cardiovascular activity in women with and without posttraumatic stress disorder (PTSD).

Methods

One hundred and one women completed 24 hours of ambulatory monitoring and standardized diagnostic and hostility measures. Generalized estimating equations analysis was used to examine the effects of group and hostility factor scores (hostile beliefs, overt hostility, and covert hostility) on ambulatory heart rate (AHR) and ambulatory systolic (ASBP) and diastolic (ADBP) blood pressure.

Results

After controlling for covariates, there was an interaction between PTSD and both hostile beliefs and overt hostility for AHR. Increases in hostility were associated with greater increases in heart rate among women with PTSD relative to those without PTSD. There was a similar interaction between hostile beliefs and group for ADBP.

Conclusions

Increased AHR and blood pressure have been linked to poor cardiovascular outcomes in nonpsychiatric populations. Individuals with PTSD display increased hostility, a construct that has also been linked to poorer cardiovascular outcomes. Increases in hostile beliefs were associated with a greater increase in ADBP among women with PTSD as compared with control subjects. These data suggest that PTSD might in part moderate the relationship between hostility and cardiovascular outcomes.

Beckmann, Nadin; Wood, Robert E.; Minbashian, Amirali (2010):

It depends how you look at it: On the relationship between neuroticism and conscientiousness at the within-and the between-person levels of analysis.

In: *Journal of Research in Personality* 44 (5), S. 593–601.

Abstract:

Research on personality structure has primarily focused on patterns of covariation between traits, and less emphasis has been put on the organization of relationships between thoughts, feelings and behaviors as they occur within individuals. Over several weeks 115 managers from large Australian companies were assessed multiple times a day employing experience-sampling methodology. Within- and between-person variation in personality responses was analyzed using hierarchical linear modeling and correlation analyses. Findings indicate that analyzing personality as a within-person phenomenon reveals information not well captured by the trait approach. While conscientiousness and neuroticism were negatively correlated at the between-person level, this relationship was reversed at the within-person level. Results are discussed in terms of the distinctness of the within- and between-person structure of personality.

Negative eating and body attitudes are associated with increased daytime ambulatory blood pressure in healthy young women.

In: *International Journal of Psychophysiology* 79 (2), S. 147–154.

Abstract:

BACKGROUND AND OBJECTIVE:

Various psychosocial stressors have been associated with increased ambulatory blood pressure (ABP) and cortisol in middle-aged women. Given that many young women report negative eating/body attitudes, we examined whether these attitudes were associated with cortisol and ABP in a cross-sectional study.

METHODS:

120 non-obese, healthy women aged 19-35 completed questionnaires, measurement of 24-h urinary free cortisol (UFC), and 12-h daytime ABP. Main and interactive effects of eating/body attitudes (average Z-score of Eating/body attitude questionnaires split at zero) and current weight loss effort (yes/no) were examined by General Linear Modeling adjusted for covariates.

RESULTS:

Women with negative eating/body attitudes were more likely to report current weight loss attempts (63% versus 21%, $p<0.001$). Eating/body attitudes or weight loss effort did not have main or interactive effects on age, physical activity level, energy intakes, general stress (average Z-score of psychosocial stress questionnaires) or UFC. Body mass index was higher among those currently trying to lose weight but did not differ by eating/body attitudes. Significant main effects of eating/body attitudes were detected on ABP: diastolic ABP (73.2 ± 0.7 versus 70.3 ± 0.8mm Hg, $p=0.011$) and mean arterial pressure (87.3 ± 0.7 versus 84.9 ± 0.8mm Hg, $p=0.032$) were higher among women with negative versus neutral/positive eating/body attitudes. There were no weight loss effort main effects for ABP, or weight loss effort-by-Eating/body attitude interactions.

CONCLUSION:

This exploratory study suggests that more negative eating/body-related attitudes may be modestly associated with higher ABP

Bedford, Jennifer L.; Linden, Wolfgang; Barr, Susan I. (2011):

Negative eating and body attitudes are associated with increased daytime ambulatory blood pressure in healthy young women.

In: *International journal of psychophysiology : official journal of the International Organization of Psychophysiology* 79 (2), S. 147–154. DOI: 10.1016/j.ijpsycho.2010.09.013.

Abstract:

BACKGROUND AND OBJECTIVE\r\nVarious psychosocial stressors have been associated with increased ambulatory blood pressure (ABP) and cortisol in middle-aged women. Given that many young women report negative eating/body attitudes, we examined whether these attitudes were associated with cortisol and ABP in a cross-sectional study.\r\nMETHODS\r\n120 non-obese, healthy women aged 19-35 completed questionnaires, measurement of 24-h urinary free cortisol (UFC), and 12-h daytime ABP. Main and interactive effects of eating/body attitudes (average Z-score of Eating/body attitude questionnaires split at zero) and current weight loss effort (yes/no) were examined by General Linear Modeling adjusted for covariates.\r\nRESULTS\r\nWomen with negative eating/body attitudes were more likely to report current weight loss attempts (63% versus 21%, p<0.001). Eating/body attitudes or weight loss effort did not have main or interactive effects on age, physical activity level, energy intakes, general stress (average Z-score of psychosocial stress questionnaires) or UFC. Body mass index was higher among those currently trying to lose weight but did not differ by eating/body attitudes. Significant main effects of eating/body attitudes were detected on ABP: diastolic ABP (73.2 ± 0.7 versus 70.3 ± 0.8mm Hg, p=0.011) and mean arterial pressure (87.3 ± 0.7 versus 84.9 ± 0.8mm Hg, p=0.032) were higher among women with negative versus neutral/positive eating/body attitudes. There were no weight loss effort main effects for ABP, or weight loss effort-by-Eating/body attitude interactions.\r\nCONCLUSION\r\nThis exploratory study suggests that more negative eating/body-related attitudes may be modestly associated with higher ABP independent of weight loss effort.

Beets, Michael W.; Beighle, Aaron; Bottai, Matteo; Rooney, Laura; Tilley, Fallon (2012):

Pedometer-determined step-count guidelines for afterschool programs.

In: *J Phys Act Health* 9 (1), S. 71–77. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00272-009&site=ehost-live.

Abstract:

Background: Policies to require afterschool programs (ASPs, 3 PM to 6 PM) to provide children a minimum of 30 minutes of moderate-to-vigorous physical activity (MVPA) exist. With few low-cost, easy-to-use measures of MVPA available to the general public, ASP providers are limited in their ability to track progress toward achieving this policy-goal. Pedometers may fill this gap, yet there are no step-count guidelines for ASPs linked to 30 minutes of MVPA. Methods: Steps and accelerometer estimates of MVPA were collected concurrently over multiple days on 245 children (8.2 years, 48% boys, BMI-percentile 68.2) attending 3 community-based ASPs. Random intercept logit models and receiver operating characteristic (ROC) analyses were used to identify a threshold of steps that corresponded with attaining 30 minutes of MVPA. Results: Children accumulated an average of 2876 steps (standard error [SE] 79) and 16.1 minutes (SE0.5) of MVPA over 111 minutes (SE1.3) during the ASP. A threshold of 4600 steps provided high specificity (0.967) and adequate sensitivity (0.646) for discriminating children who achieved the 30 minutes of MVPA; 93% of the children were correctly classified. The total area under the curve was 0.919. Children accumulating 4600 steps were 25 times more likely to accumulate 30 minutes of MVPA. Conclusions: This step threshold will provide ASP leaders with an objective, low-cost, easy-to-use tool to monitor progress toward policy-related goals. Beets, Michael W.; Bornstein, Daniel; Dowda, Marsha; Pate, Russell R. (2011):

Compliance with national guidelines for physical activity in U.S. preschoolers: measurement and interpretation.

In: *Pediatrics* 127 (4), S. 658–664. DOI: 10.1542/peds.2010-2021.

Abstract:

OBJECTIVE\r\nThe National Association for Sport and Physical Education (NASPE) guidelines for preschoolers recommend 120 minutes of physical activity daily. Two issues, however, create a situation whereby substantial variation in estimated prevalence rates of (in)active preschoolers are reported. First, NASPE guidelines have been interpreted in multiple ways. Second, objective monitoring via accelerometry is the most widely accepted measure of preschoolers' physical activity, yet multiple cut points provide vastly different estimates of physical activity. This study aimed to estimate the prevalence of preschoolers meeting NASPE guidelines and illustrate the differences among rates, given guideline interpretations, and cut points.\r\nPATIENTS AND

METHODS\r\nThree- to 5-year-old children (n = 397) wore ActiGraph accelerometers for an average of 5.9 days. NASPE guidelines were expressed in 3 ways: 120 minutes daily of light-to-vigorous physical activity; 120 minutes daily of moderate-to-vigorous physical activity; and 60 minutes daily of moderate-to-vigorous physical activity. Estimates of 120 minutes daily of light-to-vigorous physical activity, 120 minutes daily of moderate-to-vigorous physical activity, and 60 minutes daily of moderate-to-vigorous physical activity were calculated on the basis of 4 common accelerometer cut points for preschoolers: Pate, Reilly and Puyau, Sirard, and Freedson.\r\nRESULTS\r\nPrevalence rates varied considerably, with estimates ranging from 13.5% to 99.5%, 0.0% to 95.7%, and 0.5% to 99.5% for 120 minutes daily of light-to-vigorous physical activity, 120 minutes daily of moderate-to-vigorous physical activity, and 60 minutes daily of moderate-to-vigorous physical activity, respectively.\r\nCONCLUSIONS\r\nThe variation in NASPE guidelines, coupled with different accelerometer cut points, results in disparate estimates of (in)active preschoolers. This limits the ability to estimate population prevalence levels of physical activity that can be used to guide public health policy. Development of new guidelines should focus on an explicit delineation of physical activity and attempt to standardize the measurement of preschoolers' physical activity.

Beets, Michael W.; Weaver, Robert G.; Moore, Justin B.; Turner-McGrievy, Gabriel; Pate, Russell R.; Webster, Collin; Beighle, Aaron (2014):

From policy to practice: strategies to meet physical activity standards in YMCA afterschool programs.

In: *Am J Prev Med* 46 (3), S. 281–288. DOI: 10.1016/j.amepre.2013.10.012.

Abstract:

BACKGROUND: In 2011, the U.S. Young Men's Christian Association (YMCA) adopted activity standards recommending that afterschool programs (ASPs) ensure all children engage in a minimum of 30 minutes of moderate to vigorous physical activity (MVPA) daily during the ASP. ASPs decide how to accomplish this standard, for which few effective strategies exist. PURPOSE: To evaluate strategies designed to help ASPs meet the MVPA standard. DESIGN: Single group intervention with pretest and three follow-up measures repeated-cross-sectional design with a subsample cohort. SETTING/PARTICIPANTS: Four large-scale YMCA ASPs, serving approximately 500 children each day. INTERVENTION: Community-based participatory development of strategies focused on modification of program schedules, professional development training, and weekly checklists to evaluate activity opportunities. MAIN OUTCOME MEASURES: Accelerometry-derived MVPA classified as meet or fail-to-meet the 30 minutes' MVPA/day standard collected over a minimum of 4 nonconsecutive days at baseline (fall 2011) and three follow-up assessments (spring 2012, fall 2012, spring 2013). Random intercept logistic regression models evaluated the probability of meeting the standard for boys and girls, separately (analyzed summer 2013). RESULTS: A total of 895 children (aged 5-12 years, 48.4% girls) representing 3654 daily measures were collected across the four assessments. The percentage of girls and boys meeting the MVPA standard at baseline was 13.3% and 28.0%, respectively. By spring 2013, this increased to 29.3% and 49.6%. These changes represented an increase in the odds of meeting the 30 minutes' MVPA/day standard by 1.5 (95% CI=1.1, 2.0) and 2.4 (95% CI=1.2, 4.8) for girls and boys, respectively. CONCLUSIONS: The strategies developed herein represent an effective approach to enhancing current practice within YMCA ASPs to achieve existing MVPA standards. Additional work is necessary to evaluate the scalability of the strategies in a larger sample of ASPs.

Behar, J.; Roebuck, A.; Domingos, J. S.; Gederi, E.; Clifford, G. D. (2013):

A review of current sleep screening applications for smartphones.

In: *Physiol Meas* 34 (7), S. R29-R46. DOI: 10.1088/0967-3334/34/7/R29.

Abstract:

Sleep disorders are a common problem and contribute to a wide range of healthcare issues. The societal and financial costs of sleep disorders are enormous. Sleep-related disorders are often diagnosed with an overnight sleep test called a polysomnogram, or sleep study involving the measurement of brain activity through the electroencephalogram. Other parameters monitored include oxygen saturation, respiratory effort, cardiac activity (through the electrocardiogram), as well as video recording, sound and movement activity. Monitoring can be costly and removes the patients from their normal sleeping environment, preventing repeated unbiased studies. The recent increase in adoption of smartphones, with high quality on-board sensors has led to the proliferation of many sleep screening applications running on the phone. However, with the exception of simple questionnaires, no existing sleep-related application available for smartphones is based on scientific evidence. This paper reviews the existing smartphone applications landscape used in the field of sleep disorders and proposes possible advances to improve screening approaches

Behrens, Timothy K.; Dinger, Mary K. (2011):

Comparisons of accelerometer and pedometer determined steps in free living samples.

In: *J Phys Act Health* 8 (3), S. 390.

Abstract:

BACKGROUND:

The purpose of this study was to compare steps·d-1 between an accelerometer and pedometer in 2 free-living samples.

METHODS:

Data from 2 separate studies were used for this secondary analysis (Sample 1: N = 99, Male: n = 28, 20.9 ± 1.4 yrs, BMI = 27.2 ± 5.0 kg·m-2, Female: n = 71, 20.9 ± 1.7 yrs, BMI = 22.7 ± 3.0 kg·m-2; Sample 2: N = 74, Male: n = 27, 38.0 ± 9.5 yrs, BMI = 25.7 ± 4.5 kg·m-2, Female: n = 47, 38.7 ± 10.1 yrs, BMI = 24.6 ± 4.0 kg·m-2). Both studies used identical procedures and analytical strategies.

RESULTS:

The mean difference in steps·d-1 for the week was 1643.4 steps·d-1 in Study 1 and 2199.4 steps·d-1 in Study 2. There were strong correlations between accelerometer- and pedometer-determined steps·d-1 in Study 1 (r = .85, P < .01) and Study 2 (r = 0.87, P < .01). Bland-Altman plots indicated agreement without bias between steps recorded from the devices in Study 1 (r = -0.14, P < .17) and Study 2 (r = -0.09, P < .40). Correlations examining the difference between accelerometer-pedometer steps·d-1 and MVPA resulted in small, inverse correlations (range: r = -0.03 to -0.28).

CONCLUSIONS:

These results indicate agreement between accelerometer- and pedometer-determined steps·d-1; however, measurement bias may still exist because of known sensitivity thresholds between devices.

Bekman, N. M.; Winward, J. L.; Lau, L. L.; Wagner, C. C.; Brown, S. A. (2013):

The Impact of Adolescent Binge Drinking and Sustained Abstinence on Affective State.

In: *Alcohol Clin.Exp.Res* (0145-6008 (Linking)). DOI: 10.1111/acer.12096.

Abstract:

BACKGROUND: While it is clear that affect is negatively impacted by heavy drinking in adulthood and that it improves with abstinence, little is known about effects of heavy drinking on mood during adolescence. METHODS: This study examined negative mood states among 2 groups of 16- to 18-year-old high school students; youth with a history of recent heavy episodic drinking (HED; n = 39) and comparison youth with limited lifetime drinking experience (CON; n = 26). Affect was assessed at 3 time points during a 4- to 6-week period of monitored abstinence using the Hamilton Rating Scales for Anxiety and Depression; self-reports were obtained with the state portion of the State-Trait Anxiety Inventory, and experience sampling of current affect was assessed via daily text messages sent at randomly determined times in the morning, afternoon, and evening. RESULTS: Youth with a recent history of HED reported more negative affect compared with nondrinking youth during early stages of abstinence (days since last HED at assessment 1: M = 6.46; SD = 5.06); however, differences in affect were not observed after 4 to 6 weeks of abstinence. Sex differences were evident, with HED girls reporting greater depression and anxiety than HED male peers. Although not significant, response patterns indicated that boys may experience faster resolution of negative emotional states than girls with sustained abstinence. CONCLUSIONS: Findings suggest that high-dose drinking is associated with elevated negative affect for adolescents and that negative mood states may take longer to resolve for girls than for boys following heavy drinking episodes. Future research clarifying naturally occurring changes in affective response during early and sustained abstinence is necessary for improving programs designed to promote adolescent decision-making and to reduce risk for relapse

Bel-Serrat, S.; Mouratidou, T.; Huybrechts, I.; Cuenca-Garcia, M.; Manios, Y.; Gomez-Martinez, S. et al. (2014):

The role of dietary fat on the association between dietary amino acids and serum lipid profile in European adolescents participating in the HELENA Study.

In: *Eur J Clin Nutr* 68 (4), S. 464–473. DOI: 10.1038/ejcn.2013.284.

Abstract:

Background/objectives:The objective of this study was to examine the relationship between amino acid (AA) intake and serum lipid profile in European adolescents from eight European cities participating in the cross-sectional (2006-2007) HELENA (Healthy Lifestyle in Europe by Nutrition in Adolescence) study, and to assess whether this association was independent of total

fat intake.Subjects/methods:Diet, skinfold thickness, triglycerides (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), TC/HDL-c ratio, low-density lipoprotein cholesterol (LDL-c), apolipoprotein B (Apo B), apolipoprotein A1 (Apo A1) and Apo B/Apo A1 ratio were measured in 454 12.5- to 17.5-year-old adolescents (44% boys). Intake was assessed via two non-consecutive 24-h dietary recalls. Data on maternal education and sedentary behaviors were obtained via questionnaires. Physical activity was objectively measured by accelerometry.Results:Alanine, arginine, asparaginic acid, glycine, histidine, lysine and serine intakes were inversely associated with serum TG concentrations in both boys and girls. Intake of other AA like alanine and/or arginine was also inversely associated with serum TC, LDL-c and Apo B/Apo A1 ratio only in girls. An inverse association was observed between intakes of alanine, isoleucine, leucine, methionine, serine, tryptophan, tyrosine and valine and TC/HDL-c ratio among female adolescents. Similar results were found in males for serine and tryptophan intakes. It is noteworthy, however, that associations were no longer significant in both genders when total fat intake was considered as a confounding factor.Conclusions:In this sample of adolescents, the association between AA intakes and serum lipid profile did not persist when dietary fat was considered. Therefore, dietary interventions and health promotion activities should focus on fat intake to improve lipid profile and potentially prevent cardiovascular disease.

Youth-Physical Activity Towards Health: evidence and background to the development of the Y-PATH physical activity intervention for adolescents.

In: *BMC Public Health* 14, S. 122. DOI: 10.1186/1471-2458-14-122.

Abstract:

BACKGROUND: Despite known benefits of regular physical activity for health and well-being, many studies suggest that levels of physical activity in young people are low, and decline dramatically during adolescence. The purpose of the current research was to gather data on adolescent youth in order to inform the development of a targeted physical activity intervention. METHODS: Cross-sectional data on physical activity levels (using self report and accelerometry), psychological correlates of physical activity, anthropometic characteristics, and the fundamental movement skill proficiency of 256 youth (53% male, 12.40 +/- 0.51 years) were collected. A subsample (n = 59) participated in focus group interviews to explore their perceptions of health and identify barriers and motivators to participation in physical activity. RESULTS: Findings indicate that the majority of youth (67%) were not accumulating the minimum 60 minutes of physical activity recommended daily for health, and that 99.5% did not achieve the fundamental movement skill proficiency expected for their age. Body mass index data showed that 25% of youth were classified as overweight or obese. Self-efficacy and physical activity attitude scores were significantly different ($p < 0.05$) between low, moderate and high active participants. Active and inactive youth reported differences in their perceived understanding of health and their barriers to physical activity participation, with active youth relating nutrition, exercise, energy and sports with the definition of 'being healthy', and inactive youth attributing primarily nutritional concepts to 'being healthy'. CONCLUSIONS: Data show a need for targeting low levels of physical activity in youth through addressing poor health related activity knowledge and low fundamental movement skill proficiency. The Y-PATH intervention was developed in accordance with the present study findings; details of the intervention format are presented.

Bender, J. L.; Yue, R. Y.; To, M. J.; Deacken, L.; Jadad, A. R. (2013):

A Lot of Action, But Not in the Right Direction: Systematic Review and Content Analysis of Smartphone Applications for the Prevention, Detection, and Management of Cancer.

In: *J.Med.Internet.Res.* 15 (12), S. e287. DOI: 10.2196/jmir.2661.

Abstract:

BACKGROUND: Mobile phones have become nearly ubiquitous, offering a promising means to deliver health interventions. However, little is known about smartphone applications (apps) for cancer. OBJECTIVE: The purpose of this study was to characterize the purpose and content of cancer-focused smartphone apps available for use by the general public and the evidence on their utility or effectiveness. METHODS: We conducted a systematic review of the official application stores for the four major smartphone platforms: iPhone, Android, Nokia, and BlackBerry. Apps were included in the review if they were focused on cancer and available for use by the general public. This was complemented by a systematic review of literature from MEDLINE, Embase, and the Cochrane Library to identify evaluations of cancer-related smartphone apps. RESULTS: A total of 295 apps from the smartphone app stores met the inclusion criteria. The majority of apps targeted breast cancer (46.8%, 138/295) or cancer in general (28.5%, 84/295). The reported app purpose was predominantly to raise awareness about cancer (32.2%, 95/295) or to provide educational information about cancer (26.4%, 78/295), followed by apps to support fundraising efforts (12.9%, 38/295), assist in early detection (11.5%, 34/295), promote a charitable organization (10.2%, 30/295), support disease management (3.7%, 11/295), cancer prevention (2.0%, 6/295), or social support (1.0%, 3/295). The majority of the apps did not describe their organizational affiliation (64.1%, 189/295). Apps affiliated with non-profit organizations were more likely to be free

of cost (chi2 1=16.3, P<.001) and have a fundraising or awareness purpose (chi2 2=13.3, P=.001). The review of the health literature yielded 594 articles, none of which reported an evaluation of a cancer-focused smartphone application. CONCLUSIONS: There are hundreds of cancer-focused apps with the potential to enhance efforts to promote behavior change, to monitor a host of symptoms and physiological indicators of disease, and to provide real-time supportive interventions, conveniently and at low cost. However, there is a lack of evidence on their utility, effectiveness, and safety. Future efforts should focus on improving and consolidating the evidence base into a whitelist for public consumption

Bennett, Gary G.; Wolin, Kathleen Y.; Puleo, Elaine; Emmons, Karen M. (2006):

Pedometer-determined physical activity among multiethnic low-income housing residents.

In: *Med Sci Sports Exerc* 38 (4), S. 768–773. DOI: 10.1249/01.mss.0000210200.87328.3f.

Abstract:

PURPOSE\r\nWe sought to characterize pedometer-determined physical activity among a predominantly racial and ethnic minority sample of adults residing in low-income housing.\r\nMETHODS\r\nData were collected from 433 participants at baseline in a randomized colon cancer prevention intervention trial conducted within low-income housing communities. Using random effects models to control for clustering within housing sites, we examined variation in daily steps by several sociodemographic characteristics.\r\nRESULTS\r\nParticipants recorded a mean of 5326 (+/- 3871 SD) daily steps over a 5-d sampling period. Significantly lower levels of pedometer-determined physical activity were found among older-aged participants (P < 0.0001), women (P = 0.02), those who were overweight and obese (P = 0.03), those reporting no weekly exercise (P = 0.04), as well as among nonworking individuals (P < 0.0001). No significant differences were found by education or income. In multivariable analyses, age, gender, body mass index, and employment status remained significantly associated with steps.\r\nCONCLUSIONS\r\nThese findings suggest a high prevalence of physical inactivity among low-income housing residents. These data, derived from a well-characterized sample, provide useful estimates for the investigation of pedometers as measures of total accumulated physical activity among lower-income, racial and ethnic minority populations.

Bentall, Richard P.; Myin-Germeys, Inez; Smith, Angela; Knowles, Rebecca; Jones, Steven H.; Smith, Talya; Tai, Sara J. (2011):

Hypomanic personality, stability of self-esteem and response styles to negative mood.

In: *Clinical Psychology & Psychotherapy* 18 (5), S. 397–410. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-23689-006&site=ehost-live;Richard.Bentall@liverpool.ac.uk.

Abstract:

Objectives: This paper aims to study dysfunctional self-schematic processes, abnormal coping styles, over-responsiveness to reward stimuli (indicative of an over-sensitive behavioural activation system) and stability of self-esteem in relation to subclinical hypomania. Design: Three cross-sectional studies were conducted on selected students on the basis of their scores on the Hypomanic Personality Scale (HPS) (study 1) and on elevated HPS and Dysfunctional Attitude Scale scores (studies 2 and 3). Methods: In studies 1 and 2, participants completed questionnaires and kept a self-esteem diary for 6 days. In study 3, the experience sampling method was used to assess momentary self-esteem, emotion and use of different coping styles over a 6-day period. Results: Study 1 demonstrated that hypomanic traits are associated with high fluctuations in self-esteem. In study 2, high scores on both the HPS and the Dysfunctional Attitude Scale, but not the HPS alone, were associated with bipolar spectrum symptoms. These participants showed more evidence of alcohol and substance abuse, greater self-esteem fluctuation and dysfunctional coping styles (rumination and risk-taking) compared with controls. Changes in self-esteem were related to the use of these strategies. Conclusions: Vulnerability to bipolar disorder is associated with a combination of depression-related and reward-related processes. Bento, T.; Cortinhas, A.; Leitao, J. C.; Mota, M. P. (2012):

Use of accelerometry to measure physical activity in adults and the elderly.

In: *Rev.Saude Publica* (0034-8910 (Linking)). Online verfügbar unter PM:22450563.

Abstract:

OBJECTIVE: To review the use of accelerometry as an objective measure of physical activity in adults and elderly people. METHODS: A systematic review of studies on the use of accelerometty as an objective measure to assess physical activity in

adults were examined in PubMed Central, Web of Knowledge, EBSCO and Medline databases from March 29 to April 15, 2010. The following keywords were used: "accelerometry," "accelerometer," "physical activity," "PA," "patterns," "levels," "adults," "older adults," and "elderly," either alone or in combination using "AND" or "OR." The reference lists of the articles retrieved were examined to capture any other potentially relevant article. Of 899 studies initially identified, only 18 were fully reviewed, and their outcome measures abstracted and analyzed. RESULTS: Eleven studies were conducted in North America (United States), five in Europe, one in Africa (Cameroon) and one in Australia. Very few enrolled older people, and only one study reported the season or time of year when data was collected. The articles selected had different methods, analyses, and results, which prevented comparison between studies. CONCLUSIONS: There is a need to standardize study methods for data reporting to allow comparisons of results across studies and monitor changes in populations. These data can help design more adequate strategies for monitoring and promotion of physical activity

Ben-Zeev, Dror (2012):

Mobile technologies in the study, assessment, and treatment of schizophrenia.

In: *Schizophrenia Bulletin* 38 (3), S. 384–385. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-15724-006&site=ehost-live;dror.ben-zeev@dartmouth.edu.

Abstract:

The purpose of this special issue is to cultivate discussion about new opportunities for leveraging existing and emerging mobile technologies in the study of psychotic illnesses and to encourage investigators to think creatively about how these novel approaches can improve our understanding of the etiological risk factors, contextual influences, and possible treatments for schizophrenia. As mobile devices infiltrate more and more areas of life of the general population, they will undoubtedly become more prevalent among those with schizophrenia as well. Statistically, many of those who are currently growing up with these technologies in hand will go on to develop serious mental illnesses in the future. Looking forward, now is the opportune time for innovative investigators and clinicians to examine how these emerging technologies can be harnessed as a powerful new platform for research and treatment approaches that can be made available in the years ahead. Feasibility, Acceptability, and Preliminary Efficacy of a Smartphone Intervention for Schizophrenia.

In: *Schizophr Bull. DOI:* 10.1093/schbul/sbu033.

Abstract:

The FOCUS smartphone intervention was developed to provide automated real-time/real-place illness management support to individuals with schizophrenia. The system was specifically designed to be usable by people with psychotic disorders who may have cognitive impairment, psychotic symptoms, negative symptoms, and/or low reading levels. FOCUS offers users both prescheduled and on-demand resources to facilitate symptom management, mood regulation, medication adherence, social functioning, and improved sleep. In this study, 33 individuals with schizophrenia or schizoaffective disorder used FOCUS over a 1-month period in their own environments. Participants were able to learn how to use the intervention independently, and all but one participant completed the trial successfully and returned the smartphones intact. Completers used the system on 86.5% of days they had the device, an average of 5.2 times a day. Approximately 62% of use of the FOCUS intervention was initiated by the participants, and 38% of use was in response to automated prompts. Baseline levels of cognitive functioning, negative symptoms, persecutory ideation, and reading level were not related to participants' use of the intervention. Approximately 90% of participants rated the intervention as highly acceptable and usable. Paired samples t tests found significant reductions in psychotic symptoms, depression, and general psychopathology, after 1 month of FOCUS use. This study demonstrated the feasibility, acceptability, and preliminary efficacy of the FOCUS intervention for schizophrenia and introduces a new treatment model which has promise for extending the reach of evidence-based care beyond the confines of a physical clinic using widely available technologies.

Ben-Zeev, D.; Frounfelker, R.; Morris, S. B.; Corrigan, P. W. (2012):

Predictors of Self-Stigma in Schizophrenia: New Insights Using Mobile Technologies.

In: *J Dual Diagn* 8 (4), S. 305–314. DOI: 10.1080/15504263.2012.723311.

Abstract:

Self-stigma has significant negative impact on the recovery of individuals with severe mental illness, but its varying course is not well understood. Individual levels of self-stigma may vary over time and fluctuate in response to both external/contextual (i.e., location, activity, social company) and internal (i.e., psychiatric symptoms, mood) factors. The aim of this study was to examine the relationship between self-stigmatizing beliefs and these factors, as they occur in the daily life of individuals with schizophrenia. Mobile technologies were used to longitudinally track momentary levels of self-stigma, psychotic symptoms, negative affect, positive affect, activity, and immediate social and physical environment in twenty-four individuals with schizophrenia, multiple times daily, over a one-week period. Multilevel modeling showed that participants' current activity was associated with changes in self-stigma (chi2= 10.53, p <0.05), but immediate location and social company were not. Time-lagged analyses found that increases in negative affect (beta=0.11, p<0.01) and psychotic symptom severity (beta=0.16, p<0.01) predicted increases in the intensity of self-stigmatizing beliefs. Psychotic symptoms were found to be both an antecedent and a consequence (beta=0.08, p<0.01) of increased self-stigma. Our findings support a framework for understanding self-stigma as an experience that changes based on alterations in internal states and external circumstances. Mobile technologies are an effective methodology to study self-stigma and have potential to be used to deliver clinical interventions

Development and Usability Testing of FOCUS: A Smartphone System for Self-Management of Schizophrenia.

In: *Psychiatric Rehabilitation Journal*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-32035-001%26site%3dehost-live.

Abstract:

Objective: Mobile Health (mHealth) approaches can support the rehabilitation of individuals with psychiatric conditions. In the current article, we describe the development of a smartphone illness self-management system for people with schizophrenia. Methods: The research was conducted with consumers and practitioners at a community-based rehabilitation agency. Stage 1: 904 individuals with schizophrenia or schizoaffective disorder completed a survey reporting on their current use of mobile devices and interest in mHealth services. Eight practitioners completed a survey examining their attitudes and expectations from an mHealth intervention, and identified needs and potential obstacles. Stage 2: A multidisciplinary team incorporated consumer and practitioner input and employed design principles for the development of e-resources for people with schizophrenia to produce an mHealth intervention. Stage 3: 12 consumers participated in laboratory usability sessions. They performed tasks involved in operating the new system, and provided “think aloud” commentary and post-session usability ratings. Results: 570 (63%) of survey respondents reported owning a mobile device and many expressed interest in receiving mHealth services. Most practitioners believed that consumers could learn to use and would benefit from an mHealth intervention. In response, we developed a smartphone system that targets medication adherence, mood regulation, sleep, social functioning, and coping with symptoms. Usability testing revealed several design vulnerabilities, and the system was adapted to address consumer needs and preferences accordingly. Conclusions and Implications for Practice: Through a comprehensive development process, we produced an mHealth illness self-management intervention that is likely to be used successfully, and is ready for deployment and systemic evaluation in real-world conditions. Ben-Zeev, D.; McHugo, G. J.; Xie, H.; Dobbins, K.; Young, M. A. (2012):

Comparing retrospective reports to real-time/real-place mobile assessments in individuals with schizophrenia and a nonclinical comparison group.

In: *Schizophr.Bull.* 38 (3), S. 396–404. DOI: 10.1093/schbul/sbr171.

Abstract:

Retrospective reports are often used as the primary source of information for important diagnostic decisions, treatment, and clinical research. Whether such reports accurately represent individuals' past experiences in the context of a serious mental illness such as schizophrenia is unclear. In the current study, 24 individuals with schizophrenia and 26 nonclinical participants used a mobile device to complete multiple real-time/real-place assessments daily, over 7 consecutive days. At the end of the week, participants were also asked to provide a retrospective report summarizing the same period. Comparison of the data captured by the 2 methods showed that participants from both groups retrospectively overestimated the intensity of negative and positive daily experiences. In the clinical group, overestimations for affect were greater than for psychotic symptoms, which were relatively comparable to their retrospective reports. In both samples, retrospective reports were more closely associated with the week's average than the most intense or most recent ratings captured with a mobile device. Multilevel modeling revealed that much of the variability in weekly assessments was not explained by between-person differences and could not be

captured by a single retrospective estimate. Based on the findings of this study, clinicians and researchers should be aware that while retrospective summary reports of the severity of certain symptoms compare relatively well with average momentary ratings, they are limited in their ability to capture variability in one's affective or psychotic experiences over time

Ben-Zeev, Dror; Young, Michael A. (2010):

Accuracy of hospitalized depressed patients' and healthy controls' retrospective symptom reports: an experience sampling study.

In: *The Journal of nervous and mental disease* 198 (4), S. 280–285. DOI: 10.1097/NMD.0b013e3181d6141f.

Abstract:

A growing body of literature suggests that retrospective recall of psychiatric symptoms is often inaccurate and may distort knowledge about the course of illness and impact treatment. The current study examined the accuracy of retrospective recall of a variety of depressive symptoms in hospitalized depressed patients and nonclinical controls. Using the Experience Sampling Method, we compared average momentary symptom reports of 1 week to retrospective summaries of the same period. The depressed group exhibited negative biases in their recall of experienced anhedonia, sadness, confusion, and suicidality, but were relatively accurate in recall of helplessness, detachment, and self-control. Controls exhibited a different pattern; they were relatively accurate in their retrospective recall of confusion, suicidality and sadness, but exhibited positive biases in recall of anhedonia, helplessness, detachment, and self-control. Both groups exhibited comparable negative biases in their recall of experienced tension, difficulty concentrating, guilt, and fear. The findings suggest that for maximum accuracy in the assessment of depressive symptoms, scientists and practitioners should supplement retrospective self-reports with momentary measures, and consider using ambulatory assessment in cognitive behavioral treatments of depression.

Ben-Zeev, Dror; Young, Michael A.; Madsen, Joshua W. (2009):

Retrospective recall of affect in clinically depressed individuals and controls.

In: *Cognition and Emotion* 23 (5), S. 1021–1040.

Abstract:

The current study examined the nature of retrospective recall of affect in depressed participants and nonclinical controls. Utilising the Experience Sampling Method, we compared average momentary affect reports to retrospective summaries of the same period of time. Both groups exhibited exaggerated retrospective summaries of positive affect (PA) and negative affect (NA). Greater bias for PA than NA was found in the controls but not the depressed. Across groups, depressed individuals exhibited more absolute inaccuracy in their recall of NA but not PA. For depressed and nonclinical individuals, retrospective summaries of PA were better predicted by an average of all weekly momentary PA than a combination of the most intense ("peak") PA and most recent ("end") PA experiences. For nonclinical participants, retrospective NA was better predicted by an average of all weekly momentary NA. For depressed individuals, however, no clear advantage to predicting retrospective NA by average weekly NA relative to a combination of peak NA and end NA was found. Based on our findings, clinicians should realise that depressive cognition may not lie in recall that is less positive and more negative than "reality" but in retrospective intensifications of all affect that are, compared to normal, relatively greater for negative than for positive affect.

Ben-Zeev, D.; Young, M. A.; Depp, C. A. (2012):

Real-time predictors of suicidal ideation: Mobile assessment of hospitalized depressed patients.

In: *Psychiatry Res* (0165-1781 (Linking)). DOI: 10.1016/j.psychres.2011.11.025.

Abstract:

Suicidal ideation is a risk factor for suicide attempt and completion. Cross-sectional or retrospective studies cannot capture the dynamic course and possible predictors of suicidal ideation as it occurs in daily life. This study utilizes an experience sampling paradigm to identify real-time predictors of suicidal ideation in inpatients with major depressive disorder. Thirty-one depressed patients admitted to a psychiatric unit were signaled by a mobile device to record suicidal ideation, affect, and other symptoms, multiple times a day over 1-week. Participants completed a total of 1350 questionnaires. Seventy-four percent of the sample reported suicidal ideation during the week. Time-lagged analyses revealed that momentary ratings of Sadness, Tension, and Boredom (as well as suicidal ideation itself) predicted subsequent suicidal thoughts in the following hours. Baseline severity of

depression and past suicide attempts were both correlated with mean ideation severity during the week. A number of predictors identified in prior research (e.g. hopelessness) were unrelated to subsequent suicidal ideation in the current study. Momentary interventions that guide individuals through activities designed to reduce levels of Sadness, Tension, and Boredom in real-time (e.g., thought challenging, relaxation, behavioral activation) may be especially warranted

Berendsen, Brenda A. J.; Hendriks, Marike R. C.; Willems, Paul; Meijer, Kenneth; Schaper, Nicolaas C.; Savelberg, Hans H C M (2014):

A 20 min window is optimal in a non-wear algorithm for tri-axial thigh-worn accelerometry in overweight people.

In: *Physiol Meas* 35 (11), S. 2205–2212. DOI: 10.1088/0967-3334/35/11/2205.

Abstract:

A valid non-wear algorithm for activity monitors is crucial to avoid the misclassification of sedentary time as non-wear time, and vice versa. Characteristics of the algorithm, such as time windows, should be well defined and tested. Furthermore, using tri-axial data might influence the algorithm's performance. This study assessed the optimal time window length in a non-wear algorithm for overweight adults, applied to tri-axial data from sixteen participants. Ten time windows, from 10 up to 120 min, were tested with a diary as a criterion measure. We assessed the bias in non-wear time, sensitivity and specificity. The optimal time window length was based on ten participants; the validation of this time window was carried out with six other participants. The time window of 20 min showed the highest and 120 min showed the lowest mean amount of correctly classified non-wear time, at 94% and 70% respectively. Sensitivity and specificity were considered optimal in the 20 min time window. Validation of this time window demonstrated a sensitivity and specificity of 86% and 83% respectively. A 20 min time window showed the best non-wear estimations. The current study utilized tri-axial raw data and 1 s epoch data which might have facilitated the application of a short time window and thereby decreased the risk of misclassifying non-wear.

Berg, K. C.; Crosby, R. D.; Cao, L.; Peterson, C. B.; Engel, S. G.; Mitchell, J. E.; Wonderlich, S. A. (2012):

Facets of Negative Affect Prior to and Following Binge-Only, Purge-Only, and Binge/Purge Events in Women With Bulimia Nervosa.

In: *J Abnorm.Psychol.* (0021-843X (Linking)). DOI: 10.1037/a0029703.

Abstract:

Ecological momentary assessment (EMA) data suggest that global negative affect (NA) increases prior to and decreases following episodes of binge eating and purging, providing support for the affect regulation model of BN. The current study examined whether facets of NA are differentially related to bulimic behaviors. Women with bulimia nervosa (BN; n = 133) completed a 2-week EMA protocol. Momentary assessments of 4 facets of NA (Fear, Guilt, Hostility, and Sadness) were derived from the PANAS subscales. Trajectories of the NA facets were modeled prior to and following binge-only, purge-only, and binge/purge events. Fear, Guilt, Hostility, and Sadness increased prior to and decreased following binge-only and binge/purge events. The same results were found for purge-only events, with the exception that Hostility did not increase significantly prior to purging. Notably, ratings of Guilt were higher than those of Fear, Hostility, and Sadness at the time of binge-only and binge/purge events. Furthermore, post hoc analyses demonstrate that Guilt increased prior to and decreased following the 3 behavior types, even after controlling for Fear, Hostility, and Sadness. These results provide further support for the affect regulation model of BN and also suggest that guilt may be particularly important to the pathology of BN. Berg, Kelly C.; Peterson, Carol B.; Crosby, Ross D.; Cao, Li; Crow, Scott J.; Engel, Scott G.; Wonderlich, Stephen A. (2013):

Relationship between daily affect and overeating-only, loss of control eating-only, and binge eating episodes in obese adults.

In: *Psychiatry Res*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-39122-001%26site%3dehost-live.

Abstract:

The two objectives of the current study were: (1) to identify daily patterns of negative affect (NA) in obese individuals; and (2) to determine whether daily affect patterns were related to overeating without loss of control (OE-only), loss of control eating without overeating (LOC-only), and binge eating (BE) episodes. Fifty obese (BMI=40.3-&#65533;08.5) adults (84.0% female) completed a two-week ecological momentary assessment protocol during which they completed assessments of NA and indicated whether their eating episodes were characterized by OE and/or LOC. Latent growth mixture modeling (LGMM) was used to identify daily trajectories of NA. GEE analysis was used to determine whether daily affect trajectories were differentially related to the frequency of OE-only, LOC-only, and BE episodes. The LGMM analyses identified nine unique trajectories of NA. Significantly higher frequencies of OE-only and BE episodes occurred on days characterized by high or increasing levels of NA. There were no significant differences between classes for the frequency of LOC-only episodes. These data suggest that NA may act as an antecedent to OE-only and BE episodes and that targeting “problematic affect days” may reduce the occurrence of OE-only and BE episodes among obese individuals. Berger, Ann M.; Wielgus, Kimberly; Hertzog, Melody; Fischer, Patricia; Farr, Lynne (2010):

Patterns of circadian activity rhythms and their relationships with fatigue and anxiety/depression in women treated with breast cancer adjuvant chemotherapy.

In: *Support Care Cancer* 18 (1), S. 105–114. DOI: 10.1007/s00520-009-0636-0.

Abstract:

PURPOSE\r\nThe purpose of this study was to examine patterns of circadian activity rhythms and their relationship with fatigue, anxiety/depression, and demographic/medical variables in women receiving breast cancer adjuvant therapy treatments (Tx) at three times within a randomized clinical trial (RCT) designed to improve sleep and modify fatigue.\r\nMETHODS\r\nA RCT enrolled 219 women with stage I-IIIA breast cancer who were randomized 2 days prior to starting chemotherapy to a behavioral therapy sleep intervention or healthy eating control group. All cases with available data (n = 190) were included in a descriptive, correlational, repeated measures analysis. Activity data were collected continuously by wrist actigraphy for 7 days at three times: the start (Tx 1), continuation (Tx 3), and recovery (30 days after last Tx) of chemotherapy. Circadian activity rhythm parameters were generated using Action4 software (Ambulatory Monitoring, Inc.). Measures collected simultaneously included Piper Fatigue Scale, Hospital Anxiety and Depression Scale, and demographic/medical variables.\r\nRESULTS\r\nCircadian activity rhythm parameters at three times in both groups were disrupted compared to healthy adults, but similar to values of cancer patients. Significant changes in mesor, amplitude, peak activity, and 24 h autocorrelation values were found over time in both groups. The intervention group's amplitude and circadian quotient values were significantly more robust. More robust activity rhythms were associated with lower fatigue, depressive symptoms, body mass index, and higher performance status in both groups.\r\nCONCLUSIONS\r\nDisrupted patterns of circadian activity rhythms were prevalent and associated with distressing fatigue and depressive symptoms during chemotherapy and at recovery. The intervention resulted in more robust rhythms.

Personal and social-environmental correlates of objectively measured physical activity in Norwegian pre-adolescent children.

In: *Scandinavian Journal of Medicine & Science in Sports* 21 (6), S. e315-e324. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-27994-057&site=ehost-live;ingunn.holden.bergh@nih.no.

Abstract:

The aim of this study was to examine modifiable biological, psychological, behavioral and social-environmental correlates of physical activity among 1129 Norwegian 11-year-old children within a cross-sectional sample from the HEalth In Adolescents study. Physical activity was assessed by accelerometer, and weight and height were measured objectively. Age- and gender-specific cut-off points proposed by the International Obesity Task Force were used to define body mass index. Social-environmental variables were self-reported by questionnaire. Hierarchical regression (linear mixed models) revealed that normal weight children scored higher on percentage daily moderate-to-vigorous physical activity [% daily moderate to vigorous physical activity (MVPA)] than overweight/obese children (P < 0.001). Self-efficacy (P < 0.01) and perceived social support from friends (P < 0.01) were positively associated with children's % daily MVPA, and a negative association was found for computer/game-use on weekends (P < 0.01). A moderator effect of weight category (normal vs overweight/obese) in the relationship between computer/game-use on weekends and % daily MVPA was detected (P < 0.05), reflecting that higher computer/game-use on weekends was associated with lower % MVPA among the overweight/obese, but not among the normal weight. Modifiable correlates from multiple domains accounted for 14% of the variance in % daily MVPA. Prospective and

intervention studies are needed to examine whether these factors act as mediators for physical activity change in pre-adolescent children. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Bergmann, J. H.; Smith, I. C.; Mayagoitia, R. E. (2012):

Using a body sensor network to measure the effect of fatigue on stair climbing performance.

In: *Physiol Meas* 33 (2), S. 287–296. DOI: 10.1088/0967-3334/33/2/287.

Abstract:

In terms of self-rated health, the most important activities of daily living are those involving mobility. Of these activities stair climbing is regarded as the most strenuous. A loss of stair climbing ability with age is normally associated with a loss of muscle strength and power, while other factors that influence muscle function, such as fatigue, are often not taken into account. So far no research has been published on how long-lasting fatigue affects activities of daily living, despite the fact that it has been repeatedly proven, in laboratory settings, to influence muscle force production over long periods of time. Technological advances in body sensor networks (BSNs) now provide a method to measure performance during complex real-life situations. In this study the use of a BSN was explored to investigate the effects of long-lasting fatigue on stair climbing performance in 20 healthy adults. Stair climbing performance was measured before and after a fatiguing protocol using a BSN. Performance was defined by temporal and spatial parameters. Long-lasting fatigue was successfully induced in all participants using an exercise protocol. The BSN showed that post-exercise fatigue did not influence stair climbing times ($p > 0.2$) and no meaningful changes in joint angles were found. No effect on overall stair climbing performance was found, despite a clear presence of long-lasting fatigue. This study shows that physiological paradigms can be further explored using BSNs. Ecological validity of lab-based measurements can be increased by combining them with BSNs

Smoking cessation from the brain to the real world: An fMRI-experience sampling study.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (3-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-99180-174&site=ehost-live.

Abstract:

Three studies investigated the neural, affective, and cognitive processes of real-world goal pursuit in the context of cigarette smoking cessation. Thirty-one smokers (15 female) with the intention to quit completed a three-phase protocol. Before quitting, participants completed a novel neurocognitive task that assessed neural and behavioral markers of goal representation, progress monitoring, and response inhibition, and also provided physiological measures of smoking at baseline. Next, during their cessation attempt, participants completed a twenty-one day experience sampling phase in which they recorded cravings, mood, and smoking behavior, eight times throughout the waking day. Finally, approximately four weeks after their quit date, participants returned to the lab for a re-assessment of self-reported and physiological measures of smoking. All studies reported here are based on data from these phases. Study 1 investigated the neural mechanisms associated with three core components of goal pursuit—goal representation, progress monitoring, and response inhibition—individually and as they interacted with one another and with time. Though these components are frequently studied in isolation, they have never been examined as they co-occur with one another. We replicated previous findings regarding the neural bases of each of the components, and identified for the first time several regions sensitive to the interaction among components including the supramarginal gyrus and the presupplementary motor area/dorsal anterior cingulate cortex. We also found that several additional regions were recruited to support sustained (compared to transient) engagement of goal pursuit including parts of the superior parietal lobe and superior temporal gyrus. Study 2 investigated within-day fluctuations in mood, craving, and smoking in a sample of smokers throughout the first three weeks of a cessation attempt in order to better understand the relationships among these variables across time. Hierarchical linear modeling (HLM) analyses indicated that smoking and cravings declined linearly throughout the first three weeks, though mood remained stable. Further, there was a positive within-day association between negative mood and subsequent smoking which was mediated by craving concurrent with the negative mood. This mediation pattern is consistent with an associative-learning account of the mood-to-smoking link such that, among smokers, negative mood is related to craving which is in turn related to smoking. In the absence of craving, negative mood does not directly relate to smoking. Study 3 investigated whether neural activity during response inhibition within the fMRI scanner related to reductions in smoking four weeks later and to daily experiences during the cessation attempt. In a first, more global analysis, we found that activation in the basal ganglia during the response inhibition task at baseline predicted change across four weeks in total cigarette consumption as measured by exhaled carbon monoxide. In a second, more specific analysis, we found that activation in a priori regions of interest in the right inferior frontal gyrus, presupplementary motor area, and basal ganglia separately related to an attenuated within-day association between cravings at one time point and smoking at the following time point. Using SMS text messaging to assess moderators of smoking reduction: Validating a new tool for ecological measurement of health behaviors.

In: *Health Psychol* 30 (2), S. 186–194. DOI: 10.1037/a0022201.

Abstract:

OBJECTIVE\r\nUnderstanding the psychological processes that contribute to smoking reduction will yield population health benefits. Negative mood may moderate smoking lapse during cessation, but this relationship has been difficult to measure in ongoing daily experience. We used a novel form of ecological momentary assessment to test a self-control model of negative mood and craving leading to smoking lapse.\r\nDESIGN\r\nWe validated short message service (SMS) text as a user-friendly and low-cost option for ecologically measuring real-time health behaviors. We sent text messages to cigarette smokers attempting to quit eight times daily for the first 21 days of cessation (N-obs = 3,811).\r\nMAIN OUTCOME MEASURES\r\nApproximately every two hours, we assessed cigarette count, mood, and cravings, and examined between- and within-day patterns and time-lagged relationships among these variables. Exhaled carbon monoxide was assessed pre- and posttreatment.\r\nRESULTS\r\nNegative mood and craving predicted smoking two hours later, but craving mediated the mood-smoking relationship. Also, this mediation relationship predicted smoking over the next two, but not four, hours.\r\nCONCLUSION\r\nResults clarify conflicting previous findings on the relation between affect and smoking, validate a new low-cost and user-friendly method for collecting fine-grained health behavior assessments, and emphasize the importance of rapid, real-time measurement of smoking moderators.

Berkman, Elliot T.; Falk, Emily B.; Lieberman, Matthew D. (2011):

In the trenches of real-world self-control: neural correlates of breaking the link between craving and smoking.

In: *Psychological Science* 22 (4), S. 498–506. DOI: 10.1177/0956797611400918.

Abstract:

Successful goal pursuit involves repeatedly engaging self-control against temptations or distractions that arise along the way. Laboratory studies have identified the brain systems recruited during isolated instances of self-control, and ecological studies have linked self-control capacity to goal outcomes. However, no study has identified the neural systems of everyday self-control during long-term goal pursuit. The present study integrated neuroimaging and experience-sampling methods to investigate the brain systems of successful self-control among smokers attempting to quit. A sample of 27 cigarette smokers completed a go/no-go task during functional magnetic resonance imaging before they attempted to quit smoking and then reported everyday self-control using experience sampling eight times daily for 3 weeks while they attempted to quit. Increased activation in right inferior frontal gyrus, pre-supplementary motor area, and basal ganglia regions of interest during response inhibition at baseline was associated with an attenuated association between cravings and subsequent smoking. These findings support the ecological validity of neurocognitive tasks as indices of everyday response inhibition.

Berkman, Elliot T.; Giuliani, Nicole R.; Pruitt, Alicia K. (2014):

Comparison of text messaging and paper-and-pencil for ecological momentary assessment of food craving and intake.

In: *Appetite. DOI:* 10.1016/j.appet.2014.06.010.

Abstract:

Electronic devices such as mobile phones are quickly becoming a popular way to gather participant reports of everyday thoughts, feelings, and behaviors, including food cravings and intake. Electronic devices offer a number of advantages over alternative methods such as paper-and-pencil (PNP) assessment including automated prompts, on-the-fly data transmission, and participant familiarity with and ownership of the devices. However, only a handful of studies have systematically compared compliance between electronic and PNP methods of ecological momentary assessment (EMA), and none have examined eating specifically. Existing comparisons generally find greater compliance for electronic devices than PNP, but there is variability in the results across studies that may be accounted for by differences across research domains. Here, we compared the two EMA methods in an unexamined domain - eating - in terms of response rate and response latency, and their sensitivity to individual difference variables such as body mass index (BMI). Forty-four participants were randomly assigned to report on their food craving, food intake, and hunger four times each day for 2 weeks using either a PNP diary (N = 19) or text messaging (TXT; N = 25). Response rates were higher for TXT than PNP (96% vs. 70%) and latencies were faster (29 min vs. 79 min), and response rate

and latency were less influenced by BMI in the TXT condition than in the PNP condition. These results support the feasibility of using text messaging for EMA in the eating domain, and more broadly highlight the ways that research domain-specific considerations (e.g., the importance of response latency in measuring short-lived food craving) interact with assessment modality during EMA.

Bernmark, Eva; Forsman, Mikael; Wiktorin, Christina (2011):

Head movements during two computer work tasks assessed by accelerometry.

In: *Applied ergonomics* 42 (2), S. 309–313. DOI: 10.1016/j.apergo.2010.07.006.

Abstract:

We investigated whether potential differences in head inclinations and accelerations for two highly similar computer work tasks could be detected using (1) a triaxial accelerometer and (2) a simulated uniaxial accelerometer. Ten subjects' head movements were registered with a triaxial accelerometer system for two similar document-management tasks at their work place: a fully electronic document-management task and one also involving paper documents. In situations where head movements were small, a triaxial accelerometer was able to discriminate between the different degrees of static work of the neck in terms of range of head inclinations and accelerations. A difference in head acceleration was also found by using a simulated uniaxial accelerometer. Thus, in terms of head movement and for work similar to this office work, potential dynamic differences in observationally similar work tasks can be investigated by using a triaxial accelerometer. For acceleration alone, a uniaxial accelerometer can also be used.

Bexelius, C.; Sandin, S.; Trolle Lagerros, Y.; Litton, J. E.; Löf, M. (2011):

Estimation of physical activity levels using cell phone questionnaires: A comparison with accelerometry for evaluation of between-subject and within-subject variations.

In: *J Med Internet Res* 13 (3), S. 186–191. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-05747-014&site=ehost-live;marie.lof@ki.se.

Abstract:

BACKGROUND:

Physical activity promotes health and longevity. Further elaboration of the role of physical activity for human health in epidemiological studies on large samples requires accurate methods that are easy to use, cheap, and possible to repeat. The use of telecommunication technologies such as cell phones is highly interesting in this respect. In an earlier report, we showed that physical activity level (PAL) assessed using a cell phone procedure agreed well with corresponding estimates obtained using the doubly labeled water method. However, our earlier study indicated high within-subject variation in relation to between-subject variations in PAL using cell phones, but we could not assess if this was a true variation of PAL or an artifact of the cell phone technique.

OBJECTIVE:

Our objective was to compare within- and between-subject variations in PAL by means of cell phones with corresponding estimates using an accelerometer. In addition, we compared the agreement of daily PAL values obtained using the cell phone questionnaire with corresponding data obtained using an accelerometer.

METHODS:

PAL was measured both with the cell phone questionnaire and with a triaxial accelerometer daily during a 2-week study period in 21 healthy Swedish women (20 to 45 years of age and BMI from 17.7 kg/m^2 to 33.6 kg/m^2). The results were evaluated by fitting linear mixed effect models and descriptive statistics and graphs.

RESULTS:

With the accelerometer, 57% (95% confidence interval [CI] 40%-66%) of the variation was within subjects, while with the cell phone, within-subject variation was 76% (95% CI 59%-83%). The day-to-day variations in PAL observed using the cell phone questions agreed well with the corresponding accelerometer results.

CONCLUSIONS:

Both the cell phone questionnaire and the accelerometer showed high within-subject variations. Furthermore, day-to-day variations in PAL within subjects assessed using the cell phone agreed well with corresponding accelerometer values.

Consequently, our cell phone questionnaire is a promising tool for assessing levels of physical activity. The tool may be useful for large-scale prospective studies.

Bhammar, D. M.; Angadi, S. S.; Gaesser, G. A. (2012):

Effects of Fractionized and Continuous Exercise on 24-h Ambulatory Blood Pressure.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e3182663117.

Abstract:

PURPOSE: To compare the effects of fractionized aerobic exercise (three 10-min exercise sessions) and continuous exercise (one 30-min exercise session) on 24-hour ambulatory blood pressure (ABP). METHODS: Eleven healthy prehypertensive subjects (28.3 +/- 8.0 (SD) yr) completed three randomly assigned conditions: 1) three 10-min sessions of aerobic exercise (3x10-min), 2) one continuous 30-min session of aerobic exercise (1x30-min), and 3) a non-exercise control trial (Control). The mode of exercise was walking on a motor-driven treadmill at 75% - 79% of maximum heart rate (HRmax) (60% - 65% VO2peak). Twenty-four hour ABP monitoring was monitored with an automated ABP device (Oscar 2). Linear mixed models were used to compare 24-h ABP responses between trials. RESULTS: Mean (+/- SD) 24-h systolic BP was significantly lower during the 3x10-min trial (127 +/- 15 mmHg) compared to Control (130 +/- 15 mmHg) (P < .001). Although both 3x10-min and 1x30-min reduced SBP compared to Control during daytime/evening (1300 h - 2300 h), only the 3x10-min reduced SBP during nighttime (2300 h - 0800 h; 118 +/- 16 mmHg vs. 122 +/- 14 mmHg; P = 0.024) and the following morning (0800 h - 1200 h; 127 +/- 15 mmHg vs. 131 +/- 15 mmHg; P = 0.016). Over 24-h, 26.7% of SBP values during 3x10-min were normal (i.e., <120 mmHg) compared to 18.3% for 1x30-min and 19.4% for control (P < 0.001). CONCLUSIONS: In prehypertensive individuals, fractionized exercise (e.g., three 10-min aerobic exercise sessions spread out evenly throughout the day) reduces 24-h systolic ABP by more than a single 30-min exercise session. Fractionized exercise may be a viable and effective exercise alternative to continuous exercise for cardiovascular risk reduction in this population

Bharathi, Ankalmadagu V.; Kuriyan, Rebecca; Kurpad, Anura V.; Thomas, Tinku; Ebrahim, Shah; Kinra, Sanjay et al. (2010):

Assessment of physical activity using accelerometry, an activity diary, the heart rate method and the Indian migration study questionnaire in south Indian adults.

In: *Public health nutrition* 13 (1), S. 47–53. DOI: 10.1017/S1368980009005850.

Abstract:

OBJECTIVE\r\nTo validate questionnaire-based physical activity level (PAL) against accelerometry and a 24 h physical activity diary (24 h AD) as reference methods (Protocol 2), after validating these reference methods against the heart rate-oxygen consumption (HRVO2) method (Protocol 1).\r\nDESIGN\r\nCross-sectional study.\r\nSETTING\r\nTwo villages in Andhra Pradesh state and Bangalore city, South India.\r\nSUBJECTS\r\nNinety-four participants (fifty males, forty-four females) for Protocol 2; thirteen males for Protocol 1.\r\nRESULTS\r\nIn Protocol 2, mean PAL derived from the questionnaire (1.72 (sd 0.20)) was comparable to that from the 24 h AD (1.78 (sd 0.20)) but significantly higher than the mean PAL derived from accelerometry (1.36 (sd 0.20); P < 0.001). Mean bias of PAL from the questionnaire was larger against the accelerometer (0.36) than against the 24 h AD (-0.06), but with large limits of agreement against both. Correlations of PAL from the questionnaire with that of the accelerometer (r = 0.28; P = 0.01) and the 24 h AD (r = 0.30; P = 0.006) were modest. In Protocol 1, mean PAL from the 24 h AD (1.65 (sd 0.18)) was comparable, while that from the accelerometer (1.51 (sd 0.23)) was significantly lower (P < 0.001), than mean PAL obtained from the HRVO2 method (1.69 (sd 0.21)).\r\nCONCLUSIONS\r\nThe questionnaire showed acceptable validity with the reference methods in a group with a wide range of physical activity levels. The accelerometer underestimated PAL in comparison with the HRVO2 method.

Bhattacharyya, Mimi R.; Molloy, Gerard J.; Steptoe, Andrew (2008):

Depression is associated with flatter cortisol rhythms in patients with coronary artery disease.

In: *Journal of Psychosomatic Research* 65 (2), S. 107–113.

Abstract:

OBJECTIVE:

Depression is associated with coronary heart disease, but the underlying mechanisms are not fully understood. Cortisol is involved in the development of coronary artery disease (CAD), but evidence directly linking depression with cortisol in patients with CAD is limited. This study evaluated cortisol output over the day in patients with suspected CAD in relation to depressive symptoms.

METHODS:

Eighty-eight patients who were being investigated for suspected CAD (defined by clinical symptoms plus positive exercise tests or myocardial perfusion scans) took eight saliva samples over the day and evening. Depressed mood was assessed with the Beck Depression Inventory. Actigraphy was used to define time of waking objectively.

RESULTS:

The cortisol awakening response and cortisol rhythm over the remainder of the day and evening were analyzed separately. Fifty-two (61.9%) patients were later found to have definite CAD on angiography, while the remainder did not. The cortisol slope over the day was flatter in more depressed patients with CAD (P<.001) but was not related to depression in patients without CAD (P=.68). This effect was due to the combination of lower cortisol early in the day and higher cortisol in the evening in more depressed CAD patients, independent of age, gender, medication, and times of waking and sleeping (P=.003). Additionally, cortisol measured on waking and 15 and 30 min after waking was greater in CAD than in non-CAD patients (P=.04), but was not related to depression.

CONCLUSIONS:

The flatter cortisol rhythms of more depressed CAD patients may contribute to the progression of coronary atherosclerosis.

Bhopi, R.; Nagy, D.; Erichsen, D. (2012):

Can a novel smartphone application detect periodic limb movements?

In: *Stud.Health Technol.Inform.* 182 (0926-9630 (Linking)), S. 36–42. Online verfügbar unter PM:23138077.

Abstract:

Background: Periodic limb movements (PLMs) are repetitive, stereotypical and unconscious movements, typically of the legs, that occur in sleep and are associated with several sleep disorders. The gold standard for detecting PLMs is overnight electromyography which, although highly sensitive and specific, is time and labour consuming. The current generation of smart phones is equipped with tri-axial accelerometers that record movement. Aim: To develop a smart phone application that can detect PLMs remotely. Method: A leg movement sensing application (LMSA) was programmed in iOS 5x and incorporated into an iPhone 4S (Apple INC.). A healthy adult male subject underwent simultaneous EMG and LMSA measurements of voluntary stereotypical leg movements. The mean number of leg movements recorded by EMG and by the LMSA was compared. Results: A total of 403 leg movements were scored by EMG of which the LMSA recorded 392 (97%). There was no statistical difference in mean number of leg movements recorded between the two modalities (p = 0.3). Conclusion: These preliminary results indicate that a smart phone application is able to accurately detect leg movements outside of the hospital environment and may be a useful tool for screening and follow up of patients with PLMs

Biddle, Stuart J. H.; Gorely, Trish; Marshall, Simon J. (2009):

Is television viewing a suitable marker of sedentary behavior in young people?

In: *Annals of Behavioral Medicine* 38 (2), S. 147–153. DOI: 10.1007/s12160-009-9136-1.

Abstract:

BACKGROUND\r\nTelevision (TV) viewing is a highly prevalent sedentary behavior in young people and has played a significant role in the assessment of sedentary behaviors. An important question to be addressed is to what extent TV viewing is a suitable indicator, or marker, of overall levels of sedentary behavior in children and adolescents. This has not yet been attempted in youth, but has already been attempted in Australian adults.\r\nPURPOSE\r\nThis study was conducted to test whether TV viewing in UK teenagers is a marker of sedentary behavior more broadly and to see if the results mirror those of Australian adults.\r\nMETHODS\r\nEcological momentary assessment time-use diaries were completed by 561 boys and 923 girls (mean age 14.67 years) in which weekday and weekend out-of-school time behaviors were recorded every 15 min.\r\nRESULTS\r\nTV viewing was negatively associated with other leisure-time sedentary behaviors for both boys and girls for weekdays and weekends. Higher levels of TV viewing were associated with less time in other key sedentary behaviors, such as computer use in boys and motorized transport in girls.\r\nCONCLUSIONS\r\nTV viewing appears not to reflect additional time in other sedentary behaviors in British teenagers, in contrast to data from Australian women. Studies of sedentary behavior should encompass as wide a range of behaviors as possible.

Bieg, Madeleine; Goetz, Thomas; Lipnevich, Anastasiya A. (2014):

What Students Think They Feel Differs from What They Really Feel - Academic Self-Concept Moderates the Discrepancy between Students' Trait and State Emotional Self-Reports.

In: *PLoS One* 9 (3), S. e92563. DOI: 10.1371/journal.pone.0092563.

Abstract:

This study investigated whether there is a discrepancy pertaining to trait and state academic emotions and whether self-concept of ability moderates this discrepancy. A total of 225 secondary school students from two different countries enrolled in grades 8 and 11 (German sample; n = 94) and grade 9 (Swiss sample; n = 131) participated. Students' trait academic emotions of enjoyment, pride, anger, and anxiety in mathematics were assessed with a self-report questionnaire, whereas to assess their state academic emotions experience-sampling method was employed. The results revealed that students' scores on the trait assessment of emotions were generally higher than their scores on the state assessment. Further, as expected, students' academic self-concept in the domain of mathematics was shown to partly explain the discrepancy between scores on trait and state emotions. Our results indicate that there is a belief-driven discrepancy between what students think they feel (trait assessment) and what they really feel (state assessment). Implications with regard to the assessment of self-reported emotions in future studies and practical implications for the school context are discussed.

Objectively Measured Physical Activity in Children from a Southern Brazilian City: A Population-Based Study.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23223711.

Abstract:

BACKGROUND: The aim of this study was to assess physical activity (PA) patterns (intensity and prevalence) in children according to demographic, socioeconomic and familiar characteristics. METHODS: In 2010, a cross-sectional study of 239 children aged 4 to 11 was conducted, in Pelotas, Southern Brazil. PA was measured by accelerometry and classified in different intensities. Insufficient physical activity was defined as less than 60 min/day of moderate-to-vigorous PA. Descriptive analyses of accelerometry-related variables were presented. Multivariate Poisson regression models were used to estimate the association between physical insufficient PA and co-variates. RESULTS: For both sexes, around 65% of the registered time was spent in sedentary activities and less than 20 min/day in vigorous activity. Age and economic status were inversely associated to PA in all categories of PA. Moderate and vigorous activities means were higher in boys than in girls. The prevalence of insufficient PA was 34.5% in girls and 19.5% in boys. CONCLUSIONS: We found important differences in physical activity patterns according to sex and economic status, as well as a significant decline in time spent in moderate-to-vigorous PA with increasing age. Understanding the relationship between these sociodemographic factors is important to tackle low levels of PA

Evaluation of the accuracy of smartphone medical calculation apps.

In: *J Med Internet Res* 16 (2), S. e32. DOI: 10.2196/jmir.3062.

Abstract:

BACKGROUND: Mobile phones with operating systems and capable of running applications (smartphones) are increasingly being used in clinical settings. Medical calculating applications are popular mhealth apps for smartphones. These include, for example, apps that calculate the severity or likelihood of disease-based clinical scoring systems, such as determining the severity of liver disease, the likelihood of having a pulmonary embolism, and risk stratification in acute coronary syndrome. However, the accuracy of these apps has not been assessed. OBJECTIVE: The objective of this study was to evaluate the accuracy of smartphone-based medical calculation apps. METHODS: A broad search on Google Play, BlackBerry World, and the iTunes App Store was conducted to find medical calculation apps for smartphones. The list of apps was narrowed down based on inclusion and exclusion criteria focusing on functions thought to be relevant by a panel of general internists (number of functions =13). Ten case values were inputted for each function and were compared to manual calculations. For each case, the correct answer was assigned a score of 1. A score for the 10 cases was calculated based on the accuracy of the results for each function on each app. RESULTS: We tested 14 apps and 13 functions for each app if that function was available. We conducted 10 cases for each function for a total of 1240 tests. Most functions tested on the apps were accurate in their results with an overall accuracy of 98.6% (17 errors in 1240 tests). In all, 6 of 14 (43%) apps had 100% accuracy. Although 11 of 13 (85%) functions had perfect

accuracy, there were issues with 2 functions: the Child-Pugh scores and Model for End-Stage Liver Disease (MELD) scores on 8 apps. Approximately half of the errors were clinically significant resulting in a significant change in prognosis (8/17, 47%). CONCLUSIONS: The results suggest that most medical calculating apps provide accurate and reliable results. The free apps that were 100% accurate and contained the most functions desired by internists were CliniCalc, Calculate by QxMD, and Medscape. When using medical calculating apps, the answers will likely be accurate; however, it is important to be careful when calculating MELD scores or Child-Pugh scores on some apps. Despite the few errors found, greater scrutiny is warranted to ensure full accuracy of smartphone medical calculator apps.

Binder, Sabine; Deuschl, Gunther; Volkmann, Jens (2009):

Effect of cabergoline on parkinsonian tremor assessed by long-term actigraphy.

In: *Eur Neurol* 61 (3), S. 149–153. DOI: 10.1159/000186505.

Abstract:

BACKGROUND\r\nTremor is one of the cardinal symptoms in Parkinson's disease, but only few clinical studies have focussed on its therapy as the primary endpoint. One reason is the substantial fluctuation of tremor severity over time, which is difficult to capture and may render momentary clinical assessments unreliable.\r\nMETHODS\r\nWe evaluated the usefulness of a novel wrist-worn actigraph allowing long-term recordings of tremor in a pilot study, in which we assessed the therapeutic effect of cabergoline on tremor in 10 patients with tremor-dominant Parkinson's disease. Clinical data were obtained by using the Unified Parkinson's Disease Rating Scale (UPDRS Part III, item 20) and simultaneously a patient's tremor diary.\r\nRESULTS\r\nWe found a significant reduction in UPDRS motor and tremor scores, in tremor duration and tremor amplitude by actigraphy and diaries. Furthermore, we found significant correlations between actigraphy measurements and patient ratings of tremor intensity and occurrence in diaries.\r\nCONCLUSION\r\nLong-term actigraphy is a reliable method to assess tremor occurrence and severity and may be used to document antitremor effects in clinical studies.

Bindhim, Nasser F.; Hawkey, Alexandra; Trevena, Lyndal (2014):

A Systematic Review of Quality Assessment Methods for Smartphone Health Apps.

In: *Telemed J E Health. DOI:* 10.1089/tmj.2014.0088.

Abstract:

Abstract Introduction: There are large numbers of health-related applications (apps) available in various app stores for many smartphone devices. Consequently, increasing numbers of articles are attempting to evaluate the content and the quality of health-related smartphone apps for specific health conditions. The aim of this article is to describe and summarize the methodologies used to determine the quality of health-related apps targeting health consumers and to propose a set of criteria for evaluating the quality of smartphone health-related apps. Materials and Methods: In 2013, literature searches were performed using Medline and CINAHL, and we included all articles that had the aim of assessing the quality of health-related smartphone apps. The assessment method used in these studies was summarized and scored using a set of quality criteria developed for this study. Results: From 606 articles generated by the search, only 10 met the inclusion criteria. Based on our quality criteria, the mean score was 5.05 out of 8 (range, 2-7). Eighty percent of the studies did not identify the app store country in which the apps were found. Forty percent of the studies did not clearly mention whether they only had assessed the app description or had downloaded the app content for evaluation. Sixty percent of the studies did not provide a list of the apps they had evaluated. Overall, we identified six evaluation methodologies used to assess the quality of health-related apps described in Results. Conclusions: This article provides a summary of currently used methods for assessing the quality of smartphone health-related apps and proposes a set of criteria to enable future studies to consistently review health-related app quality in a standardized manner.

Bindhim, Nasser F.; McGeechan, Kevin; Trevena, Lyndal (2014):

Assessing the effect of an interactive decision-aid smartphone smoking cessation application (app) on quit rates: a double-blind automated randomised control trial protocol.

In: *BMJ Open* 4 (7), S. e005371. DOI: 10.1136/bmjopen-2014-005371.

Abstract:

INTRODUCTION: In a previous study exploring the feasibility of a smoking cessation application (app), we found that about 77% of the respondents from three countries were ready to quit in the next 30 days without significant differences between countries in terms of age, operating system and number of quitting attempts. However, the efficacy of smartphone apps for smoking cessation has not yet been established. This study tests the efficacy of a smartphone smoking cessation decision-aid app compared with an app that contains only smoking cessation information. METHODS AND ANALYSIS: This is an automated double-blind, randomised controlled trial of a smoking cessation app that contains the eligibility requirements and baseline questionnaire and will randomise the participants into one of the two subapps (the intervention and the control). Participants will be recruited directly from the Apple app stores in Australia, Singapore, the UK and the USA. Daily smokers aged 18 and above will be randomised into one of the subapps after completing the baseline questionnaire. Abstinence rates will be measured at 10 days, 1 month, 3 months and 6 months, with the 1-month follow-up abstinence rate as the primary outcome. Logistic regression mixed models will be used to analyse the primary outcome. ETHICS AND DISSEMINATION: This study was approved by the University of Sydney's Human Ethics Committee. The results of the trial will be published in peer-reviewed journals according to the CONSORT statement. TRIAL REGISTRATION NUMBER: Australian New Zealand ClinicalTrial RegistryACTRN12613000833763.

Bindhim, Nasser F.; McGeechan, Kevin; Trevena, Lyndal (2014):

Who Uses Smoking Cessation Apps? A Feasibility Study Across Three Countries via Smartphones.

In: *JMIR Mhealth Uhealth* 2 (1), S. e4. DOI: 10.2196/mhealth.2841.

Abstract:

BACKGROUND: Smartphone use is growing worldwide. While hundreds of smoking cessation apps are currently available in the app stores, there is no information about who uses them. Smartphones also offer potential as a research tool, but this has not previously been explored. OBJECTIVE: This study aims to measure and compare the uptake of a smoking cessation app over one year in Australia, the United Kingdom, and the United States. It also assesses the feasibility of conducting research via an app, describing respondents' characteristics (demographics, smoking status, and other health related app use), and examining differences across countries. METHODS: This is a cross-sectional exploratory study of adults 18 years and older, passively recruited over one year in 2012, who downloaded this study app (Quit Advisor) via the two largest app stores (Apple and Android). RESULTS: The total number of app downloads after one year was 1751, 72.98% (1278/1751) of them were Apple operation system users. Of these 1751 participants, 47.68% (835/1751) were from the United States, 29.18% (511/1751) were from the United Kingdom, and 16.68% (292/1751) were from Australia. There were 602 participants, 36.75% (602/1638) that completed a questionnaire within the app. Of these 602 participants, 58.8% (354/602) were female and the mean age was 32 years. There were no significant differences between countries in terms of age, operation system used, number of quitting attempts, and language spoken at home. However, there were significant differences between countries in terms of gender and stage of change. There were 77.2% (465/602) of the respondents that were ready to quit in the next 30 days and the majority of these had never sought professional help (eg, "Quitline"). More than half had downloaded smoking cessation apps in the past and of these, three-quarters had made quitting attempts (lasted at least 24 hours) using an app before. Respondents who had attempted to quit three times or more in the previous year were more likely to have tried smoking cessation apps (OR 3.3, 95% CI 2.1-5.2). There were 50.2% (302/602) of the respondents that had used other health related apps before. Of these, 89.4% (270/302) were using health related apps at least once a week, but 77.5% (234/302) never checked the credibility of the health app publishers before downloading. CONCLUSIONS: A smartphone app was able to reach smokers across three countries that were not seeking professional help, but were ready to quit within the next 30 days. Respondents were relatively young and almost demographically similar across all three countries. They also frequently used other health related apps, mostly without checking the credibility of their publishers.

Birnbaum, Gurit E.; Reis, Harry T.; Mikulincer, Mario; Gillath, Omri; Orpaz, Ayala (2006):

When sex is more than just sex: attachment orientations, sexual experience, and relationship quality.

In: *Journal of Personality and Social Psychology* 91 (5), S. 929–943. DOI: 10.1037/0022-3514.91.5.929.

Abstract:

The authors explored the contribution of individual differences in attachment orientations to the experience of sexual intercourse and its association with relationship quality. In Study 1, 500 participants completed self-report scales of attachment orientations and sexual experience. The findings indicated that whereas attachment anxiety was associated with an ambivalent construal of sexual experience, attachment avoidance was associated with more aversive sexual feelings and cognitions. In Study

2, 41 couples reported on their attachment orientations and provided daily diary measures of sexual experiences and relationship interactions for a period of 42 days. Results showed that attachment anxiety amplified the effects of positive and negative sexual experiences on relationship interactions. In contrast, attachment avoidance inhibited the positive relational effect of having sex and the detrimental relational effects of negative sexual interactions. The authors discuss the possibility that attachment orientations are associated with different sex-related strategies and goals within romantic relationships.

Bisconti, Toni L.; Bergeman, Cindy S.; Boker, Steven M. (2006):

Social support as a predictor of variability: an examination of the adjustment trajectories of recent widows.

In: *Psychology and Aging* 21 (3), S. 590–599. DOI: 10.1037/0882-7974.21.3.590.

Abstract:

The variability pattern of emotional well-being in recent widows across a 98-day period beginning in the first month post-loss has previously been modeled by dynamical systems and shown to be an oscillating process that damps across time. The goal of the present study was to examine how variables that comprise the social support network predict characteristics of these emotional shifts in 28 recent widows. In the present study, emotional support seeking led to a steeper overall trend, whereas perceived control for social support led to a shallower overall trend. When examining intraindividual variability, instrumental support seeking predicted a slower damping rate. Understanding the individual differences in the variability patterns of recent widows is a necessary step in identifying the etiology of adjustment to widowhood.

Bishop, George D.; Ng, Daniel P. K.; Ngau, Francis; Nurbaya, Siti (2010):

Ethnicity, gender, genotype, and anger as related to nocturnal dipping.

In: *Psychophysiology* 47 (6), S. 1094–1101.

Abstract:

Bishop, Pek, and Ngau (2005) found a significant interaction in Singapore between anger and nocturnal dipping among Indians but not Chinese and Malays. The current study examines the role of 5-HTTLPR genotype in this relationship. Two hundred thirty-one undergraduates participated in up to 4 days of 24-h ambulatory monitoring, completed the State-Trait Anger Expression Inventory, and provided blood samples for genotyping of 5-HTTLPR. Results indicated individuals with two copies of the short allele (SS) showed reduced dipping when they were high in Outward Anger (OA) but increased dipping when they were low in OA. Further, for Indian men only, dipping was reduced for individuals having the SS genotype when they were low on Anger In and increased when they were high on Anger In. These data provide further evidence for the role of 5-HTTLPR in cardiovascular risk as well as ethnic differences in the 5-HTTLPR-phenotype relationship. They also provide further evidence for 5-HTTLPR as a "plasticity gene."

Bishop, George D.; Ngau, Francis; Pek, Jolynn (2008):

Domain-specific assessment of anger expression and ambulatory blood pressure.

In: *Personality and Individual Differences* 44 (8), S. 1726–1737.

Abstract:

Bongard and al'Absi (2003) proposed domain-specific anger expression as an improved method for measuring the expression of anger with stronger links to cardiovascular parameters. We tested this proposal by relating their domain-specific measure to ambulatory blood pressure. One hundred and forty-nine Singapore young adults responded to a modified version of the State-Trait Anger Expression Inventory that measured anger expression at home, school/work and leisure and then underwent 24 h ambulatory blood pressure monitoring. Results indicated significant differences in reported anger expression in the three domains measured and also showed that domain-specific measures of anger expression were more strongly related to ambulatory blood pressure than was the general measure of anger expression. These results provide additional evidence for the importance of measures of anger expression that take account of the specific context in which anger occurs.

Bishop, George D.; Pek, Jolynn; Ngau, Francis (2006):

Blunted cardiovascular responses to daytime activities as related to reduced nocturnal blood pressure decline.

In: *Annals of Behavioral Medicine* 31 (3), S. 248–253. DOI: 10.1207/s15324796abm3103_6.

Abstract:

BACKGROUND: Individuals showing less than a 10% decline in blood pressure at night ("nondippers") are known to be at increased risk for hypertension and other cardiovascular conditions. PURPOSE: This research tested the assertion by Raikkonen et al. (1) that nondippers show blunted cardiovascular responses to activities during daytime hours. METHODS: Ambulatory blood pressure and impedance monitoring was performed with 149 young adults in Singapore. At each daytime blood pressure reading, participants completed a computerized questionnaire indicating location, posture, physical activities, feelings, and social interactions. RESULTS: Significant interactions between dipper status and feeling tired, location, posture, and physical activity provided qualified support for the blunting hypothesis. However, blunting of BP responses was not attributable to blunting of either cardiac output or total peripheral resistance responses. CONCLUSION: Nondippers appear to show blunted daytime responses to certain types of daytime activities. However, these effects are limited and appear to be the result of different mechanisms than those responsible for reduced nighttime blood pressure decline.

Björling, Elin A. (2009):

The momentary relationship between stress and headaches in adolescent girls.

In: *Headache* 49 (8), S. 1186–1197. DOI: 10.1111/j.1526-4610.2009.01406.x.

Abstract:

OBJECTIVE\r\nThe objective of this study was to compare the relationship between repeated momentary reports of stress and headaches in female adolescents with varying degrees of headache frequency.\r\nBACKGROUND\r\nHeadaches are the most common form of pain reported by adolescents affecting more than a third of all adolescents. High levels of stress during adolescence may predispose an adolescent to experience headaches in adulthood. Randomized, momentary data collection of stress and headaches provides the most accurate data regarding the adolescent experience of these variables.\r\nMETHODS\r\nThe research methodology, ecological momentary assessment, is a valid approach to better understand the relationship between stress and headaches in adolescence. Data were obtained by each participant's use of an electronic diary (ED), which captured repeated momentary reports of perceived stress, head pain, and stress-related symptoms in female adolescents with varying degrees of recurrent headache. Seven times per day for the 21-day study period, teen girls responded to ED questions about their current stress levels, head pain, and stress-related symptoms. Based on participants' momentary reports of headaches, Low Headache, Moderate Headache, and Chronic Headache groups were created. General estimating equation models were used to analyze the relationship between momentary variables as well as the lag effect between stress and head pain.\r\nRESULTS\r\nThirty-one participants, aged 14-18 years, completed 2841 randomized ED reports and reported 674 occurrences of headache. The Chronic Headache and Moderate Headache groups reported significantly increased levels of stress, head pain, and headaches. The relationship between momentary stress and head pain was significantly strong both within and across participants. The strength of this relationship increased with increased headache activity. A significant lag effect was found between stress and headaches; however, the effect of depression as a moderator of the stress and headache relationship remains unclear.\r\nCONCLUSION\r\nPerceived stress and head pain was highly correlated in these female adolescents. Given the large population of teens affected by headaches, a plausible next step would be to validate these results in other samples and to determine methods with which to identify teens who may be at risk for a pattern of increasing stress and headaches.

Bjornson, Kristie; Song, Kit; Lisle, Jennifer; Robinson, Sarah; Killien, Elizabeth; Barrett, Terry; Zhou, Chuan (2010):

Measurement of walking activity throughout childhood: influence of leg length.

In: *Pediatric Exercise Science* 22 (4), S. 581.

Abstract:

The aim of this study was to describe walking (stride) activity frequency and intensity in 428 children ages 2-15 years with a single accelerometer-based device. With comparison with published pedometer-determined data, the influence of leg length was examined. Decline in stride frequency and intensity throughout childhood increased with adjustment for leg length. The accelerometer-based device documented higher stride counts than published pedometer-based data with the greatest discrepancy in 4-5 year olds. Recommended walking levels for optimal weight throughout childhood should be examined with knowledge of the device measurement differences and the natural history of walking activity changes with age.

Black, Anne C.; Harel, Ofer; Matthews, Gregory (2012):

Techniques for analyzing intensive longitudinal data with missing values. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 339–356. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-019%26site%3dehost-live.

Abstract:

(from the chapter) Longitudinal studies are unique in their requirement of respondents to provide data repeatedly over time. Such studies may require multiple responses in a day, as may occur with experience sampling (or ecological momentary sampling), or may require participants to respond less frequently over a longer period of time. Particular threats to repeated measures studies, and specifically those involving momentary assessment, are fatigue, forgetfulness, noncompliance, and dropout. The result is unplanned missing data (MD). In this chapter, we discuss the problems and causes of missing data in studies of daily life that involve repeated measures, recommend techniques to prevent or minimize the occurrence of missing data, outline how analysts can determine what assumptions are most appropriate for their data, and review typical and best practices for handling incomplete intensive longitudinal data. We present a motivating example, using a subset of data collected by Conner (2009), in which university students were asked to provide daily diary data about their alcohol use and well-being over a 21-day period. In the example, we impose missing values on two variables and illustrate model parameter estimation with various MD techniques, demonstrating the impact of MD and the utility of informed methods for deriving unbiased and efficient estimates. Blaes, Aurélie; Baquet, Georges; van Praagh, Emmanuel; Berthoin, Serge (2011):

Physical activity patterns in French youth--from childhood to adolescence--monitored with high-frequency accelerometry.

In: *American journal of human biology : the official journal of the Human Biology Council* 23 (3), S. 353–358. DOI: 10.1002/ajhb.21142.

Abstract:

OBJECTIVES\r\nTo investigate changes in time spent in light (LPA), moderate (MPA), vigorous (VPA), very high physical activity (VHPA) from childhood to adolescence, according to age and sex, when measured with high frequency accelerometry.\r\nMETHODS\r\nThree hundred and sixty-one children, 94 preschoolers (Ps), 156 from primary schools (PS) and 111 from junior high schools (JHS)) were involved in this study. The children's physical activity was assessed with a uniaxial accelerometer over a seven-day period. The epoch duration was set at 5 s and data collected between 7 am and 9 pm. The times spent below and above different PA thresholds, corresponding from LPA (<3 METs) to VHPA (>9 METs), were calculated.\r\nRESULTS\r\nDuring the week, the boys spent significantly more time in MPA to VHPA than the girls ($p < 0.001$). From Ps to PS, LPA remained stable, while VPA and VHPA decreased significantly ($p < 0.05$). From PS to JHS, time spent in LPA, VPA, and VHPA increased significantly ($p < 0.05$). On the contrary, MPA increased significantly ($p < 0.05$) between Ps and PS and decreased significantly ($p < 0.05$) from PS to JHS. From PS to JHS, time spent in LPA increased significantly more during free days than during school days ($p < 0.05$) while VPA and VHPA increased significantly ($p < 0.05$) more during school days than during free days.\r\nCONCLUSIONS\r\nModerate to very high PA decreased from childhood to adolescence. Changes in PA patterns were associated with an increase of LPA and a concomitant decrease of MPA, while changes were more pronounced during free days than during school days.

"Right on all Occasions?" - On the Feasibility of Laterality Research Using a Smartphone Dichotic Listening Application.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 42. DOI: 10.3389/fpsyg.2013.00042.

Abstract:

Most psychological experimentation takes place in laboratories aiming to maximize experimental control; however, this creates artificial environments that are not representative of real-life situations. Since cognitive processes usually take place in noisy environments, they should also be tested in these contexts. The recent advent of smartphone technology provides an ideal medium for such testing. In order to examine the feasibility of mobile devices (MD) in psychological research in general, and laterality research in particular, we developed a MD version of the widely used speech laterality test, the consonant-vowel

dichotic listening (DL) paradigm, for use with iPhones/iPods. First, we evaluated the retest reliability and concurrent validity of the DL paradigm in its MD version in two samples tested in controlled, laboratory settings (Experiment 1). Second, we explored its ecological validity by collecting data from the general population by means of a free release of the MD version (iDichotic) to the iTunes App Store (Experiment 2). The results of Experiment 1 indicated high reliability (r(ICC) = 0.78) and validity (r(ICC) = 0.76-0.82) of the MD version, which consistently showed the expected right ear advantage (REA). When tested in real-life settings (Experiment 2), participants (N = 167) also showed a significant REA. Importantly, the size of the REA was not dependent on whether the participants chose to listen to the syllables in their native language or not. Together, these results establish the current MD version as a valid and reliable method for administering the DL paradigm both in experimentally controlled as well as uncontrolled settings. Furthermore, the present findings support the feasibility of using smartphones in conducting large-scale field experiments

Bloemers, Jos; Gerritsen, Jeroen; Bults, Richard; Koppeschaar, Hans; Everaerd, Walter; Olivier, Berend; Tuiten, Adriaan (2010):

Induction of sexual arousal in women under conditions of institutional and ambulatory laboratory circumstances: a comparative study.

In: *Journal of Sexual Medicine* 7 (3), S. 1160–1176. DOI: 10.1111/j.1743-6109.2009.01660.x.

Abstract:

INTRODUCTION\r\nMeasuring under naturally occurring circumstances increases ecological validity. We developed an ambulatory psychophysiological laboratory that allows experiments to be performed at home.\r\nAIMS\r\nTo compare institutional laboratory task measures with ambulatory laboratory task measures.\r\nMAIN OUTCOME MEASURES\r\nVaginal pulse amplitude (VPA), clitoral blood volume (CBV), subjective report of sexual arousal, preconscious attentional bias for erotic stimuli, subjective reports about feeling at ease, tense, anxious or inhibited.\r\nMETHODS\r\nVPA and CBV were measured in eight women with hypoactive sexual desire disorder (HSDD) and eight healthy controls while exposed to neutral and erotic film clips both in the institute's laboratory and at home. Before and after film clip presentations, subjects performed an emotional Stroop task and completed two questionnaires.\r\nRESULTS\r\nIn healthy controls, genital measures of sexual arousal were significantly increased at home compared with the institutional laboratory, whereas no differences were observed between the institutional laboratory and the at home measurements in women with HSDD. The responses at home were significantly higher in healthy controls compared with women with HSDD. Subjective experience of genital responding increased at home for both groups of women. Concordance between subjective experience and genital sexual arousal was more pronounced in the institutional laboratory setting. Preconscious attentional bias was stronger in the institutional laboratory for both groups of women. Healthy controls felt more at ease and less inhibited at home while subjects with HSDD did not.\r\nCONCLUSIONS\r\nThe use of an ambulatory laboratory is a valuable tool allowing psychophysiological (sex) research under more natural circumstances (e.g., a participant's home). In this study, the increase in ecological validity resulted in a qualitative differentiation between the healthy controls and the women with HSDD in the home setting, which is not apparent in the artificial setting of the institutional laboratory.

Blood, Emily A.; Shrier, Lydia A. (2013):

The temporal relationship between momentary affective states and condom use in depressed adolescents.

In: *Archives of Sexual Behavior*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-00722-001%26site%3dehost-live;emily.blood@childrens.harvard.edu.

Abstract:

Depressed adolescents are more likely to engage in sexual risk behaviors than their non-depressed peers. The objectives of this study were (1) to examine whether affective states predicted subsequent condom use, directly or indirectly through contextual factors and (2) to compare results obtained from structural equation models versus non-linear mixed effects models. This study used ecological momentary assessment to collect data on in-the-moment affective states and sexual behavior from 51 depressed adolescents (7 male, 44 female) aged 15–22-�years. The association between positive and negative affect and condom use during a subsequent sex event was explored using several structural equation models and non-linear mixed effects models. Potential mediation by substance use before sex, partner type, reason for sex, and who wanted sex was examined. Neither positive nor negative affect was directly associated with condom use in any models; however, negative affect was associated with increased likelihood of sex with a non-main partner, which, in turn, was associated with increased condom use. Both structural equation models and non-linear mixed effects models successfully modeled the relationship between affect and condom use in momentary data while correctly accounting for the correlation of multiple observations from the same individual. The benefit of structural equation modeling was the ability to directly model the mediation of this effect by contextual factors. In

this sample of depressed adolescents, negative and positive affect did not appear to be directly predictive of condom use during a subsequent sex event, although may indirectly affect condom use through sex with a non-main partner. Combining accelerometry and HR for assessing preschoolers' physical activity.

In: *Med Sci Sports Exerc* 42 (12), S. 2237–2243. DOI: 10.1249/MSS.0b013e3181e27b5d.

Abstract:

PURPOSE\r\nWith rising obesity and rapidly decreasing levels of physical activity (PA) in young children, accurate PA measurement is needed for early screening and intervention evaluation. Although the combination of accelerometry (ACC) with HR recordings is accurate in assessing PA intensity in older children, its utility in correctly classifying PA in preschoolers is unknown.\r\nMETHODS\r\nThirty-three children (64% were boys) were recruited from four German preschools. Data included direct observation and Actiheart (CamNtech, Cambridge, UK) monitoring during 2.5 T 0.7 h (derivation data) and 1.5 T 0.3 h (validation data). Observers assessed PA using the Children's Activity Rating Scale (CARS). Moderate-to-vigorous PA (MVPA) was defined by a CARS score of 4 or 5, and sedentary behavior (SB) was defined by a CARS score of 1 or 2. Actiheart recordings were linked to CARS level, with means and 95% confidence intervals calculated for ACC and HR at each observed CARS level and for MVPA/SB. Using receiver operating characteristic analysis, gender-specific ACC and HR cutoffs for correctly classifying MVPA and SB were first determined in a derivation data set and then tested in a separate validation data set of observations.\r\nRESULTS\r\nBy combining HR and ACC cutoffs, 91% and 87% of the 15-s intervals observed as MVPA were correctly classified in girls and boys, respectively. Although generally lower, correct classification rates for SB were highest when only ACC cutoffs were applied (69% for girls and 67% for boys) rather than when combined cutoffs were used.\r\nCONCLUSIONS\r\nDevices that combine HR and ACC data yield an accurate classification of MVPA in preschoolers but perform less well for classifying SB. These differences underscore the need to match evaluation methods with the objectives of future PA interventions.

Bogers, R. P.; Bolte, J. F.; Houtveen, J. H.; Lebret, E.; van Strien, R. T.; Schipper, C. M. et al. (2013):

Design of an ecological momentary assessment study of exposure to radiofrequency electromagnetic fields and non-specific physical symptoms.

In: *BMJ Open* 3 (8), S. e002933. DOI: 10.1136/bmjopen-2013-002933.

Abstract:

INTRODUCTION: Idiopathic Environmental Intolerance (IEI) attributed to electromagnetic fields (EMF) refers to self-reported sensitivity mainly characterised by the attribution of non-specific physical symptoms to low-level EMF exposure emitted from sources such as mobile phones. Scientific studies have not provided evidence for the existence of IEI-EMF, but these studies did not resemble the real-life situation or suffered from poor exposure characterisation and biased recall of health symptoms. To improve existing methods for the study of IEI-EMF, an Ecological Momentary Assessment (EMA) study is designed. METHODS AND ANALYSIS: The study is an EMA study in which respondents carry personal exposure metres (exposimeters) that measure radiofrequency (RF) EMF, with frequent assessment of health symptoms and perceived EMF exposure through electronic diary registration during five consecutive days. Participants will be a selection from an epidemiological study who report to be sensitive to RF EMF. The exposimeters measure electric field strength in 12 frequency bands. Diary questions include the occurrence and severity of 10 non-specific physical symptoms, mood states and perceived exposure to (sources of) EMF. The relationship of actual and perceived EMF exposure and mood with non-specific physical symptoms will be analysed using multilevel regression analysis with time-shift models. DISCUSSION: The study has several advantages over previous studies, including assessment of personal EMF exposure and non-specific physical symptoms by an ecological method with a minimised chance of recall bias. The within-person design reduces confounding by time-stable factors (eg, personal characteristics). In the conduct of the study and the analysis and interpretation of its outcomes, some methodological issues including a high participant burden, reactivity, compliance to the study protocol and the potential of chance findings due to multiple statistical testing will be accounted for and limited as much as possible

Multimethod analyses of discretionary time use and health behaviors among urban low-income African-American adolescents: A pilot study.

In: *Journal of Developmental and Behavioral Pediatrics* 34 (8), S. 589–598. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-36758-009%26site%3dehost-live;kburdette@luc.edu.

Abstract:

Objective: The objective of this pilot study was to examine the relations between discretionary time (DT) social context, health behaviors (dietary intake and physical activity), and body mass index (BMI) in a sample of urban low-income African-American early adolescents. Methods: Multiple methods were used, including accelerometers, 24-hour dietary recalls, anthropometric measurements, and Experience Sampling Method (ESM). Participants included 9 boys (mean = 12.9 years) and 16 girls (mean = 12.9 years). Sixteen participants were at a healthy weight (10 girls and 6 boys), and 9 were overweight or obese (5 girls and 3 boys). Results: Eighth graders had higher BMI z scores, engaged in less healthful eating during DT, and spent less time in vigorous exercise in DT than sixth graders. Participants spent the majority of DT with siblings, which was associated with increased light physical activity as measured by accelerometers. The ESM data suggested that adolescents engaged in increased physical activity and decreased sedentary activity when with peers but increased sedentary activity when with parents. Increased percentage of DT spent with parents was associated with increased daily fat intake. Data also indicate high consumption of unhealthy foods across all DT social contexts and activities. Conclusions: Peers may provide a protective social context with regard to obesity-related health behaviors. Targeting changes in health behaviors during the middle school years may be an effective means of decreasing obesity risk among urban African-American adolescents. Interventions for urban African-American early adolescents may benefit from facilitating physical activity with peers and targeting change in family health behaviors. Young urban african american adolescents' experience of discretionary time activities.

In: *Journal of Research on Adolescence* 18 (3), S. 517–539.

Abstract:

This cross-sectional study examined the daily discretionary time experiences of 246 (107 boys, 139 girls) fifth through eighth grade urban African American adolescents using the Experience Sampling Method. Relations between the types of activities (i.e., active structured, active unstructured, passive unstructured) engaged in during discretionary time and self-reported levels of motivated engagement, positive affect, confidence, and perceived alienation were explored. Results indicated that active structured activities occupied a small but important amount of young adolescents' discretionary time. Adolescents experienced the highest mean levels of motivated engagement and confidence, and the lowest mean levels of alienation when involved in these types of activities. Higher levels of positive affect were associated with participation in active as opposed to passive activities. Findings suggest that urban African American young adolescents experience more positive emotional states when they are involved in active, structured activities.

Home Blood Pressure Monitoring: A Few minutes of Rest Before Measurement May Not Be Appropriate.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu001.

Abstract:

BACKGROUND: Home blood pressure measurement (HBPM) is recommended for the diagnosis and follow-up of hypertensive patients. While measurement protocols emphasize a rest period before taking the measurement, this directive has not been supported by any specific study to date. This analysis aimed to determine whether the respect or nonrespect of rest before HBPM could introduce a difference between daytime ambulatory blood pressure measurement (ABPM) and HBPM; whether this rest is observed "in real life" among educated hypertensive patients. METHODS: In this open, prospective study we compared HBPM, with and without rest, and ABPM among 52 office/clinically controlled hypertensive patients. HBPM was performed during 3 days (French HAS instructions); 24-hour ABPM was performed within 3 days of HBPM. All patients who regularly performed HBPM before the study were asked how they practiced HBPM in real life. RESULTS: There was a differential impact of rest on differences observed in daytime ABPM and HBPM. Systolic HBPM decreased with rest, while diastolic HBPM did not significantly increase. HBPM systolic BP (SBP) without rest was not significantly different from daytime ABPM SBP (P = 0.27).

HBPM SBP without rest was lower than daytime and 24-hour systolic ABPM. Diastolic HBPM after rest was not significantly different from daytime diastolic ABPM (P = 0.09). None of the 38 patients who regularly performed HBPM were compliant with a period of rest before beginning the measurements. CONCLUSIONS: Rest before HBPM induces a bias that underestimates SBP vs. daytime ABPM and perhaps complicates patient adherence to HBPM protocols.

Bolkhovsky, J. B.; Scully, C. G.; Chon, K. H. (2012):

Statistical analysis of heart rate and heart rate variability monitoring through the use of smart phone cameras.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 1610–1613. DOI: 10.1109/EMBC.2012.6346253.

Abstract:

Video recordings of finger tips made using a smartphone camera contain a pulsatile component caused by the cardiac pulse equivalent to that present in a photoplethysmographic signal. By performing peak detection on the pulsatile signal it is possible to extract a continuous heart rate signal. We performed direct comparisons between 5-lead electrocardiogram based heart rate variability measurements and those obtained from an iPhone 4s and Motorola Droid derived pulsatile signal to determine the accuracy of heart rate variability measurements obtained from the smart phones. Monitoring was performed in the supine and tilt positions for independent iPhone 4s (2 min recordings, n=9) and Droid (5 min recordings, n=13) experiments, and the following heart rate and heart rate variability parameters were estimated: heart rate, low frequency power, high frequency power, ratio of low to high frequency power, standard deviation of the RR intervals, and root mean square of successive RR-differences. Results demonstrate that accurate heart rate variability parameters can be obtained from smart phone based measurements

Bolszak, Sylvain; Casartelli, Nicola C.; Impellizzeri, Franco M.; Maffiuletti, Nicola A. (2014):

Validity and reproducibility of the Physical Activity Scale for the Elderly (PASE) questionnaire for the measurement of the physical activity level in patients after total knee arthroplasty.

In: *BMC Musculoskelet Disord* 15, S. 46. DOI: 10.1186/1471-2474-15-46.

Abstract:

BACKGROUND: The need for valid and reproducible questionnaires to routinely assess the physical activity level of patients after total knee arthroplasty (TKA) is of particular concern in clinical settings. Aims of this study were to evaluate the validity and reproducibility of the physical activity scale for the elderly (PASE) questionnaire in TKA patients, with a particular view on gender differences. METHODS: A total of 50 elderly patients (25 women and 25 men aged 70 +/- 6 years) following primary unilateral TKA were recruited. The reproducibility was evaluated by administering the PASE questionnaire during two occasions separated by 7 days. The construct (criterion) validity was investigated by comparing the physical activity level reported by patients in the PASE questionnaire to that measured by accelerometry. Reproducibility was evaluated using intraclass correlation coefficients (ICC3,1) for reliability and standard error of measurement (SEM) and smallest detectable change (SDC) for agreement, while validity was investigated with Pearson correlation coefficients. RESULTS: Reliability of the PASE total score was acceptable for men (ICC = 0.77) but not for women (ICC = 0.58). Its agreement was low for both men and women, as witnessed by high SEM (32% and 35%, respectively) and SDC (89% and 97%, respectively). Construct validity of the PASE total score was low in both men (r = 0.45) and women (r = 0.06). CONCLUSIONS: The PASE questionnaire has several validity and reproducibility shortcomings, therefore its use is not recommended for the assessment of physical activity level in patients after TKA, particularly in women.

Pre-to Postoperative Physical Activity Changes in Bariatric Surgery Patients: Self Report vs. Objective Measures.

In: *Obesity* 18 (12), S. 2395–2397.

Abstract:

Bariatric surgery patients report significant pre- to postoperative increases in physical activity (PA). However, it is unclear whether objective measures would corroborate these changes. The present study compared self-reported and accelerometer-based estimates of changes in moderate-to-vigorous intensity PA (MVPA) from pre- (pre-op) to 6 months postsurgery (post-op). Twenty bariatric surgery (65% laparoscopic-adjustable gastric banding, 35% gastric bypass) patients (46.2 ± 9.8 years, 88% female, pre-op BMI = 50.8 ± 9.7 kg/m2) wore RT3 accelerometers as an objective measure of MVPA and completed the Paffenbarger Physical Activity Questionnaire (PPAQ) as a subjective measure before and 6 months after bariatric surgery. Time (min/week) spent in MVPA was calculated for the PPAQ and RT3 (≥1-min and ≥10-min bouts) at pre-op and post-op. Self-reported MVPA increased fivefold from pre-op to post-op (44.6 ± 80.8 to 212.3 ± 212.4 min/week; P < 0.005). By contrast, the RT3 showed nonsignificant decreases in MVPA for both ≥1-min (186.0 ± 169.0 to 151.2 ± 118.3 min/week) and ≥10-min (41.3 ± 109.3 to 39.8 ± 71.3 min/week) bouts. At pre-op, the percentage of participants who accumulated ≥150-min/week of MVPA in bouts ≥10-min according to the PPAQ and RT3 was identical (10%). However, at post-op, 55% of participants reported compliance with the recommendation compared to 5% based on RT3 measurement (P = 0.002). Objectively-measured changes in MVPA from pre-op to 6 months post-op appear to be much smaller than self-reported changes. Further research involving larger samples is needed to confirm these findings and to determine whether self-report and objective PA measures are differentially associated with surgical weight loss outcomes.

Bond, Dale S.; Thomas, J. Graham; Ryder, Beth A.; Vithiananthan, Sivamainthan; Pohl, Dieter; Wing, Rena R. (2013):

Ecological momentary assessment of the relationship between intention and physical activity behavior in bariatric surgery patients.

In: *International Journal of Behavioral Medicine* 20 (1), S. 82–87. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-06261-012%26site%3dehost-live;dbond@lifespan.org.

Abstract:

Background: Performing habitual physical activity (PA) is challenging for many bariatric surgery patients. Purpose: We used electronic ecological momentary assessment to naturalistically examine whether insufficient PA among bariatric surgery patients was due to infrequent PA intentions or inadequate follow through on PA intentions. Method: Twenty-one patients 6-months post-bariatric surgery were recruited from multiple clinics in Providence, Rhode Island, USA. Participants used a palmtop computer upon waking for 6 days to indicate whether they intended to be active, and if so, the amount of PA they intended to perform in bouts ≥10 min. Each evening, participants reported PA minutes and barriers encountered that day. Results: All 21 participants reported intending to be active on at least 1 day but only 9 (42%) intended to be active on ≥70% of days. Twelve (57%) participants performed PA on each of the days they intended, but none achieved the amount of PA they intended on all of these days. Overall, participants had PA intentions on 81 of 123 days (66%); these were partially implemented (≥10 PA minutes) on 49 days, but fully implemented on only 15 days. Participants spent 34 min in PA, or 20 fewer minutes than intended. “Lack of time” was the only frequently cited barrier, particularly on days that PA was neither intended nor performed. Conclusion: Few patients intended to be active on a near daily basis and all patients had difficulty in implementing their intentions. Interventions that target planning strategies may help facilitate PA intentions and limit discrepancy between intended and actual PA. Bond, Dale S.; Thomas, J. Graham; Raynor, Hollie A.; Moon, Jon; Sieling, Jared; Trautvetter, Jennifer et al. (2014):

B-MOBILE - A Smartphone-Based Intervention to Reduce Sedentary Time in Overweight/Obese Individuals: A Within-Subjects Experimental Trial.

In: *PLoS One* 9 (6), S. e100821. DOI: 10.1371/journal.pone.0100821.

Abstract:

PURPOSE: Excessive sedentary time (SED) has been linked to obesity and other adverse health outcomes. However, few sedentary-reducing interventions exist and none have utilized smartphones to automate behavioral strategies to decrease SED. We tested a smartphone-based intervention to monitor and decrease SED in overweight/obese individuals, and compared 3 approaches to prompting physical activity (PA) breaks and delivering feedback on SED. DESIGN AND METHODS: Participants [N = 30; Age = 47.5(13.5) years; 83% female; Body Mass Index (BMI) = 36.2(7.5) kg/m2] wore the SenseWear Mini Armband (SWA) to objectively measure SED for 7 days at baseline. Participants were then presented with 3 smartphone-based PA break conditions in counterbalanced order: (1) 3-min break after 30 SED min; (2) 6-min break after 60 SED min; and (3) 12-min break after 120 SED min. Participants followed each condition for 7 days and wore the SWA throughout. RESULTS: All PA break conditions yielded significant decreases in SED and increases in light (LPA) and moderate-to-vigorous PA (MVPA) (p<0.005). Average % SED at baseline (72.2%) decreased by 5.9%, 5.6%, and 3.3% [i.e. by mean (95% CI) -47.2(-66.3, -28.2), -44.5(-65.2, -

23.8), and -26.2(-40.7, -11.6) min/d] in the 3-, 6-, and 12-min conditions, respectively. Conversely, % LPA increased from 22.8% to 26.7%, 26.7%, and 24.7% [i.e. by 31.0(15.8, 46.2), 31.0(13.6, 48.4), and 15.3(3.9, 26.8) min/d], and % MVPA increased from 5.0% to 7.0%, 6.7%, and 6.3% (i.e. by 16.2(8.5, 24.0), 13.5(6.3, 20.6), and 10.8(4.2, 17.5) min/d] in the 3-, 6-, and 12-min conditions, respectively. Planned pairwise comparisons revealed the 3-min condition was superior to the 12-min condition in decreasing SED and increasing LPA ($p<0.05$). CONCLUSION: The smartphone-based intervention significantly reduced SED. Prompting frequent short activity breaks may be the most effective way to decrease SED and increase PA in overweight/obese individuals. Future investigations should determine whether these SED reductions can be maintained long-term. TRIAL REGISTRATION: ClinicalTrials.gov NCT01688804.

Bonmati-Carrion, M. A.; Middleton, B.; Revell, V.; Skene, D. J.; Rol, M. A.; Madrid, J. A. (2013):

Circadian phase asessment by ambulatory monitoring in humans: Correlation with dim light melatonin onset.

In: *Chronobiol.Int.* (0742-0528 (Linking)). DOI: 10.3109/07420528.2013.820740.

Abstract:

The increased prevalence of circadian disruptions due to abnormal coupling between internal and external time makes the detection of circadian phase in humans by ambulatory recordings a compelling need. Here, we propose an accurate practical procedure to estimate circadian phase with the least possible burden for the subject, that is, without the restraints of a constant routine protocol or laboratory techniques such as melatonin quantification, both of which are standard procedures. In this validation study, subjects (N = 13) wore ambulatory monitoring devices, kept daily sleep diaries and went about their daily routine for 10 days. The devices measured skin temperature at wrist level (WT), motor activity and body position on the arm, and light exposure by means of a sensor placed on the chest. Dim light melatonin onset (DLMO) was used to compare and evaluate the accuracy of the ambulatory variables in assessing circadian phase. An evening increase in WT: WTOnset (WTOn) and "WT increase onset" (WTiO) was found to anticipate the evening increase in melatonin, while decreases in motor activity (Activity Offset or AcOff), body position (Position Offset (POff)), integrative TAP (a combination of WT, activity and body position) (TAPOffset or TAPOff) and an increase in declared sleep propensity were phase delayed with respect to DLMO. The phase markers obtained from subjective sleep (R = 0.811), WT (R = 0.756) and the composite variable TAP (R = 0.720) were highly and significantly correlated with DLMO. The findings strongly support a new method to calculate circadian phase based on WT (WTiO) that accurately predicts and shows a temporal association with DLMO. WTiO is especially recommended due to its simplicity and applicability to clinical use under conditions where knowing endogenous circadian phase is important, such as in cancer chronotherapy and light therapy

Bonomi, A. G.; Plasqui, G.; Goris, A. H. C.; Westerterp, K. R. (2012):

Aspects of activity behavior as a determinant of the physical activity level.

In: *Scandinavian Journal of Medicine & Science in Sports* 22 (1), S. 139–145. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-01552-019&site=ehost-live;a.bonomi@HB.unimaas.nl.

Abstract:

This study investigated which aspects of the individuals' activity behavior determine the physical activity level (PAL). Habitual physical activity of 20 Dutch adults (age: 26-60 years, body mass index: 24.5 ± 2.7 kg/m(2)) was measured using a tri-axial accelerometer. Accelerometer output was used to identify the engagement in different types of daily activities with a classification tree algorithm. Activity behavior was described by the daily duration of sleeping, sedentary behavior (lying, sitting, and standing), walking, running, bicycling, and generic standing activities. Simultaneously, the total energy expenditure (TEE) was measured using doubly labeled water. PAL was calculated as TEE divided by sleeping metabolic rate. PAL was significantly associated ($P<0.05$) with sedentary time ($R=-0.72$), and the duration of walking ($R=0.49$), bicycling ($R=0.77$), and active standing ($R=0.62$). A negative association was observed between sedentary time and the duration of active standing ($R=-0.87$; $P<0.001$). A multiple-linear regression analysis showed that 75% of the variance in PAL could be predicted by the duration of bicycling (Partial R(2) =59%; $P<0.01$), walking (Partial R(2) =9%; $P<0.05$) and being sedentary (Partial R(2) =7%; $P<0.05$). In conclusion, there is objective evidence that sedentary time and activities related to transportation and commuting, such as walking and bicycling, contribute significantly to the average PAL.

Boon, R. M.; Hamlin, M. J.; Steel, G. D.; Ross, J. J. (2010):

Validation of the New Zealand Physical Activity Questionnaire (NZPAQ-LF) and the International Physical Activity Questionnaire (IPAQ-LF) with accelerometry.

In: *British Journal of Sports Medicine* 44 (10), S. 741–746. DOI: 10.1136/bjsm.2008.052167.

Abstract:

BACKGROUND\r\nValidation of instruments used to measure physical activity patterns is essential when attempting to assess the effectiveness of physical activity interventions.\r\nOBJECTIVES\r\nTo assess the validity of two self-report physical activity questionnaires on a representative sample of New Zealand adults.\r\nMETHODS\r\n70 adults aged 18-65 years from around Christchurch, New Zealand were required to wear an ActiGraph GT1M accelerometer during all waking hours for 7 consecutive days. Immediately following the 7 day accelerometer period participants were required to complete the long forms of both the New Zealand Physical Activity Questionnaire (NZPAQ-LF) and the International Physical Activity Questionnaire (IPAQ-LF).\r\nRESULTS\r\nBoth the NZPAQ-LF and the IPAQ-LF questionnaires showed small to moderate correlations with ActiGraph data for time spent in moderate-intensity physical activity (r=0.19-0.30) and total physical activity (sum of moderate and vigorous-intensity physical activity, r=0.30-0.32). In comparison with the ActiGraph data, both self-report questionnaires tended to overestimate activity levels by approximately 165%. Total physical activity levels gathered from both questionnaires were strongly correlated with each other (r=0.79) and showed good levels of agreement in the Bland-Altman plots.\r\nCONCLUSIONS\r\nThe long forms of the NZPAQ and IPAQ were found to have acceptable validity when detecting participants' ability to meet activity guidelines based on exercise duration, but a significant amount of overestimation was evident. This presents a need for both instruments to be further developed and tested in order to increase validity.

Booth, J. N.; Leary, S. D.; Joinson, C.; Ness, A. R.; Tomporowski, P. D.; Boyle, J. M.; Reilly, J. J. (2014):

Associations between objectively measured physical activity and academic attainment in adolescents from a UK cohort.

In: *Br.J.Sports Med.* 48 (3), S. 265–270. DOI: 10.1136/bjsports-2013-092334.

Abstract:

BACKGROUND: To test for cross-sectional (at age 11) and longitudinal associations between objectively measured free-living physical activity (PA) and academic attainment in adolescents.Method Data from 4755 participants (45% male) with valid measurement of PA (total volume and intensity) by accelerometry at age 11 from the Avon Longitudinal Study of Parents and Children (ALSPAC) was examined. Data linkage was performed with nationally administered school assessments in English, Maths and Science at ages 11, 13 and 16. RESULTS: In unadjusted models, total volume of PA predicted decreased academic attainment. After controlling for total volume of PA, percentage of time spent in moderate-vigorous intensity PA (MVPA) predicted increased performance in English assessments in both sexes, taking into account confounding variables. In Maths at 16 years, percentage of time in MVPA predicted increased performance for males (standardised beta=0.11, 95% CI 0.00 to 0.22) and females (beta=0.08, 95% CI 0.00 to 0.16). For females the percentage of time spent in MVPA at 11 years predicted increased Science scores at 11 and 16 years (beta=0.14 (95% CI 0.03 to 0.25) and 0.14 (0.07 to 0.21), respectively). The correction for regression dilution approximately doubled the standardised beta coefficients. CONCLUSIONS: Findings suggest a long-term positive impact of MVPA on academic attainment in adolescence

Borgogna, Nicholas; Lockhart, Ginger; Grenard, Jerry L.; Barrett, Tyson; Shiffman, Saul; Reynolds, Kim D. (2014):

Ecological Momentary Assessment of Urban Adolescents' Technology Use and Cravings for Unhealthy Snacks and Drinks: Differences by Ethnicity and Sex.

In: *J Acad Nutr Diet. DOI:* 10.1016/j.jand.2014.10.015.

Abstract:

BACKGROUND: Adolescents' technology use is generally associated with food cravings, but it is not clear whether specific types of technology elicit particular types of cravings or whether personal characteristics play a role in these associations. OBJECTIVE: We examined whether momentary associations between four technology types (ie, television, video games, computer messaging, and phone messaging) and cravings for unhealthy snack foods and sweetened drinks were moderated by youths' sex, ethnicity, body mass index, and age. METHODS: Urban adolescents (N=158) aged 14 to 17 years provided momentary information about their technology use and food cravings during the course of 1 week and completed survey reports of their personal characteristics. We used multilevel modeling to determine momentary associations and interactions. RESULTS: Non-Hispanic adolescents showed stronger associations between television exposure and cravings for sweet snacks, salty snacks, and

sweetened drinks. Being Hispanic was associated with stronger associations between phone messaging and cravings for sweet snacks, salty snacks, and sweetened drinks. Males showed stronger associations between video game use and salty snack cravings. CONCLUSIONS: As the public health field continues to monitor the effects of technology use on adolescents' eating and overall health, it will be important to determine the extent to which these groups are differentially affected by different forms of technology.

Invisible computing: automatically using the many bits of data we create.

In: *Philosophical Transactions of the Royal Society of London A: Mathematical, Physical and Engineering Sciences* 366 (1881), S. 3669–3683. DOI: 10.1098/rsta.2008.0128.

Abstract:

As we go about our work and our daily lives, we leave a trail of bits behind. Every electronic device we interact with can keep a record of our actions. Even the devices themselves can keep track of their location and radio interactions, even without user involvement. The challenge of invisible computing is to make this wealth of data useful. This paper presents two examples of what has come to be known as 'invisible computing', namely, devices recording, distilling and rendering these many bits of data without unduly taxing human users. The first example is focused on a work environment. Labscape automates the record keeping required of experimenters in a cell biology laboratory. The second example looks at more ad hoc interactions. RFID Ecosystem is a collection of radio-frequency identification (RFID) readers and databases that collect the sightings of passive RFID tags, attached to people and objects, as they move throughout a large building. It provides services such as people and object finding as well as diary keeping.

Changes to volumetric bone mineral density and bone strength after stroke: A prospective study.

In: *Int J Stroke. DOI:* 10.1111/ijs.12228.

Abstract:

RATIONALE AND AIM: Stroke survivors experience accelerated bone loss and increased fracture risk, particularly in paretic weight bearing limbs. Understanding how these changes unfold and their relationship to stroke severity and physical activity could help in the development of targeted interventions to prevent or reduce the severity of these outcomes. The primary aim of this study is to investigate the time course and magnitude of changes in volumetric bone mineral density within the first year after stroke, and to examine relationships with physical activity and motor recovery. DESIGN: This is a prospective, observational study of 43 nondiabetic, nonambulant adults with first ever hemispheric stroke. PRIMARY OUTCOME: The primary outcome was the difference in six-month change of total volumetric bone mineral density between paretic and nonparetic distal tibiae, measured at 7% of bone length site using high-resolution peripheral quantitative computed tomography. SECONDARY OUTCOMES: The secondary outcomes are cortical and trabecular volumetric bone mineral density, cortical thickness, and total and cross-sectional areas of distal tibiae and radii of paretic and nonparetic limbs. Also included are total body and regional bone mineral density derived using dual-energy X-ray absorptiometry, physical activity measured using accelerometry, and motor recovery (Chedoke McMaster Stroke Assessment). DISCUSSION: Measuring the timing and magnitude of changes to volumetric bone mineral density and bone structure from immediately after stroke, and relationships between these changes with physical activity and motor recovery will provide the basis for targeted interventions to reduce fracture risk in stroke survivors.

Cardiovascular changes in workers exposed to fine particulate dust.

In: *Int J Occup Med Environ Health* 27 (1), S. 78–92. DOI: 10.2478/s13382-014-0234-3.

Abstract:

OBJECTIVES: Epidemiological studies provide evidence that airborne particulate matter may contribute to the increased incidence and mortality rates due to pulmonary and cardiovascular diseases. Only some of them address the problem of occupational exposure to particulate air pollution. The aim of our study was to assess cardiovascular reaction and autonomic

regulation in workers exposed to fine particles. MATERIALS AND METHODS: All workers had medical examination, resting ECG with heart rate variability analysis (HRV), 24-h ECG, and ambulatory blood pressure monitoring (ABPM) performed. The subjects were 20 male workers (mean age: 32.14.0 year) of a ceramic ware factory exposed to the dust and 20 workers who were not exposed (mean age: 39.4+/-7.8 year). The period of employment under exposure amounted to 5.6+/-2.1 year. Dust exposure was measured using individual dosimeters. RESULTS: The geometric mean total dust concentration was 44+/-1.5 mg/m(3) and the FPD (fine particulate dust) concentration amounted to 11.5+/-1.6 mg/m(3). No abnormalities were noted in the resting ECG in both groups, in 24-h ECG 2 subjects, both from exposed and control groups, had ventricular heart rhythm and repolarization disturbances. Blood pressure in ABPM, both systolic as well as diastolic, was normal and did not differ between the groups. Resting heart rate in the exposed group was significantly lower (p = 0.038) than in the control group. In the exposed group STD R-R from short-term records was significantly higher (p = 0.01). Fast Fourier Transform (FFT) analysis showed that the low frequency power spectrum (LF) did not differ in the exposed and the control group, while high frequency (HF) was significantly higher in the exposed group. LF/HF ratio was significantly lower in the exposed in comparison with the control group. CONCLUSIONS: Although we did not reveal significant abnormalities in ECG as well as in ABPM in the exposed group, it seems that neurovegetative disturbances (parasympathetic predominance) may serve as an early indicator of fine particulate dust effect on cardiovascular system.

Measuring and Influencing Physical Activity with Smartphone Technology: A Systematic Review.

In: *Sports Med. DOI:* 10.1007/s40279-014-0142-5.

Abstract:

BACKGROUND: Rapid developments in technology have encouraged the use of smartphones in physical activity research, although little is known regarding their effectiveness as measurement and intervention tools. OBJECTIVE: This study systematically reviewed evidence on smartphones and their viability for measuring and influencing physical activity. DATA SOURCES: Research articles were identified in September 2013 by literature searches in Web of Knowledge, PubMed, PsycINFO, EBSCO, and ScienceDirect. STUDY SELECTION: The search was restricted using the terms (physical activity OR exercise OR fitness) AND (smartphone* OR mobile phone* OR cell phone*) AND (measurement OR intervention). Reviewed articles were required to be published in international academic peer-reviewed journals, or in full text from international scientific conferences, and focused on measuring physical activity through smartphone processing data and influencing people to be more active through smartphone applications. STUDY APPRAISAL AND SYNTHESIS METHODS: Two reviewers independently performed the selection of articles and examined titles and abstracts to exclude those out of scope. Data on study characteristics, technologies used to objectively measure physical activity, strategies applied to influence activity; and the main study findings were extracted and reported. RESULTS: A total of 26 articles (with the first published in 2007) met inclusion criteria. All studies were conducted in highly economically advantaged countries; 12 articles focused on special populations (e.g. obese patients). Studies measured physical activity using native mobile features, and/or an external device linked to an application. Measurement accuracy ranged from 52 to 100 % (n = 10 studies). A total of 17 articles implemented and evaluated an intervention. Smartphone strategies to influence physical activity tended to be ad hoc, rather than theory-based approaches; physical activity profiles, goal setting, real-time feedback, social support networking, and online expert consultation were identified as the most useful strategies to encourage physical activity change. Only five studies assessed physical activity intervention effects; all used step counts as the outcome measure. Four studies (three pre-post and one comparative) reported physical activity increases (12-42 participants, 800-1,104 steps/day, 2 weeks-6 months), and one case-control study reported physical activity maintenance (n = 200 participants; >10,000 steps/day) over 3 months. LIMITATIONS: Smartphone use is a relatively new field of study in physical activity research, and consequently the evidence base is emerging. CONCLUSIONS: Few studies identified in this review considered the validity of phone-based assessment of physical activity. Those that did report on measurement properties found average-to-excellent levels of accuracy for different behaviors. The range of novel and engaging intervention strategies used by smartphones, and user perceptions on their usefulness and viability, highlights the potential such technology has for physical activity promotion. However, intervention effects reported in the extant literature are modest at best, and future studies need to utilize randomized controlled trial research designs, larger sample sizes, and longer study periods to better explore the physical activity measurement and intervention capabilities of smartphones.

Borujeny, G. T.; Yazdi, M.; Keshavarz-Haddad, A.; Borujeny, A. R. (2013):

Detection of epileptic seizure using wireless sensor networks.

In: *J.Med.Signals Sens.* 3 (2), S. 63–68. Online verfügbar unter PM:24098859.

Abstract:

The monitoring of epileptic seizures is mainly done by means of electroencephalogram (EEG) monitoring. Although this method is accurate, it is not comfortable for the patient as the EEG-electrodes have to be attached to the scalp which hampers the patient's movement. This makes long-term home monitoring not feasible. In this paper, the aim is to propose a seizure detection system based on accelerometry for the detection of epileptic seizure. The used sensors are wireless, which can improve quality of life for the patients. In this system, three 2D accelerometer sensors are positioned on the right arm, left arm, and left thigh of an epileptic patient. Datasets from three patients suffering from severe epilepsy are used in this paper for the development of an automatic detection algorithm. This monitoring system is based on Wireless Sensor Networks and can determine the location of the patient when a seizure is detected and then send an alarm to hospital staff or the patient's relatives. Our wireless sensor nodes are MICAz Motes developed by Crossbow Technology. The proposed system can be used for patients living in a clinical environment or at their home, where they do only their daily routines. The analysis of the recorded data is done by an Artificial Neural Network and K Nearest-Neighbor to recognize seizure movements from normal movements. The results show that K Nearest Neighbor performs better than Artificial Neural Network for detecting these seizures. The results also show that if at least 50% of the signal consists of seizure samples, we can detect the seizure accurately. In addition, there is no need for training the algorithm for each new patient

Boschen, Mark J.; Casey, Leanne M. (2008):

The use of mobile telephones as adjuncts to cognitive behavioral psychotherapy.

In: *Professional Psychology: Research and Practice* 39 (5), S. 546.

Abstract:

BACKGROUND:

As healthcare services become progressively more stretched, there is increasing discussion of ways in which technological adjuncts may be used to deliver more cost-efficient services. Before widespread implementation, however, the use of these adjuncts requires proper scrutiny of their effects on psychological practice.

AIMS:

This research examined the effectiveness of SMS reminders on client appointment attendance and dropout in a psychological treatment setting. It was predicted that the reminders would result in increased initial appointment attendance, increased total appointment attendance, and decreased client dropout.

METHOD:

A randomized controlled trial investigated the impact of SMS appointment reminders (two levels: present or absent) on client attendance (three levels: attended, rescheduled, or did not attend) and dropout (two levels: completed treatment or terminate early). Participants (N = 140) at an outpatient psychology clinic were randomly allocated to either receive an SMS appointment reminder one day before their scheduled appointment, or to receive no reminder.

RESULTS:

No significant differences were found between the SMS and no SMS conditions in relation to appointment attendance. There were more client dropouts in the SMS compared to the no SMS condition.

CONCLUSIONS:

The SMS appointment reminders were not effective at increasing appointment attendance. The current research suggests that there is more to client non-attendance in psychological settings than the simple forgetting of appointments. Technological adjuncts may be useful in increasing the cost-efficiency of current services; however, this research highlights the importance of understanding the effects of technology before widespread implementation.

Validation of the DynaPort MiniMod during sleep: a pilot study.

In: *Perceptual and motor skills* 111 (3), S. 936–946.

Abstract:

To measure activity during sleep, polysomnography and actigraphy are often used. The DynaPort MiniMod measures movement intensity and body position day and night. The goal was to examine the validity of the DynaPort MiniMod in assessing physical activity and body posture during sleep. In Study A, 10 healthy participants slept with the DynaPort MiniMod and the Actiwatch for one night. In Study B, 8 participants suspected of having Obstructive Sleep Apnoea Syndrome slept for one night with the

DynaPort MiniMod and underwent complete polysomnography as part of the typical care protocol. In Study A, there was a significant moderate correlation (r = .70) between the movement scores of the Actiwatch and the DynaPort MiniMod. In Study B, a high intraclass correlation (r = .84) between body posture scores of the DynaPort MiniMod and the polysomnography position sensor was observed. The DynaPort MiniMod is a valid measurement device for physical activity during sleep.

Bouchard; Trudeau, F. (2008):

Estimation of energy expenditure in a work environment: comparison of accelerometry and oxygen consumption/heart rate regression.

In: *Ergonomics* 51 (5), S. 663–670.

Abstract:

The aim of this study was to compare estimation of energy expenditure (EE) in working environments, either from accelerometry or from an individual oxygen consumption/heart rate (VO(2)/HR) regression curve. The study participants were 46 volunteer workers aged 27+/-6 years old. A significant correlation between EE predicted by the VO(2)/HR curve and the accelerometer was observed (r=0.78, p <0.01). However, more disparities were observed between the two methods when the mean job intensity was not within 16% and 23% higher than resting HR. The accelerometer overestimated by a mean of 34.4% the prediction by VO(2)/HR regression if the intensity of the task was lower than a total of 1000 kcal/shift and underestimated the prediction by a mean of -24.9% if EE estimation of the work shift was higher than a total of 1500 kcal/shift. Despite a high correlation between both methods in the whole group, EE evaluated by accelerometry does not correspond to EE predicted by the VO(2)/HR regression curves when evaluated individually.

Bouhanick, B.; Bongard, V.; Amar, J.; Bousquel, S.; Chamontin, B. (2008):

Prognostic value of nocturnal blood pressure and reverse-dipping status on the occurrence of cardiovascular events in hypertensive diabetic patients.

In: *Diabetes & metabolism* 34 (6), S. 560–567.

Abstract:

AIM:

To assess whether reverse-dipping status is associated with cardiovascular (CV) events such as CV death, myocardial infarction (MI) or stroke in diabetic patients with hypertension.

METHODS:

A total of 97 diabetic patients underwent their first ambulatory blood pressure monitoring (ABPM 1). "Reverse dippers" were defined as patients with a nighttime systolic and/or diastolic blood pressure (BP) greater than daytime systolic and/or diastolic BP. Other patients were called "others". A second ABPM (ABPM 2) was done after a median delay of 2.6 years. Patients were then followed for a further 2.9-year median period (total median follow-up: 5.5 years).

RESULTS:

After ABPM 1, CV events occurred in 53% of the reverse dippers (n=15) and in 29% of the others (n=82). Kaplan-Meier curves showed significant differences between the two groups (P=0.003). Mean nighttime systolic BP on ABPM 1 was 148+/-23 mmHg and 142+/-19 mmHg in patients who did and did not experience a CV event, respectively. With Cox analysis adjusted for confounders, a 10 mmHg increase in nighttime systolic BP was associated with a 35% increase in the risk of a CV event (hazard ratio [HR]: 1.35, P=0.003). The HR for a CV event in reverse- versus nonreverse-dipping status was 2.79 (P=0.023). After ABPM 2, the relationship between the reverse-dipping status and occurrence of CV events was no longer evident (P=0.678). Nighttime systolic BP remained predictive of CV events (P=0.001).

CONCLUSION:

These findings suggest that nighttime systolic BP per se appeared to be a stronger predictor of an excess risk of CV events compared with reverse-dipping status.

Bourne, Simon; Cohet, Catherine; Kim, Viktoriya; Barton, Anna; Tuck, Andy; Aris, Emmanuel et al. (2014):

Acute Exacerbation and Respiratory InfectionS in COPD (AERIS): protocol for a prospective, observational cohort study.

In: *BMJ Open* 4 (3), S. e004546. DOI: 10.1136/bmjopen-2013-004546.

Abstract:

INTRODUCTION: The aetiology of acute exacerbations of chronic obstructive pulmonary disease (COPD) remains incompletely understood and strategies for treatment and prevention have not altered significantly for many years. Improved understanding of the role of respiratory pathogens in acute exacerbations of COPD (AECOPD) is required and the use of molecular microbiological techniques may lead to insights into host-pathogen interactions and the development of more targeted therapeutic approaches. METHODS AND ANALYSES: Acute Exacerbation and Respiratory InfectionS in COPD (AERIS) is a longitudinal epidemiological study to assess how changes in the COPD airway microbiome contribute to the incidence and severity of AECOPD. Patients with COPD aged 40-85 are followed monthly for 2 years, and reviewed within 72 h of onset of symptoms of AECOPD. Exacerbations are detected using daily electronic diary cards. Blood, sputum, nasopharyngeal and urine samples are collected at prespecified timepoints. Molecular diagnostic and typing techniques are used to describe the dynamics of airway infection during AECOPD and stable disease, and associations with clinical outcome. This study aims to refine the case definition of AECOPD to reflect the possible microbiological aetiology. AERIS will assess the impact of AECOPD on health-related quality of life and healthcare resource utilisation, and the possible interactions between nutritional status, infection and immune responses. ETHICS AND DISSEMINATION: AERIS is conducted in accordance with the Declaration of Helsinki and Good Clinical Practice, and has been approved by the institutional ethics and review board. All participants must provide written informed consent. The results obtained will be disseminated at international medical conferences and in peer-reviewed publications. DISCUSSION: Few other studies have addressed the complexity of the microbiological and systemic components of COPD or employed real-time electronic tracking of symptoms to identify AECOPD and potential aetiological triggers. RESULTS: Results of AERIS will increase our understanding of the contribution of pathogens to AECOPD, potentially leading to new targeted therapeutic and preventative interventions. TRIAL REGISTRATION NUMBER: ClinicalTrials.gov NCT01360398.

Bowen, K. S.; Birmingham, W.; Uchino, B. N.; Carlisle, M.; Smith, T. W.; Light, K. C. (2012):

Specific dimensions of perceived support and ambulatory blood pressure: Which support functions appear most beneficial and for whom?

In: *Int.J Psychophysiol.* (0167-8760 (Linking)). DOI: 10.1016/j.ijpsycho.2012.03.004.

Abstract:

Perceived support has been related to lower cardiovascular morbidity and mortality. However, little is known about the specific functional components of support responsible for such links. We tested if emotional, informational, tangible, and belonging support predicted ambulatory blood pressure (ABP) and interpersonal interactions (e.g., responsiveness), and if such links were moderated by gender. In this study, 94 married couples underwent 12h of ABP monitoring during daily life which included a night at home with their spouse. They completed a short-form of the interpersonal support evaluation list that provides information on total (global) support, as well as specific dimensions of support. Results revealed that global support scores did not predict ABP during daily life. However, separating out distinct support components revealed that emotional support was a significant predictor of lower ambulatory systolic and diastolic blood pressure, primarily for women. Finally, emotional support predicted greater partner responsiveness and self-disclosure, along with less perceived partner negativity although these results were not moderated by gender. These data are discussed in terms of the importance of considering specific support components and the contextual processes that might influence such links

Bowen, Kimberly S.; Uchino, Bert N.; Birmingham, Wendy; Carlisle, McKenzie; Smith, Timothy W.; Light, Kathleen C. (2014):

The stress-buffering effects of functional social support on ambulatory blood pressure.

In: *Health Psychol* 33 (11), S. 1440–1443. DOI: 10.1037/t06207-000;

Abstract:

Objective: Social support is a reliable predictor of cardiovascular health. According to the buffering hypothesis, stress is 1 mechanism by which support is able to affect physiological processes. However, most of the experimental evidence for the hypothesis comes from laboratory studies. Ambulatory blood pressure (ABP) protocols examine participants in their natural environment, where they are more likely to encounter personally relevant real-world stressors. Furthermore, prior work shows that examining support by its specific functional components reveals additional independent links to health. Methods: The current study aimed to examine the stress-buffering effects of functional social support on ABP. One hundred eighty-eight

participants completed a 1-day ABP assessment along with measures of functional social support and both global perceived stress and momentary stress at time of reading. Results: Results indicated main effects for both stress measures. Global support, emotional, tangible, and informational support only moderated the effects of momentary stress, but not global stress, in predicting ABP. Informational support was the most consistent stress-buffering predictor of ABP, predicting both ambulatory systolic and diastolic blood pressure. Conclusions: The predicted values in ABP for informational support achieved health-relevant differences, emphasizing the value of examining functional support beyond global support alone. Boyle, Justin; Bidargaddi, Niranjan; Sarela, Antti; Karunanithi, Mohan (2009):

Automatic detection of respiration rate from ambulatory single-lead ECG.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 13 (6), S. 890–896. DOI: 10.1109/TITB.2009.2031239.

Abstract:

Ambulatory electrocardiography is increasingly being used in clinical practice to detect abnormal electrical behavior of the heart during ordinary daily activities. The utility of this monitoring can be improved by deriving respiration, which previously has been based on overnight apnea studies where patients are stationary, or the use of multilead ECG systems for stress testing. We compared six respiratory measures derived from a single-lead portable ECG monitor with simultaneously measured respiration air flow obtained from an ambulatory nasal cannula respiratory monitor. Ten controlled 1-h recordings were performed covering activities of daily living (lying, sitting, standing, walking, jogging, running, and stair climbing) and six overnight studies. The best method was an average of a 0.2-0.8 Hz bandpass filter and RR technique based on lengthening and shortening of the RR interval. Mean error rates with the reference gold standard were +/-4 breaths per minute (bpm) (all activities), +/-2 bpm (lying and sitting), and +/-1 breath per minute (overnight studies). Statistically similar results were obtained using heart rate information alone (RR technique) compared to the best technique derived from the full ECG waveform that simplifies data collection procedures. The study shows that respiration can be derived under dynamic activities from a single-lead ECG without significant differences from traditional methods.

Bracht, T.; Federspiel, A.; Schnell, S.; Horn, H.; Hofle, O.; Wiest, R. et al. (2012):

Cortico-cortical white matter motor pathway microstructure is related to psychomotor retardation in major depressive disorder.

In: *PLoS One* 7 (12), S. e52238. DOI: 10.1371/journal.pone.0052238.

Abstract:

Alterations of brain structure and function have been associated with psychomotor retardation in major depressive disorder (MDD). However, the association of motor behaviour and white matter integrity of motor pathways in MDD is unclear. The aim of the present study was to first investigate structural connectivity of white matter motor pathways in MDD. Second, we explore the relation of objectively measured motor activity and white matter integrity of motor pathways in MDD. Therefore, 21 patients with MDD and 21 healthy controls matched for age, gender, education and body mass index underwent diffusion tensor imaging and 24 hour actigraphy (measure of the activity level) the same day. Applying a probabilistic fibre tracking approach we extracted connection pathways between the dorsolateral prefrontal cortex (dlPFC), the rostral anterior cingulate cortex (rACC), the pre-supplementary motor area (pre-SMA), the SMA-proper, the primary motor cortex (M1), the caudate nucleus, the putamen, the pallidum and the thalamus. Patients had lower activity levels and demonstrated increased mean diffusivity (MD) in pathways linking left pre-SMA and SMA-proper, and right SMA-proper and M1. Exploratory analyses point to a positive association of activity level and mean-fractional anisotropy in the right rACC-pre-SMA connection in MDD. Only MDD patients with low activity levels had a negative linear association of activity level and mean-MD in the left dlPFC-pre-SMA connection. Our results point to structural alterations of cortico-cortical white matter motor pathways in MDD. Altered white matter organisation of rACC-pre-SMA and dlPFC-pre-SMA pathways may contribute to movement initiation in MDD

Bracht, T.; Heidemeyer, K.; Koschorke, P.; Horn, H.; Razavi, N.; Wopfner, A. et al. (2012):

Comparison of objectively measured motor behavior with ratings of the motor behavior domain of the Bern Psychopathology Scale (BPS) in schizophrenia.

In: *Psychiatry Res* (0165-1781 (Linking)). DOI: 10.1016/j.psychres.2011.12.038.

Abstract:

Motor symptoms in schizophrenia are frequent and relevant to diagnosis and antipsychotic therapy. To date motor symptoms are difficult to assess and their pathobiology is a widely unresolved issue. The Bern Psychopathology Scale for the assessment of system-specific psychotic symptoms (BPS) was designed to identify homogenous patient groups by focusing on three domains: language, affectivity and motor behavior. The present study aimed to validate the motor behavior domain of the BPS using wrist actigraphy. In total, 106 patients were rated with the BPS and underwent 24h continuous actigraphy recording. The ratings of the global severity of the motor behavior domain (GSM) as well as the quantitative and the subjective items of the motor behavior domain of the BPS were significantly associated with actigraphic variables. In contrast, the qualitative items of the motor domain failed to show an association with actigraphy. Likewise, scores of the language and the affectivity domains were not related to actigraphic measures. In conclusion, we provided substantial external validity for global, quantitative and subjective ratings of the BPS motor behavior domain. Thus, the BPS is suitable to assess the dimension of quantitative motor behavior in the schizophrenia spectrum

Bracht, T.; Schnell, S.; Federspiel, A.; Razavi, N.; Horn, H.; Strik, W. et al. (2013):

Altered cortico-basal ganglia motor pathways reflect reduced volitional motor activity in schizophrenia.

In: *Schizophr.Res* 143 (2-3), S. 269–276. DOI: 10.1016/j.schres.2012.12.004.

Abstract:

Little is known about the neurobiology of hypokinesia in schizophrenia. Therefore, the aim of this study was to investigate alterations of white matter motor pathways in schizophrenia and to relate our findings to objectively measured motor activity. We examined 21 schizophrenia patients and 21 healthy controls using diffusion tensor imaging and actigraphy. We applied a probabilistic fibre tracking approach to investigate pathways connecting the dorsolateral prefrontal cortex (dlPFC), the rostral anterior cingulate cortex (rACC), the pre-supplementary motor area (pre-SMA), the supplementary motor area proper (SMA-proper), the primary motor cortex (M1), the caudate nucleus, the striatum, the pallidum and the thalamus. Schizophrenia patients had lower activity levels than controls. In schizophrenia we found higher probability indices forming part of a bundle of interest (PIBI) in pathways connecting rACC, pre-SMA and SMA-proper as well as in pathways connecting M1 and pre-SMA with caudate nucleus, putamen, pallidum and thalamus and a reduced spatial extension of motor pathways in schizophrenia. There was a positive correlation between PIBI and activity level in the right pre-SMA-pallidum and the left M1-thalamus connection in healthy controls, and in the left pre-SMA-SMA-proper pathway in schizophrenia. Our results point to reduced volitional motor activity and altered motor pathway organisation in schizophrenia. The identified associations between the amount of movement and structural connectivity of motor pathways suggest dysfunction of cortico-basal ganglia pathways in the pathophysiology of hypokinesia in schizophrenia. Schizophrenia patients may use cortical pathways involving the supplementary motor area to compensate for basal ganglia dysfunction

Bradley, R. H.; McRitchie, S.; Houts, R. M.; Nader, P.; O'Brien, M. (2011):

Parenting and the decline of physical activity from age 9 to 15.

In: *Int J Behav Nutr Phys Act* 8. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32527-001%26site%3dehost-live;robert.bradley@asu.edu.

Abstract:

Background: There is a rapid decline in moderate-to-vigorous physical activity (MVPA) during middle childhood and adolescence. Information on the environmental factors implicated in this decline is limited. This study focuses on family factors associated with the rate of decline in objectively measured physical activity during middle childhood and adolescence. Methods: Longitudinal analysis of 801 participants from 10 US sites in the NICHD Study of Early Child Care and Youth Development whose data included accelerometer-determined levels of moderate-to-vigorous physical activity (MVPA) between ages 9 and 15 years, as well as family process, BMI and demographic information. The sample included an even split of boys (49%) and girls (51%), was predominantly white (77%), and contained about 26% low income and 19% single parent families. The outcome measure was mean MVPA. It was based on 4 to 7 days of monitored physical activity. Results: Boys with lower parental monitoring scores and more days of parental encouragement had significantly more minutes of MVPA at age 9 years. The effect of parental monitoring, however, was moderated by early puberty. High parental monitoring was associated with decreased activity levels for boys experiencing later puberty and increased activity for boy experiencing early puberty. Minutes of MVPA for boys living in the Midwest decreased at significantly faster rates than boys living in any other region; and boys in the South declined faster than boys in the West. Girls in the Midwest and South declined faster than girls in the West and Northeast. Among girls, more days of parental exercise and transportation to activities were associated with more MVPA per day at age 9. However, more

parental transportation to activities and less monitoring was associated with faster linear declines in daughters' MVPA between the ages of 9 and 15 years. For girls who experienced puberty early, parental encouragement was associated with more MVPA. Conclusions: Parenting processes, such as monitoring and encouragement, as well as the parents' own level of physical activity, showed significant, but small, gender-specific associations with MVPA levels at age nine and the linear rate of decline in MVPA between ages 9 and 15. Brage, Søren; Ekelund, Ulf; Brage, Niels; Hennings, Mark A.; Froberg, Karsten; Franks, Paul W.; Wareham, Nicholas J. (2007):

Hierarchy of individual calibration levels for heart rate and accelerometry to measure physical activity.

In: *Journal of Applied Physiology* 103 (2), S. 682–692.

Abstract:

Combining accelerometry with heart rate (HR) monitoring may improve precision of physical activity measurement. Considerable variation exists in the relationships between physical activity intensity (PAI) and HR and accelerometry, which may be reduced by individual calibration. However, individual calibration limits feasibility of these techniques in population studies, and less burdensome, yet valid, methods of calibration are required. We aimed to evaluate the precision of different individual calibration procedures against a reference calibration procedure: a ramped treadmill walking-running test with continuous measurement of PAI by indirect calorimetry in 26 women and 25 men [mean (SD): 35 (9) yr, 1.69 (0.10) m, 70 (14) kg]. Acceleration (along the longitudinal axis of the trunk) and HR were measured simultaneously. Alternative calibration procedures included treadmill testing without calorimetry, submaximal step and walk tests with and without calorimetry, and nonexercise calibration using sleeping HR and gender. Reference accelerometry and HR models explained >95% of the between-individual variance in PAI ($P < 0.001$). This fraction dropped to 73 and 81%, respectively, for accelerometry and HR models calibrated with treadmill tests without calorimetry. Step-test calibration captured 62-64% (accelerometry) and 68% (HR) of the variance between individuals. Corresponding values were 63-76% and 59-61% for walk-test calibration. There was only little benefit of including calorimetry during step and walk calibration for HR models. Nonexercise calibration procedures explained 54% (accelerometry) and 30% (HR) of the between-individual variance. In conclusion, a substantial proportion of the between-individual variance in relationships between PAI, accelerometry, and HR is captured with simple calibration procedures, feasible for use in epidemiological studies.

Bramlage, Peter; Zemmrich, Claudia; Gansz, Andrea; Sturm, Claus-Dieter; Fimmers, Rolf; Nadal, Jennifer et al. (2014):

Daytime systolic ambulatory blood pressure with a two-step switch from candesartan to olmesartan monotherapy and the fixed-dose combination of olmesartan/amlodipine in patients with uncontrolled essential hypertension (SEVICONTROL-2).

In: *J Clin Hypertens (Greenwich)* 16 (1), S. 41–46. DOI: 10.1111/jch.12227.

Abstract:

The objective of this study was to investigate the efficacy of the fixed-dose combination olmesartan/amlodipine 40/10 mg in patients with moderate essential hypertension not controlled on candesartan 32 mg. This was a prospective, single-arm, phase IV study. The primary endpoint was the change in mean daytime systolic blood pressure (BP). A total of 77 of 89 screened patients started candesartan 32 mg, 62 olmesartan 40 mg, and 57 olmesartan 40 mg/amlodipine 10 mg. Mean daytime systolic BP was reduced by 9.8+/-15.2 mm Hg ($P<.001$) vs candesartan monotherapy. Office BP reduction was 9.2+/-18.8/5.0+/-8.9 mm Hg ($P<0.001$). Treatment goals (<140/90 mm Hg for office and <135/85 mm Hg for ambulatory BP) were achieved in 58.2% and 78.4% of patients, respectively. There was one drug-related adverse event (edema) and no serious adverse events. Patients of Caucasian ethnicity with moderate essential hypertension uncontrolled on candesartan experienced a further drop in BP using olmesartan and amlodipine.

Estimating Energy Expenditure from Raw Accelerometry in Three Types of Locomotion.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e318260402b.

Abstract:

PURPOSE: Accuracy of estimating activity-related energy expenditure (AEE) from raw body acceleration may improve by using prediction equations that are specific for the type of activity. The current study aims to improve published equations by deriving an equation for over-ground walking and to evaluate whether over-ground cycling and stair walking require specific prediction equations. METHODS: Participants (91M/95F, 8-81years) were equipped with a tri-axial accelerometer (DynaPort MiniMod) on their lower back. Total energy expenditure (TEE) was measured using a mobile oxygen analyzer (MetaMax 3b). Resting energy expenditure (REE) was measured over 30 min, following which a physical activity course was completed involving walking on level ground at slow (8 min), normal (8 min) and fast speed (3 min), stair-walking (3 min), and cycling (8 min). AEE was calculated as

Brans, K.; Van,Mechelen,I; Rime, B.; Verduyn, P. (2013):

The relation between social sharing and the duration of emotional experience.

In: *Cogn Emot* (0269-9931 (Linking)). DOI: 10.1080/02699931.2012.762758.

Abstract:

People often socially share their emotions to regulate them. Two-mode theory of social sharing states that cognitive sharing will contribute to emotional recovery, whereas socio-affective sharing will only temporarily alleviate emotional distress. Previous studies supporting this theory, measured emotional recovery in terms of residual emotional intensity. Until now, another important time-dynamic aspect of emotions, emotion duration, has been largely ignored. In two experience sampling studies we addressed this gap. In Study 1, participants reported on the duration of anger, fear, and sadness episodes; additionally time-varying information on the occurrence and mode of sharing was collected. This study revealed that sharing led to a shortening in emotion duration, in particular when it was socio-affective in nature. In Study 2 we investigated whether this result could be interpreted in terms of our measure of duration primarily reflecting emotional relief rather than recovery. In this study, the same method as in Study 1 was used; additionally, residual emotional intensity was measured three days after emotion onset. Study 2 largely replicated the findings from Study 1. Furthermore, duration appeared to be empirically distinct from residual intensity. Finally, no relation between sharing and residual intensity was found, even when considering the sharing mode

Bray, Rebecca Scott (2013):

Paradoxical justice: the case of Ian Tomlinson.

In: *J Law Med* 21 (2), S. 447–472.

Abstract:

On 1 April 2009, 47-year-old London newspaper vendor Ian Tomlinson collapsed and died during the G20 protests in central London. The initial autopsy found death consistent with "natural causes". However, that finding was disputed after the public release of mobile phone video footage showing a police officer striking and pushing Tomlinson to the ground. The release of this footage changed the course of events in the case: further post-mortem examinations found blunt force trauma to Tomlinson's body; the Independent Police Complaints Commission launched a criminal investigation; and a coronial inquest opened that was presided over by public order policing expert Judge Peter Thornton QC. On 3 May 2011, a coronial jury delivered a verdict of "unlawful killing", finding police actions against Tomlinson "excessive and unreasonable". The Crown Prosecution Service then revised its decision not to prosecute the officer filmed striking and pushing Tomlinson, and on 19 July 2012 the officer was acquitted of manslaughter. This case highlights a number of key issues discussed in this article, including the symbolic and practical importance of open inquests in allaying suspicion and rumour; the ordeal of death investigation proceedings as obstacles to justice; and the seeming contra-indications for justice thrown up by divergent legal outcomes. In high-profile matters such as the Tomlinson case, these issues are further underscored by the "new publicity" around inquests in a multi-media digital age.

Bregvadze TR, Tseluĭko VI, Mishchuk NE. (2013):

Influence of treatment with olmesartan on ambulatory blood pressure monitoring parameters in patients with arterial hypertension.

In: *Georgian Med News* (225), S. 60–67.

Abstract:

Hypertension is the most common disease of the cardiovascular system. Active treatment of hypertension with adequate control of blood pressure (BP) can prevent complications, improve life quality and increase life expectancy. One of the interesting new antihypertensive agents, from the group of angiotensin receptor blockers is olmesartan. The obvious advantages of ambulatory blood pressure monitoring to traditional one-time measurements of BP make this method perspective for quality control of anti-hypertensive therapy. The aim of this study was to evaluate the influence of treatment with olmesartan on ambulatory blood pressure monitoring parameters in patients with hypertension. 38 out-patients with hypertension at the age of 25-84 years (mean 55,3+/-10,6) were studied. Patients received olmesartan 20 mg daily as monotherapy (20 patients (52,6%)) or in combination with other antihypertensive agents (18 patients (47,4%)). Treatment continued for 6 months. The complex examination included: measurement of office brachial BP, electrocardiography, echocardiography and ambulatory blood pressure monitoring (ABPM). As a result of treatment, office BP and diurnal BP, according to ABPM, significantly decreased; the favorable circadian BP profile dynamics were found: significantly less frequently observed lack of reduction in BP during night (daily index - non-dipper) - 18% vs. 64% (p <0,001), while the number of individuals with normal daily index (dipper) increased significantly - 76% vs. 28% (p <0,001). Also there was determined the significant reduction in daytime and nighttime systolic BP variability - by 1.5 mmHg and 2.1 mmHg, respectively, with the normalization of these parameters at the end of the observation period. The presented results allow conclude, that treatment of hypertensive patients with olmesartan provides significant decline not only in office BP, but also in diurnal BP, normalizes BP of active and passive periods, also - daily index and reduces BP variability.

Breland, J. Y.; Yeh, V. M.; Yu, J. (2013):

Adherence to evidence-based guidelines among diabetes self-management apps.

In: *Transl.Behav.Med* 3 (3), S. 277–286. DOI: 10.1007/s13142-013-0205-4.

Abstract:

Smartphone apps can provide real-time, interactive self-management aid to individuals with diabetes. It is currently unclear whether existing diabetes self-management apps follow evidence-based guidelines. The purpose of this study was to evaluate the extent to which existing diabetes self-management apps address the seven self-management behaviors recommended by the American Association of Diabetes Educators (the AADE7). The term "diabetes" identified relevant self-management apps via the Apple App Store search engine in March 2012. Ratings were based on app descriptions and downloads. Chi-square analyses assessed differences in apps based on developer type. Apps promoted a median of two AADE7 skills. Overall reliability between description and download ratings was good (kappa = .66). Reliability of individual skills was variable (kappa = .25 to .91). Most diabetes apps do not conform to evidence-based recommendations, and future app reviews would benefit from testing app performance. Future apps may also benefit from theory-based designs

Motor control accuracy: A consequential probe of individual differences in emotion regulation.

In: *Emotion*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24213-001&site=ehost-live.

Abstract:

Two studies (total N = 147) sought to model emotion-regulation processes in cognitive-motoric terms. Hostile or nonhostile thoughts were primed and, immediately following, individuals held a joystick as accurately as possible on a presented visual target. Study 1 revealed that the activation of hostile thoughts impaired motor control at low levels of agreeableness but facilitated motor control at high levels of agreeableness, consistent with emotion-regulation views of this trait. Study 2 did not assess the trait of agreeableness but rather sought to determine whether better motor control following activated hostile thoughts would predict lesser reactivity to stressors in an experience-sampling protocol. It did, and relevant results are reported for daily anger, negative affect, and positive affect. In addition, and consistent with the agreeableness findings of Study 1, better motor control that follows hostile thoughts predicted greater empathy on high-stress days. Motor control probes of the present type thus appear consequential in understanding emotion-regulation processes and successes in emotion regulation. Risk Stratification by Ambulatory Blood Pressure Monitoring Across JNC Classes of Conventional Blood Pressure.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu002.

Abstract:

BACKGROUND: Guidelines propose classification of conventional blood pressure (CBP) into normotension (<120/<80mm Hg), prehypertension (120-139/80-89mm Hg), and hypertension (>/=140/>/=90mm Hg). METHODS: To assess the potential differential contribution of ambulatory blood pressure (ABP) in predicting risk across CBP strata, we analyzed outcomes in 7,826 untreated people recruited from 11 populations. RESULTS: During an 11.3-year period, 809 participants died (276 cardiovascular deaths) and 639, 383, and 225 experienced a cardiovascular, cardiac, or cerebrovascular event. Compared with normotension (n = 2,639), prehypertension (n = 3,076) carried higher risk (P </= 0.015) of cardiovascular (+41%) and cerebrovascular (+92%) endpoints; compared with hypertension (n = 2,111) prehypertension entailed lower risk (P </= 0.005) of total mortality (-14%) and cardiovascular mortality (-29%) and of cardiovascular (-34%), cardiac (-33%), or cerebrovascular (-47%) events. Multivariable-adjusted hazard ratios (HRs) for stroke associated with 24-hour and daytime diastolic ABP (+5mm Hg) were higher (P </= 0.045) in normotension than in prehypertension and hypertension (1.98 vs.1.19 vs.1.28 and 1.73 vs.1.09 vs. 1.24, respectively) with similar trends (0.03 </= P </= 0.11) for systolic ABP (+10mm Hg). However, HRs for fatal endpoints and cardiac events associated with ABP did not differ significantly (P >/= 0.13) across CBP categories. Of normotensive and prehypertensive participants, 7.5% and 29.3% had masked hypertension (daytime ABP >/=135/>/=85mm Hg). Compared with true normotension (P </= 0.01), HRs for stroke were 3.02 in normotension and 2.97 in prehypertension associated with masked hypertension with no difference between the latter two conditions (P = 0.93). CONCLUSION: ABP refines risk stratification in normotension and prehypertension mainly by enabling the diagnosis of masked hypertension.

Bricker, Jonathan B.; Mull, Kristin E.; Kientz, Julie A.; Vilardaga, Roger; Mercer, Laina D.; Akioka, Katrina J.; Heffner, Jaimee L. (2014):

Randomized, controlled pilot trial of a smartphone app for smoking cessation using acceptance and commitment therapy.

In: *Drug Alcohol Depend* 143, S. 87–94. DOI: 10.1016/j.drugalcdep.2014.07.006.

Abstract:

BACKGROUND: There is a dual need for (1) innovative theory-based smartphone applications for smoking cessation and (2) controlled trials to evaluate their efficacy. Accordingly, this study tested the feasibility, acceptability, preliminary efficacy, and mechanism of behavioral change of an innovative smartphone-delivered acceptance and commitment therapy (ACT) application for smoking cessation vs. an application following US Clinical Practice Guidelines. METHOD: Adult participants were recruited nationally into the double-blind randomized controlled pilot trial (n=196) that compared smartphone-delivered ACT for smoking cessation application (SmartQuit) with the National Cancer Institute's application for smoking cessation (QuitGuide). RESULTS: We recruited 196 participants in two months. SmartQuit participants opened their application an average of 37.2 times, as compared to 15.2 times for QuitGuide participants (p<0001). The overall quit rates were 13% in SmartQuit vs. 8% in QuitGuide (OR=2.7; 95% CI=0.8-10.3). Consistent with ACT's theory of change, among those scoring low (below the median) on acceptance of cravings at baseline (n=88), the quit rates were 15% in SmartQuit vs. 8% in QuitGuide (OR=2.9; 95% CI=0.6-20.7). CONCLUSIONS: ACT is feasible to deliver by smartphone application and shows higher engagement and promising quit rates compared to an application that follows US Clinical Practice Guidelines. As results were limited by the pilot design (e.g., small sample), a full-scale efficacy trial is now needed.

A network approach to psychopathology: new insights into clinical longitudinal data.

In: *PLoS One* 8 (4), S. e60188. DOI: 10.1371/journal.pone.0060188.

Abstract:

In the network approach to psychopathology, disorders are conceptualized as networks of mutually interacting symptoms (e.g., depressed mood) and transdiagnostic factors (e.g., rumination). This suggests that it is necessary to study how symptoms dynamically interact over time in a network architecture. In the present paper, we show how such an architecture can be constructed on the basis of time-series data obtained through Experience Sampling Methodology (ESM). The proposed methodology determines the parameters for the interaction between nodes in the network by estimating a multilevel vector autoregression (VAR) model on the data. The methodology allows combining between-subject and within-subject information in

a multilevel framework. The resulting network architecture can subsequently be analyzed through network analysis techniques. In the present study, we apply the method to a set of items that assess mood-related factors. We show that the analysis generates a plausible and replicable network architecture, the structure of which is related to variables such as neuroticism; that is, for subjects who score high on neuroticism, worrying plays a more central role in the network. Implications and extensions of the methodology are discussed

Flow situations during everyday practice in a medical hospital ward. Results from a study based on experience sampling method.

In: *BMC nursing* 10, S. 3. DOI: 10.1186/1472-6955-10-3.

Abstract:

BACKGROUND\r\nNursing is a constant balance between strain and stimulation and work and health research with a positive reference point has been recommended. A health-promoting circumstance for subjective experience is flow, which is a psychological state, when individuals concurrently experience happiness, motivation and cognitive efficiency. Flow situations can be identified through individuals' estimates of perceived challenge and skills. There is, to the best of our knowledge, no published study of flow among health care staff. The aim of this study was to identify flow-situations and study work-related activities and individual factors associated with flow situations, during everyday practice at a medical emergency ward in Sweden, in order to increase the knowledge on salutogenic health-promoting factors.\r\nMETHODS\r\nThe respondents consisted of 17 assistant nurses and 14 registered nurses, who randomly and repeatedly answered a small questionnaire, through an experience sampling method, during everyday nursing practice. The study resulted in 497 observations. Flow situations were defined as an exact match between a high challenge and skill estimation and logistic regression models were used to study different variables association to flow situations.\r\nRESULTS\r\nThe health care staff spent most of its working time in individual nursing care and administrative and communicative duties. The assistant nurses were more often occupied in individual nursing care, while the registered nurses were more involved in medical care and administrative and communicative duties. The study resulted in 11.5% observations of flow situations but the relative number of flow situations varied between none to 55% among the participants. Flow situations were positively related to medical care activities and individual cognitive resources. Taking a break was also positively associated with flow situations among the assistant nurses.\r\nCONCLUSIONS\r\nThe result showed opportunities for work-related interventions, with an adherent increase in flow situations, opportunity for experience of flow and work-related health among the nursing staff in general and among the assistant nurses in particular.

Brodbeck, J.; Bachmann, M. S.; Znoj, H. (2013):

Distinct coping strategies differentially predict urge levels and lapses in a smoking cessation attempt.

In: *Addict.Behav.* 38 (6), S. 2224–2229. DOI: 10.1016/j.addbeh.2013.02.001.

Abstract:

This study analysed mechanisms through which stress-coping and temptation-coping strategies were associated with lapses. Furthermore, we explored whether distinct coping strategies differentially predicted reduced lapse risk, lower urge levels, or a weaker association between urge levels and lapses during the first week of an unassisted smoking cessation attempt. Participants were recruited via the internet and mass media in Switzerland. Ecological momentary assessment (EMA) with mobile devices was used to assess urge levels and lapses. Online questionnaires were used to measure smoking behaviours and coping variables at baseline, as well as smoking behaviour at the three-month follow-up. The sample consisted of 243 individuals, aged 20 to 40, who reported 4199 observations. Findings of multilevel regression analyses show that coping was mainly associated with a reduced lapse risk and not with lower urge levels or a weaker association between urge levels and lapses. 'Calming down' and 'commitment to change' predicted a lower lapse risk and also a weaker relation between urge levels and lapses. 'Stimulus control' predicted a lower lapse risk and lower urge levels. Conversely, 'task-orientation' and 'risk assessment' were related to higher lapse risk and 'risk assessment' also to higher urge levels. Disengagement coping i.e. 'eating or shopping', 'distraction', and 'mobilising social support' did not affect lapse risk. Promising coping strategies during the initial stage of smoking cessation attempt are targeted directly at reducing the lapse risk and are characterised by engagement with the stressor or one's reactions towards the stressor and a focus on positive consequences instead of health risks

Brodbeck, Jeannette; Bachmann, Monica S.; Brown, Anna; Znoj, Hans Joerg (2014):

Effects of depressive symptoms on antecedents of lapses during a smoking cessation attempt: An ecological momentary assessment study.

In: *Addiction*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-21711-001%26site%3dehost-live.

Abstract:

Abstract Aims To investigate pathways through which momentary negative affect and depressive symptoms affect risk of lapse during smoking cessation attempts. Design Ecological momentary assessment was carried out during 2 weeks after an unassisted smoking cessation attempt. A 3-month follow-up measured smoking frequency. Setting Data were collected via mobile devices in German-speaking Switzerland. Participants A total of 242 individuals (age 20–40, 67% men) reported 7112 observations. Measurements Online surveys assessed baseline depressive symptoms and nicotine dependence. Real-time data on negative affect, physical withdrawal symptoms, urge to smoke, abstinence-related self-efficacy and lapses. Findings A two-level structural equation model suggested that on the situational level, negative affect increased the urge to smoke and decreased self-efficacy (β = 0.20; β = −0.12, respectively), but had no direct effect on lapse risk. A higher urge to smoke (β = 0.09) and lower self-efficacy (β = −0.11) were confirmed as situational antecedents of lapses. Depressive symptoms at baseline were a strong predictor of a person's average negative affect (β = 0.35, all P < 0.001). However, the baseline characteristics influenced smoking frequency 3 months later only indirectly, through influences of average states on the number of lapses during the quit attempt. Conclusions Controlling for nicotine dependence, higher depressive symptoms at baseline were associated strongly with a worse longer-term outcome. Negative affect experienced during the quit attempt was the only pathway through which the baseline depressive symptoms were associated with a reduced self-efficacy and increased urges to smoke, all leading to the increased probability of lapses. Broderick, J. M.; Ryan, J.; O'Donnell, D. M.; Hussey, J. (2014):

A guide to assessing physical activity using accelerometry in cancer patients.

In: *Support Care Cancer* 22 (4), S. 1121–1130. DOI: 10.1007/s00520-013-2102-2.

Abstract:

Increased physical activity (PA) has been associated with a decreased risk for the occurrence and recurrence of many cancers. PA is an important outcome measure in rehabilitation interventions within cancer and may be used as a proxy measure of recovery or deterioration in health status following treatment and in the palliative care setting. PA is a complex multi-dimensional construct which is challenging to measure accurately. Factors such as technical precision and feasibility influence the choice of PA measurement tool. Laboratory-based methods are precise and mainly used for validation purposes, but their clinical applicability is limited. Self-report methods such as questionnaires are widely used due to their simplicity and reasonable cost; however, accuracy can be questionable. Objective methods such as pedometers measure step count but do not measure intensity, frequency or duration of activity. Accelerometers can measure PA behaviour at both ends of the movement spectrum from sedentary to vigorous levels of activity and can also provide objective data about the frequency, intensity, type and duration of PA. Balancing precision with ease of use, accelerometry may be the best measure of PA in cancer-based studies, but only a small number of studies have incorporated this measurement. This review will provide a background to PA and an overview of accelerometer measurement as well as technical and practical considerations, so this useful tool could be more widely incorporated into clinical trial research within cancer.

Validity and reliability of patient-reported outcomes measurement information system (PROMIS) instruments in osteoarthritis.

In: *Arthritis Care Res (Hoboken.)* (2151-464X (Linking)). DOI: 10.1002/acr.22025.

Abstract:

OBJECTIVE.: Evaluation of known group validity, ecological validity, and test-retest reliability of four domain instruments from the Patient Reported Outcomes Measurement System (PROMIS) in osteoarthritis (OA) patients. METHODS.: Recruitment of an osteoarthritis sample and a comparison general population (GP) through an Internet survey panel. Pain intensity, pain interference, physical functioning, and fatigue were assessed for 4 consecutive weeks with PROMIS short forms on a daily basis and compared with same-domain Computer Adaptive Test (CAT) instruments that use a 7-day recall. Known group validity (comparison of OA and GP), ecological validity (comparison of aggregated daily measures with CATs), and test-retest reliability

were evaluated. RESULTS.: The recruited samples matched (age, sex, race, ethnicity) the demographic characteristics of the U.S. sample for arthritis and the 2009 Census for the GP. Compliance with repeated measurements was excellent: > 95%. Known group validity for CATs was demonstrated with large effect sizes (pain intensity: 1.42, pain interference: 1.25, and fatigue: .85). Ecological validity was also established through high correlations between aggregated daily measures and weekly CATs (>/= .86). Test-retest validity (7-day) was very good (>/= .80). CONCLUSION.: PROMIS CAT instruments demonstrated known group and ecological validity in a comparison of osteoarthritis patients with a general population sample. Adequate test-retest reliability was also observed. These data provide encouraging initial data on the utility of these PROMIS instruments for clinical and research outcomes in osteoarthritis patients. (c) 2013 by the American College of Rheumatology

Broderick, Joan E.; Schwartz, Joseph E.; Vikingstad, Gregory; Pribbernow, Michelle; Grossman, Steven; Stone, Arthur A. (2008):

The accuracy of pain and fatigue items across different reporting periods.

In: *Pain* 139 (1), S. 146–157.

Abstract:

The length of the reporting period specified for items assessing pain and fatigue varies among instruments. How the length of recall impacts the accuracy of symptom reporting is largely unknown. This study investigated the accuracy of ratings for reporting periods ranging from 1 day to 28 days for several items from widely used pain and fatigue measures (SF36v2, Brief Pain Inventory, McGill Pain Questionnaire, Brief Fatigue Inventory). Patients from a community rheumatology practice (N=83) completed momentary pain and fatigue items on average of 5.4 times per day for a month using an electronic diary. Averaged momentary ratings formed the basis for comparison with recall ratings interspersed throughout the month referencing 1-day, 3-day, 7-day, and 28-day periods. As found in previous research, recall ratings were consistently inflated relative to averaged momentary ratings. Across most items, 1-day recall corresponded well to the averaged momentary assessments for the day. Several, but not all, items demonstrated substantial correlations across the different reporting periods. An additional 7 day-by-day recall task suggested that patients have increasing difficulty actually remembering symptom levels beyond the past several days. These data were collected while patients were receiving usual care and may not generalize to conditions where new interventions are being introduced and outcomes evaluated. Reporting periods can influence the accuracy of retrospective symptom reports and should be a consideration in study design.

Brondolo, Elizabeth; Grantham, Kamau Imarogbe; Karlin, William; Taravella, Joseph; Mencía-Ripley, Aida; Schwartz, Joseph E. et al. (2009):

Trait hostility and ambulatory blood pressure among traffic enforcement agents: the effects of stressful social interactions.

In: *Journal of Occupational Health Psychology* 14 (2), S. 110–121. DOI: 10.1037/a0014768.

Abstract:

This study investigated the hypothesis that trait hostility is associated with heightened cardiovascular reactivity to potentially stressful social interactions but not to nonsocial activities in the workplace. Participants were 73 (39 women) New York City traffic enforcement agents (TEAs) who patrol the streets and issue summonses for vehicular and parking violations. During their patrols, TEAs face potentially stressful interactions when they encounter motorists and pedestrians who may be angry about receiving summonses. Mood and ambulatory blood pressure were initially measured when TEAs were recently hired and attending classes at the training academy (Time 1), and were subsequently assessed again once the TEAs began independently patrolling the city streets (Time 2). Random effects regression models yielded a significant interaction of hostility and work activity on ambulatory systolic blood pressure at Time 2. For those high in hostility, but not for those low in hostility, systolic blood pressure levels were higher while interacting with members of the public than during nonsocial work activities. The findings support the notion that situational factors affect the association of hostility to cardiovascular reactivity, and that interpersonal stressors in the workplace elicit cardiovascular activation among those high in hostility.

Brondolo, Elizabeth; Libby, Daniel J.; Denton, Ellen-Ge; Thompson, Shola; Beatty, Danielle L.; Schwartz, Joseph et al. (2008):

Racism and ambulatory blood pressure in a community sample.

In: *Psychosomatic Medicine* 70 (1), S. 49–56.

Abstract:

OBJECTIVE:

Racism has been identified as a psychosocial stressor that may contribute to disparities in the prevalence of cardiovascular disease. The goal of the present article was to investigate the relationship of perceived racism to ambulatory blood pressure (ABP) in a sample of American-born Blacks and Latinos.

METHODS:

Participants included English-speaking Black or Latino(a) adults between the ages of 24 and 65. They completed daily mood diaries and measures of perceived racism, socioeconomic status, and hostility. Participants were outfitted with ABP monitors; 357 provided data on waking hours only, and 245 provided data on both waking and nocturnal ABP.

RESULTS:

Perceived racism was positively associated with nocturnal ABP even when controlling for personality factors and socioeconomic status.

CONCLUSIONS:

The results suggest that racism may influence cardiovascular disease risk through its effects on nocturnal BP recovery.

Food and Drug Administration regulation of diabetes-related mHealth technologies.

In: *J Diabetes Sci Technol* 7 (2), S. 296–301. Online verfügbar unter PM:23566984.

Abstract:

mHealth smartphone applications (apps) offer great promise for managing people with diabetes, as well as those with prediabetes. But to realize that potential, industry needs to get clarity from the U.S. Food and Drug Administration (FDA) regarding the scope of its regulatory oversight. Certain smartphone apps, when properly understood, simply help people live healthier lives, assisting with dietary choices, monitoring exercise, and recording other factors important to overall health. The manufacturers of such apps, in an effort to promote their products but also to educate customers, might wish to explain how using the app can help reduce the risk of developing diabetes. Right now, though, the mere mention of the disease "diabetes" would cause the app to be regulated by the FDA. Such regulation, we submit, discourages the kind of education and motivational messages that our country needs to stem the tide of this disease. Further, should the app simply receive data from a blood glucose meter and graph that data for easier comprehension by the patient, the app would become a class II medical device that requires FDA clearance. Again, we submit that such simple software functionality should not be so discouraged. In this article, we identify the issues that we believe need to be clarified by the FDA in order to unleash the potential of mHealth technology in the diabetes space

Brown, B. M.; Peiffer, J. J.; Sohrabi, H. R.; Mondal, A.; Gupta, V. B.; Rainey-Smith, S. R. et al. (2012):

Intense physical activity is associated with cognitive performance in the elderly.

In: *Transl.Psychiatry* 2 (2158-3188 (Linking)), S. e191. DOI: 10.1038/tp.2012.118.

Abstract:

Numerous studies have reported positive impacts of physical activity on cognitive function. However, the majority of these studies have utilised physical activity questionnaires or surveys, thus results may have been influenced by reporting biases. Through the objective measurement of routine levels of physical activity via actigraphy, we report a significant association between intensity, but not volume, of physical activity and cognitive functioning. A cohort of 217 participants (aged 60-89 years) wore an actigraphy unit for 7 consecutive days and underwent comprehensive neuropsychological assessment. The cohort was stratified into tertiles based on physical activity intensity. Compared with individuals in the lowest tertile of physical activity intensity, those in the highest tertile scored 9%, 9%, 6% and 21% higher on the digit span, digit symbol, Rey Complex Figure Test (RCFT) copy and Rey Figure Test 30-min recall test, respectively. Statistically, participants in the highest tertile of physical activity intensity performed significantly better on the following cognitive tasks: digit symbol, RCFT copy and verbal fluency test (all $P<0.05$). The results indicate that intensity rather than quantity of physical activity may be more important in the association between physical activity and cognitive function

Brown, Daniel E.; Sievert, Lynnette Leidy; Morrison, Lynn A.; Reza, Angela M.; Mills, Phoebe S. (2009):

Do Japanese American women really have fewer hot flashes than European Americans? The Hilo Women's Health Study.

In: *Menopause (New York, N.Y.)* 16 (5), S. 870–876. DOI: 10.1097/gme.0b013e31819d88da.

Abstract:

OBJECTIVE\r\nMany studies have found a significantly lower frequency of reported hot flashes (HFs) in Japanese and Japanese American (JA) populations, leading to speculation about possible dietary, genetic, or cultural differences. These studies have relied on subjective reports of HFs. Accordingly, the purpose of this study was to compare both reported and objective HFs measured by sternal and nuchal skin conductance among JA and European American (EA) women.\r\nMETHODS\r\nTwo surveys of HF frequencies were carried out among women of either EA or JA ethnicity; aged 45 to 55 years; living in Hilo, Hawaii; and not using exogenous hormones. The first was a postal questionnaire (n = 325); the second was carried out during a clinical study of HFs (n = 134). Women in the second group underwent 24-hour ambulatory and 3-hour laboratory monitoring for objective HFs measured through skin conductance at sternal and nuchal sites. Subjective HFs were recorded on the monitor or in a diary.\r\nRESULTS\r\nJAs were significantly less likely to report having had HFs in the previous 2 weeks compared with EAs (postal sample: JAs, 30.9%; EAs, 43.9%; chi(2) = 6.9, P < 0.01; monitored sample: JAs, 26.1%; EAs, 46.6%; chi(2) = 5.3, P < 0.05). JAs were also significantly less likely to report experiencing other symptoms (15 of 30 in the postal sample; 6 of 30 in the monitored sample) than EAs. However, JAs did not significantly differ in likelihood of reporting subjective HFs during the 24-hour ambulatory period (JAs, 51.1%; EAs, 55.8%; chi(2) = 0.3, NS), nor in percentage of individuals displaying one or more objective HFs as measured by the skin conductance monitor (JAs, 77.8%; EAs, 72.1%; chi(2) = 0.5, NS). JAs also did not have a significantly fewer number of objective HFs (t = 0.2, NS) nor of subjective HFs (t = 0.8, NS) during the monitoring period, and these results were unchanged when analyses controlled for menopause status and body mass index.\r\nCONCLUSIONS\r\nThe common finding of fewer reported HFs in people of Japanese ancestry may be a consequence of reporting bias: JAs report fewer symptoms of many conditions compared with people from other ethnic groups. This is probably due to cultural conceptions of what is appropriate to report.

Brown, Barbara B.; Wilson, Laura; Tribby, Calvin P.; Werner, Carol M.; Wolf, Jean; Miller, Harvey J.; Smith, Ken R. (2014):

Adding maps (GPS) to accelerometry data to improve study participants' recall of physical activity: a methodological advance in physical activity research.

In: *Br J Sports Med* 48 (13), S. 1054–1058. DOI: 10.1136/bjsports-2014-093530.

Abstract:

OBJECTIVE: Obtaining the 'when, where and why' of healthy bouts of moderate-to-vigorous physical activity (MVPA) provides insights into natural PA. DESIGN: In Salt Lake City, Utah, adults wore accelerometer and Global Positioning System (GPS) loggers for a week in a cross-sectional study to establish baseline travel and activity patterns near a planned Complete Street intervention involving a new rail line, new sidewalks and a bike path. RESULTS: At the end of the week, research assistants met with the 918 participants who had at least three 10 h days of good accelerometer readings. Accelerometer and GPS data were uploaded and integrated within a custom application, and participants were provided with maps and time information for past MVPA bouts of >/=3 min to help them recall bout details. Participants said that 'getting someplace' was, on average, a more important motivation for their bouts than leisure or exercise. A series of recall tests showed that participants recalled most bouts they were asked about, regardless of the duration of the bout, suggesting that participant perceptions of their shorter lifestyle bouts can be studied with this methodology. Visual prompting with a map depicting where each bout took place yielded more accurate recall than prompting with time cues alone. CONCLUSIONS: These techniques provide a novel way to understand participant memories of the context and subjective assessments associated with healthy bouts of PA. Prompts with time-stamped maps that illustrate places of MVPA offer an effective method to improve understanding of activity and its supportive sociophysical contexts.

Crowdsourcing for cognitive science--the utility of smartphones.

In: *PLoS One* 9 (7), S. e100662. DOI: 10.1371/journal.pone.0100662.

Abstract:

By 2015, there will be an estimated two billion smartphone users worldwide. This technology presents exciting opportunities for cognitive science as a medium for rapid, large-scale experimentation and data collection. At present, cost and logistics limit most study populations to small samples, restricting the experimental questions that can be addressed. In this study we

investigated whether the mass collection of experimental data using smartphone technology is valid, given the variability of data collection outside of a laboratory setting. We presented four classic experimental paradigms as short games, available as a free app and over the first month 20,800 users submitted data. We found that the large sample size vastly outweighed the noise inherent in collecting data outside a controlled laboratory setting, and show that for all four games canonical results were reproduced. For the first time, we provide experimental validation for the use of smartphones for data collection in cognitive science, which can lead to the collection of richer data sets and a significant cost reduction as well as provide an opportunity for efficient phenotypic screening of large populations.

Objective adherence monitoring in multiple sclerosis: initial validation and association with self-report.

In: *Multiple sclerosis (Houndmills, Basingstoke, England)* 16 (1), S. 112–120. DOI: 10.1177/1352458509351897.

Abstract:

Poor adherence to medication is commonplace and contributes to poor health outcomes among numerous patient populations. Studies that have examined treatment adherence in multiple sclerosis focus exclusively on retrospective self-reports and/or imprecise measures of treatment discontinuation. To help address these methodological limitations, the present longitudinal study compared adherence outcomes for patients with multiple sclerosis using retrospective self-reports, adherence diaries, and a novel electronic monitoring device. Sixty-seven patients with relapsing-remitting multiple sclerosis were followed for a period of eight weeks during which they used a medication diary and a sharps container that captured electronically the time and date of each needle disposal. The patients also reported at the outset and conclusion of the study how frequently they missed doses. All measures of adherence were highly correlated. Patients reported better adherence than was indicated by medication diaries and electronic monitoring of needle disposals. Nearly one-fifth of the sample exhibited poor adherence, missing more than 20% of their prescribed medication. The results support the validity of electronic monitoring of needle disposal as an effective means of measuring adherence to disease modifying therapies in multiple sclerosis. In contrast, studies employing only self-report may underestimate poor adherence. Larger scale studies that employ prospective objective methods are necessary to gain a better understanding of adherence patterns in multiple sclerosis.

Bruehl, S.; Liu, X.; Burns, J. W.; Chont, M.; Jamison, R. N. (2012):

Associations between daily chronic pain intensity, daily anger expression, and trait anger expressiveness: An ecological momentary assessment study.

In: *Pain* (0304-3959 (Linking)). DOI: 10.1016/j.pain.2012.08.001.

Abstract:

Links between elevated trait anger expressiveness (anger-out) and greater chronic pain intensity are well documented, but pain-related effects of expressive behaviors actually used to regulate anger when it is experienced have been little explored. This study used ecological momentary assessment methods to explore prospective associations between daily behavioral anger expression and daily chronic pain intensity. Forty-eight chronic low back pain (LBP) patients and 36 healthy controls completed electronic diary ratings of momentary pain and behavioral anger expression in response to random prompts 4 times daily for 7days. Across groups, greater trait anger-out was associated with greater daily behavioral anger expression ($P<0.001$). LBP participants showed higher levels of daily anger expression than controls ($P<0.001$). Generalized estimating equation analyses in the LBP group revealed a lagged main effect of greater behavioral anger expression on increased chronic pain intensity in the subsequent assessment period ($P<0.05$). Examination of a traitxsituation model for anger-out revealed prospective associations between elevated chronic pain intensity and later increases in behavioral anger expression that were restricted largely to individuals low in trait anger-out ($P<0.001$). Traitxsituation interactions for trait anger suppression (anger-in) indicated similar influences of pain intensity on subsequent behavioral anger expression occurring among low anger-in persons ($P<0.001$). Overlap with trait and state negative affect did not account for study findings. This study for the first time documents lagged within-day influences of behavioral anger expression on subsequent chronic pain intensity. Trait anger regulation style may moderate associations between behavioral anger expression and chronic pain intensity

Bruin, Eling D.; Hartmann, Antonia; Uebelhart, Daniel; Murer, Kurt; Zijlstra, Wiebren (2008):

Wearable systems for monitoring mobility-related activities in older people: a systematic review.

In: *Clinical Rehabilitation* 22 (10-11), S. 878–895.

Abstract:

OBJECTIVE:

The use of wearable motion-sensing technology offers important advantages over conventional methods for obtaining measures of physical activity and/or physical functioning in aged individuals. This review aims to identify the actual state of applying wearable systems for monitoring mobility-related activity in older populations. In this review we focus on technologies and applications, research designs, feasibility and adherence aspects, and clinical relevance of wearable motion-sensing technology.

DATA SOURCES:

PubMed (MEDLINE since 1990), Ovid (BIOSIS, CINAHL), and Cochrane (Central) and reference lists of all relevant articles were searched.

REVIEW METHODS:

Two authors independently reviewed randomized and non-randomized trials on people above 65 years systematically. Quality of selected articles was scored and study results were summarised and discussed.

RESULTS:

Two hundred and twenty-seven abstracts were considered. After application of inclusion criteria and full text reading, 42 articles were taken into account in a full text review. Twenty of these papers evaluated walking with step counters, other papers used varying accelerometry approaches for obtaining overall activity measures (n = 16), or for monitoring changes in body postures and activity patterns (n = 17). Seven studies explicitly mentioned feasibility and/or adherence aspects. Eight studies presented outcome evaluations of interventions. Eight articles were representing descriptive research designs, three articles were using mixed descriptive and exploratory research designs, 23 articles used exploratory research-type designs, and eight articles used experimental research designs.

CONCLUSION:

Although feasible methods for monitoring human mobility are available, evidence-based clinical applications of these methods in older populations are in need of further development.

Bruining, Nico; Caiani, Enrico; Chronaki, Catherine; Guzik, Przemyslaw; van der Velde, Enno (2014):

Acquisition and analysis of cardiovascular signals on smartphones: potential, pitfalls and perspectives: by the Task Force of the e-Cardiology Working Group of European Society of Cardiology.

In: *Eur J Prev Cardiol* 21 (2 Suppl), S. 4–13. DOI: 10.1177/2047487314552604.

Abstract:

Smartphones, mobile applications ('apps'), social media, analytics, and the cloud are profoundly changing the practice of medicine and the way health decisions are made. With the constant progress of technology, the measurement of vital signals becomes easier, cheaper, and practically a standard approach in clinical practice. The interest in measuring vital signals goes beyond medical professionals to the general public, patients, informal caregivers, and healthy individuals, who frequently lack any formal medical training. On smartphone platforms such as iOS and Android, a proliferation of health or medical 'apps' acquire and analyse a variety of vital signs through embedded sensors, interconnected devices or peripherals utilising on occasion analytics and social media. Smartphone vendors compete with traditional medical device manufacturers in the grey area between health care, wellness, and fitness, as US and EU regulatory bodies are setting and revising rules for these new technologies. On the other hand, in the absence of robust validation results, clinicians are hesitant to trust measurements by apps or recommend specific apps to their patients, partly also due to lack of a cost reimbursement policy. This review focuses on the acquisition and analysis on smartphones of three important vital signs in the cardiovascular and respiratory field as well as in rehabilitation i.e. heart or pulse rate, blood pressure, and blood oxygenation. The potential, pitfalls, and perspectives on mobile devices and smartphone apps for health management by patients and healthy individuals are discussed.

Bryant, Lauren; Coffey, Anna; Povinelli, Daniel J.; Pruett, John R. J. (2013):

Theory of mind experience sampling in typical adults.

In: *Conscious Cogn* 22 (3), S. 697–707. DOI: 10.1037/t15170-000;

Abstract:

We explored the frequency with which typical adults make Theory of Mind (ToM) attributions, and under what circumstances these attributions occur. We used an experience sampling method to query 30 typical adults about their everyday thoughts. Participants carried a Personal Data Assistant (PDA) that prompted them to categorize their thoughts as Action, Mental State, or Miscellaneous at approximately 30 pseudo-random times during a continuous 10-h period. Additionally, participants noted the direction of their thought (self versus other) and degree of socializing (with people versus alone) at the time of inquiry. We were interested in the relative frequency of ToM (mental state attributions) and how prominent they were in immediate social exchanges. Analyses of multiple choice answers suggest that typical adults: (1) spend more time thinking about actions than mental states and miscellaneous things, (2) exhibit a higher degree of own- versus other-directed thought when alone, and (3) make mental state attributions more frequently when not interacting (offline) than while interacting with others (online). A significant 3-way interaction between thought type, direction of thought, and socializing emerged because action but not mental state thoughts about others occurred more frequently when participants were interacting with people versus when alone; whereas there was an increase in the frequency of both action and mental state attributions about the self when participants were alone as opposed to socializing. A secondary analysis of coded free text responses supports findings 1–3. The results of this study help to create a more naturalistic picture of ToM use in everyday life and the method shows promise for future study of typical and atypical thought processes. Buchman, A. S.; Boyle, P. A.; Yu, L.; Shah, R. C.; Wilson, R. S.; Bennett, D. A. (2012):

Total daily physical activity and the risk of AD and cognitive decline in older adults.

In: *Neurology* 78 (17), S. 1323–1329. DOI: 10.1212/WNL.0b013e3182535d35.

Abstract:

OBJECTIVE: Studies examining the link between objective measures of total daily physical activity and incident Alzheimer disease (AD) are lacking. We tested the hypothesis that an objective measure of total daily physical activity predicts incident AD and cognitive decline. METHODS: Total daily exercise and nonexercise physical activity was measured continuously for up to 10 days with actigraphy (Actical(R); Philips Healthcare, Bend, OR) from 716 older individuals without dementia participating in the Rush Memory and Aging Project, a prospective, observational cohort study. All participants underwent structured annual clinical examination including a battery of 19 cognitive tests. RESULTS: During an average follow-up of about 4 years, 71 subjects developed clinical AD. In a Cox proportional hazards model adjusting for age, sex, and education, total daily physical activity was associated with incident AD (hazard ratio = 0.477; 95% confidence interval 0.273-0.832). The association remained after adjusting for self-report physical, social, and cognitive activities, as well as current level of motor function, depressive symptoms, chronic health conditions, and APOE allele status. In a linear mixed-effect model, the level of total daily physical activity was associated with the rate of global cognitive decline (estimate 0.033, SE 0.012, p = 0.007). CONCLUSIONS: A higher level of total daily physical activity is associated with a reduced risk of AD

Buchman, Aron S.; Wilson, Robert S.; Bennett, David A. (2008):

Total daily activity is associated with cognition in older persons.

In: *The American Journal of Geriatric Psychiatry* 16 (8), S. 697–701.

Abstract:

OBJECTIVES:

The authors tested the hypothesis that total daily physical activity is related to the level of cognition in older persons.

DESIGN:

Cross-sectional study.

SETTING:

Retirement communities across the Chicago metropolitan area.

PARTICIPANTS:

Five hundred twenty-one older persons without dementia.

MEASUREMENTS:

Participants underwent structured evaluation of cognition and objective measures of total daily physical activity were collected using actigraphy.

RESULTS:

In a linear regression model adjusted for age, sex, and education, total daily activity was associated with a global measure of cognition. By contrast, self-report physical activity was not associated with cognition. Further analyses showed that total daily activity was related to all five cognitive subscales.

CONCLUSIONS:

Objective measures of total daily physical activity were associated with a broad range of cognitive abilities in older persons. These findings support the link between physical activity and cognition in the elderly.

Buck, Rhiannon; Morley, Stephen (2006):

A daily process design study of attentional pain control strategies in the self-management of cancer pain.

In: *Eur J Pain* 10 (5), S. 385–398. DOI: 10.1016/j.ejpain.2005.04.001.

Abstract:

This study investigated the use of attentional control strategies in the self-management of pain using daily process design methodology. Twenty six cancer patients with pain completed diaries 3 times daily for 10 days. Diaries incorporated measures of pain intensity, affect, coping, coping efficacy, and the novelty and predictability of pain, and participants completed a cross-sectional measure of catastrophizing. At the across-person level, focusing on pain was associated with increased negative affect, and the use of pain focusing strategies was positively correlated with experiencing pain that was novel in its location or quality. Distractions that were interesting, important and pleasant were positively correlated with positive affect, perceptions of control over pain and ability to decrease pain. Over-prediction of pain was positively correlated with catastrophizing, and negatively correlated with perceptions of control over and ability to decrease pain. The within-person analysis (ARIMA modelling) showed that catastrophizing moderated the effects of pain focusing strategies, novel pain and over-predictions of pain. Meta-analysis of the ARIMA models revealed that the within-person effects of using attentional strategies did not generalize across the sample. These findings indicated that the effects of distraction strategies are influenced by their motivational-affective significance rather than the frequency with which they are used, and provided further evidence that the threat value of pain influences the way in which people cope with their pain. Theoretical and clinical implications are discussed.

Buckner, Julia D.; Zvolensky, Michael J.; Smits, Jasper A. J.; Norton, Peter J.; Crosby, Ross D.; Wonderlich, Stephen A.; Schmidt, Norman B. (2011):

Anxiety sensitivity and marijuana use: an analysis from ecological momentary assessment.

In: *Depression and anxiety* 28 (5), S. 420–426. DOI: 10.1002/da.20816.

Abstract:

BACKGROUND\r\nThe cognitive factor of Anxiety Sensitivity (AS; the fear of anxiety and related bodily sensations) is theorized to play a role in cannabis use and its disorders. Lower-order facets of AS (physical concerns, mental incapacitation concerns, and social concerns) may be differentially related to cannabis use behavior. However, little is known about the impact of AS facets on the immediate antecedents of cannabis use.\r\nMETHODS\r\nThis study used ecological momentary assessment (EMA) to prospectively examine the relations between specific facets of AS, cannabis craving, state anxiety, and cannabis use in the natural environment using real-world data about ad lib cannabis use episodes. Participants were 49 current cannabis users (38.8% female).\r\nRESULTS\r\nAS-mental incapacitation fears were related to significantly greater severity of cannabis-related problems at baseline. During the EMA period, AS-mental incapacitation and AS-social concerns significantly interacted with cannabis craving to prospectively predict subsequent cannabis use. Specifically, individuals with higher craving and either higher AS-mental incapacitation or AS-social concerns were the most likely to subsequently use cannabis. In contrast to prediction, no AS facet significantly moderated the relationship between state anxiety and cannabis use.\r\nCONCLUSIONS\r\nThese findings suggest facets of AS (mental incapacitation and social fears) interact with cannabis craving to predict cannabis use. Findings also suggest differential relations between facets of AS and cannabis-related behaviors.

Buffart, Laurien M.; van den Berg-Emons, Rita J; Burdorf, Alex; Janssen, Wim G.; Stam, Henk J.; Roebroeck, Marij E. (2008):

Cardiovascular disease risk factors and the relationships with physical activity, aerobic fitness, and body fat in adolescents and young adults with myelomeningocele.

In: *Arch Phys Med Rehabil* 89 (11), S. 2167–2173.

Abstract:

OBJECTIVES:

To describe cardiovascular disease (CVD) risk factors in adolescents and young adults with myelomeningocele (MMC) and to explore relationships with physical activity, aerobic fitness, and body fat.

DESIGN:

Cross-sectional study.

SETTING:

Outpatient clinic.

PARTICIPANTS:

Adolescents and young adults (N=31) with MMC (58% men) age 16 through 30 years; 13 were ambulatory and 18 were nonambulatory.

INTERVENTIONS:

Not applicable.

MAIN OUTCOME MEASURES:

We studied biologic and lifestyle-related CVD risk factors, including lipid and lipoprotein profiles, blood pressure, aerobic fitness (Vo(2)peak), body fat, daily physical activity, and smoking behavior. We considered subjects at increased CVD risk when 2 or more of the following risk factors clustered: systolic blood pressure, total serum cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), and cigarette smoking. Relationships were studied using regression analyses.

RESULTS:

Levels of TC, low-density lipoprotein cholesterol, and triglycerides were elevated in 29%, 38%, and 3% of the participants, respectively. HDL-C was reduced in 19%. Hypertension was found in 20%, and 19% were current cigarette smokers. Based on the clustering of risk factors, 42% of the participants were at increased CVD risk: 15% of ambulatory participants and 61% of nonambulatory participants (P=.03). Adjusted for sex and ambulatory status, participants with higher aerobic fitness tended to be more likely to have no CVD risk (odds ratio=13.0; P=.07). CVD risk was not associated to physical activity and body fat.

CONCLUSIONS:

A large proportion of the study sample was at CVD risk, indicated by clustering of risk factors. Improving aerobic fitness in young adults with MMC may contribute in reducing CVD risk; this needs to be confirmed in future studies.

Bukara-Radujkovic, G.; Zdravkovic, D.; Lakic, S. (2011):

Short-term use of continuous glucose monitoring system adds to glycemic control in young type 1 diabetes mellitus patients in the long run: a clinical trial.

In: *Vojnosanit.Pregl.* 68 (8), S. 650–654. Online verfügbar unter PM:21991787.

Abstract:

BACKGROUND/AIM: Balancing strict glycemic control with setting realistic goals for each individual child and family can optimize growth, ensure normal pubertal development and emotional maturation, and control long term complications in children with type 1 diabetes (T1DM). The aim of this study was to evaluate the efficacy of short-term continuous glucose monitoring system (CGMS) application in improvement of glycemic control in pediatric type 1 diabetes mellitus (T1DM) patients. METHODS. A total of 80 pediatric T1DM patients were randomly assigned into the experimental and the control group. The experimental group wore CGMS sensor for 72 hours at the beginning of the study. Self-monitored blood glucose (SMBG) levels and hemoglobin A1c (HbA1c) levels were obtained for both groups at baseline, and at 3 and 6 months. RESULTS. There was a significant improvement in HbA1c ($p < 0.001$), in both the experimental and the control group, without a significant difference between the groups. Nevertheless, after 6 months the improvement of mean glycemia was noticed only in the experimental group. This finding was accompanied with a decrease in the number of hyperglycemic events and no increase in the number of hypoglycemic events in the experimental group. CONCLUSIONS: The results suggest that the CGMS can be considered as a

valuable tool in treating pediatric T1DM patients, however further research is needed to more accurately estimate to what extent, if any, it outperforms intensive self-monitoring of blood glucose

Buller, D. B.; Borland, R.; Bettinghaus, E. P.; Shane, J. H.; Zimmerman, D. E. (2013):

Randomized Trial of a Smartphone Mobile Application Compared to Text Messaging to Support Smoking Cessation.

In: *Telemed.J.E.Health* (1530-5627 (Linking)). DOI: 10.1089/tmj.2013.0169.

Abstract:

Abstract Background: Text messaging has successfully supported smoking cessation. This study compares a mobile application with text messaging to support smoking cessation. Materials and Methods: Young adult smokers 18-30 years old (n=102) participated in a randomized pretest-posttest trial. Smokers received a smartphone application (REQ-Mobile) with short messages and interactive tools or a text messaging system (onQ), managed by an expert system. Self-reported usability of REQ-Mobile and quitting behavior (quit attempts, point-prevalence, 30-day point-prevalence, and continued abstinence) were assessed in posttests. Results: Overall, 60% of smokers used mobile services (REQ-Mobile, 61%, mean of 128.5 messages received; onQ, 59%, mean of 107.8 messages), and 75% evaluated REQ-Mobile as user-friendly. A majority of smokers reported being abstinent at posttest (6 weeks, 53% of completers; 12 weeks, 66% of completers [44% of all cases]). Also, 37% (25%of all cases) reported 30-day point-prevalence abstinence, and 32% (22% of all cases) reported continuous abstinence at 12 weeks. OnQ produced more abstinence ($p<0.05$) than REQ-Mobile. Use of both services predicted increased 30-day abstinence at 12 weeks (used, 47%; not used, 20%; $p=0.03$). Conclusions: REQ-Mobile was feasible for delivering cessation support but appeared to not move smokers to quit as quickly as text messaging. Text messaging may work better because it is simple, well known, and delivered to a primary inbox. These advantages may disappear as smokers become more experienced with new handsets. Mobile phones may be promising delivery platforms for cessation services using either smartphone applications or text messaging

Bullimore, Mark A.; Reuter, Kathleen S.; Jones, Lisa A.; Mitchell, G. Lynn; Zoz, Jessica; Rah, Marjorie J. (2006):

The study of progression of adult nearsightedness (SPAN): design and baseline characteristics.

In: *Optometry and vision science: official publication of the American Academy of Optometry* 83 (8), S. 594.

Abstract:

PURPOSE:

The Study of Progression of Adult Nearsightedness (SPAN) is a 5-year observational study to determine the risk factors associated with adult myopia progression. Candidate risk factors include: a high proportion of time spent performing near tasks, performing near tasks at a close distance, high accommodative convergence/accommodation (AC/A) ratio, and high accommodative lag.

METHODS:

Subjects between 25 and 35 years of age, with at least -0.50 D spherical equivalent of myopia (cycloplegic autorefraction), were recruited from the faculty and staff of The Ohio State University. Progression is defined as an increase in myopia of at least -0.75 D spherical equivalent as determined by cycloplegic autorefraction. Annual testing includes visual acuity, noncycloplegic autorefraction and autokeratometry, phoria, accommodative lag, response AC/A ratio, cycloplegic autorefraction, videophakometry, ultrasound, and partial coherence interferometry (IOLMaster). Participants' near activities were assessed using the experience sampling method (ESM). Subjects carried a pager for two 1-week periods and were paged randomly throughout the day. Each time they were paged, they dialed into an automated telephone survey and reported their visual activity at that time. From these responses, the proportion of time spent performing near work was estimated.

RESULTS:

Three-hundred ninety-six subjects were enrolled in SPAN. The mean (+/- standard deviation) age at baseline was 30.7 +/- 3.5 years, 66% were female, 80% were white, 11% were black, and 8% were Asian/Pacific Islander. The mean level of myopia (spherical equivalent) was -3.54 +/- 1.77 D, the mean axial length by IOLMaster was 24.6 +/- 1.1 mm, and subjects were 1.7 +/- 4.0 Delta exophoric. Refractive error was associated with the number of myopic parents ($F = 3.83$, $p = 0.023$), and the number of myopic parents was associated with the age of myopia onset ($chi2 = 13.78$, $p = 0.001$). In a multivariate analysis, onset of myopia (early vs. late) still had a significant effect on degree of myopia ($F = 115.1$, $p < 0.001$), but the number of myopic parents was no longer significant ($F = 0.65$, $p = 0.52$). For the ESM, the most frequently reported visual task was computer use (mean, 18.9%; range, 0-60.0%) and, overall, subjects reported near work activity 34.1% of the time (range, 0-67.3%).

CONCLUSIONS:

The design of SPAN and the baseline characteristics of the cohort have been described. Parental history of myopia is related to the degree of myopia at baseline, but this effect is mediated by the age of onset of myopia.

Buman, Matthew P.; Hekler, Eric B.; Haskell, William L.; Pruitt, Leslie; Conway, Terry L.; Cain, Kelli L. et al. (2010):

Objective light-intensity physical activity associations with rated health in older adults.

In: *Am J Epidemiol* 172 (10), S. 1155–1165.

Abstract:

The extent to which light-intensity physical activity contributes to health in older adults is not well known. The authors examined associations between physical activity across the intensity spectrum (sedentary to vigorous) and health and well-being variables in older adults. Two 7-day assessments of accelerometry from 2005 to 2007 were collected 6 months apart in the observational Senior Neighborhood Quality of Life Study of adults aged >65 years in Baltimore, Maryland, and Seattle, Washington. Self-reported health and psychosocial variables (e.g., lower-extremity function, body weight, rated stress) were also collected. Physical activity based on existing accelerometer thresholds for moderate/vigorous, high-light, low-light, and sedentary categories were examined as correlates of physical health and psychosocial well-being in mixed-effects regression models. Participants (N = 862) were 75.4 (standard deviation, 6.8) years of age, 56% female, 71% white, and 58% overweight/obese. After adjustment for study covariates and time spent in moderate/vigorous physical activity and sedentary behavior, low-light and high-light physical activity were positively related to physical health (all P < 0.0001) and well-being (all P < 0.001). Additionally, replacing 30 minutes/day of sedentary time with equal amounts of low-light or high-light physical activity was associated with better physical health (all P < 0.0001). Objectively measured light-intensity physical activity is associated with physical health and well-being variables in older adults.

Bump Buddy and Baby Buddy smartphone apps trialled

(2013). In: *Nurs.Child Young.People.* 25 (6), S. 5. Online verfügbar unter PM:23988096.

Abstract:

TWO FREE mobile phone apps to help young women prepare for parenthood are being tested with the backing of the RCN, Royal College of Paediatrics and Child Health, and the Royal College of Midwives

Mobile-based asthma action plans for adolescents.

In: *J Asthma*, S. 1–4. DOI: 10.3109/02770903.2014.995307.

Abstract:

Abstract Purpose: To examine feasibility and utilization of a mobile asthma action plan (AAP) among adolescents. Methods: Adolescents (aged 12-17 years) with persistent asthma had their personalized AAP downloaded to a smartphone application. Teens were prompted by the mobile application to record either daily symptoms or peak flow measurements and to record medications. Once data were entered, the application provided immediate feedback based on the teen's AAP instructions. Asthma Control Test (ACT(R)) and child asthma self-efficacy scores were examined pre- and post-intervention. Results: Adolescents utilized the mobile AAP a median 4.3 days/week. Participant satisfaction was high with 93% stating that they were better able to control asthma by utilizing the mobile AAP. For participants with uncontrolled asthma at baseline, median (interquartile range) ACT scores improved significantly from 16 (5) to 18 (8) [p = 0.03]. Median asthma attack prevention self-efficacy scores improved from 34 (3.5) to 36 (5.3) [p = 0.04]. Conclusions: Results suggest that personalized mobile-based AAPs are a feasible method to communicate AAP instructions to teens.

An assessment of daily food intake in participants with anorexia nervosa in the natural environment.

In: *Int J Eat Disord* 42 (4), S. 371–374. DOI: 10.1002/eat.20628.

Abstract:

OBJECTIVE\r\nTo examine the caloric intake in women with anorexia nervosa (AN) and how it varies by day as a function of the presence or absence of binge eating and/or purging behaviors.\r\nMETHOD\r\nFemale participants with AN (n = 84, mean age = 24.4, range 18-51) were recruited from three different sites. Data on food intake were obtained through the use of 24-h dietary recall using the Nutritional Data Systems for Research, and data on binge eating and purging behaviors were collected on palmtop computers using an ecological momentary assessment paradigm. Daily macronutrient intake was compared on days during which binge eating and/or purging behaviors did or did not occur.\r\nRESULTS\r\nOn days during which binge eating and purging behaviors both occurred, participants reported significantly greater kilocalorie intake when compared with days when neither behavior occurred, or when only binge eating or purging occurred. Binge eating episodes were only modest in size on days when purging did not occur. Energy intake overall was higher than expected.\r\nDISCUSSION\r\nIntake on days where binge eating occurred varied dramatically based on whether or not purging occurred. Whether markedly increased binge eating intake was causally related to purging is unclear. Nonetheless eating episodes were at times quite large and equivalent to those reported by participants with bulimia nervosa in other research.

Night/day ratios of ambulatory blood pressure among healthy adolescents: Roles of race, socioeconomic status, and psychosocial factors.

In: *Annals of Behavioral Medicine* 46 (2), S. 217–226. DOI: 10.1037/t01038-000;

Abstract:

Background: Elevated nighttime blood pressure (BP) predicts hypertension and its complications in adulthood. Purpose: This study aimed to assess the independent effects of race and family income on night/day BP among adolescents and to examine whether negative emotions, low positive resources, and unpleasant interactions during the day are also related. Methods: Healthy African American and Caucasian high school students (N=239) wore an ambulatory BP monitor for 48 h, recorded quality of ongoing interpersonal interactions, and completed questionnaires. Results: African Americans and those with lower family income had higher night/day BP ratios. African Americans reporting greater negative emotions, lower positive resources, and more unpleasant interactions had higher night/day BP ratios. Conclusions: Racial differences in night BP emerge by adolescence, independent of family income. African Americans, especially those high in negative emotions and low in positive resources, may be at higher relative risk for hypertension later in life in part due to elevated night BP. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Home lighting before usual bedtime impacts circadian timing: a field study.

In: *Photochem Photobiol* 90 (3), S. 723–726.

Abstract:

Laboratory studies suggest that evening light before bedtime can suppress melatonin. Here, we measured the range of evening light intensity people can generate with their household lights, and for the first time determined if varying home light before usual bedtime can shift circadian phase. This was a 3-week study with two counterbalanced conditions separated by a 5-day break. In a dim week, eight healthy subjects minimized their home light exposure from 4 h before habitual bedtime until a self-selected bedtime. In a bright week, the subjects maximized their home lighting for the same time. The dim light melatonin onset (DLMO) was assessed after each week. On average subjects maximized their lights to approximately 65 lux and minimized their lights to approximately 3 lux. Wrist actigraphy indicated that subjects went to bed slightly later when lights were maximized (average 14 min later, P = 0.05), but wake time did not change. Every subject had a later DLMO after the week of maximum versus minimum light exposure (average 1:03 h later, P < 0.001). These results demonstrate that the light intensity people can generate at home in the few hours before habitual bedtime can alter circadian timing. People should reduce their evening light exposure to lessen circadian misalignment.

Palm or cell? Comparing personal digital assistants and cell phones for experience sampling research.

In: *Social Science Computer Review* 31 (2), S. 244–251. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-07289-009%26site%3dehost-live;t;kmedding@uncg.edu;p;cjburgin@uncg.edu.

Abstract:

Personal digital assistants (PDA), particularly Palm Pilots, are popular data collection devices in experience sampling research. The declining availability of such devices, however, has prompted researchers to explore alternative technologies for signaling participants and collecting responses. The present research considers interactive voice response (IVR) methods, which can deliver questions and collect data using common cell phones. Participants completed an experience sampling study using either a PDA (n = 428) or a cell phone under three different conditions (IVR condition n = 98; IVR Callback condition n = 93; IVR Callback Comeback condition n = 94). We found that response rates were higher when people used PDAs (69%) than when they used their cell phones (IVR condition = 51%), but response rates increased when people could call back within a few minutes of missing a signal (IVR Callback condition = 58%) and had a face-to-face meeting with a researcher midweek (IVR Callback Comeback = 64%). The daily life ratings were similar across the conditions. The findings are encouraging for researchers interested in using IVR cell phone methods for ecological momentary assessment, but more work is needed to develop procedures or incentives that increase response rates. SMART trial: A randomized clinical trial of self-monitoring in behavioral weight management-design and baseline findings.

In: *Contemporary clinical trials* 30 (6), S. 540–551. DOI: 10.1016/j.cct.2009.07.003.

Abstract:

BACKGROUND\r\nThe primary form of treatment for obesity today is behavioral therapy. Self-monitoring diet and physical activity plays an important role in interventions targeting behavior and weight change. The SMART weight loss trial examined the impact of replacing the standard paper record used for self-monitoring with a personal digital assistant (PDA). This paper describes the design, methods, intervention, and baseline sample characteristics of the SMART trial.\r\nMETHODS\r\nThe SMART trial used a 3-group design to determine the effects of different modes of self-monitoring on short- and long-term weight loss and on adherence to self-monitoring in a 24-month intervention. Participants were randomized to one of three conditions (1) use of a standard paper record (PR); (2) use of a PDA with dietary and physical activity software (PDA); or (3), use of a PDA with the same software plus a customized feedback program (PDA + FB).\r\nRESULTS\r\nWe screened 704 individuals and randomized 210. There were statistically but not clinically significant differences among the three cohorts in age, education, HDL cholesterol, blood glucose and systolic blood pressure. At 24 months, retention rate for the first of three cohorts was 90%.\r\nCONCLUSIONS\r\nTo the best of our knowledge, the SMART trial is the first large study to compare different methods of self-monitoring in a behavioral weight loss intervention and to compare the use of PDAs to conventional paper records. This study has the potential to reveal significant details about self-monitoring patterns and whether technology can improve adherence to this vital intervention component.

Perceptions of successful cues to action and opportunities to augment behavioral triggers in diabetes self-management: qualitative analysis of a mobile intervention for low-income Latinos with diabetes.

In: *J Med Internet Res* 16 (1), S. e25. DOI: 10.2196/jmir.2881.

Abstract:

BACKGROUND: The increasing prevalence of diabetes and the associated cost of managing this complicated disease have a significant impact on public health outcomes and health expenditures, especially among resource-poor Latino patients. Mobile health (mHealth) may be the solution to reaching this group and improving their health. OBJECTIVE: In this qualitative study, we examined nuances of motivation, intention, and triggers to action effected by TExT-MED (Trial to Examine Text Messaging for Emergency Department patient with Diabetes), an mHealth intervention tailored to low-income, urban Latinos with diabetes. TExT-MED is a fully-automated, text message-based program designed to increase knowledge, self-efficacy, and subsequent disease management and glycemic control. METHODS: We conducted 5 focus group interviews with 24 people who participated in TExT-MED. We employed a modified grounded theory analytic approach-an iterative process of coding and immersion in the data used to recognize the patterns and links between concepts voiced by the participants. We coded data to identify themes of participant experiences, motivations, and responses to the program. We organized themes into a theory of TExT-MED's action. RESULTS: Participants enjoyed their experience with TExT-MED and believed it improved their diabetes management. Through analysis of the transcripts, we identified that the strengths of the program were messages that cued specific behaviors such as medication reminders and challenge messages. Our analysis also revealed that increasing personalization of message delivery and content could augment these cues. CONCLUSIONS: This in-depth qualitative analysis of TExT-MED shows that low-income Latino patients will accept text messages as a behavioral intervention. This mHealth intervention acts as a behavioral trigger rather than an education platform. Personalization is an opportunity to enhance these cues to action and further research should be conducted on the ideal forms of personalization.

Temporal associations between spouse criticism/hostility and pain among patients with chronic pain: A within-couple daily diary study.

In: *Pain* (0304-3959 (Linking)). DOI: 10.1016/j.pain.2013.07.053.

Abstract:

Chronic musculoskeletal pain can strain marriages, perhaps even to the point of engendering spouse criticism and hostility directed toward patients. Such negative spouse responses may have detrimental effects on patient well-being. While results of cross-sectional studies support this notion, we extended these efforts by introducing expressed emotion (EE) and interpersonal theoretical perspectives, and by using electronic diary methods to capture both patient and spouse reports in a prospective design. Patients with chronic low back pain (CLBP) and their spouses (N=105 couples) reported on perceived spouse behavior and patient pain 5 times/day for 14days using Personal Data Assistants (PDAs). Concurrent and lagged within-couple associations between patient's perceptions of spouse criticism/hostility and patient self-reported pain and spouses' observations of patient pain behaviors revealed that (1) patient perceived spouse criticism and hostility were correlated significantly with pain intensity, and spouse observed patient pain behavior was related significantly with patient perceived hostility at the same time point; (2) patient perceived spouse hostility significantly predicted patient pain intensity 3hours later, and spouse observed pain behaviors significantly predicted patient perceived spouse hostility 3hours later. Results support both EE and interpersonal models, and imply that a comprehensive model would combine these conceptualizations to fully illustrate how spouse criticism/hostility and patient pain interact to produce a negative spiral. Given that marital interactions are amenable to clinical intervention, improved insight into how spouse behavior and patient pain are tightly linked will encourage productive translational efforts to target this neglected area

Burrow, A. L.; Hill, P. L. (2013):

Derailed by Diversity? Purpose Buffers the Relationship Between Ethnic Composition on Trains and Passenger Negative Mood.

In: *Pers.Soc.Psychol.Bull* (0146-1672 (Linking)). DOI: 10.1177/0146167213499377.

Abstract:

Many individuals feel socially isolated and distressed in ethnically diverse settings. Purpose in life may buffer this form of distress by fostering one's sense of having a meaningful direction, which may also be of significance to others. In two experience-sampling studies with ethnically diverse participants, we examined associations between the ethnic composition of urban trains and passenger distress, and tested purpose as a moderator of these relationships. Study 1 showed that participants of all ethnic backgrounds reported greater negative mood when the percentage of ethnic out-group members aboard their train increased. However, individual differences in purpose significantly attenuated this effect. Study 2 replicated and extended these findings experimentally by showing that relative to a control condition, briefly writing about purpose prior to boarding trains also diminished the impact of ethnic composition on negative mood. The discussion addresses strategies for promoting positive adjustment in our increasingly diverse society

Evidence that the subtypes of antisocial behavior questionnaire (STAB) predicts momentary reports of acting-out behaviors.

In: *Personality and Individual Differences* 48 (8), S. 917–920.

Abstract:

There is growing recognition that substantively important distinctions exist across physically aggressive, rule-breaking, and socially aggressive forms of antisocial behavior. Even so, one limitation to accumulating additional scientific insights into the correlates and origins of these three varieties of antisocial behavior has been the lack of an efficient self-report assessment in the public domain. The Subtypes of the Antisocial Behavior Questionnaire (STAB) was developed to address this need. Although there is already a good deal of psychometric support for the STAB, prior research has yet to examine its “ecological” validity. In other words, it remains unclear whether the STAB scales would predict the frequency of acting-out behaviors in daily life. The current study sought to examine this question via an electronic diary study, in which participants reported on their momentary behaviors on multiple occasions in their natural environments. Analyses revealed that each STAB scale uniquely predicted only the momentary acting-out behaviors characteristic of that scale. Such findings provide further support for the STAB as a promising self-report measure of physically aggressive, rule-breaking, and socially aggressive forms of antisocial behavior.

Functional somatic symptoms and psychological states: an electronic diary study.

In: *Psychosomatic Medicine* 71 (1), S. 77–83. DOI: 10.1097/PSY.0b013e31818f2acb.

Abstract:

OBJECTIVE\r\nTo investigate the links between functional physical symptoms and psychological states in a sample of patients with persistent medically unexplained symptoms. Despite the epidemiological evidence for links between physical symptoms and mental processes, prior diary studies have shown inconsistent associations and generally been limited to single symptom and psychological variable pairs.\r\nMETHODS\r\nTwenty-six patients with at least three functional physical symptoms completed twice daily self-report measures of symptoms, fatigue, anxiety, stress, mood, and symptom concern using electronic diaries over 12 weeks. Associations between physical symptoms and psychological variables were measured by linear mixed effects models at the levels of diary entry and individual.\r\nRESULTS\r\nDespite high baseline questionnaire scores for depression and anxiety, diary ratings of anxiety and stress were relatively low. Fixed effects regression coefficients varied between symptoms and psychological variables; for instance, the fixed effects regression coefficient (95% Confidence Intervals) for fatigue as the outcome variable was 0.39 (0.31-0.47) with low mood and 0.05 (-0.01-0.10) with stress as the predictor. Random effects coefficients showed less variation between individuals for fatigue and musculoskeletal pain than for other symptoms.\r\nCONCLUSION\r\nSelf-reported mood and symptom concern were more strongly associated with functional physical symptoms than anxiety or stress. We suggest that one reason patients with functional somatic symptoms reject psychosomatic explanations is because they do not experience sufficient correlation between symptoms and psychological states.

A Virtual Hope Box Smartphone App as an Accessory to Therapy: Proof-of-Concept in a Clinical Sample of Veterans.

In: *Suicide Life Threat Behav. DOI:* 10.1111/sltb.12103.

Abstract:

A "Hope Box" is a therapeutic tool employed by clinicians with patients who are having difficulty coping with negative thoughts and stress, including patients who may be at risk of suicide or nonsuicidal self-harm. We conducted a proof-of-concept test of a "Virtual" Hope Box (VHB)-a smartphone app that delivers patient-tailored coping tools. Compared with a conventional hope box integrated into VA behavioral health treatment, high-risk patients and their clinicians used the VHB more regularly and found the VHB beneficial, useful, easy to set up, and said they were likely to use the VHB in the future and recommend the VHB to peers.

Businelle, Michael S.; Lam, Cho Y.; Kendzor, Darla E.; Cofta-Woerpel, Ludmila; McClure, Jennifer B.; Cinciripini, Paul M.; Wetter, David W. (2013):

Alcohol consumption and urges to smoke among women during a smoking cessation attempt.

In: *Experimental and Clinical Psychopharmacology* 21 (1), S. 29–37. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-03347-002%26site%3dehost-live;michael.businelle@utsouthwestern.edu.

Abstract:

Laboratory and ad libitum smoking studies have indicated that alcohol consumption increases the frequency and intensity of smoking urges. However, few studies have examined the relation between smoking urges and alcohol use in natural settings during a quit attempt. The purpose of this study was to examine the relationships between smoking urge and alcohol use in women who reported drinking on at least one occasion during the first 7 days of a smoking quit attempt (N = 134). Participants were asked to use a palmtop computer to complete assessments that recorded smoking urges and recent alcohol use. Multilevel analyses examined the relation between smoking urge parameters and alcohol use. Smoking urges were higher during assessments where alcohol had been recently consumed compared to assessments where no alcohol had been consumed. Interestingly, the first urge rating of the day was higher and urges were more volatile on days where alcohol would eventually be consumed as compared to days where no alcohol was consumed. A closer examination of urge parameters on drinking days indicated that smoking urge trajectory was significantly flatter and urge volatility was significantly higher following alcohol consumption. However, smoking urge trajectory also flattened later in the day on nondrinking days. The findings suggest that there may be reciprocal relations between smoking urge and alcohol use (e.g., higher initial urges and more volatile urges may increase the likelihood of alcohol use, and alcohol use may impact within-day smoking urge parameters), and these relations could potentially impact smoking cessation and relapse. Businelle, Michael S.; Ma, Ping; Kendzor, Darla E.; Reitzel, Lorraine R.; Chen, Minxing; Lam, Cho Y. et al. (2014):

Predicting quit attempts among homeless smokers seeking cessation treatment: An ecological momentary assessment study.

In: *Nicotine & Tobacco Research* 16 (10), S. 1371–1378. DOI: 10.1037/t32635-000;

Abstract:

Introduction: Homeless adults are more likely to smoke tobacco and are less likely to successfully quit smoking than smokers in the general population, despite comparable numbers of cessation attempts and desire to quit. To date, studies that have examined smoking cessation in homeless samples have used traditional lab/clinic-based assessment methodologies. Real-time assessment of key variables may provide new insights into the process of quitting among homeless smokers. Methods: The purpose of the current study was to identify predictors of a quit attempt using real-time assessment methodology during the 6 days prior to a scheduled quit attempt among homeless adults seeking care at a shelter-based smoking cessation clinic. Parameters for multiple variables (i.e., motivation for quitting, smoking expectancies, quit self-efficacy, smoking urges, negative affect, positive affect, restlessness, hostility, and stress) were calculated and were used as predictors of biochemically verified quit date abstinence (i.e., ≥13 hr abstinent) using logistic regression analyses. Results: Participants (n = 57) were predominantly male (59.6%), non-White (68.4%), and smoked an average of 18 cigarettes per day. A total of 1,132 ecological momentary

assessments (83% completion rate) were collected at random times (i.e., up to 4 assessments/day) during the 6 days prior to a scheduled quit attempt. Results indicated that declining (negative slope) negative affect, restlessness, and stress predicted quit date abstinence. Additionally, increasing positive coping expectancies across the prequit week predicted quit date abstinence. Conclusions: Study findings highlight multiple variables that may be targeted during the precessation period to increase smoking cessation attempts in this difficult to treat population of smokers. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

A pilot study of actigraphy as an objective measure of SSRI activation symptoms: Results from a randomized placebo controlled psychopharmacological treatment study.

In: *Psychiatry Res. DOI:* 10.1016/j.psychres.2014.11.070.

Abstract:

Selective serotonin reuptake inhibitors (SSRIs) are an efficacious and effective treatment for pediatric obsessive-compulsive disorder (OCD) but have received scrutiny due to a potential side effect constellation called activation syndrome. While recent research introduced a subjective measure of activation syndrome, objective measures have not been tested. This pilot study, using data from a larger randomized-controlled trial, investigated the potential of actigraphy to provide an objective measure of activation symptoms in 44 youths with OCD beginning an SSRI medication regimen. Data were collected over the first four weeks of a multi-site, parallel, double-blind, randomized, placebo controlled psychopharmacological treatment study and statistical modeling was utilized to test how activation syndrome severity predicts daily and nightly activity levels. Results indicated that youths with higher activation symptoms had lower daytime activity levels when treatment averages were analyzed; in contrast youths who experienced onset of activation symptoms one week were more likely to have higher day-time and night-time activity ratings that week. Results support actigraphy as a potential objective measure of activation symptoms. Subsequent studies are needed to confirm these findings and test clinical applications for use by clinicians to monitor activation syndrome during SSRI treatment. National Institutes of Health (5UO1 MH078594-01); NCT00382291.

Bussmann, Johannes B. J.; Ebner-Priemer, Ulrich W. (2012):

Ambulatory assessment of movement behavior: Methodology, measurement, and application. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 235–250. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-013%26site%3dehost-live.

Abstract:

(from the chapter) Behavior is central to psychology in almost any definition of the field. A specific sub-domain of behavior is movement behavior, the overt performance of postures, movements, and activities in daily life, and its covert physiological consequences. Although overt behavior is a core aspect of psychology, assessment strategies have tended to focus on emotional, cognitive, or physiological responses. However, there is converging evidence that movement behavior is a unique and relevant domain of interest that cannot accurately be assessed by self-reports, questionnaires, or other instruments. The methodology of ambulatory assessment of movement behavior has benefited from a number of major developments over the last 15 years: New movement sensors and advanced computer algorithms allow precise, long-term, and user-friendly assessment of movement behavior, such as the amount of physical activity, momentary posture, basic types of motion, as well as movement pathologies in everyday life. Movement behavior thus includes not only quantitative aspects such as the amount and intensity of postures, movements, and activities but also qualitative aspects related to "how people move," such as smoothness of movement, speed, and movement patterns. With this overview, we aim to introduce recent developments in ambulatory activity monitoring to a broad readership in psychology. We (1) report on some conceptual issues around the assessment of movement behavior; (2) provide a summary of techniques and instruments used to assess activity, postures, and movement; (3) discuss methodological aspects of measurement; and (4) demonstrate recent applications of ambulatory assessment of physical activity, posture, and movement within a wide range of psychological topics. Bussmann, Johannes B. J.; Ebner-Priemer, Ulrich W.; Fahrenberg, Jochen (2009):

Ambulatory activity monitoring: progress in measurement of activity, posture, and specific motion patterns in daily life.

In: *European Psychologist* 14 (2), S. 142–152.

Abstract:

Behavior is central to psychology in almost any definition. Although observable activity is a core aspect of behavior, assessment strategies have tended to focus on emotional, cognitive, or physiological responses. When physical activity is assessed, it is done so mostly with questionnaires. Converging evidence of only a moderate association between self-reports of physical activity and objectively measured physical activity does raise questions about the validity of these self-reports. Ambulatory activity monitoring, defined as the measurement strategy to assess physical activity, posture, and movement patterns continuously in everyday life, has made major advances over the last decade and has considerable potential for further application in the assessment of observable activity, a core aspect of behavior. With new piezoresistive sensors and advanced computer algorithms, the objective measurement of physical activity, posture, and movement is much more easily achieved and measurement precision has improved tremendously. With this overview, we introduce to the reader some recent developments in ambulatory activity monitoring. We will elucidate the discrepancies between objective and subjective reports of activity, outline recent methodological developments, and offer the reader a framework for developing insight into the state of the art in ambulatory activity-monitoring technology, discuss methodological aspects of time-based design and psychometric properties, and demonstrate recent applications. Although not yet main stream, ambulatory activity monitoring – especially in combination with the simultaneous assessment of emotions, mood, or physiological variables – provides a comprehensive methodology for psychology because of its suitability for explaining behavior in context.

Bussmann, J. B.; Van Den Berg-Emons Rj (2013):

To total amount of activity... and beyond: perspectives on measuring physical behavior.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 463. DOI: 10.3389/fpsyg.2013.00463.

Abstract:

The aim of this paper is to describe and discuss some perspectives on definitions, constructs, and outcome parameters of physical behavior. The paper focuses on the following constructs: Physical activity and active lifestyle vs. sedentary behavior and sedentary lifestyle; Amount of physical activity vs. amount of walking; Detailed body posture and movement data vs. overall physical activity data; Behavioral context of activities; Quantity vs. quality; Physical behavior vs. physiological response. Subsequently, the following outcome parameters provided by data reduction procedures are discussed: Distribution of length of bouts; Variability in bout length; Time window; Intensity and intensity threshold. The overview indicates that physical behavior is a multi-dimensional construct, and it stresses the importance and relevance of constructs and parameters other than total amount of physical activity. It is concluded that the challenge for the future will be to determine which parameters are most relevant, valid and responsive. This is a matter for physical behavior researchers to consider, that is critical to multi-disciplinary collaboration

Butler, Andrew C.; Hokanson, Jack E.; Flynn, Heather A. (1994):

A comparison of self-esteem lability and low trait self-esteem as vulnerability factors for depression.

In: *Journal of Personality and Social Psychology* 66 (1), S. 166.

Abstract:

Self-esteem lability (SEL), defined as daily event-related variability in state self-esteem, and low trait self-esteem (TSE) were assessed among 205 male and female undergraduates who were currently depressed, previously depressed (PD), and never depressed (ND). SEL scores were derived for the effect of positive, negative, and combined events on state self-esteem over 30 days. Consistent with psychodynamic and cognitive theories, SEL was found to be a better index of depression proneness than TSE. PD Ss showed higher lability on all SEL scores than ND controls but did not differ from controls on TSE. Ss were reassessed 5 mo later, and new cases showed higher premorbid SEL than ND controls but did not differ from controls on premorbid TSE. SEL at Time 1 was found to increase risk for depression at Time 2 among Ss reporting high life stress at Time 2. Theoretical and methodological implications are discussed. Butler, Jorie M.; Whalen, Carol K.; Jamner, Larry D. (2009):

Bummed out now, feeling sick later: weekday versus weekend negative affect and physical symptom reports in high school freshmen.

In: *The Journal of adolescent health : official publication of the Society for Adolescent Medicine* 44 (5), S. 452–457. DOI: 10.1016/j.jadohealth.2008.09.005.

Abstract:

PURPOSE\r\nThis study examined adolescent negative affect (NA) in daily life on school days and weekend days during the spring and associations with physical symptoms during the following summer.\r\nMETHODS\r\nUsing experience sampling methodology (ESM), participants provided electronic diary (eDiary) reports of NA on weekdays (Thursday and Friday) and weekend days during their 9th grade year. In telephone interviews during the winter and summer months they reported physical symptoms. Multiple regression analyses were conducted to examine associations between weekday NA, weekend NA, and their interaction and four constellations of physical symptoms reported in summer (pain, respiratory, gastrointestinal, and immune symptoms).\r\nRESULTS\r\nFindings indicated that weekend NA was associated with later reports of pain, respiratory, and immune symptoms. For gastrointestinal symptoms only adolescents who reported low NA on both weekend and school days reported fewer gastric symptoms than other adolescents.\r\nCONCLUSIONS\r\nMapping the predictors and correlates of weekend NA may be important not only for understanding teenage mood patterns but also for enhancing the interpretation of physical symptom reporting by adolescents.

Butte, Nancy F.; Puyau, Maurice R.; Adolph, Anne L.; Vohra, Firoz A.; Zakeri, Issa (2007):

Physical activity in nonoverweight and overweight Hispanic children and adolescents.

In: *Med Sci Sports Exerc* 39 (8), S. 1257–1266.

Abstract:

BACKGROUND: Despite the high prevalence of childhood obesity among U.S. Hispanic children and adolescents, quantitative, objective data on their patterns and levels of physical activity are scarce. OBJECTIVES: 1) To describe qualitatively the types of physical activities in which nonoverweight and overweight Hispanic children and adolescents participate; 2) to use accelerometry to quantitatively describe the duration, intensity, and frequency of physical activity; 3) to examine the influence of age, gender, and BMI status on physical activity levels; and 4) to determine the relationships between physical activity and adiposity, fitness, and risk for the metabolic syndrome.

METHODS: Cross-sectional assessment of physical activity using accelerometers was made for three continuous days in 897 nonoverweight and overweight Hispanic children, ages 4-19 yr. Ancillary measurements included blood pressure, anthropometry, body composition by dual-energy x-ray absorptiometry, fitness by VO2peak test, and metabolic risk factors, using standard clinical and biochemical methods.

RESULTS: Types and levels of physical activity were influenced by age, gender, and body mass index (BMI) status. Total physical activity counts declined markedly with increasing age (P = 0.001) and were consistently higher in boys than in girls (P = 0.001). Total activity counts were lower (P = 0.002) and sedentary activity counts were higher in overweight than in nonoverweight children (P = 0.001). Sleep duration (min.d(-1)) was slightly lower in overweight compared with nonoverweight children, ages 4-8 yr (P = 0.03). Physical activity levels were significantly associated with percent FM, VO2peak, fasting serum insulin, and waist circumference, although the strength of the associations were generally low.

CONCLUSION: Efforts should be made to shift the time in sedentary activity to light activity, and to increase the time spent in moderate to vigorous activity in U.S. Hispanic children and adolescents, with special attention given to the overweight, girls, and adolescents.

Butte, Nancy F.; Wong, William W.; Adolph, Anne L.; Puyau, Maurice R.; Vohra, Firoz A.; Zakeri, Issa F. (2010):

Validation of cross-sectional time series and multivariate adaptive regression splines models for the prediction of energy expenditure in children and adolescents using doubly labeled water.

In: *The Journal of nutrition* 140 (8), S. 1516–1523.

Abstract:

Accurate, nonintrusive, and inexpensive techniques are needed to measure energy expenditure (EE) in free-living populations. Our primary aim in this study was to validate cross-sectional time series (CSTS) and multivariate adaptive regression splines (MARS) models based on observable participant characteristics, heart rate (HR), and accelerometer counts (AC) for prediction of minute-by-minute EE, and hence 24-h total EE (TEE), against a 7-d doubly labeled water (DLW) method in children and adolescents. Our secondary aim was to demonstrate the utility of CSTS and MARS to predict awake EE, sleep EE, and activity EE (AEE) from 7-d HR and AC records, because these shorter periods are not verifiable by DLW, which provides an estimate of the individual's mean TEE over a 7-d interval. CSTS and MARS models were validated in 60 normal-weight and overweight participants (ages 5-18 y). The Actiheart monitor was used to simultaneously measure HR and AC. For prediction of TEE, mean absolute errors were 10.7 +/- 307 kcal/d and 18.7 +/- 252 kcal/d for CSTS and MARS models, respectively, relative to DLW. Corresponding root mean square error values were 305 and 251 kcal/d for CSTS and MARS models, respectively. Bland-Altman plots indicated that the predicted values were in good agreement with the DLW-derived TEE values. Validation of CSTS and MARS models based on participant characteristics, HR monitoring, and accelerometry for the prediction of minute-by-minute EE, and hence 24-h TEE, against the DLW method indicated no systematic bias and acceptable limits of agreement for pediatric groups and individuals under free-living conditions.

Buysse, Daniel J.; Thompson, Wesley; Scott, John; Franzen, Peter L.; Germain, Anne; Hall, Martica et al. (2007):

Daytime symptoms in primary insomnia: a prospective analysis using ecological momentary assessment.

In: *Sleep Medicine* 8 (3), S. 198–208.

Abstract:

OBJECTIVES:

To prospectively characterize and compare daytime symptoms in primary insomnia (PI) and good sleeper control (GSC) subjects using ecological momentary assessment; to examine relationships between daytime symptom factors, retrospective psychological and sleep reports, and concurrent sleep diary reports.

METHODS:

Subjects included 47 PI and 18 GSC. Retrospective self-reports of daytime and sleep symptoms were collected. Daytime symptoms and sleep diary information were then collected for 1 week on hand-held computers. The Daytime Insomnia Symptom Scale (DISS) consisted of 19 visual analog scales completed four times per day. Factors for the DISS were derived using functional principal components analysis. Nonparametric tests were used to contrast DISS, retrospective symptom ratings, and sleep diary results in PI and GSC subjects, and to examine relationships among them.

RESULTS:

Four principal components were identified for the DISS: Alert Cognition, Negative Mood, Positive Mood, and Sleepiness/Fatigue. PI scored significantly worse than GSC on all four factors ($p<0.0003$ for each). Among PI subjects DISS scales and retrospective psychological symptoms were related to each other in plausible ways. DISS factors were also related to self-report measures of sleep, whereas retrospective psychological symptom measures were not.

CONCLUSIONS:

Daytime symptom factors of alertness, positive and negative mood, and sleepiness/fatigue, collected with ecological momentary assessment, showed impairment in PI versus GSC. DISS factors showed stronger relationships to retrospective sleep symptoms and concurrent sleep diary reports than retrospective psychological symptoms. The diurnal pattern of symptoms may inform studies of the pathophysiology and treatment outcome of insomnia.

Bylsma, Lauren M.; Rottenberg, Jonathan (2011):

Uncovering the Dynamics of Emotion Regulation and Dysfunction in Daily Life with Ecological Momentary Assessment. In: Ivan Nyklíček, Ad Vingerhoets und Marcel Zeelenberg (Hg.): Emotion Regulation and Well-Being.

New York, NY: Springer New York, S. 225–244.

Abstract:

The Ecological Momentary Assessment (EMA) method permits researchers to overcome some of the limitations of typical self-report methods and enable study of the dynamics of experiences and behaviors as they occur over time and across settings in daily life. Since Myin-Germeys and colleagues (Psychological Medicine:1533–1547, 2009) recently published an excellent general overview of EMA applications in psychopathology research, this chapter focuses specifically on EMA applications for understandingemotion in psychopathology. We briefly survey EMA methods developed over the past 30 years. Next, we explain the utility of using EMA to study emotional functioning, highlighting selected areas in emotion research where the potential of EMA modalities for clinical description, assessment, and clinical interventions are beginning to be realized. Our discussion of applications draws upon our own work with mood and anxiety disorders. Finally, we discuss the promise of EMA for improving the assessment and treatment of emotional disorders, as well as highlighting several priority areas for future investigation.

Bylsma, Lauren M.; Taylor-Clift, April; Rottenberg, Jonathan (2011):

Emotional reactivity to daily events in major and minor depression.

In: *Journal of Abnormal Psychology* 120 (1), S. 155–167. DOI: 10.1037/a0021662.

Abstract:

Although emotional dysfunction is an important aspect of major depressive disorder (MDD), it has rarely been studied in daily life. Peeters, Nicolson, Berkhof, Delespaul, and deVries (2003) observed a surprising mood-brightening effect when individuals with MDD reported greater reactivity to positive events. To better understand this phenomenon, we conducted a multimethod assessment of emotional reactivity to daily life events, obtaining detailed reports of appraisals and event characteristics using the experience-sampling method and the Day Reconstruction Method (Kahneman, Krueger, Schkade, Schwarz, & Stone, 2004) in 35 individuals currently experiencing a major depressive episode, 26 in a minor depressive (mD) episode, and 38 never-depressed healthy controls. Relative to healthy controls, both mood-disordered groups reported greater daily negative affect and lower positive affect and reported events as less pleasant, more unpleasant, and more stressful. Importantly, MDD and mD individuals reported greater reductions in negative affect following positive events, an effect that converged across assessment methods and was not explained by differences in prevailing affect, event appraisals, or medications. Implications of this curious mood-brightening effect are discussed.

Byrd, James B.; Brook, Robert D. (2014):

Arm position during ambulatory blood pressure monitoring: a review of the evidence and clinical guidelines.

In: *J Clin Hypertens (Greenwich)* 16 (3), S. 225–230. DOI: 10.1111/jch.12255.

Abstract:

Ambulatory blood pressure monitoring (ABPM) offers advantages over clinic blood pressure measurement. Supporting the arm at the level of the right atrium has long been standard in clinic blood pressure measurement. In contrast, there is no consensus regarding arm position in the guidelines addressing ABPM. Research studies have used a variety of arm positions during ABPM. Discussed in this review are the merits of ABPM and a review of the several arm positions recommended in ABPM guidelines, suggested by cuff manufacturers, and used in research studies. To address this lack of standardization, a rationale for a clinically reasonable arm position during ABPM is offered. Specifically, the authors recommend advising the patient to keep the arm still and relaxed straight down at the side of the body when the cuff is going to inflate, when safe to do so.

Byrd-Williams, Courtney E.; Belcher, Britni R.; Spruijt-Metz, Donna; Davis, Jaimie N.; Ventura, Emily E.; Kelly, Louise et al. (2010):

Increased physical activity and reduced adiposity in overweight Hispanic adolescents.

In: *Med Sci Sports Exerc* 42 (3), S. 478–484. DOI: 10.1249/MSS.0b013e3181b9c45b.

Abstract:

PURPOSE\r\nThe objectives of this study were to examine 1) whether changes in total physical activity (PA; counts per minute, cpm) and time spent in moderate to vigorous PA (MVPA) are associated with changes in adiposity and 2) whether energy intake influences the relationship between changes in PA and changes in adiposity in overweight Hispanic adolescents.\r\nMETHODS\r\nAnalysis included 38 overweight (body mass index, >85th percentile) Hispanic adolescents with complete pretest and posttest data on relevant variables after participating in a 16-wk intervention. The intervention treatment did not influence PA, so the sample was combined and the randomization group was adjusted for in the analysis. Body composition by dual-energy x-ray absorptiometry, 7-d PA by accelerometry, and dietary intake by 3-d diet records were assessed before and after intervention.\r\nRESULTS\r\nWithin individuals, the mean increase of PA (n = 19) and mean decrease of PA (n = 19) was approximately 105 cpm. A 100-cpm increase in total PA was associated with a decrease of 1.3 kg of fat mass and 0.8% body fat after adjusting for pretest adiposity, PA, age, sex, and treatment (P < 0.05). Controlling for energy intake modestly strengthened the relationships between total PA and fat mass and percent body fat. Changes in MVPA were not related to changes in adiposity after controlling for total PA (P > 0.05).\r\nCONCLUSIONS\r\nIncreasing total PA by 28% (100 cpm) was associated with a decrease of 1.4 kg of fat mass and 1% body fat for 16 wk in overweight Hispanic adolescents independent of intervention group assignment. Increases in total PA, compared with MVPA, may be sufficient to improve body composition in overweight Hispanic adolescents.

Byun, W.; Blair, S. N.; Pate, R. R. (2013):

Objectively measured sedentary behavior in preschool children: comparison between Montessori and traditional preschools.

In: *Int.J Behav.Nutr.Phys.Act.* 10 (1479-5868 (Linking)), S. 2. DOI: 10.1186/1479-5868-10-2.

Abstract:

BACKGROUND: This study aimed to compare the levels of objectively-measured sedentary behavior in children attending Montessori preschools with those attending traditional preschools. METHODS: The participants in this study were preschool children aged 4 years old who were enrolled in Montessori and traditional preschools. The preschool children wore ActiGraph accelerometers. Accelerometers were initialized using 15-second intervals and sedentary behavior was defined as <200 counts/15-second. The accelerometry data were summarized into the average minutes per hour spent in sedentary behavior during the in-school, the after-school, and the total-day period. Mixed linear regression models were used to determine differences in the average time spent in sedentary behavior between children attending traditional and Montessori preschools, after adjusting for selected potential correlates of preschoolers' sedentary behavior. RESULTS: Children attending Montessori preschools spent less time in sedentary behavior than those attending traditional preschools during the in-school (44.4. min/hr vs. 47.1 min/hr, P = 0.03), after-school (42.8. min/hr vs. 44.7 min/hr, P = 0.04), and total-day (43.7 min/hr vs. 45.5 min/hr, P = 0. 009) periods. School type (Montessori or traditional), preschool setting (private or public), socio-demographic factors (age, gender, and socioeconomic status) were found to be significant predictors of preschoolers' sedentary behavior. CONCLUSIONS: Levels of objectively-measured sedentary behavior were significantly lower among children attending Montessori preschools compared to children attending traditional preschools. Future research should examine the specific characteristics of Montessori

preschools that predict the lower levels of sedentary behavior among children attending these preschools compared to children attending traditional preschools

Byun, W.; Dowda, M.; Pate, R. R. (2011):

Correlates of objectively measured sedentary behavior in US preschool children.

In: *Pediatrics* 128 (5), S. 937–945. DOI: 10.1542/peds.2011-0748.

Abstract:

OBJECTIVE: To identify correlates of objectively measured sedentary behavior in a diverse sample of preschool children. METHODS: A total of 331 children (51% male, 51% black) from a wide range of ethnic and socioeconomic backgrounds in greater Columbia, South Carolina, were recruited for this study. Sedentary behavior (minutes/hour) was measured by using ActiGraph accelerometers (<37.5 counts per 15 seconds) over a 2-week period. All potential correlates except for anthropometric data of children were measured by a parent survey. Correlation and regression analyses were conducted to examine associations between 29 potential correlates across multiple domains (demographic, biological, psychosocial, behavioral, and physical environmental) and sedentary behavior measured by accelerometry in preschool children. RESULTS: Girls spent more time in sedentary behavior than boys (33.2 vs 32.4 minutes/hour; P = .05). Six and 8 potential correlates were found to be significant in univariate analyses for boys and girls, respectively. In the gender-specific final model, for boys, a child's weekday TV/video games and physical activity equipment in the home were significant correlates of sedentary behavior (R(2) = 0.091). For girls, BMI z score and child's athletic coordination were significantly associated with sedentary behavior (R(2) = 0.069). CONCLUSION: Several factors were identified as correlates of objectively measured sedentary behavior in American preschool children. However, there were no common correlates that influenced sedentary behavior for both boys and girls. Future interventions for reducing sedentary behavior could target correlates identified in this study

Byun, W.; Liu, J.; Pate, R. R. (2013):

Association between objectively measured sedentary behavior and body mass index in preschool children.

In: *Int.J Obes.(Lond)* (0307-0565 (Linking)). DOI: 10.1038/ijo.2012.222.

Abstract:

Objective:To determine the association between accelerometry-derived sedentary behavior and body mass index (BMI) z-score in preschool children, and to determine whether the association changed when applying three different accelerometry cutpoints for sedentary behavior.Design and subjects:Cross-sectional design. Data came from two completed studies: Children's Activity and Movement in Preschool Study (CHAMPS) and the Environmental Determinants of Physical Activity in Preschool Children (EDPAPC) study. Children of ages 3-5 years with complete data on sedentary behavior, BMI z-score, physical activity and other covariates were included in the analyses (N=263 in CHAMPS and N=155 in EDPAPC). Accelerometry data were summarized as time spent in sedentary behavior (min h(-1)) using three different cutpoints developed specifically for preschool children (<37.5, <200 and <373 counts per 15 s). Linear mixed regression models were used to determine the association between time spent in sedentary behavior and BMI z-score; age, gender, race, parental education, preschools and moderate-to-vigorous physical activity (MVPA) were included as covariates.Results:In both CHAMPS and EDPAPC studies, no independent association between time spent in sedentary behavior and BMI z-score was observed after adjusting for MVPA. The observed null association between sedentary behavior and BMI z-score was maintained even with different sedentary behavior cutpoints.Conclusions:Regardless of cutpoints used, accelerometry-derived sedentary behavior was not independently associated with BMI z-score in two independent samples of preschool children. Longitudinal studies addressing this research question are needed.International Journal of Obesity advance online publication, 15 January 2013; doi:10.1038/ijo.2012.222

Cagnacci, A.; Ferrari, S.; Napolitano, A.; Piacenti, I.; Arangino, S.; Volpe, A. (2012):

Combined oral contraceptive containing drospirenone does not modify 24-h ambulatory blood pressure but increases heart rate in healthy young women: prospective study.

In: *Contraception* (0010-7824 (Linking)). DOI: 10.1016/j.contraception.2012.12.002.

Abstract:

BACKGROUND: Hypertension is a primary cardiovascular risk factor. Oral contraceptives (OCs) may increase blood pressure and cardiovascular events. We evaluated whether an OC containing ethynylestradiol (EE) in association with the spironolactone-derived progestin drospirenone (DRSP) influences 24-h ambulatory blood pressure of normotensive women. STUDY DESIGN: Twenty-four-hour blood pressure was measured every 30 min by an ambulatory blood pressure device in 18 normotensive healthy women prior to and after 6 months of use of an OC containing 30 mcg EE and 3 mg DRSP. RESULTS: OC induced no modification in 24-h, nighttime and daytime blood pressure. Heart rate increased about 4 beats/min in the 24-h ($p<.05$) and daytime ($p<.02$) measurements. CONCLUSIONS: In normotensive women, an OC containing 30 mcg EE plus 3 mg DRSP does not modify blood pressure, and significantly increases 24-h and daytime heart rate. These data suggest a neutral effect on hypertension-associated cardiovascular risk and point out an unreported effect on heart rate of which cause and effect require further evaluation

Cakici, Musa; Dogan, Adnan; Oylumlu, Muhammed; Uckardes, Fatih; Davutoglu, Vedat (2014):

Impaired circadian rhythm of blood pressure in normotensive patients with rheumatic mitral valve stenosis.

In: *Blood Press Monit* 19 (2), S. 76–80. DOI: 10.1097/MBP.0000000000000025.

Abstract:

BACKGROUND: The aim of the present cross-sectional study was to evaluate either non-dipper-type or dipper-type circadian rhythm of blood pressure (BP) in normotensive rheumatic mitral stenosis (MS) patients. METHODS AND RESULTS: Eighty-eight normotensive rheumatic mitral valve disease (RMVD) patients and 41 normal participants were enrolled in the study. All participants underwent ambulatory blood pressure monitoring. Nocturnal BP dipping was calculated as follows: (awake BP-asleep BP)x100/awake BP. Patients with a nocturnal reduction in average daytime systolic BP and diastolic BP of less than 10% were classified as nondippers. Patients with RMVD were divided into two groups with respect to the top and bottom 1.5 cm of the mitral valve area (MVA). There was a highly significant relationship between the two groups with control in the frequency of a nondipping status (chi=22.721; d.f.=2; $P<0.001$). Afterwards, the Mann-Whitney U-test was used to compare the two groups and the control group. There was no difference in the frequency of nondipping between patients with an MVA of greater than 1.5 cm and the control group ($P>0.05$). However, the nondipping level was higher in patients with an MVA of less than 1.5 cm than in the control group and in patients with RMVD with an MVA of greater than 1.5 cm ($P<0.001$ and <0.001, respectively). CONCLUSION: The circadian BP rhythm is impaired and the incidence of nondipping BP is higher in patients with MS than in normal patients. Moreover, we believe that autonomic nervous system dysfunction in patients with MS may be detected efficiently using ambulatory blood pressure monitoring.

Camburn, Eric M.; Spillane, James P.; Sebastian, James (2010):

Assessing the utility of a daily log for measuring principal leadership practice.

In: *Educational Administration Quarterly*, S. 0013161X10377345.

Abstract:

Purpose: This study examines the feasibility and utility of a daily log for measuring principal leadership practice. Setting and Sample: The study was conducted in an urban district with approximately 50 principals. Approach: The log was assessed against two criteria: (a) Is it feasible to induce strong cooperation and high response rates among principals with a daily instrument? and (b) Can daily logs accurately measure important aspects of principal leadership? The first criterion was assessed through a discussion of data collection procedures and results. The second criterion was assessed through mixed-method analyses comparing daily logs, observations, and an experience-sampling instrument. Results: The authors found that substantial participant contact time and strategic follow-up achieved strong cooperation and yielded high response rates. The accuracy of the log was confirmed through comparisons with an experience-sampling instrument and direct observations. The results also contribute to a broader understanding of how principals allocate their time across leadership domains. Like earlier structured observation studies, the authors found that principals spend more time on management, personnel issues, and student affairs and less time on instructional leadership than advocated by leadership scholars and professional standards. Implications for Research and Practice: Daily logs appear to be a viable means of measuring important aspects of principal practice and overcoming measurement errors associated with one-time surveys that are common in leadership research. Strategies used to maintain high participation rates are discussed in detail, and an example of a district's adaptation of the daily log methodology is provided.

Campana, Kristie L.; Hammoud, Sammira (2013):

Incivility from patients and their families: can organisational justice protect nurses from burnout?

In: *J Nurs Manag. DOI:* 10.1111/jonm.12201.

Abstract:

AIM: To determine whether interpersonal and informational justice influence the association between daily experiences of incivility and burnout among nurses. BACKGROUND: Research has suggested that incivility is a concern for managers. Nurses regularly experience incivility, particularly from their patients and patients' families. Incivility, in turn, can increase symptoms of burnout. METHOD: Seventy-five nurses provided data on interpersonal and informational justice within their organisation. During five working days, nurses completed a twice-daily survey assessing incivility and burnout. Hierarchical linear modelling analyses examined the main effects and interaction effects of the three variables on burnout. RESULT: Incivility was positively associated with burnout. In addition, interpersonal justice strengthened the incivility-burnout relationship. Informational justice did not significantly affect the incivility-burnout relationship. CONCLUSION: Incivility is associated with more burnout. The work environment also influences burnout; when organisations provide informational justice, nurses experience less burnout. In organisations where interpersonal justice is high, nurses are more likely to experience burnout. IMPLICATIONS FOR NURSING MANAGEMENT: Nursing managers can help employees by ensuring that management's decisions are transparent. In addition, managers should be aware that in organisations with higher interpersonal justice, nurses might be more likely to experience symptoms of burnout as a result of incivility from patients and their families.

Campbell, Patrick; Ghuman, Nimrta; Wakefield, Dorothy; Wolfson, Leslie; White, William B. (2010):

Long-term reproducibility of ambulatory blood pressure is superior to office blood pressure in the very elderly.

In: *J Hum Hypertens* 24 (11), S. 749–754.

Abstract:

Although it is known that reproducibility of ambulatory blood pressure (BP) is superior to office BP in middle-aged subjects, little is known in older age groups. Hence, we compared the long-term reproducibility of ambulatory and office BP readings in subjects over the age of 75 years. A cohort of 72 subjects 75-90 years of age (mean, 82 years at baseline) had repeat office and ambulatory BPs 2 years apart under similar conditions. On the same day, patients underwent office BP measurements by a semi-automated device and then by ambulatory BP monitoring. Awake and sleep periods were divided according to a diary kept by each patient. The agreement between studies was assessed using the standard deviation of the differences (SDD) and Bland-Altman plots. There were minimal mean changes in office, 24-h, and awake and sleep mean BP values between baseline and 2 years later. The SDDs between visits were lower for 24-h BP compared with the office BP (11.7/5.9 mm Hg versus 17.8/9.0 mm Hg, P<0.01). The SDD for 24-h BP was also lower than the SDDs for the awake and sleep BP (P<0.05). Nocturnal BPs defined by absolute values were more reproducible than categories of dippers and non-dippers. These data demonstrate that long-term reproducibility of 24-h BP is superior to office measurements for very elderly subjects. In a clinical trial involving this age group, far fewer subjects would be required if 24-h BP was the primary efficacy endpoint rather than the office BP.

Campbell, Tavis S.; Lavoie, Kim L.; Bacon, Simon L.; Scharf, Deborah; Aboussafy, David; Ditto, Blaine (2006):

Asthma self-efficacy, high frequency heart rate variability, and airflow obstruction during negative affect in daily life.

In: *International journal of psychophysiology : official journal of the International Organization of Psychophysiology* 62 (1), S. 109–114. DOI: 10.1016/j.ijpsycho.2006.02.005.

Abstract:

BACKGROUND\r\nEmotional stress has been considered an important asthma trigger for years, though the mechanisms by which stress may exacerbate asthma remain poorly understood. The stress-asthma morbidity association could occur through cognitive-behavioral pathways, such as decreased asthma self-efficacy and disorganized self-care, or through the more direct physiological effects of stress on autonomic (parasympathetic) nervous system activity. No study has examined how these two mechanisms may interact to contribute to greater airflow obstruction during emotional stress in daily life. This study investigated associations between peak expiratory flow rate (PEFR) and high frequency heart rate variability (HFHRV) during periods of negative affect and physical activity in daily life in patients with higher versus lower asthma self-efficacy scores.\r\nMETHODS\r\nFifty-three patients with mild to moderate asthma completed the Asthma Self-Efficacy Scale (ASES) and

underwent a 15 h ambulatory assessment of daytime HFHRV and PEFR, while completing self-report diaries of their physical activities and affect.\r\nRESULTS\r\nIn patients with lower asthma self-efficacy scores, increased levels of negative affect during daily life were associated with higher levels of HFHRV and decreased PEFR relative to patients with higher asthma self-efficacy scores. Increased levels of physical activity were associated with decreased levels of HFHRV irrespective of asthma self-efficacy scores.\r\nCONCLUSIONS\r\nFindings suggest that lower asthma self-efficacy may be associated with increased parasympathetic activity and airflow obstruction during periods of negative affect during daily life.

Cano, Miguel ángel; Lam, Cho Y.; Chen, Minxing; Adams, Claire E.; Correa-Fernández, Virmarie; Stewart, Diana W. et al. (2014):

Positive smoking outcome expectancies mediate the association between negative affect and smoking urge among women during a quit attempt.

In: *Experimental and Clinical Psychopharmacology* 22 (4), S. 332–340. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-16295-001%26site%3dehost-live.

Abstract:

Ecological momentary assessment was used to examine associations between negative affect, positive smoking outcome expectancies, and smoking urge during the first 7 days of a smoking quit attempt. Participants were 302 female smokers who enrolled in an individually tailored smoking cessation treatment study. Multilevel mediation analysis was used to examine the temporal relationship among the following: (a) the effects of negative affect and positive smoking outcome expectancies at 1 assessment point (e.g., time j) on smoking urge at the subsequent time point (e.g., time j + 1) in Model 1; and, (b) the effects of negative affect and smoking urge at time j on positive smoking outcome expectancies at time j + 1 in Model 2. The results from Model 1 showed a statistically significant effect of negative affect at time j on smoking urge at time j + 1, and this effect was mediated by positive smoking outcome expectancies at time j, both within- and between-participants. In Model 2, the within-participant indirect effect of negative affect at time j on positive smoking outcome expectancies at time j + 1 through smoking urge at time j was nonsignificant. However, a statistically significant indirect between-participants effect was found in Model 2. The findings support the hypothesis that urge and positive smoking outcome expectancies increase as a function of negative affect, and suggest a stronger effect of expectancies on urge as opposed to the effect of urge on expectancies. A better regulation is required in viral hepatitis smartphone applications.

In: *Farm Hosp* 38 (n02), S. 112–117.

Abstract:

Aim. To describe the characteristics and content of the available viral hepatitis mobile applications, as well as assess the level of participation of medical professionals in their development. Methods. A descriptive observational study was carried out in September 2013. We searched smartphone apps specifically relating to the viral hepatitis for using a keyword search with the following terms; <<hepatitis>>, <<hepatology>>, <<hbv>> and <<hcv>> in the Google Play Store (Android) and the Apple App Store (iOS). Data recorded included: name, platform, category, cost, user star rating, number of downloads, date the app was updated by the developer and target audience. We analysed the content of the applications, and these were then categorised based on the viral hepatitis type into three groups. We conducted an analysis in which we specifically examined the authorship in order to assess the prevalence of health professional participation in their development. Results. A total of 33 apps were included (from 232 that were identified), among which there were 10 duplicates. Most of these apps were uploaded under the medical category. Three had ratings less than 3.9 stars (out of 5). Only 6 apps had exceeded 1000 downloads. A total of 12 apps were aimed at health professionals, while 4 focused on patients (7 for both of them). The participation of health professionals in the development of apps was 56.6%. Conclusions. Viral hepatitis apps are available for both professionals and patients; however, much of the information contained within them is often not validated. They should be certificated.

Cao, Tingting; Thompson, Jonathan E. (2014):

Remote sensing of atmospheric optical depth using a smartphone sun photometer.

In: *PLoS One* 9 (1), S. e84119. DOI: 10.1371/journal.pone.0084119.

Abstract:

In recent years, smart phones have been explored for making a variety of mobile measurements. Smart phones feature many advanced sensors such as cameras, GPS capability, and accelerometers within a handheld device that is portable, inexpensive, and consistently located with an end user. In this work, a smartphone was used as a sun photometer for the remote sensing of atmospheric optical depth. The top-of-the-atmosphere (TOA) irradiance was estimated through the construction of Langley plots on days when the sky was cloudless and clear. Changes in optical depth were monitored on a different day when clouds intermittently blocked the sun. The device demonstrated a measurement precision of 1.2% relative standard deviation for replicate photograph measurements (38 trials, 134 datum). However, when the accuracy of the method was assessed through using optical filters of known transmittance, a more substantial uncertainty was apparent in the data. Roughly 95% of replicate smart phone measured transmittances are expected to lie within +/-11.6% of the true transmittance value. This uncertainty in transmission corresponds to an optical depth of approx. +/-0.12-0.13 suggesting the smartphone sun photometer would be useful only in polluted areas that experience significant optical depths. The device can be used as a tool in the classroom to present how aerosols and gases effect atmospheric transmission. If improvements in measurement precision can be achieved, future work may allow monitoring networks to be developed in which citizen scientists submit acquired data from a variety of locations.

Post-paracentesis circulatory derangements are related to monocyte activation.

In: *Liver Int. DOI:* 10.1111/liv.12450.

Abstract:

BACKGROUND & AIMS: Post-paracentesis circulatory dysfunction is associated with development of hepatorenal syndrome and increased mortality. The impact of large volume paracentesis (LVP) on the 24-h blood pressure (BP) profile is unknown, and the relationship to Na+ -retentive and pro-inflammatory cytokines also remains unknown. The aims of this study were to (i) define the effects of LVP with albumin administration on 24-h BP profiles, and (ii) relate changes in BP over time to changes in Na+ -retentive hormones, clinical factors and inflammatory cytokines. METHODS: Ten patients undergoing LVP had 24-h ambulatory BP monitoring performed pre- and post-paracentesis. Markers of the innate immune system, bacterial translocation and Na+ -retentive hormones were drawn pre- and post-LVP. RESULTS: Mean arterial pressure (MAP) dropped in nine of the 10 patients in the 24 h following a paracentesis compared to 24 h preceding the procedure (mean drop of 5.5 mmHg, $P < 0.005$). A mixed effects model was used to define time-covariate interactions in predicting changes in BP profile. Monocyte chemotactic protein-1 (MCP1) was associated with Deltasystolic BP (beta = -0.011, $P < 0.05$), Deltadiastolic BP (beta = -0.012, $P < 0.05$) and DeltaMAP (beta = -0.012, $P < 0.05$). Plasma renin activity was also significantly associated with Deltasystolic BP (beta = -0.21, $P < 0.05$). Renal function was also significantly reduced following LVP. CONCLUSIONS: Systolic, diastolic and MAP decreased over 24 h after LVP compared to the 24 h pre-LVP. This drop is related to increases in MCP-1 after LVP. Increased MCP-1, a marker of monocyte activation, was strongly related to changes in BP.

Case 9-Psychophysiological assessment and biofeedback during official baseball games: Procedures, methodologies, findings and critical issues in applied sport psychology. In: W.Alex Edmonds und Gershon Tenenbaum (Hg.): Case studies in applied psychophysiology: Neurofeedback and biofeedback treatments for advances in human performance:

Wiley-Blackwell, S. 160–200. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-03157-011%26site%3dehost-live.

Abstract:

(from the chapter) This chapter presents a validated multifaceted assessment and intervention protocol (Carlstedt Protocol; CP) that has been used on hundreds of athletes over the last 15 years. It is conceptually based on an integrative individual-differences model of peak performance that is supported by strong construct validity and an extensive evolving database of psychophysiological and performance relationships and findings across numerous sports. The CP stresses ecological validity, real-time psychophysiological monitoring, biofeedback-based multimodal intervention and importantly, extensive efficacy testing. The protocol involves a step-by-step hierarchical evidence-based approach that is predicated on the comprehensive assessment of athlete mind-body-motor response tendencies in pre-intervention and intervention phases prior to, during and after practice and official competition (real games/matches). The goal of the protocol is to establish statistical relationships

between interventions and objective macro and micro outcome measures of a specific sport, the benchmark for determining whether a mental training method works and to what extent. It was designed to bring accountability to the assessment and intervention process in the fields of sport psychology and biofeedback. Readers will be exposed to specific components of the CP that were applied to starting players on an elite youth baseball team. Group data and findings will be presented along with contrasting case studies that demonstrate wide variability in terms of outcome or intervention efficacy, considerations that are crucial to higher evidentiary athlete assessment and mental training will be featured. It should be noted that this is the first study on record in which athletes' psychophysiological responses were monitored and measured during official league games over the course of an entire season. Pre-intervention assessment and intervention phases (biofeedback) were carried out prior to every at-bat (over 1200 data points/repeated measures; about 100-150 at-bats per player). Complete datasets of psychometric, behavioral, psychophysiological (heart rate variability) and critical moment performance statistics (predictor and macro-micro criterion measures) were generated for analysis and athlete (client) feedback purposes. In addition to discussing group and case study findings, particular attention will be paid to critical issues in applied sport psychology/sport psychophysiology and biofeedback. A goal of this chapter is not only to present data and findings on athletes who have experienced the CP but also advocate for the integration of procedures and methodologies that are vital to evidence-based applied sport psychology, the credibility of the field of sport psychology/biofeedback and its practitioners. Consequently, points of critique and rationale for doing specific things within the protocol will be discussed throughout the chapter. As I progress through specific procedures of the CP player data will be inserted along with comments regarding their relevance. Certain procedures, methods and response outtakes (e.g. heart rate variability reports) will also be shown and discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

[Walking activity in prosthesis-bearing lower-limb amputees].

In: *Revue de chirurgie orthopedique et reparatrice de l'appareil moteur* 93 (2), S. 109–115.

Abstract:

PURPOSE OF THE STUDY:

A large body of literature has been devoted to gait analysis in amputees. Most studies have been conducted in the laboratory setting where numerous variables are analyzed: gait efficiency, energy cost, walking velocity. At the present time however, data are lacking on the real-life use of walking prostheses. Little is known about how long patients wear their prosthesis or how difficult it is for them to walk during different periods of the day. Currently, such information depends on the quality of the interview and the patient-physician relationship. A precise assessment of walking activity in amputees and use of prostheses would be a valuable source of information for therapists and would provide complimentary information to that collected from laboratory gait analysis. The purpose of this study was to study walking activity in home-dwelling prosthesis-bearing lower-limb amputees and to determine variables affecting walking performance. To our knowledge, this is the first published study on this topic.

MATERIAL AND METHODS:

The series included home-dwelling prosthesis-wearing lower-limb amputees (Syme amputation or more proximal) who were able to get up and go without assistance. A StepWatch3 recorder was implanted on the prosthesis for 15 consecutive days. Variables recorded were number of steps, total walking time, and walking velocity. Variables which might affect walking in prosthesis-wearing amputees were also recorded: body mass index, use of a walking aid, level and reason for amputation, age at amputation and at recording, time between amputation and recording.

RESULTS:

From June 2004 to May 2005, 43 patients wore the StepWatch3 for the scheduled 15 days during their daily activities. Mean age at amputation was 42 years (range 13-78 years) and at recording 52 years (range 25-85 years). Considered separately, gait parameters showed that all of the patients wore their prosthesis daily and that the best walking performance was significantly observed among below-knee amputees who did not use a walking aid and who underwent amputation for a non-vascular cause. Multivariate analysis revealed that above-knee amputees lost 93 minutes of walking time per day (21% loss), and that amputees who used a walking aid lost 58 minutes per day (13% loss). Daily walking time declined 2.5 minutes per year of age. Body mass index was not correlated with total daily walking time but had a direct significant effect on walking velocity.

Laboratory-based, cue-elicited craving and cue reactivity as predictors of naturally occurring smoking behavior.

In: *Addict Behav* 34 (6-7), S. 536–541. DOI: 10.1016/j.addbeh.2009.03.022.

Abstract:

Cigarette craving, one hallmark sign of nicotine dependence, is often measured in laboratory settings using cue reactivity methods. How lab measures of cue reactivity relate to real world smoking behavior is unclear, particularly among non-treatment seeking smokers. Within a larger study of hormonal effects on cue reactivity (N=78), we examined the predictive relationship of cue reactivity to smoking, each measured in several ways. Results indicated that cue-evoked craving in response to stressful imagery, and to a lesser extent, in vivo smoking cues, significantly predicted smoking behavior during the week following testing. However, this predictive relationship was absent upon controlling for reactivity to neutral cues. Nicotine dependence may moderate the relationship between cue reactivity and actual smoking, such that this predictive relationship is less robust among highly dependent smokers than among smokers low in nicotine dependence. The question of whether cue-elicited craving predicts smoking among smokers not in treatment is best answered with a qualified yes, depending on how craving is manipulated and measured. Our findings highlight important methodological and theoretical considerations for cue reactivity research.

Hyperactivity in Anorexia Nervosa: Warming up not just burning-off calories.

In: *PLoS One* 7 (7). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-20940-001&site=ehost-live;m.j.h.kas@umcutrecht.nl.

Abstract:

Excessive physical activity is a common feature in Anorexia Nervosa (AN) that interferes with the recovery process. Animal models have demonstrated that ambient temperature modulates physical activity in semi-starved animals. The aim of the present study was to assess the effect of ambient temperature on physical activity in AN patients in the acute phase of the illness. Thirty-seven patients with AN wore an accelerometer to measure physical activity within the first week of contacting a specialized eating disorder center. Standardized measures of anxiety, depression and eating disorder psychopathology were assessed. Corresponding daily values for ambient temperature were obtained from local meteorological stations. Ambient temperature was negatively correlated with physical activity (p = −.405) and was the only variable that accounted for a significant portion of the variance in physical activity (p = .034). Consistent with recent research with an analogous animal model of the disorder, our findings suggest that ambient temperature is a critical factor contributing to the expression of excessive physical activity levels in AN. Keeping patients warm may prove to be a beneficial treatment option for this symptom. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Contemporary Vascular Smartphone Medical Applications.

In: *Ann.Vasc.Surg.* (0890-5096 (Linking)). DOI: 10.1016/j.avsg.2012.10.013.

Abstract:

BACKGROUND: Use of smartphones and medical mHealth applications (apps) within the clinical environment provides a potential means for delivering elements of vascular care. This article reviews the contemporary availability of apps specifically themed to major vascular diseases and the opportunities and concerns regarding their integration into practice. METHODS: Smartphone apps relating to major vascular diseases were identified from the app stores for the 6 most popular smartphone platforms, including iPhone, Android, Blackberry, Nokia, Windows, and Samsung. Search terms included peripheral artery (arterial) disease, varicose veins, aortic aneurysm, carotid artery disease, amputation, ulcers, hyperhydrosis, thoracic outlet syndrome, vascular malformation, and lymphatic disorders. RESULTS: Forty-nine vascular-themed apps were identified. Sixteen (33%) were free of charge. Fifteen apps (31%) had customer satisfaction ratings, but only 3 (6%) had greater than 100. Only 13 apps (27%) had documented medical professional involvement in their design or content. CONCLUSIONS: The integration of apps into the delivery of care has the potential to benefit vascular health care workers and patients. However, high-quality apps designed by clinicians with vascular expertise are currently lacking and represent an area of concern in the mHealth market. Improvement in the quality and reliability of these apps will require the development of robust regulation

A wearable system for gait training in subjects with Parkinson's disease.

In: *Sensors (Basel)* 14 (4), S. 6229–6246. DOI: 10.3390/s140406229.

Abstract:

In this paper, a system for gait training and rehabilitation for Parkinson's disease (PD) patients in a daily life setting is presented. It is based on a wearable architecture aimed at the provision of real-time auditory feedback. Recent studies have, in fact, shown that PD patients can receive benefit from a motor therapy based on auditory cueing and feedback, as happens in traditional rehabilitation contexts with verbal instructions given by clinical operators. To this extent, a system based on a wireless body sensor network and a smartphone has been developed. The system enables real-time extraction of gait spatio-temporal features and their comparison with a patient's reference walking parameters captured in the lab under clinical operator supervision. Feedback is returned to the user in form of vocal messages, encouraging the user to keep her/his walking behavior or to correct it. This paper describes the overall concept, the proposed usage scenario and the parameters estimated for the gait analysis. It also presents, in detail, the hardware-software architecture of the system and the evaluation of system reliability by testing it on a few subjects.

Casaseca-De-La-Higuera, P.; Martin-Martinez, D.; Alberola-Lopez, S.; Andres-De-Llano, J. M.; Lopez-Villalobos, J. A.; Ramon-Garmendia, Leiza J.; Alberola-Lopez, C. (2012):

Automatic diagnosis of ADHD based on multichannel nonlinear analysis of actimetry registries.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 4204–4207. DOI: 10.1109/EMBC.2012.6346894.

Abstract:

Attention-Deficit Hyperactivity Disorder (ADHD) is the most common mental health problem in childhood and adolescence. It is commonly diagnosed by means of subjective methods which tend to overestimate the severity of the pathology. A number of objective methods also exist, but they are either expensive or time-consuming. Some recent proposals based on nonlinear processing of activity registries have deserved special attention. Since they rely on actigraphy measurements, they are both inexpensive and non-invasive. Among these methods, those shown to have higher reliability are based on single-channel complexity assessment of the activity patterns. This way, potentially useful information related to the interaction between the different channels is discarded. In this paper we propose a new methodology for ADHD diagnosis based on joint complexity assessment of multichannel activity registries. Results on real data show that the proposed method constitute a useful diagnostic aid tool reaching 87:10% sensitivity and 84.38% specificity. The combination of ADHD indicators extracted with the proposed method with single-channel complexity-based indices previously proposed lead to sensitivity and specifity values above 90%

Patients' experiences of using a smartphone application to increase physical activity: the SMART MOVE qualitative study in primary care.

In: *Br J Gen Pract* 64 (625), S. e500-8. DOI: 10.3399/bjgp14X680989.

Abstract:

BACKGROUND: Regular physical activity is known to help prevent and treat numerous non-communicable diseases. Smartphone applications (apps) have been shown to increase physical activity in primary care but little is known regarding the views of patients using such technology or how such technology may change behaviour. AIM: To explore patients' views and experiences of using smartphones to promote physical activity in primary care. DESIGN AND SETTING: This qualitative study was embedded within the SMART MOVE randomised controlled trial, which used an app (Accupedo-Pro Pedometer) to promote physical activity in three primary care centres in the west of Ireland. METHOD: Taped and transcribed semi-structured interviews with a purposeful sample of 12 participants formed the basis of the investigation. Framework analysis was used to analyse the data. RESULTS: Four themes emerged from the analysis: transforming relationships with exercise; persuasive technology tools; usability; and the cascade effect. The app appeared to facilitate a sequential and synergistic process of positive change, which occurred in the relationship between the participants and their exercise behaviour; the study has termed this the 'Know-Check-Move' effect. Usability challenges included increased battery consumption and adjusting to carrying the smartphone on their person. There was also evidence of a cascade effect involving the families and communities of participants. CONCLUSION: Notwithstanding technological challenges, an app has the potential to positively transform, in a unique way, participants' relationships with exercise. Such interventions can also have an associated cascade effect within their wider families and communities.

Catalino, Lahnna I.; Furr, R. Michael; Bellis, Freida A. (2012):

A multilevel analysis of the self-presentation theory of social anxiety: Contextualized, dispositional, and interactive perspectives.

In: *Journal of Research in Personality*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-12161-001&site=ehost-live.

Abstract:

According to self-presentation theory, social anxiety is determined by impression motivation and impression efficacy. However, researchers have not evaluated the theory's applicability from contextual and dispositional perspectives in an integrated manner, nor have they examined a fundamental interactive facet of the theory. In three studies, we examined these issues using hypothetical situations and experience sampling methodology. Results demonstrated the theory's applicability at the contextual and dispositional level, providing insight into people's general tendencies to experience social anxiety and their momentary experiences of social anxiety. Results also revealed the predicted interaction between impression motivation and impression efficacy - high impression efficacy weakens the association between impression motivation and social anxiety. These studies expand understanding of the personological and situational factors that drive social anxiety. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Causland, Finnian R. Mc; Sacks, Frank M.; Forman, John P. (2014):

Marital status, dipping and nocturnal blood pressure: results from the Dietary Approaches to Stop Hypertension trial.

In: *J Hypertens* 32 (4), S. 756–761. DOI: 10.1097/HJH.0000000000000107.

Abstract:

OBJECTIVE: Blood pressure normally declines during the night ('dipping'); a blunted nocturnal decline is an important cardiovascular risk factor. Marriage may be associated with lower ambulatory blood pressure, although this may be confounded by socio-economic and dietary factors. We examined the association of marital status with nocturnal dipping and night-time SBP amongst individuals on a controlled diet. METHODS: We analysed 325 individuals enrolled in the Dietary Approaches to Stop Hypertension trial who had available 24-h SBP data and who ingested a control diet. Logistic and linear regression models were fit to estimate the association of marital status with nocturnal dipping and mean night-time SBP. RESULTS: Of the 325 individuals, 52.9% were men, the average age was 45.1 years and 48.9% reported being married. Compared with nonmarried individuals, those who were married had greater adjusted odds of dipping [odds ratio (OR) 2.26; 95% confidence interval (CI) 1.26-4.03; P = 0.01]. In adjusted models, being married was associated with lower night-time SBP (-2.4 mmHg; 95% CI -3.8 to -0.9 mmHg; P = 0.002), with the suggestion of a greater association in married men compared with married women (-3.1 vs. -1.7 mmHg); there was less difference for married nonblacks compared with married blacks (-2.7 and -2.4 mmHg, respectively). CONCLUSION: Being married is independently associated with a greater likelihood of nocturnal dipping and with lower night-time SBP among individuals participating in a controlled dietary intervention; the association was particularly strong in married men. Marital status is a variable that may be considered in future analyses of ambulatory blood pressure.

Cavanagh, Peter R.; Gopalakrishnan, Raghavan; Rice, Andrea J.; Genc, Kerim O.; Maender, Christian C.; Nystrom, Peter G. et al. (2009):

An ambulatory biomechanical data collection system for use in space: design and validation.

In: *Aviation, space, and environmental medicine* 80 (10), S. 870–881.

Abstract:

INTRODUCTION:

Loss in bone mineral density and muscle strength in astronauts following long-duration spaceflight have been well documented, but the altered force and movement environments in microgravity which may contribute to these changes have not been well characterized. This paper describes the instrumentation, software, and data collection procedures developed for the "Foot" experiment that was conducted on the International Space Station (ISS) to provide insight into the biomechanics of daily activity in a microgravity environment.

METHODS:

The instrumentation used for data collection included the Ambulatory Data Acquisition System (ADAS), ADAS electromyography (EMG) modules, the Joint Excursion System, and the Total Force-Foot Ground interface system, which were all integrated into a specially designed Lower Extremity Monitoring Suit. There were 14 total channels of data that were collected at sampling rates between 8 Hz and 1024 Hz, including 7 channels of EMG, 4 channels of joint angle data, 2 channels of in-shoe ground reaction force, and a marker channel for event recording. Data were typically collected for between 6.5 and 11.8 h of activity during 4 d on Earth and 4-7 d in flight.

RESULTS:

Exemplar data sets collected preflight on astronauts in 1 g to validate the instrumentation are presented.

DISCUSSION:

We conclude that the system provides valid and useful biomechanical information on long-term activity. The analysis of data collected on-orbit using the system described here will be presented in a series of future papers characterizing the biomechanics of astronaut activity during complete working days on the Earth and on the ISS.

Cazzulino, Francesca; Burke, Rita V.; Muller, Valerie; Arbogast, Helen; Upperman, Jeffrey S. (2014):

Cell phones and young drivers: a systematic review regarding the association between psychological factors and prevention.

In: *Traffic Inj Prev* 15 (3), S. 234–242. DOI: 10.1080/15389588.2013.822075.

Abstract:

OBJECTIVE: Cell phone use among young drivers has become increasingly common in recent years. Young people are the most likely to accept the use of new technology and least likely to understand the risks associated with cell phone use while driving (CPWD; defined here as talking on the phone only) and texting while driving (TextWD). Due to inexperience, young drivers are the most at risk when using cell phones while driving and therefore should be the target of the majority of prevention strategies. The intent of this review is to determine factors that influence young drivers to engage in CPWD and TextWD and suggest a basis for prevention campaigns and strategies that can effectively prevent current and future generations from using cell phones while driving. METHODS: We conducted a search for original articles in PubMed, the Cochrane Library, and Web of Science. All abstracts were reviewed and for those that met the inclusion criteria, full articles were obtained and assessed. RESULTS: Four hundred and twelve articles were identified in the search and, of those, 37 full-text articles were obtained. A total of 29 articles about the frequency of CPWD and the psychological effects influencing young driver's tendency to engage in CPWD were included. There was a high frequency of both CPWD and TextWD despite a high perceived risk of both behaviors. This discrepancy was explained by a high perceived controllability, the effect of social norms, call importance, and lack of effective law enforcement. The intervention strategies reviewed were also found to be ineffective over the long term. CONCLUSIONS: The systematic review reveals that young drivers are an at-risk group for distracted driving. We propose preventative strategies based on identifying factors that influence drivers to engage in CPWD and TextWD as well as by reviewing strategies found in the reviewed articles. Further research is necessary to determine the effectiveness of these proposed strategies.

Ceja, Lucia; Navarro, Jose (2012):

'Suddenly I get into the zone': Examining discontinuities and nonlinear changes in flow experiences at work.

In: *Human Relations* 65 (9), S. 1101–1127. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-24007-004%26site%3dehost-live;j.navarro@ub.edu;lceja@iese.edu.

Abstract:

Work-related flow is defined as a sudden and enjoyable merging of action and awareness that represents a peak experience in the daily lives of workers. Employees' perceptions of challenge and skill and their subjective experiences in terms of enjoyment, interest and absorption were measured using the experience sampling method, yielding a total of 6981 observations from a sample of 60 employees. Linear and nonlinear approaches were applied in order to model both continuous and sudden changes. According to the R-&#65533;, AICc and BIC indexes, the nonlinear dynamical systems model (i.e. cusp catastrophe model) fit the data better than the linear and logistic regression models. Likewise, the cusp catastrophe model appears to be especially powerful for modelling those cases of high levels of flow. Overall, flow represents a nonequilibrium condition that combines continuous and abrupt changes across time. Research and intervention efforts concerned with this process should focus on the variable of challenge, which, according to our study, appears to play a key role in the abrupt changes observed in work-related flow. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Celis-Morales, C. A.; Perez-Bravo, F.; Ibanez, L.; Salas, C.; Bailey, M. E.; Gill, J. M. (2012):

Objective vs. self-reported physical activity and sedentary time: effects of measurement method on relationships with risk biomarkers.

In: *PLoS One* 7 (5), S. e36345. DOI: 10.1371/journal.pone.0036345.

Abstract:

PURPOSE: Imprecise measurement of physical activity variables might attenuate estimates of the beneficial effects of activity on health-related outcomes. We aimed to compare the cardiometabolic risk factor dose-response relationships for physical activity and sedentary behaviour between accelerometer- and questionnaire-based activity measures. METHODS: Physical activity and sedentary behaviour were assessed in 317 adults by 7-day accelerometry and International Physical Activity Questionnaire (IPAQ). Fasting blood was taken to determine insulin, glucose, triglyceride and total, LDL and HDL cholesterol concentrations and homeostasis model-estimated insulin resistance (HOMA(IR)). Waist circumference, BMI, body fat percentage and blood pressure were also measured. RESULTS: For both accelerometer-derived sedentary time (<100 counts.min(-1)) and IPAQ-reported sitting time significant positive (negative for HDL cholesterol) relationships were observed with all measured risk factors--i.e. increased sedentary behaviour was associated with increased risk (all p </= 0.01). However, for HOMA(IR) and insulin the regression coefficients were >50% lower for the IPAQ-reported compared to the accelerometer-derived measure (p<0.0001 for both interactions). The relationships for moderate-to-vigorous physical activity (MVPA) and risk factors were less strong than those observed for sedentary behaviours, but significant negative relationships were observed for both accelerometer and IPAQ MVPA measures with glucose, and insulin and HOMA(IR) values (all p<0.05). For accelerometer-derived MVPA only, additional negative relationships were seen with triglyceride, total cholesterol and LDL cholesterol concentrations, BMI, waist circumference and percentage body fat, and a positive relationship was evident with HDL cholesterol (p = 0.0002). Regression coefficients for HOMA(IR), insulin and triglyceride were 43-50% lower for the IPAQ-reported compared to the accelerometer-derived MVPA measure (all p</=0.01). CONCLUSION: Using the IPAQ to determine sitting time and MVPA reveals some, but not all, relationships between these activity measures and metabolic and vascular disease risk factors. Using this self-report method to quantify activity can therefore underestimate the strength of some relationships with risk factors

A processual analysis of basic emotions and sources of concerns as they are lived before and after a competition.

In: *Psychology of Sport and Exercise* 7 (3), S. 287–307.

Abstract:

Objectives

To examine the natural flow of (a) pre- and post-competition temporal patterns of intensity, frequency and daily mean level (a composite measure of frequency and intensity) of basic emotions and (b) frequency of reports of competition-related and competition-extraneous concerns across time.

Method

The Experience Sampling Method (ESM) was used, which permits the monitoring of the spontaneous flow of daily affective and cognitive experiences in the athletes' habitual environment. Thirty-nine male elite martial artists were assessed on 12 basic emotions and concerns at five random times a day across 1 week before and 3 days after a competition. On the competition day, the participants were assessed 1 h before and immediately after the contest.

Results

Different patterns of change were observed for intensity and frequency of emotions and frequency of competition-related and competition-extraneous concerns. Frequency of fear was the most reactive affective component to competition vicinity. Increased frequency of some outcome-contingent negative emotions persisted for three days post-competition. The presence of negative emotions was the lowest in the post-competition days.

Conclusions

This study confirms that, for a better understanding of the process of competitive stress, monitoring of both intensity and frequency of a wide range of emotions is needed. This research area may also benefit from analysing possible psychological spill-over between sport, competition and other life domains.

Measuring walking within and outside the neighborhood in Chinese elders: reliability and validity.

In: *BMC.Public Health* 11 (1471-2458 (Linking)), S. 851. DOI: 10.1186/1471-2458-11-851.

Abstract:

ABSTRACT: BACKGROUND: Walking is a preferred, prevalent and recommended activity for aging populations and is influenced by the neighborhood built environment. To study this influence it is necessary to differentiate whether walking occurs within or outside of the neighborhood. The Neighborhood Physical Activity Questionnaire (NPAQ) collects information on setting-specific physical activity, including walking, inside and outside one's neighborhood. While the NPAQ has shown to be a reliable measure in adults, its reliability in older adults is unknown. Additionally its validity and the influence of type of neighborhood on reliability and validity have yet to be explored. METHODS: The NPAQ walking component was adapted for Chinese speaking elders (NWQ-CS). Ninety-six Chinese elders, stratified by social economic status and neighborhood walkability, wore an accelerometer and completed a log of walks for 7 days. Following the collection of valid data the NWQ-CS was interviewer-administered. Fourteen to 20 days (average of 17 days) later the NWQ-CS was re-administered. Test-retest reliability and validity of the NWQ-CS were assessed. RESULTS: Reliability and validity estimates did not differ with type of neighborhood. NWQ-CS measures of walking showed moderate to excellent reliability. Reliability was generally higher for estimates of weekly frequency than minutes of walking. Total weekly minutes of walking were moderately related to all accelerometry measures. Moderate-to-strong associations were found between the NWQ-CS and log-of-walks variables. The NWQ-CS yielded statistically significantly lower mean values of total walking, weekly minutes of walking for transportation and weekly frequency of walking for transportation outside the neighborhood than the log-of-walks. CONCLUSIONS: The NWQ-CS showed measurement invariance across types of neighborhoods. It is a valid measure of walking for recreation and frequency of walking for transport. However, it may systematically underestimate the duration of walking for transport in samples that engage in high levels of this type of walking

Chaix, Basile; Kestens, Yan; Duncan, Scott; Merrien, Claire; Thierry, Benoit; Pannier, Bruno et al. (2014):

Active transportation and public transportation use to achieve physical activity recommendations? A combined GPS, accelerometer, and mobility survey study.

In: *Int J Behav Nutr Phys Act* 11 (1), S. 124. DOI: 10.1186/s12966-014-0124-x.

Abstract:

BackgroundAccurate information is lacking on the extent of transportation as a source of physical activity, on the physical activity gains from public transportation use, and on the extent to which population shifts in the use of transportation modes could increase the percentage of people reaching official physical activity recommendations.MethodsIn 2012 inverted question mark2013, 234 participants of the RECORD GPS Study (French Paris region, median age inverted question mark= inverted question mark58) wore a portable GPS receiver and an accelerometer for 7 consecutive days and completed a 7-day GPS-based mobility survey (participation rate inverted question mark= inverted question mark57.1%). Information on transportation modes and accelerometry data aggregated at the trip level [number of steps taken, energy expended, moderate to vigorous physical activity (MVPA), and sedentary time] were available for 7,644 trips. Associations between transportation modes and accelerometer-derived physical activity were estimated at the trip level with multilevel linear models.ResultsParticipants spent a median of 1h58min per day in transportation (8.2% of total time). Thirty-eight per-cent of steps taken, 31% of energy expended, and 33% of MVPA over 7 days were attributable to transportation. Walking and biking trips but also public transportation trips with all four transit modes examined were associated with greater steps, MVPA, and energy expenditure when compared to trips by personal motorized vehicle. Two simulated scenarios, implying a shift of approximately 14% and 33% of all motorized trips to public transportation or walking, were associated with a predicted 6 point and 13 point increase in the percentage of participants achieving the current physical activity recommendation.ConclusionsCollecting data with GPS receivers, accelerometers, and a GPS-based electronic mobility survey of activities and transportation modes allowed us to investigate relationships between transportation modes and physical activity at the trip level. Our findings suggest that an increase in active transportation participation and public transportation use may have substantial impacts on the percentage of people achieving physical activity recommendations.

GPS tracking in neighborhood and health studies: A step forward for environmental exposure assessment, a step backward for causal inference?

In: *Health & Place* 21, S. 46–51. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-13026-007%26site%3dehost-live;yan.kestens@umontreal.ca;labadi@u707.jussieu.fr;lewin@u707.jussieu.fr;camille.perchoux@umontreal.ca;karusisi@u707.jussieu.fr;merrien@u707.jussieu.fr;scott.duncan@aut.ac.nz;julie.meline@inserm.fr;chaix@u707.jussieu.fr.

Abstract:

Recent studies have relied on GPS tracking to assess exposure to environmental characteristics over daily life schedules. Combining GPS and GIS allows for advances in environmental exposure assessment. However, biases related to selective daily mobility preclude assessment of environmental effects, to the extent that these studies may represent a step backward in terms of assessment of causal effects. A solution may be to integrate the Public health/Nutrition approach and the Transportation approach to GPS studies, so as to combine a GPS and accelerometer data collection with an electronic mobility survey. Correcting exposure measures and improving study designs with this approach may permit mitigating biases related to selective daily mobility. Mood and personality-based models of substance use.

In: *Psychology of Addictive Behaviors* 24 (1), S. 129–136. DOI: 10.1037/a0018184.

Abstract:

Mood and personality-based vulnerabilities have been extensively examined in patients with substance use disorders, but their relevance as models of etiology remains to be fully investigated. The present investigation examined mood and personality-based models of substance use in a nonclinical sample of young adults. Two-hundred and twelve individuals were assessed for personality and clinical characteristics and participated in computerized ambulatory monitoring of mood states and substance use over a 1-week period. Personality factors were strong predictors of substance use frequency over the previous 30 days, as well as of substance use in daily life using ambulatory monitoring. A linear increase was also observed in the intensity of novelty seeking and antisocial personality traits as a function of the social deviance of substances used. However, mood disorder history was related only to the use of illicit drugs other than cannabis, and fluctuations in mood states did not prospectively predict daily use of substances in a manner consistent with self-medication. Moreover, there was little evidence that personality characteristics moderated relations between mood states and substance use in daily life. The relevance of results for mood and personality models of substance use etiology is discussed.

Day-to-Day Variation in Food Intake and Energy Expenditure in Healthy Women: The Dietitian II Study.

In: *J Acad Nutr.Diet.* (2212-2672 (Electronic)). DOI: 10.1016/j.jand.2013.07.001.

Abstract:

Because day-to-day food intake varies, we tested the hypothesis that ad libitum food intake and energy expenditure show corrective responses over periods of 1 to 10 days in healthy young women. Food intake and accelerometry measurements were collected daily for 17 days in 15 young women. Total daily energy expenditure (TDEE) using doubly labeled water was also measured. The daily deviations in macronutrient and energy intake and energy expenditure from the average values were compared with the deviations observed over succeeding intervals to estimate the corrective responses. The intraindividual coefficients of variation for energy intake averaged +/-25%, ranging from 16% to 34%. TDEE had a coefficient of variation of 8.3%, and accelerometry had a coefficient of variation of 8.4% (range=4.6% to 16.4%). Energy expenditure by accelerometry (2,087+/-191 kcal/day) was not significantly different from TDEE (2,128+/-177 kcal/day), but reported daily energy intake was 20.4% lower (1,693+/-276 kcal/day). There were significant corrective responses in energy from fat and total energy intake. This occurred from Days 3 to 6, with a peak at Day 5 that disappeared when data were randomized within each subject. Human beings show corrective responses to deviations from average energy and macronutrient intakes with a lag time of 3 to 6 days, but not 1 to 2 days. These corrective responses are likely to play a role in bringing about weight stability

Smart homes - current features and future perspectives.

In: *Maturitas* 64 (2), S. 90–97. DOI: 10.1016/j.maturitas.2009.07.014.

Abstract:

In an ageing world, maintaining good health and independence for as long as possible is essential. Instead of hospitalization or institutionalization, the elderly and disabled can be assisted in their own environment 24h a day with numerous 'smart' devices. The concept of the smart home is a promising and cost-effective way of improving home care for the elderly and the disabled in a non-obtrusive way, allowing greater independence, maintaining good health and preventing social isolation. Smart homes are equipped with sensors, actuators, and/or biomedical monitors. The devices operate in a network connected to a remote centre for data collection and processing. The remote centre diagnoses the ongoing situation and initiates assistance procedures as required. The technology can be extended to wearable and in vivo implantable devices to monitor people 24h a day both inside and outside the house. This review describes a selection of projects in developed countries on smart homes examining the various technologies available. Advantages and disadvantages, as well as the impact on modern society, are discussed. Finally, future perspectives on smart homes as part of a home-based health care network are presented.

Chandler, Megan M. (2013):

The antecedents and consequences of core affect variability at work.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 74 (2-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99161-127%26site%3dehost-live.

Abstract:

The purpose of the present study was to investigate the antecedents and consequences of intra-individual variability in affect at work. In particular, the current study sought to investigate how aspects of the job, social characteristics, and individual differences relate to the variability in affective experience over time using experience sampling methodology. The current study also sought to investigate how affect variability relates to well-being and performance outcomes. The present study operationalized within-person affect variability using three calculations employed by Kuppens, van Mechelen, Nezlek, Dossche, and Timmermans (2007), and attempted to improve upon these operationalizations by testing key assumptions of the calculations used in Kuppens et al. (2007) and making modifications to the calculations as necessary. The current study found that various aspects of one's work environment (i.e., role ambiguity, affect in others) and individual differences (i.e., BIS/BAS; Action-State Preoccupation) were related to the variability in one's affective experience at work. Additionally, the present study found that the variability of one's affective experiences, and more specifically Spin, were significantly related to important work outcomes such as task performance, emotional exhaustion, and job satisfaction. Thus, the present study contributed to the literature on workplace affect by (a) advancing the operationalization of within-person affect variability, (b) examining this variability in a work context, and (c) testing the links of both individual difference and work context variables with this within-person variability. Chang, Ta-Yuan; Lai, Yu-An; Hsieh, Hsiu-Hui; Lai, Jim-Shoung; Liu, Chiu-Shong (2009):

Effects of environmental noise exposure on ambulatory blood pressure in young adults.

In: *Environ Res* 109 (7), S. 900–905. DOI: 10.1016/j.envres.2009.05.008.

Abstract:

Epidemiological studies have demonstrated that environmental noise exposure is associated with hypertension in middle-aged and older populations, but the relationship in the young subpopulation and between the genders is still unclear. This panel study investigated effects of environmental noise exposure on 24-h ambulatory blood pressure in 60 adults aged 18-32 years. Individual noise exposure and personal blood pressure were measured simultaneously for 30 males and 30 females. Linear mixed-effects regression models were applied to estimate effects. Total subjects (56.6+/-16.5A-weighted decibels (dBA)) had transient elevations of 1.15 (95% CI=0.86-1.43)mmHg SBP and 1.16 (0.93-1.38)mmHg DBP at daytime, as well as 0.74 (0.21-1.26)mmHg SBP and 0.77 (0.34-1.20)mmHg DBP at nighttime, significantly associated with a 5-dBA increase in noise exposure. Such effects on SBP and DBP still persisted at the 30- and 60-min time-lagged noise exposure. Per 5-dBA increase in 24-h average noise exposure was significantly associated with sustained increments of 1.15 (0.76-1.54)mmHg SBP and 1.27 (0.96-1.58)mmHg DBP in males (57.4+/-16.0dBA), as well as the higher levels of 1.65 (1.36-1.94)mmHg SBP and 1.51 (1.27-1.75)mmHg DBP in females (55.9+/-17.0dBA). We found that environmental noise exposure may have elevated effects on adults' blood pressure. Young females are more susceptible to noise exposure than males.

Chang, Kang Ming; Liu, Shin Hong (2011):

Wireless portable electrocardiogram and a tri-axis accelerometer implementation and application on sleep activity monitoring.

In: *Telemedicine and e-Health* 17 (3), S. 177–184. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-12456-005&site=ehost-live;changkm@asia.edu.tw.

Abstract:

Night-to-night variability of sleep activity requires more home-based portable sleep monitoring instead of clinical polysomnography examination in the laboratory. In this article, a wireless sleep activity monitoring system is described. The system is light and small for the user. Sleep postures, such as supine or left/right side, were observed by a signal from a tri-axis accelerometer. An overnight electrocardiogram was also recorded with a single lead. Using an MSP430 as microcontroller, both physiological signals were transmitted by a Bluetooth chip. A Labview-based interface demonstrated the recorded signal and sleep posture. Three nights of sleep recordings were used to examine night-to-night variability. The proposed system can record overnight heart rate. Results show that sleep posture and posture change can be precisely detected via tri-axis accelerometer information. There is no significant difference within subject data sets, but there are statistically significant differences among subjects, both for heart rate and for sleep posture distribution. The wireless transmission range is also sufficient for home-based users. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Chang, Ta-Yuan; Liu, Chiu-Shong; Hwang, Bing-Fang; Hsieh, Hsiu-Hui; Bao, Bo-Ying; Chen, Chiou-Jong et al. (2014):

Acute effects of noise exposure on 24-h ambulatory blood pressure in hypertensive adults.

In: *J Hypertens. DOI:* 10.1097/HJH.0000000000000418.

Abstract:

OBJECTIVE:: Noise exposure is associated with elevated blood pressure, but the effects on susceptible workers have not been reported. This repeated-measure study investigated the effects of noise exposure on 24-h ambulatory blood pressure among hypertensive, pre-hypertensive, and normotensive adults. METHODS:: We enrolled 113 volunteers in an occupational cohort in 2009. Individual noise exposure and personal blood pressure were measured simultaneously over 24 h on working and non-working days. Linear mixed-effects regressions were used to estimate the effects on SBP and DBP by controlling for potential confounders. RESULTS:: Each A-weighted decibel (dBA) increase in a 30-min time-lagged exposure was associated with transient elevations of work-time SBP [0.30 (95% confidence interval: 0.06, 0.54) mmHg] on working days as well as sleep-time SBP [0.39 (0.12, 0.66) mmHg] and DBP [0.33 (0.14, 0.51) mmHg] on non-working days among 19 hypertensive adults. In contrast, 46 normotensive workers had transient increases in work-time SBP [0.16 (0.03, 0.29) mmHg] and DBP [0.25 (0.15, 0.34) mmHg] on working days as well as sleep-time SBP [0.17 (0.06, 0.29) mmHg] and DBP [0.21 (0.14, 0.29) mmHg] on non-working days caused by a 1-dBA increase in the current exposure. All groups had sustained increases in 24-h average ambulatory SBP and DBP induced by noise exposure on 2 days, but the hypertensive workers had the most pronounced increase in SBP. CONCLUSION:: Hypertensive adults are more susceptible to noise exposure with a greater effect on ambulatory SBP. These results suggest a need for more protection for this subpopulation.

Chantler, Ingrid; Mitchell, Duncan; Fuller, Andrea (2009):

Actigraphy quantifies reduced voluntary physical activity in women with primary dysmenorrhea.

In: *J Pain* 10 (1), S. 38–46.

Abstract:

We assessed whether an activity data logger was able to detect and measure the reduced physical activity reported by women with moderate to severe primary dysmenorrhea. Twelve young women with a history of primary dysmenorrhea and 12 young women without a history of dysmenorrhea wore an activity data logger on their hip for 3 days when menstruating and for 3 matched days of the week when not menstruating. A visual analog scale was use to assess intensity of pain. When menstruating, the women with a history of primary dysmenorrhea, compared with when they were not menstruating, were significantly less active by about 40% on their day of worst pain (P < .001), day of intermediate pain (P < .001), and day of least pain (P < .001). There was no significant difference in the voluntary physical activity of the group on the 3 menstrual days. The women without a history of dysmenorrhea experienced mild menstrual pain but no significant decrease in physical activity (P = .82). We show that

data loggers are able to detect and quantify the decrease in physical activity reported by the women with a history of moderate to severe dysmenorrhea and that menstrual pain but not menstruation itself was associated with decreased voluntary physical activity.

PERSPECTIVE:

We have shown that a miniature activity data logger, when worn on the hip of women with a history of dysmenorrhea, detected a 40% decrease in physical activity when the women were experiencing moderate to severe primary dysmenorrhea. Actigraphy is a useful tool for measuring pain-related debilitation and its management.

Chaput, J.-P.; Lambert, M.; Mathieu, M.-E.; Tremblay, M. S.; O' Loughlin, J.; Tremblay, A. (2012):

Physical activity vs. sedentary time: Independent associations with adiposity in children.

In: *Pediatric Obesity* 7 (3), S. 251–258. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-12138-008&site=ehost-live;jpchaput@cheo.on.ca.

Abstract:

OBJECTIVE:

To investigate the independent associations between objectively measured levels of movement intensity (i.e., time spent sedentary and at light, moderate and vigorous intensities) and indicators of adiposity in a cohort of Canadian children.

METHODS:

A cross-sectional study was conducted in 550 Caucasian children aged 8-10 years with at least one obese biological parent. Physical activity and sedentary time (accelerometer over 7 d) and indicators of adiposity (% body fat measured by dual-energy X-ray absorptiometry and waist-to-height ratio) were objectively measured. We examined the associations between levels of movement intensity and adiposity in multi-level linear regression models adjusted for age, sex, sleep duration, energy intake, sexual maturation, parental socioeconomic status and parental body mass index.

RESULTS:

Objectively measured sedentary time was not associated with adiposity indicators in this cohort (unadjusted and adjusted models). However, moderate-to-vigorous physical activity (MVPA) was inversely associated with % body fat (adj. $\beta = -0.047$; $P = 0.02$) and waist-to-height ratio (adj. $\beta = -0.071$; $P < 0.001$), independent of sedentary time and other covariates. Additionally, we observed that children who did not accumulate ≥60 min d(-1) of MVPA were more likely to be overweight or obese compared to those who met the recommendation (odds ratio [OR] 2.22, 95% confidence interval [CI] 1.45-3.38). In contrast, there was no difference in the likelihood of being categorized as overweight or obese between those who met the recommendation of ≤2 h d(-1) of screen time and those who did not meet this recommendation (OR 1.27, 95% CI 0.75-2.01).

CONCLUSION:

The present study suggests that MVPA is independently associated with adiposity indices in this sample of children while sedentary time is not. Future studies should examine the best approach to increase MVPA in children and youth.

Charani, Esmita; Castro-Sanchez, Enrique; Moore, Luke S. P.; Holmes, Alison (2014):

Do smartphone applications in healthcare require a governance and legal framework? It depends on the application!

In: *BMC Med* 12, S. 29. DOI: 10.1186/1741-7015-12-29.

Abstract:

The fast pace of technological improvement and the rapid development and adoption of healthcare applications present crucial challenges for clinicians, users and policy makers. Some of the most pressing dilemmas include the need to ensure the safety of applications and establish their cost-effectiveness while engaging patients and users to optimize their integration into health decision-making. Healthcare organizations need to consider the risk of fragmenting clinical practice within the organization as a result of too many apps being developed or used, as well as mechanisms for app integration into the wider electronic health records through development of governance framework for their use. The impact of app use on the interactions between clinicians and patients needs to be explored, together with the skills required for both groups to benefit from the use of apps. Although healthcare and academic institutions should support the improvements offered by technological advances, they must strive to do so within robust governance frameworks, after sound evaluation of clinical outcomes and examination of potential unintended consequences.

Chastin, Sebastien F. M.; Dall, Philippa M.; Tigbe, William W.; Grant, Margaret P.; Ryan, Cormac G.; Rafferty, Danny; Granat, Malcolm H. (2009):

Compliance with physical activity guidelines in a group of UK-based postal workers using an objective monitoring technique.

In: *European journal of applied physiology* 106 (6), S. 893–899. DOI: 10.1007/s00421-009-1090-x.

Abstract:

Compliance with physical activity (PA) recommendations was assessed using objective PA monitoring of ambulatory activity, in two healthy groups of individuals with active and sedentary occupations. The study showed generally low compliance with the guidelines (53% with 10,000 steps a day; 10% with 30 min of moderate activity a day; and 1% with 30 min of moderate activity a day in bouts of at least 10 min (ACSM)). Adherence to guidelines decreased as more rigorous conditions were applied to the PA data. Use of an objective monitor revealed that health enhancing bouts of activity were performed in periods of approximately 1-min duration, which may be due to unavoidable environmental interruptions. These bouts of activity are much shorter than those advocated in the ACSM guidelines, raising questions regarding how actual behaviour, based on objective monitoring, can be reconciled with guidelines based on self-reported PA.

Chastin, S. F. M.; Mandrichenko, O.; Helbostadt, J. L.; Skelton, D. A. (2014):

Associations between objectively-measured sedentary behaviour and physical activity with bone mineral density in adults and older adults, the NHANES study.

In: *Bone* 64, S. 254–262. DOI: 10.1016/j.bone.2014.04.009.

Abstract:

BACKGROUND: Lack of physical activity (PA) is an important modifiable risk factor for bone mineral density (BMD). Time spent in sedentary behaviour (SB), or time spent in non-exercising seated and reclining postures, has recently emerged as a new public health risk, independent of the amount of time someone spends being active. As national surveys report that adults spend on average 8h per day being sedentary, rising to 10h a day in older age, it has been hypothesised that a repeated exposure to sitting in modern daily life, whether it is for travelling, working or leisure, might have a deleterious effect on bone health in a way that mirrors the results of studies into the effect of lengthy periods of bed-rest. The aim of this study was to investigate for the first time a) how time spent in SB is associated with bone mineral density (BMD), b) whether this association changes depending on the amount of time spent engaging in different intensity levels of PA, and c) if the pattern of accumulation of SB and long uninterrupted periods of SB are associated with BMD. METHODS: The 2005/2006 National Health and Nutrition Examination Survey (NHANES), is a cross-sectional study of a representative sample of the US population that is conducted biannually by the National Centers for Disease Control. PA and SB were assessed objectively over 7days using an Actigraph accelerometer and BMD was measured via dual-energy X-ray absorptiometry. In this study, data are presented on four regions of the femur (femoral neck, trochanter, inter trochanter and total femur) and total spine (L1-L4). The associations between BMD, SB and PA levels were examined using multiple linear regressions stratified by gender. In addition, the association between the pattern of accumulation of SB (quantified as frequency and duration of SB) and BMD was also investigated. All models were adjusted for known risk factors associated with BMD. In total, data for 2117 individuals, aged 23-90+years (males N=1158), were available to analyse SB and femur BMD and 1942 individuals (males N=1053) for analysis of SB and spine BMD. RESULTS: There was no evidence of an association between SB time and hip or spinal BMD in men. For men, time spent doing moderate to vigorous activity (MVPA) and vigorous activity (VIG) was associated with higher total femur and the other hip sub-region BMD. The regression coefficient was BMVPA=0.306 (95% CI: 0.021-0.591)g/cm(2) for each 10minute increment in daily MVPA. For VIG, the regression coefficient is BVIG=0.320 (95% CI: 0.058-0.583) but this cannot be interpreted linearly as time spent in vigorous activity was square root transformed. In women, SB was negatively associated with total femur BMD and all sub-regions but not MVPA nor VIG. The regression coefficient for total femur BMD was BSB=-0.159 (95% CI: -0.241-0.076)g/cm(2) for each 10minute increment spent being sedentary each day. In addition, the duration of SB bouts was deleteriously associated with BMD for the total femur and of other hip sub-regions, but the number of bouts of SB did not have a significant effect. These associations were found to be independent of the amount of MVPA and VIG that women engage in. No associations were found between SB or PA and spinal BMD for either men or women. CONCLUSIONS: These results provide the first evidence that repeated exposure to sitting (SB), measured objectively in daily life, is deleteriously associated with BMD of the total femur and of all hip sub-regions in women, independent of the amount of time women engage in moderate and vigorous activity. This suggests that SB might be a risk factor for bone health in women independent of whether they engage in physical activity. In addition, the duration of SB bouts, rather than their frequency, appears to be deleteriously associated with BMD of the total femur and of all hip sub-regions. Future research should investigate the effect on bone health of interventions which set out to reduce SB and the duration of SB bouts in comparison, and as adjunct, to the promotion of PA. For men, SB is not significantly associated with BMD of the femur or spine and the results appear to confirm that moderate and vigorous activity has a protective effect.

Chastin, Sebastien Fm; Mandrichenko, Oleksii; Skelton, Dawn A. (2014):

The frequency of osteogenic activities and the pattern of intermittence between periods of physical activity and sedentary behaviour affects bone mineral content: the cross-sectional NHANES study.

In: *BMC Public Health* 14, S. 4. DOI: 10.1186/1471-2458-14-4.

Abstract:

BACKGROUND: Sedentary behaviours, defined as non exercising seated activities, have been shown to have deleterious effects on health. It has been hypothesised that too much sitting time can have a detrimental effect on bone health in youth. The aim of this study is to test this hypothesis by exploring the association between objectively measured volume and patterns of time spent in sedentary behaviours, time spent in specific screen-based sedentary pursuits and bone mineral content (BMC) accrual in youth. METHODS: NHANES 2005-2006 cycle data includes BMC of the femoral and spinal region via dual-energy X-ray absorptiometry (DEXA), assessment of physical activity and sedentary behaviour patterns through accelerometry, self reported time spent in screen based pursuits (watching TV and using a computer), and frequency of vigorous playtime and strengthening activities. Multiple regression analysis, stratified by gender was performed on N = 671 males and N = 677 females aged from 8 to 22 years. RESULTS: Time spent in screen-based sedentary behaviours is negatively associated with femoral BMC (males and females) and spinal BMC (females only) after correction for time spent in moderate and vigorous activity. Regression coefficients indicate that an additional hour per day of screen-based sitting corresponds to a difference of -0.77 g femoral BMC in females [95% CI: -1.31 to -0.22] and of -0.45 g femoral BMC in males [95% CI: -0.83 to -0.06]. This association is attenuated when self-reported engagement in regular (average 5 times per week) strengthening exercise (for males) and vigorous playing (for both males and females) is taken into account. Total sitting time and non screen-based sitting do not appear to have a negative association with BMC, whereas screen based sedentary time does. Patterns of intermittence between periods of sitting and moderate to vigorous activity appears to be positively associated with bone health when activity is clustered in time and inter-spaced with long continuous bouts of sitting. CONCLUSIONS: Some specific sedentary pursuits (screen-based) are negatively associated with bone health in youth. This association is specific to gender and anatomical area. This relationship between screen-based time and bone health is independent of the total amount of physical activity measured objectively, but not independent of self-reported frequency of strengthening and vigorous play activities. The data clearly suggests that the frequency, rather than the volume, of osteogenic activities is important in counteracting the effect of sedentary behaviour on bone health. The pattern of intermittence between sedentary periods and activity also plays a role in bone accrual, with clustered short bouts of activity interspaced with long periods of sedentary behaviours appearing to be more beneficial than activities more evenly spread in time.

Cheatham, Scott W.; Kolber, Morey J.; Ernst, Michael P. (2014):

The Concurrent Validity of Resting Pulse Rate Measurements: A Comparison of Two Smartphone Applications, Polar H7 Belt Monitor, and Pulse Oximeter with Bluetooth(R).

In: *J Sport Rehabil. DOI:* 10.1123/jsr.2013-0145.

Abstract:

CONTEXT: Pulse rate is commonly measured manually or with commercial wrist or belt monitors. More recently, pulse rate monitoring has become convenient with the use of mobile technology that allows monitoring through the smartphone camera. This optical technology offers many benefits, albeit the clinimetric properties have not been extensively studied. DESIGN: Observational study of reliability Setting: University kinesiology laboratory. PARTICIPANTS: Thirty healthy, recreationally active adults. INTERVENTION: Concurrent measurement of pulse rate using two smartphone applications (Fingertip, Face-scan,) with the Polar(R) H7 belt and pulse oximeter. MAIN OUTCOME MEASURE: Average resting pulse rate for 5 minutes in three positions (supine, sitting, and prone). RESULTS: Concurrent validity in supine and standing was good between the two applications and the Polar H7 (intraclass correlation coefficient: ICC-0.80-0.98) and pulse oximeter (ICC-0.82-0.98). For sitting, the validity was good between the fingertip application, Polar H7 (ICC-0.97) and pulse oximeter (ICC-0.97). The face-scan application had moderate validity with the Polar H7 (ICC-0.74) and pulse oximeter (ICC-0.69). The minimal detectable change (MDC90) between the fingertip application and Polar H7 ranged from 1.38-4.36 beats per minute (BPM) and 0.69-2.97 BPM for the pulse oximeter with all three positions. The MDC90 between the face-scan application and Polar H7 ranged from 11.88-12.83 BPM and 0.59-17.72 BPM for the pulse oximeter. The 95% limits of agreement (LOA) suggests that the fingertip application may vary between 2.40-3.59 BPM with the Polar H7 and 3.40-3.42 BPM with the pulse oximeter. The face-scan application may vary between 3.46-3.52 BPM with the Polar H7 and 2.54-3.46 BPM with the pulse oximeter. CONCLUSION: Pulse rate measurements may be effective using a finger-tip application, belt monitor, and pulse oximeter. The fingertip scanner showed superior results compared to the face-scanner which only demonstrated modest validity when compared to the Polar H7 and pulse oximeter.

Assessment of autonomic control and respiratory sinus arrhythmia using point process models of human heart beat dynamics.

In: *Biomedical Engineering, IEEE Transactions on* 56 (7), S. 1791–1802.

Abstract:

BACKGROUND:

Accelerometers measure intensity, frequency, and duration of physical activity. However, the scarcity of reports on data reduction makes comparing accelerometer results across studies difficult.

METHODS:

Participants were asked to wear a triaxial accelerometer (RT3) for ?10 hours for at least 4 days, including one weekend day. We summarize our data-cleaning procedures and assess the impact of defining a usable day of measurements as at least 6, 8, or 10 hours of wear time, and of standardizing data to a 12-hour day.

RESULTS:

Eighty-two percent of participants met wear time requirements; 93% met requirements when we defined a day as 8-or-more hours of wear time. Normalization of data to a 12-hour day had little impact on estimates of daily moderate-to-vigorous physical activity (MVPA; 16.9 vs. 17.1 minutes); restricting MVPA to activities occurring in bouts of 10 minutes or longer had greater impact (16.9 vs. 6.3 minutes per day).

CONCLUSION:

Our account of accelerometry quality-control and data-cleaning procedures documents the small impact of variations in daily wear time requirements on MVPA estimates, and the larger impact of evaluating total MVPA vs. MVPA occurring in extended bouts. This paper should allow other researchers to duplicate or revise our methods as needed.

Assessment of autonomic control and respiratory sinus arrhythmia using point process models of human heart beat dynamics.

In: *IEEE transactions on bio-medical engineering* 56 (7), S. 1791–1802. DOI: 10.1109/TBME.2009.2016349.

Abstract:

Tracking the autonomic control and respiratory sinus arrhythmia (RSA) from electrocardiogram and respiratory measurements is an important problem in cardiovascular control. We propose a point process adaptive filter algorithm based on an inverse Gaussian model to track heart beat intervals that incorporates respiratory measurements as a covariate and provides an analytic form for computing a dynamic estimate of RSA gain. We use Kolmogorov-Smirnov tests and autocorrelation function analyses to assess model goodness-of-fit. We illustrate the properties of the new dynamic estimate of RSA in the analysis of simulated heart beat data and actual heart beat data recorded from subjects in a four-state postural study of heart beat dynamics: control, sympathetic blockade, parasympathetic blockade, and combined sympathetic and parasympathetic blockade. In addition to giving an accurate description of the heart beat data, our adaptive filter algorithm confirms established findings pointing at a vagally mediated RSA and provides a new dynamic RSA estimate that can be used to track cardiovascular control between and within a broad range of postural, pharmacological, and age conditions. Our paradigm suggests a possible framework for designing a device for ambulatory monitoring and assessment of autonomic control in both laboratory research and clinical practice.

Feasibility and usability of experience sampling methodology for capturing everyday experiences of individuals with autism spectrum disorders.

In: *Disabil Health J* 7 (3), S. 361–366. DOI: 10.1016/j.dhjo.2014.04.004.

Abstract:

BACKGROUND: Understanding experiences from the perspective of adults with autism spectrum disorders (ASD), in the myriad of circumstances in which they find themselves every day, is crucial for developing client-centered interventions. However, capturing these experiences can be difficult. OBJECTIVE: To investigate the feasibility and usability of experience sampling

method (ESM), an ecological momentary assessment, for studying individuals with ASD. METHODS: Four participants (2 males) with Asperger's syndrome or high functioning autism aged 16-32 years carried an iPod touch or iPhone with a pre-installed ESM survey exploring the situation and their perceived internal experiences. Participants were asked to respond to the survey 7 times daily, at random times generated by the device, for 7 days. RESULTS: A high signal response rate (mean = 71%) and a short average time required for survey completion (mean = 1 min 42 s) supported feasibility of the ESM for use in research with individuals with ASD. Participants reported that the questions were straightforward and that survey completion interfered very little with everyday activities, supporting acceptability of the method. Results of a split-week analysis revealed consistency of experiences; correlations among experiences that are linked logically provided evidence of the internal logic of data gathered using the ESM. Through graphic analysis, we illustrated the usability of ESM for capturing the influence of everyday contexts on internal experiences/perceptions. CONCLUSIONS: The ESM holds promise for examining the impact of social context on the everyday experiences of individuals with ASD.

Fine particulate matter results in hemodynamic changes in subjects with blunted nocturnal blood pressure dipping.

In: *Environ Res* 131C, S. 1–5. DOI: 10.1016/j.envres.2014.01.009.

Abstract:

Particulate matter with aerodynamic diameter of <2.5mum (PM2.5) is associated with blood pressure and hemodynamic changes. Blunted nocturnal blood pressure dipping is a major risk factor for cardiovascular events; limited information is available on whether PM2.5 exposure-related hemodynamic changes vary with day-night blood pressure circadian rhythms. In this study, we enrolled 161 subjects and monitored the changes in ambulatory blood pressure and hemodynamics for 24h. The day-night blood pressure and cardiovascular metrics were calculated according to the sleep-wake cycles logged in the subjects diary. The effects of PM2.5 exposure on blood pressure and hemodynamic changes were analyzed using generalized linear mixed-effect model. After adjusting for potential confounders, a 10-mug/m3 increase in PM2.5 was associated with 1.0mmHg [95% confidence interval (CI): 0.2-1.8mmHg] narrowing in the pulse pressure, 3.1% (95% CI: 1.4-4.8%) decrease in the maximum rate of left ventricular pressure rise, and 3.6% (95% CI: 1.6-5.7%) increase in systemic vascular resistance among 79 subjects with nocturnal blood pressure dip of <10%. In contrast, PM2.5 was not associated with any changes in cardiovascular metrics among 82 subjects with nocturnal blood pressure dip of >/=10%. Our findings demonstrate that short-term exposure to PM2.5 contributes to pulse pressure narrowing along with cardiac and vasomotor dysfunctions in subjects with nocturnal blood pressure dip of <10%.

Chen, Y. W.; Cordier, R.; Brown, N. (2013):

A preliminary study on the reliability and validity of using experience sampling method in children with autism spectrum disorders.

In: *Dev.Neurorehabil.* (1751-8423 (Linking)). DOI: 10.3109/17518423.2013.855274.

Abstract:

Abstract Objective: This study investigated the feasibility of using experience sampling method (ESM) to study everyday experiences in children with autism spectrum disorders. Methods: Six boys, aged 8-12 years, with high-functioning autism or Asperger syndrome carried an iPod touch with a pre-installed ESM survey about what they were doing, where, with whom and the quality of their experiences and associated emotions. They were randomly signalled seven times daily for seven consecutive days to respond to the survey. Results: The average signal response rates (56.8%) was acceptable and the mean time of survey completion (1 minute 53 seconds) was within acceptable range. Split-week analysis supported the consistency of experiences reporting while correlations among theoretically linked quality of experiences and emotions showed the internal logic of participants' responses; thus supporting internal reliability and validity, respectively. Conclusion: The study demonstrated the feasibility and usefulness of using ESM in exploring participants' everyday life experiences

A web-based system for home monitoring of patients with Parkinson's disease using wearable sensors.

In: *Biomedical Engineering, IEEE Transactions on* 58 (3), S. 831–836.

Abstract:

This letter introduces MercuryLive, a platform to enable home monitoring of patients with Parkinson's disease (PD) using wearable sensors. MercuryLive contains three tiers: a resource-aware data collection engine that relies upon wearable sensors, web services for live streaming and storage of sensor data, and a web-based graphical user interface client with video conferencing capability. Besides, the platform has the capability of analyzing sensor (i.e., accelerometer) data to reliably estimate clinical scores capturing the severity of tremor, bradykinesia, and dyskinesia. Testing results showed an average data latency of less than 400 ms and video latency of about 200 ms with video frame rate of about 13 frames/s when 800 kb/s of bandwidth were available and we used a 40% video compression, and data feature upload requiring 1 min of extra time following a 10 min interactive session. These results indicate that the proposed platform is suitable to monitor patients with PD to facilitate the titration of medications in the late stages of the disease.

Cheng, Nicholas M.; Chakrabarti, Rahul; Kam, Jonathan K. (2014):

iPhone Applications for Eye Care Professionals: A Review of Current Capabilities and Concerns.

In: *Telemed J E Health* 20 (4), S. 385–387. DOI: 10.1089/tmj.2013.0173.

Abstract:

Abstract Purpose: To quantitatively review and categorize the eye care-related iPhone((R)) (Apple((R)), Cupertino, CA) applications ("apps") currently available, evaluate qualified professional involvement in app development, and suggest future needs in this emerging area of mobile health. Materials and Methods: The Apple iTunes((R)) store was searched for iPhone eye care-themed apps using the general terms "ophthalmology," "ophthalmologist," "optometry," "optometrist," "eye care," and "ocular," in addition to terms based on the Centers for Disease Control and Prevention's common eye conditions. Data collected from each app included publication date, target audience, category of app, estimated number of downloads, average user rating, and documented involvement of qualified professionals. Results: In total, 182 apps were identified. The majority of apps lacked community user ratings and had 3,000 or fewer downloads (84% and 69%, respectively). Consistent with other medical specialties, only 37% of apps had documented qualified professional involvement in their development. When stratified by intended audience, 52% and 44% of apps designed for ophthalmologists and optometrists, respectively, had professional input, compared with 31% for non-eye care clinicians and 21% for the general public. Conclusions: Smartphone apps are likely to become of increasingly greater relevance to the modern eye care professional with tremendous versatility in daily practice.

However, despite the rapid emergence of eye care apps, a low level of qualified professional involvement in app development and a lack of peer review after publishing remain. There is a clear need for evidence-based principles and standards of app development to be adopted in this emerging area.

The effect of continuous nursing intervention guided by chronotherapeutics on ambulatory blood pressure of older hypertensive patients in the community.

In: *J Clin Nurs. DOI:* 10.1111/jocn.12502.

Abstract:

AIMS AND OBJECTIVES: To explore the effect of continuous nursing intervention guided by chronotherapeutics so as to provide the easy, noninvasive, effective and acceptable intervention for older hypertensive patients in the community. BACKGROUND: Many researchers studied the effect of administration at different times on blood pressure control and circadian rhythm. However, the individual administrative time was set ambiguously in previous studies. DESIGN: A semi-experimental study. METHODS: In the study, 90 eligible patients were recruited and separated into three groups randomly, which were the control group, intervention group A (behaviour and chronotherapy intervention) and intervention group B (behaviour intervention). At 6 and 12 months after the study, the intervention groups were measured 24-hour ambulatory blood pressure monitoring. RESULTS: There were significant differences in ambulatory blood pressure monitoring parameters of the two intervention groups at different measurement times, and there were interaction between measurement time and different groups. The number of patients with dipper increased and reverse dipper decreased in group A as the intervention applied. There were statistical differences between two groups. The number of patients with morning surge in group A decreased more, and there were statistical differences between two groups at six months after the intervention. CONCLUSIONS: The behaviour and chronotherapy intervention based on the patients' ambulatory blood pressure monitoring can control casual blood pressure much better and last longer, which can also improve patients' indexes of ambulatory blood pressure monitoring better than behaviour intervention only. The behaviour and chronotherapy intervention can increase patients' nocturnal blood pressure drop, increase the number of patients with dipper and decrease reverse dipper, and improve blood pressure surge in the morning. RELEVANCE TO CLINICAL PRACTICE: Nurses can use continuous nursing intervention guided by chronotherapeutics to help improve hypertension of older patients better in the community.

Cheung, V. H.; Gray, L.; Karunanithi, M. (2011):

Review of accelerometry for determining daily activity among elderly patients.

In: *Arch.Phys.Med.Rehabil.* 92 (6), S. 998–1014. DOI: 10.1016/j.apmr.2010.12.040.

Abstract:

OBJECTIVES: To review studies that used accelerometers to classify human movements and to appraise their potential to determine the activities of older patients in hospital settings. DATA SOURCES: MEDLINE, CINAHL, and Web of Science electronic databases. A search constraint of articles published in English language between January 1980 and March 2010 was applied. STUDY SELECTION: All studies that validated the use of accelerometers to classify human postural movements and mobility were included. Studies included participants from any age group. All types of accelerometers were included. Outcome measures criteria explored within the studies were comparisons of derived classifications of postural movements and mobility against those made by using observations. Based on these criteria, 54 studies were selected for detailed review from 526 initially identified studies. DATA EXTRACTION: Data were extracted by the first author and included characteristics of study participants, accelerometers used, body positions of device attachment, study setting, duration, methods, results, and limitations of the validation studies. DATA SYNTHESIS: The accelerometer-based monitoring technique was investigated predominantly on a small sample of healthy adult participants in a laboratory setting. Most studies applied multiple accelerometers on the sternum, wrists, thighs, and shanks of participants. Most studies collected validation data while participants performed a predefined standardized activity protocol. CONCLUSIONS: Accelerometer devices have the potential to monitor human movements continuously to determine postural movements and mobility for the assessment of functional ability. Future studies should focus on long-term monitoring of free daily activity of a large sample of mobility-impaired or older hospitalized patients, who are at risk for functional decline. Use of a single waist-mounted triaxial accelerometer would be the most practical and useful option

Chih, M. Y.; Patton, T.; McTavish, F. M.; Isham, A. J.; Judkins-Fisher, C. L.; Atwood, A. K.; Gustafson, D. H. (2013):

Predictive modeling of addiction lapses in a mobile health application.

In: *J Subst.Abuse Treat.* (0740-5472 (Linking)). DOI: 10.1016/j.jsat.2013.08.004.

Abstract:

The chronically relapsing nature of alcoholism leads to substantial personal, family, and societal costs. Addiction-comprehensive health enhancement support system (A-CHESS) is a smartphone application that aims to reduce relapse. To offer targeted support to patients who are at risk of lapses within the coming week, a Bayesian network model to predict such events was constructed using responses on 2,934 weekly surveys (called the Weekly Check-in) from 152 alcohol-dependent individuals who recently completed residential treatment. The Weekly Check-in is a self-monitoring service, provided in A-CHESS, to track patients' recovery progress. The model showed good predictability, with the area under receiver operating characteristic curve of 0.829 in the 10-fold cross-validation and 0.912 in the external validation. The sensitivity/specificity table assists the tradeoff decisions necessary to apply the model in practice. This study moves us closer to the goal of providing lapse prediction so that patients might receive more targeted and timely support

Active commuting to school in children and adolescents: an opportunity to increase physical activity and fitness.

In: *Scandinavian journal of public health* 38 (8), S. 873–879.

Abstract:

AIMS:

The purpose was to describe the patterns of commuting to school in young people and to examine its associations with physical activity (PA) and cardiorespiratory fitness.

METHODS:

The sample comprised 2271 Estonian and Swedish children and adolescents (1218 females) aged 9-10 years and 15-16 years. Data were collected in 1998/99. Mode of commuting to and from school was assessed by questionnaire. Time spent (min/day) in PA and average PA (counts/min) was measured by accelerometry. Cardiorespiratory fitness was assessed by means of a maximal cycle ergometer test.

RESULTS:

Sixty-one percent of the participants reported active commuting to school (ACS). Estonian youth showed lower levels of ACS than Swedish (odds ratio, 0.64; 95% confidence interval, 0.53-0.76) and girls reported lower levels than boys (0.74; 0.62-0.88). ACS boys showed higher PA levels than non-ACS boys for moderate, vigorous, MVPA, and average PA levels (all $p \leq 0.01$). Participants who cycled to school had higher cardiorespiratory fitness than walkers or passive travellers ($p < 0.001$).

CONCLUSIONS:

Nearly two-thirds of the participants actively commuted to school. ACS may provide an opportunity to increase levels of daily PA, especially in boys, and cardiorespiratory fitness, especially if cycling. Public health strategies should develop and test ACS patterns to get more evidence and promote bike-friendly environments.

Cho, Jaehee; Park, Dongjin; Lee, H. Erin (2014):

Cognitive factors of using health apps: systematic analysis of relationships among health consciousness, health information orientation, eHealth literacy, and health app use efficacy.

In: *J Med Internet Res* 16 (5), S. e125. DOI: 10.2196/jmir.3283.

Abstract:

BACKGROUND: Interest in smartphone health apps has been increasing recently. However, we have little understanding of the cognitive and motivational factors that influence the extent of health-app use. OBJECTIVE: This study aimed to examine the effects of four cognitive factors-health consciousness, health information orientation, eHealth literacy, and health-app use efficacy-on the extent of health-app use. It also explored the influence of two different use patterns-information and information-behavior use of health apps-with regard to the relationships among the main study variables. METHODS: We

collected and analyzed 765 surveys in South Korea. According to the results, there was a negligible gender difference: males (50.6%, 387/765) and females (49.4%, 378/765). All participants were adults whose ages ranged from 19 to 59. In order to test the proposed hypotheses, we used a path analysis as a specific form of structural equation modeling. RESULTS: Through a path analysis, we discovered that individuals' health consciousness had a direct effect on their use of health apps. However, unlike the initial expectations, the effects of health information orientation and eHealth literacy on health-app use were mediated by health-app use efficacy. CONCLUSIONS: The results from the path analysis addressed a significant direct effect of health consciousness as well as strong mediating effects of health-app use efficacy. These findings contribute to widening our comprehension of the new, digital dimensions of health management, particularly those revolving around mobile technology.

Choi, Leena; Chen, Kong Y.; Acra, Sari A.; Buchowski, MacIej S. (2010):

Distributed lag and spline modeling for predicting energy expenditure from accelerometry in youth.

In: *Journal of applied physiology (Bethesda, Md. : 1985)* 108 (2), S. 314–327. DOI: 10.1152/japplphysiol.00374.2009.

Abstract:

Movement sensing using accelerometers is commonly used for the measurement of physical activity (PA) and estimating energy expenditure (EE) under free-living conditions. The major limitation of this approach is lack of accuracy and precision in estimating EE, especially in low-intensity activities. Thus the objective of this study was to investigate benefits of a distributed lag spline (DLS) modeling approach for the prediction of total daily EE (TEE) and EE in sedentary (1.0-1.5 metabolic equivalents; MET), light (1.5-3.0 MET), and moderate/vigorous (> or = 3.0 MET) intensity activities in 10- to 17-year-old youth (n = 76). We also explored feasibility of the DLS modeling approach to predict physical activity EE (PAEE) and METs. Movement was measured by Actigraph accelerometers placed on the hip, wrist, and ankle. With whole-room indirect calorimeter as the reference standard, prediction models (Hip, Wrist, Ankle, Hip+Wrist, Hip+Wrist+Ankle) for TEE, PAEE, and MET were developed and validated using the fivefold cross-validation method. The TEE predictions by these DLS models were not significantly different from the room calorimeter measurements (all P > 0.05). The Hip+Wrist+Ankle predicted TEE better than other models and reduced prediction errors in moderate/vigorous PA for TEE, MET, and PAEE (all P < 0.001). The Hip+Wrist reduced prediction errors for the PAEE and MET at sedentary PA (P = 0.020 and 0.021) compared with the Hip. Models that included Wrist correctly classified time spent at light PA better than other models. The means and standard deviations of the prediction errors for the Hip+Wrist+Ankle and Hip were 0.4 +/- 144.0 and 1.5 +/- 164.7 kcal for the TEE, 0.0 +/- 84.2 and 1.3 +/- 104.7 kcal for the PAEE, and -1.1 +/- 97.6 and -0.1 +/- 108.6 MET min for the MET models. We conclude that the DLS approach for accelerometer data improves detailed EE prediction in youth.

Choi, Jounghwa; Noh, Ghee-Young; Park, Dong-Jin (2014):

Smoking cessation apps for smartphones: content analysis with the self-determination theory.

In: *J Med Internet Res* 16 (2), S. e44. DOI: 10.2196/jmir.3061.

Abstract:

BACKGROUND: Smartphones are increasingly receiving attention from public health scholars and practitioners as a means to assist individuals' health management. A number of smartphone apps for smoking cessation are also available; however, little effort has been made to evaluate the content and functions of these apps employing a theoretical framework. OBJECTIVE: The present study aims to analyze and evaluate the contents of smoking cessation apps available in South Korea employing the self-determination theory (SDT) as a theoretical framework for analysis. This study analyzes the extent to which smoking cessation apps have features that satisfy the basic needs identified in the SDT, which stimulate autonomous motivation. The type of motivational goal content manifested in the apps and how the goal content was framed are also explored. By assessing the features of smoking cessation apps based on the SDT, this study aims to offer direction for improvement for these apps. METHODS: Out of 309 apps identified from the iTunes store and Google Play (excluding 27 duplications), 175 apps were randomly drawn and analyzed. The coding scheme was drafted by the authors based on the SDT and gain/loss framing theory and was further finely tuned through the process of coder training and by establishing intercoder reliability. Once the intercoder reliability was established, the coders divided up the rest of the sample and coded them independently. RESULTS: The analysis revealed that most apps (94.3%, 165/175) had at least one feature that tapped at least 1 of the 3 basic needs. Only 18 of 175 apps (10.3%) addressed all 3 basic needs. For goal content, money (53.7%, 94/175) showed the highest frequency, followed by health (32.0%, 56/175), time (7.4%, 13/175), and appearance (1.1%, 2/175), suggesting that extrinsic goals are more dominantly presented in smoking cessation apps. For the framing of goal content, gain framing appeared more frequently (41.7%, 73/175). CONCLUSIONS: The results suggest that these smoking cessation apps may not sufficiently stimulate autonomous motivation; a small number of apps addressed all 3 basic needs suggested by the SDT (ie, autonomy, competence, and relatedness). The apps

also tended to present extrinsic goal content (primarily in terms of money) over intrinsic ones (ie, health) by primarily adopting gain framing. Implications of these findings for public health practitioners and consumers are discussed.

Choi, Jong Min; Sohn, Junil; Ku, Yunseo; Kim, Dongwook; Lee, Junghak (2013):

Phoneme-based self hearing assessment on a smartphone.

In: *IEEE J Biomed Health Inform* 17 (3), S. 526–529.

Abstract:

Phonemes provide an interesting alternative to pure tones in hearing tests.We propose a new smartphone-based method for self-hearing assessment using the four Korean phonemes which are similar to the English phonemes /a/, /i/, /sh/, and /s/. We conducted tests on 15 subjects diagnosed with mild to severe hearing loss and estimated their conventional pure-tone hearing thresholds from their phoneme hearing thresholds using regression analysis. The phoneme-based self-hearing assessment was found to be sufficiently reliable in estimating the hearing thresholds of hearing impaired subjects. The difference between the hearing thresholds obtained through conventional pure-tone audiometry and those obtained using our method was 5.6 dB HL on average. The proposed hearing assessment was able to significantly reduce the mean test time compared to conventional pure-tone audiometry.

Choi, L.; Ward, S. C.; Schnelle, J. F.; Buchowski, M. S. (2012):

Assessment of Wear/Nonwear Time Classification Algorithms for Triaxial Accelerometer.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e318258cb36.

Abstract:

PURPOSE: To assess performance of existing wear/nonwear time classification algorithms for accelerometry data collected in the free-living environment using a wrist-worn triaxial accelerometer and a waist-worn uniaxial accelerometer in older adults. METHODS: Twenty-nine adults aged 76 to 96 years wore wrist accelerometers for approximately 24-h per day and waist accelerometers during waking for approximately 7 days of free-living. Wear and nonwear times were classified by existing algorithms (Alg[Actilife], Alg[Troiano] and Alg[Choi]) and compared with wear and nonwear times identified by data plots and diary records. Using bias and probability of correct classification, performance of the algorithms, two time-windows (60- and 90-min), andvector magnitude (VM) vs. vertical axis (V) counts from a triaxial accelerometer, were compared. RESULTS: Automated algorithms (Alg[Choi] and Alg[Troiano]) classified wear/nonwear time intervals more accurately from VM than V counts. The use of 90-min time window improved wear/nonwear classification accuracy when compared with the 60-min window. The Alg[Choi] and Alg[Troiano] performed better than the manufacturer-provided algorithm (Alg[Actilife]), and Alg[Choi] performed better than Alg[Troiano] for wear/nonwear time classification using data collected by both accelerometers. CONCLUSIONS: Triaxial wrist-worn accelerometer can be used for an accurate wear/nonwear time classification in free-living older adults. The use of 90-min window and VM counts improves performance of commonly used algorithms for wear/nonwear classification for both uniaxial and triaxial accelerometers

Christensen, Arne; Osterberg, Lars G.; Hansen, Ebba Holme (2009):

Electronic monitoring of patient adherence to oral antihypertensive medical treatment: a systematic review.

In: *J Hypertens* 27 (8), S. 1540–1551. DOI: 10.1097/HJH.0b013e32832d50ef.

Abstract:

Poor patient adherence is often the reason for suboptimal blood pressure control. Electronic monitoring is one method of assessing adherence. The aim was to systematically review the literature on electronic monitoring of patient adherence to self-administered oral antihypertensive medications. We searched the Pubmed, Embase, Cinahl and Psychinfo databases and websites of suppliers of electronic monitoring devices. The quality of the studies was assessed according to the quality criteria proposed by Haynes et al. Sixty-two articles were included; three met the criteria proposed by Haynes et al. and nine reported the use of electronic adherence monitoring for feedback interventions. Adherence rates were generally high, whereas average study quality was low with a recent tendency towards improved quality. One study detected investigator fraud based on electronic monitoring data. Use of electronic monitoring of patient adherence according to the quality criteria proposed by Haynes et al. has been rather limited during the past two decades. Electronic monitoring has mainly been used as a

measurement tool, but it seems to have the potential to significantly improve blood pressure control as well and should be used more widely.

Chuang, Kai Jen; Coull, Brent A.; Zanobetti, Antonella; Suh, Helen; Schwartz, Joel; Stone, Peter H. et al. (2008):

Particulate air pollution as a risk factor for ST-segment depression in patients with coronary artery disease.

In: *Circulation* 118 (13), S. 1314–1320.

Abstract:

BACKGROUND:

The association of particulate matter (PM) with cardiovascular morbidity and mortality is well documented. PM-induced ischemia is considered a potential mechanism linking PM to adverse cardiovascular outcomes.

METHODS AND RESULTS:

In a repeated-measures study including 5979 observations on 48 patients 43 to 75 years of age, we investigated associations of ambient pollution with ST-segment level changes averaged over half-hour periods measured in the modified V(5) position by 24-hour Holter ECG monitoring. Each patient was observed up to 4 times within 1 year after a percutaneous intervention for myocardial infarction, acute coronary syndrome without infarction, or stable coronary artery disease without acute coronary syndrome. Elevation in fine particles (PM(2.5)) and black carbon levels predicted depression of half-hour-averaged ST-segment levels. An interquartile increase in the previous 24-hour mean black carbon level was associated with a 1.50-fold increased risk of ST-segment depression > or =0.1 mm (95% CI, 1.19 to 1.89) and a -0.031-mm (95% CI, -0.042 to -0.019) decrease in half-hour-averaged ST-segment level (continuous outcome). Effects were greatest within the first month after hospitalization and for patients with myocardial infarction during hospitalization or with diabetes.

CONCLUSIONS:

ST-segment depression is associated with increased exposure to PM(2.5) and black carbon in cardiac patients. The risk of pollution-associated ST-segment depression may be greatest in those with myocardial injury in the first month after the cardiac event.

Chung, L. M.; Law, Q. P.; Fong, S. S.; Chung, J. W. (2014):

Teledietetics improves weight reduction by modifying eating behavior: a randomized controlled trial.

In: *Telemed.J.E.Health* 20 (1), S. 55–62. DOI: 10.1089/tmj.2013.0104.

Abstract:

Abstract Background: Weight reduction without behavioral modification is not sustainable. However, with a technology application such as teledietetics, the recording process could be a cognitive cue for individuals to change their eating behavior. This study tested obese participants to determine whether teledietetics shows better results in weight reduction. Study Design and Methods: We conducted a double-blinded randomized controlled trial. The participants in the food diary (FD) and electronic diary (ED) groups recorded their dietary intakes in logbooks and on an electronic diary system, respectively. The participants in the control group (CG) did nothing. Subjects were adults 20-60 years of age with a body mass index (BMI) of >/=25 kg/m(2). The ED and FD groups were the intervention groups and were compared with the CG group. The participants' body weights, BMIs, fat percentages, waist-to-hip ratios (WHRs), and mean arterial pressures (MAPs) were measured before the study, at Week 6, and at Week 12. Demographic data were collected using self-administered questionnaires. A chi-squared test and descriptive statistics were used to describe the demographic and biomeasurement data. Repeated-measures analysis of variance was used to evaluate the effectiveness of the three groups over time. Results: Significant decreases in body weight (F1.705,86.950=20.508, p<0.001) and BMI (F1.657, 84.486=21.256, p<0.001) and insignificant decreases in fat percentage (F2,94=0.547, p=0.581), WHR (F1.785,91.052=2.888, p=0.067), and MAP (F2,94=7.542, p=0.0001) were observed among the three measurement times. Conclusions: Electronic dietary records were better than food diaries in terms of fat percentage reduction in our trials, indicating that teledietetics increases healthy-eating awareness

Cichelero, Fabio Tremea; Martinez, Denis; Fuchs, Sandra Costa; Gus, Miguel; Moreira, Leila Beltrami; Fuchs, Flavio Danni (2014):

The effect of antihypertensive agents on sleep apnea: protocol for a randomized controlled trial.

In: *Trials* 15, S. 1. DOI: 10.1186/1745-6215-15-1.

Abstract:

BACKGROUND: Obstructive sleep apnea (OSA) and hypertension are well-known cardiovascular risk factors. Their control could reduce the burden of heart disease across populations. Several drugs are used to control hypertension, but the only consistently effective treatment of OSA is continuous positive airway pressure. The identification of a drug capable of improving OSA and hypertension simultaneously would provide a novel approach in the treatment of both diseases. METHODS/DESIGN: This is a randomized double-blind clinical trial, comparing the use of chlorthalidone with amiloride versus amlodipine as a first drug option in patients older than 40 years of age with stage I hypertension (140 to 159/90 to 99 mmHg) and moderate OSA (15 to 30 apneas/hour of sleep). The primary outcomes are the variation of the number of apneas per hour and blood pressure measured by ambulatory blood pressure monitoring. The secondary outcomes are adverse events, somnolence scale (Epworth), ventilatory parameters and C reactive protein levels. The follow-up will last 8 weeks. There will be 29 participants per group. The project has been approved by the ethics committee of our institution. DISCUSSION: The role of fluid retention in OSA has been known for several decades. The use of diuretics are well established in treating hypertension but have never been appropriately tested for sleep apnea. As well as testing the efficacy of these drugs, this study will help to understand the mechanisms that link hypertension and sleep apnea and their treatment. TRIAL REGISTRATION: ClinicalTrials.gov: NCT01896661.

Ciolac, Emmanuel G.; Guimarães, Guilherme V.; D´ávila, Veridiana M.; Bortolotto, Luiz A.; Doria, Egídio L.; Bocchi, Edimar A. (2008):

Acute aerobic exercise reduces 24-h ambulatory blood pressure levels in long-term-treated hypertensive patients.

In: *Clinics (Sao Paulo)* 63 (6), S. 753–758. DOI: 10.1590/S1807-59322008000600008.

Abstract:

BACKGROUND:

Even with anti-hypertensive therapy, it is difficult to maintain optimal systemic blood pressure values in hypertensive patients. Exercise may reduce blood pressure in untreated hypertensive, but its effect when combined with long-term anti-hypertensive therapy remains unclear. Our purpose was to evaluate the acute effects of a single session of aerobic exercise on the blood pressure of long-term-treated hypertensive patients.

METHODS:

Fifty treated hypertensive patients (18/32 male/female; 46.5+/-8.2 years; Body mass index: 27.8+/-4.7 kg/m(2)) were monitored for 24 h with respect to ambulatory (A) blood pressure after an aerobic exercise session (post-exercise) and a control period (control) in random order. Aerobic exercise consisted of 40 minutes on a cycle-ergometer, with the mean exercise intensity at 60% of the patient's reserve heart rate.

RESULTS:

Post-exercise ambulatory blood pressure was reduced for 24 h systolic (126+/-8.6 vs. 123.1+/-8.7 mmHg, p=0.004) and diastolic blood pressure (81.9+/-8 vs. 79.8+/-8.5 mmHg, p=0.004), daytime diastolic blood pressure (85.5+/-8.5 vs. 83.9+/-8.8 mmHg, p=0.04), and nighttime S (116.8+/-9.9 vs. 112.5+/-9.2 mmHg, p<0.001) and diastolic blood pressure (73.5+/-8.8 vs. 70.1+/-8.4 mmHg, p<0.001). Post-exercise daytime systolic blood pressure also tended to be reduced (129.8+/-9.3 vs. 127.8+/-9.4 mmHg, p=0.06). These post-exercise decreases in ambulatory blood pressure increased the percentage of patients displaying normal 24h systolic blood pressure (58% vs. 76%, p=0.007), daytime systolic blood pressure (68% vs. 82%, p=0.02), and nighttime diastolic blood pressure (56% vs. 72%, p=0.02). Nighttime systolic blood pressure also tended to increase (58% vs. 80%, p=0.058).

CONCLUSION:

A single bout of aerobic exercise reduced 24h ambulatory blood pressure levels in long-term-treated hypertensive patients and increased the percentage of patients reaching normal ambulatory blood pressure values. These effects suggest that aerobic exercise may have a potential role in blood pressure management of long-term-treated hypertensive.

Ciolac, Emmanuel G.; Guimarães, Guilherme V.; Bortolotto, Luiz A.; Doria, Egidio L.; Bocchi, Edimar A. (2009):

Acute effects of continuous and interval aerobic exercise on 24-h ambulatory blood pressure in long-term treated hypertensive patients.

In: *Int J Cardiol* 133 (3), S. 381–387.

Abstract:

BACKGROUND:

Despite antihypertensive therapy, it is difficult to maintain optimal systemic blood pressure (BP) values in hypertensive patients (HPT). Exercise may reduce BP in untreated HPT. However, evidence regarding its effect in long-term antihypertensive therapy is lacking. Our purpose was to evaluate the acute effects of 40-minute continuous (CE) or interval exercise (IE) using cycle ergometers on BP in long-term treated HPT.

METHODS:

Fifty-two treated HPT were randomized to CE (n=26) or IE (n=26) protocols. CE was performed at 60% of reserve heart rate (HR). IE alternated consecutively 2 min at 50% reserve HR with 1 min at 80%. Two 24-h ambulatory BP monitoring were made after exercise (postexercise) or a nonexercise control period (control) in random order.

RESULTS:

CE reduced mean 24-h systolic (S) BP (2.6+/-6.6 mm Hg, p=0.05) and diastolic (D) BP (2.3+/-4.6, p=0.01), and nighttime SBP (4.8+/-6.4, p<0.001) and DBP (4.6+/-5.2 mm Hg, p=0.001). IE reduced 24-h SBP (2.8+/-6.5, p=0.03) and nighttime SBP (3.4+/-7.2, p=0.02), and tended to reduce nighttime DBP (p=0.06). Greater reductions occurred in higher BP levels. Percentage of normal ambulatory BP values increased after CE (24-h: 42% to 54%; daytime: 42% to 61%; nighttime: 61% to 69%) and IE (24-h: 31% to 46%; daytime: 54% to 61%; nighttime: 46% to 69%).

CONCLUSION:

CE and IE reduced ambulatory BP in treated HPT, increasing the number of patients reaching normal ambulatory BP values. These effects suggest that continuous and interval aerobic exercise may have a role in BP management in treated HPT.

Actigraphic assessment of periodic leg movements in patients with restless legs syndrome.

In: *J Sleep Res* (0962-1105 (Linking)). DOI: 10.1111/jsr.12053.

Abstract:

The diagnosis of restless legs syndrome (RLS) relies upon diagnostic criteria which are based on history only, and dopaminergic treatment is not normally the first choice of treatment for all patients. It would be worthwhile to identify patients non-responsive to dopaminergic treatment beforehand, because they may suffer from a restless legs-like syndrome and may require alternative treatment. We included retrospectively 24 adult patients fulfilling the four essential criteria for restless legs and 12 age-matched healthy controls. They were investigated by ambulatory actigraphy from both legs over three nights, and patients started treatment with dopamine agonists after this diagnostic work-up. We examined 12 responders to dopaminergic treatment and 12 non-responders and studied the association between response to dopaminergic treatment and the periodic limb movement index (PLMI) as assessed with actigraphy. Demographic characteristics, excessive daytime sleepiness and fatigue at baseline were similar in all three groups. Baseline RLS severity was similar between responders and non-responders [International Restless Legs Severity Scale (IRLS): 25 +/- 9 and 24 +/- 8]. Group comparisons of PLMI before treatment initiation showed significant differences between the three groups. Post-hoc pairwise comparisons revealed that healthy controls had significantly lower PLMI (4.9 +/- 4.5) than responders (29.3 +/- 22.7) and non-responders (13.3 +/- 11.2). Similarly, the PLMI in responders was lower than in non-responders. PLMI day-to-day variability did not differ between responders and non-responders and there was no correlation between treatment effect, as assessed by the decrease of the IRLS and baseline PLMI. Our retrospective study indicates that actigraphy to assess periodic limb movements may contribute to a better diagnosis of dopamine-responsive restless legs syndrome

Claessens, Brigitte J. C.; van Eerde, Wendelien; Rutte, Christel G.; Roe, Robert A. (2010):

Things to do today...: A daily diary study on task completion at work.

In: *Applied Psychology* 59 (2), S. 273–295.

Abstract:

Relatively little is known about how goals in complex jobs are translated into action and how they are completed in real life settings. This study addressed the question to what extent planned work may actually be completed on a daily basis. The completion of daily work goals was studied in a sample of 878 tasks identified by 29 R&D engineers with the help of a daily diary. Multilevel analysis was used to analyse the joint effect of task attributes, perceived job characteristics, and personality attributes on the completion of planned work goals. At the level of task attributes, we found that priority, urgency, and lower importance were related to task completion, and at the individual level, conscientiousness, emotional stability, and time management training. Task completion was not related to task attractiveness, workload, job autonomy, planning, or perceived control of time.

Clarkson, Gail P.; Hodgkinson, Gerard P. (2007):

What can occupational stress diaries achieve that questionnaires can't?

In: *Personnel Review* 36 (5), S. 684–700.

Abstract:

Purpose – The paper aims to demonstrate the efficacy of the qualitative occupational stress diary as a means by which to attain additional depth of insight into the way people experience stress, to foster individual reflection and self-assessment, and as an aid to the development of context sensitive interventions. Design/methodology/approach – Using a free response format, a critical incident diary was completed by 15 clerical workers, employed in a higher education organisation, over five consecutive working days. Findings – The factors constituting causes and consequences of occupational stress were cognitively framed differently from one day to the next and it is unlikely that these insights would have been attained had we employed a series of preformed quantitative response scales. The diary facilitated self-reflection and was reported to have cathartic qualities. Research implications/limitations – There is a need for context specific, tailored intervention measures. Accumulation of corroborating descriptions of how people respond to specific stressors will contribute to the development of such measures. The work reported now needs to be extended to larger groups and over longer periods to identify the most frequently used coping strategies, and which are most efficacious in a given situation. Practical implications – The qualitative occupational stress diary is a simple but powerful self-reflective tool, which may lead to therapeutic outcomes. Originality/value – A growing number of researchers are critical of the practical influence of quantitative measures of occupational stress and coping. The study illustrates how the qualitative occupational stress diary might usefully complement traditional methods for research and intervention purposes.

Clays, E.; De, Bacquer D.; Van, Herck K.; De, Backer G.; Kittel, F.; Holtermann, A. (2012):

Occupational and leisure time physical activity in contrasting relation to ambulatory blood pressure.

In: *BMC Public Health* 12 (1), S. 1002. DOI: 10.1186/1471-2458-12-1002.

Abstract:

ABSTRACT: BACKGROUND: While moderate and vigorous leisure time physical activities are well documented to decrease the risk for cardiovascular disease, several studies have demonstrated an increased risk for cardiovascular disease in workers with high occupational activity. Research on the underlying causes to the contrasting effects of occupational and leisure time physical activity on cardiovascular health is lacking. The aim of this study was to examine the relation of objective and self-report measures of occupational and leisure time physical activity with 24-h ambulatory systolic blood pressure (BP). METHODS: Results for self-reported physical activity are based on observations in 182 workers (60% male, mean age 51 years), while valid objective physical activity data were available in 151 participants. The usual level of physical activity was assessed by 5 items from the Job Content Questionnaire (high physical effort, lifting heavy loads, rapid physical activity, awkward body positions and awkward positions of head or arms at work) and one item asking about the general level of physical activity during non-working time. On a regular working day, participants wore an ambulatory BP monitor and an accelerometer physical activity monitor during 24 h. Associations were examined by means of Analysis of Covariance. RESULTS: Workers with an overall high level of self-reported occupational physical activity as well as those who reported to often lift heavy loads at work had a higher mean systolic BP at work, at home and during sleep. However, no associations were observed between objectively measured occupational physical activity and BP. In contrast, those with objectively measured high proportion of moderate and vigorous leisure time physical activity had a significantly lower mean systolic BP during daytime, while no differences were observed according to self-reported level of leisure time physical activity. CONCLUSIONS: These findings suggest that workers reporting static occupational physical activities, unlike general physically demanding tasks characterized by dynamic movements of large muscle groups, are related to a higher daily systolic BP, while high objective levels of moderate and vigorous leisure time physical activity are related to lower

daytime systolic BP. Ambulatory systolic BP may be a physiological explanatory factor for the contrasting effects of occupational and leisure time physical activity

Clays, Els; Leynen, Francoise; Bacquer, Dirk; Kornitzer, Marcel; Kittel, France; Karasek, Robert; Backer, Guy (2007):

High job strain and ambulatory blood pressure in middle-aged men and women from the Belgian job stress study.

In: *Journal of Occupational and Environmental Medicine* 49 (4), S. 360–367.

Abstract:

OBJECTIVE:

The aim of this study was to assess whether job strain is associated with 24-hour ambulatory blood pressure measurements within a subsample of the Belgian Job Stress Project (BELSTRESS) population.

METHODS:

A group of 89 middle-aged male and female workers perceiving high job strain and an equally large group of workers perceiving no high job strain wore an ambulatory blood pressure monitor for 24 hours on a regular working day.

RESULTS:

Mean ambulatory blood pressure at work, at home, and while asleep was significantly higher in workers with job strain as compared with others. The associations between job strain and ambulatory blood pressure were independent from the covariates.

CONCLUSIONS:

Within this study, high job strain was an important independent risk factor for higher ambulatory blood pressure at work, at home, and during sleep in a group of men and women.

Clayton, Anita H. (2012):

eDiary and Female Sexual Distress Scale in evaluating distress in hypoactive sexual desire disorder (HSDD).

In: *Journal of Sexual Medicine* 9 (7). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-17967-036&site=ehost-live.

Abstract:

Assessment of sexual distress is an integral component in the diagnosis of female sexual dysfunction, and is measured as a patient-reported outcome. Three prospective, non-treatment, 4-week validation studies, two North American (N = 220; N = 255) and one European (N = 253), evaluated sexually related distress in women aged 18–65 years with generalized, acquired hypoactive sexual desire disorder (HSDD), other types of female sexual dysfunction (FSD), and no FSD, as determined with a standard diagnostic interview by an expert clinician. Instruments evaluated include the 12-item Female Sexual Distress Scale (FSDS), the 13-item FSDS Revised (FSDS-R), and a single question about sexually related distress measured using a daily electronic diary (eDiary). The completion rate was >98% in all three studies, and 94% of the women recorded data at a >75% compliance rate. All three measures demonstrated significantly greater distress in women with HSDD when compared with women with no FSD. Levels of distress in women with other forms of FSD were comparable to the women with HSDD. In addition, a floor effect in improvement is also limiting. The short study period (4 weeks) is the primary limitation of this study. Discriminant validity was demonstrated in that all three measures confirmed more distress in women with HSDD vs. women with no FSD. Weekly and monthly measures showed a higher frequency of distress and less variability than daily measures. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Cleland, Verity; Crawford, David; Baur, Louise A.; Hume, Clare; Timperio, Anna; Salmon, Jo (2008):

A prospective examination of children's time spent outdoors, objectively measured physical activity and overweight.

In: *International Journal of Obesity* 32 (11), S. 1685–1693.

Abstract:

OBJECTIVE:

This study aimed to determine whether time spent outdoors was associated with objectively measured physical activity, body mass index (BMI) z-score and overweight in elementary-school aged children, cross-sectionally and prospectively over 3 years.

METHODS:

Three-year cohort study with data collected during 2001 and 2004. Nineteen randomly selected state elementary schools across Melbourne, Australia. One hundred and eighty eight 5-6-year-old and 360 10-12-year-old children. Baseline parent reports of children's time spent outdoors during warmer and cooler months, on weekdays and weekends. At baseline and follow-up, children's moderate and vigorous physical activity (MVPA) was objectively assessed by accelerometry, and BMI z-score and overweight was calculated from measured height and weight.

RESULTS:

Cross-sectionally, each additional hour outdoors on weekdays and weekend days during the cooler months was associated with an extra 27 min week(-1) MVPA among older girls, and with an extra 20 min week(-1) MVPA among older boys. Longitudinally, more time outdoors on weekends predicted higher MVPA on weekends among older girls and boys (5 min week(-1)). The prevalence of overweight among older children at follow-up was 27-41% lower among those spending more time outdoors at baseline.

CONCLUSION:

Encouraging 10-12-year-old children to spend more time outdoors may be an effective strategy for increasing physical activity and preventing increases in overweight and obesity. Intervention research investigating the effect of increasing time outdoors on children's physical activity and overweight is warranted.

Clements, C. M.; Buller, M. J.; Welles, A. P.; Tharion, W. J. (2012):

Real time gait pattern classification from chest worn accelerometry during a loaded road march.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 364–367. DOI: 10.1109/EMBC.2012.6345944.

Abstract:

Accelerometers, whether in smart phones or wearable physiological monitoring systems are becoming widely used to identify movement and activities of free living individuals. Although there has been much work in applying computationally intensive methods to this problem, this paper focuses on developing a real-time gait analysis approach that is intuitive, requires no individual calibration, can be extended to complex gait analysis, and can readily be adopted by ambulatory physiological monitors for use in real time. Chest-mounted tri-axial accelerometry data were collected from sixty-one male U.S. Army Ranger candidates engaged in an 8 or 12 mile loaded (35 Kg packs) timed road march. The pace of the road march was such that volunteers needed to both walk and run. To provide intuitive features we examined the periodic patterns generated from 4s periods of movement from the vertical and longitudinal accelerometer axes. Applying the "eigenfaces" face recognition approach we used Principal Components Analysis to find a single basis vector from 10% of the data (n=6) that could distinguish patterns of walk and run with a classification rate of 95% and 90% (n=55) respectively. Because these movement features are based on a gridded frequency count, the method is applicable for use by body-worn microprocessors

Cleveland, H. Harrington; Harris, Kitty S. (2010):

The role of coping in moderating within-day associations between negative triggers and substance use cravings: A daily diary investigation.

In: *Addict Behav* 35 (1), S. 60–63.

Abstract:

To address the lack of research examining within-person processes associated with the maintenance of abstinence from substance use, this study examines both associations between negative affect and social experiences and same-day levels of substance use cravings among college students in 'Twelve-Step' substance abuse recovery and the role of coping strategies in moderating these within-day associations. The sample consisted of 1222 end-of-day reports made by 55 recovering college students, 39 males and 16 females. Findings include that daily cravings were predicted by same-day negative affect and each of four negative social experiences. Moreover, each of these within-day associations was moderated by individuals' levels of avoidance coping. In contrast, problem-solving coping only moderated the associations between negative affect and cravings.

These findings document a within-day mechanism through which coping strategies, especially avoidance coping, may influence daily variation in cravings and in turn affect abstinence.

Cliff, D. P.; Okely, A. D.; Burrows, T. L.; Jones, R. A.; Morgan, P. J.; Collins, C. E.; Baur, L. A. (2013):

Objectively measured sedentary behavior, physical activity, and plasma lipids in overweight and obese children.

In: *Obesity (Silver.Spring)* 21 (2), S. 382–385. DOI: 10.1002/oby.20005.

Abstract:

OBJECTIVE: This study examines the associations between objectively measured sedentary behavior, light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA), and plasma lipids in overweight and obese children. DESIGN AND METHODS: Cross-sectional analyses were conducted among 126 children aged 5.5-9.9 years. Sedentary behavior, LPA, and MVPA were assessed using accelerometry. Fasting blood samples were analyzed for plasma lipids (high-density lipoprotein cholesterol [HDL-C], low-density lipoprotein cholesterol [LDL-C], total cholesterol [TC], and triglycerides [TG]). RESULTS: MVPA was not related to plasma lipids (P > 0.05). Independent of age, sex, energy intake, and waist circumference z-score, sedentary behavior and LPA were associated with HDL-C (beta = -0.23, 95% CI -0.42 to -0.04, P = 0.020; beta = 0.20, 95% CI 0.14 to 0.39, P = 0.036, respectively). The strength of the associations remained after additionally adjusting for MVPA (sedentary behavior: beta = -0.22, 95% CI -0.44 to 0.006, P = 0.056; LPA: beta = 0.19, 95% CI -0.005 to 0.38, P = 0.056, respectively). CONCLUSION: Substituting at least LPA for sedentary time may contribute to the development of healthy HDL-C levels among overweight and obese children, independent of their adiposity. Comprehensive prevention and treatment strategies to improve plasma HDL-C among overweight and obese children should target reductions in total sedentary time and promote the benefits of LPA, in addition to promoting healthy levels of adiposity, healthy dietary behaviors, and MVPA

Cocker, K.; Cardon, G.; Bourdeaudhuij, I. (2006):

Validity of the inexpensive Stepping Meter in counting steps in free living conditions: a pilot study.

In: *British Journal of Sports Medicine* 40 (8), S. 714–716. DOI: 10.1136/bjsm.2005.025296.

Abstract:

OBJECTIVES\r\nTo evaluate if inexpensive Stepping Meters are valid in counting steps in adults in free living conditions.\r\nMETHODS\r\nFor six days, 35 healthy volunteers wore a criterion Yamax Digiwalker and five Stepping Meters every day until all 973 pedometers had been tested. Steps were recorded daily, and the differences between counts from the Digiwalker and the Stepping Meter were expressed as a percentage of the valid value of the Digiwalker step counts. The criterion used to determine if a Stepping Meter was valid was a maximum deviation of 10% from the Digiwalker step counts.\r\nRESULTS\r\nA total of 252 (25.9%) Stepping Meters met the criterion, whereas 74.1% made an overestimation or underestimation of more than 10%. In more than one third (36.6%) of the invalid Stepping Meters, the deviation was greater than 50%. Most (64.8%) of the invalid pedometers overestimated the actual steps taken.\r\nCONCLUSIONS\r\nInexpensive Stepping Meters cannot be used in community interventions as they will give participants the wrong message.

Cohall, Damian H.; Scantlebury-Manning, Thea; James, Stephen; Hall, Kiana; Ferrario, Carlos M. (2014):

Renin-angiotensin-aldosterone system gender differences in an Afro-Caribbean population.

In: *J Renin Angiotensin Aldosterone Syst. DOI:* 10.1177/1470320314523659.

Abstract:

Hypothesis / introduction:Prior studies have denoted gender differences in the expression and therapeutic benefits of hypertension treatment and clinical outcomes. This study documents for the first time gender differences in the expression of blood and urine angiotensin peptides in normotensive Afro-Caribbean Barbadians (25 males; 26 females). MATERIALS AND METHODS: Participants provided clinical anthropometric measurements, 24h ambulatory blood pressure and urine collections, and a blood sample for measurements of angiotensin peptides. RESULTS: Plasma renin activity ranged between 0.00 and 3.00 ng/ml/h. Plasma and urinary Ang II were comparable in both genders, while urinary Ang-(1-7) was greater in females ($p<0.05$). Urinary Ang-(1-7) and office systolic blood pressure correlated significantly in females only ($p<0.01$), while plasma Ang-(1-7) and

Ang II correlated significantly in both genders (p>0.05). CONCLUSIONS: A shift in the balance between Ang II and Ang-(1-7) and their respective pressor and depressor axes might be markers of the cardio-renal protective mechanisms that may be present in females of Afro-Caribbean descent.

Lifestyle Modification in Blood Pressure Study II (LIMBS): Study protocol of a randomized controlled trial assessing the efficacy of a 24week structured yoga program versus lifestyle modification on blood pressure reduction.

In: *Contemp.Clin.Trials* 36 (1), S. 32–40. DOI: 10.1016/j.cct.2013.05.010.

Abstract:

Hypertension is a major public health issue affecting 68million adults in the United States. Lifestyle modifications including complementary therapies such as the movement based mind body practice of yoga have become increasingly popular in the United States and have been considered as a potential alternative to medication in blood pressure reduction. We completed a pilot study in 2009 which showed meaningful decreases in 24-hour ambulatory blood pressure readings after a 12week period of yoga participation. Based on data from our pilot study we are now completing The Lifestyle Modification and Blood Pressure Study (LIMBS II) which is a phase 2 randomized controlled trial designed to determine the effects of yoga therapy and enhanced lifestyle modification on lowering blood pressure in pre-hypertensive and stage 1 hypertensive subjects. Using 24-hour ambulatory blood pressure monitoring, LIMBS II aims to compare the effects on blood pressure reduction in subjects randomized for 24weeks to one of the three following groups: yoga therapy versus blood pressure education program (sodium restriction and walking program) versus a combination program that involves components of both groups. LIMBS II will also examine the impact that changes in blood pressure have on cerebral blood flow. If successful, the LIMBS study will determine if yoga therapy combined with enhanced lifestyle modification will result in clinically meaningful decreases in blood pressure and thus can be implemented as an alternative to drug therapy for patients with prehypertension and stage 1 hypertension

Negative affective spillover from daily events predicts early response to cognitive therapy for depression.

In: *Journal of Consulting and Clinical Psychology* 76 (6), S. 955.

Abstract:

This study evaluated the predictive role of depressed outpatients' (N = 62) affective reactivity to daily stressors in their rates of improvement in cognitive therapy (CT). For 1 week before treatment, patients completed nightly electronic diaries that assessed daily stressors and negative affect (NA). The authors used multilevel modeling to compute each patient's within-day relationship between daily stressors and daily NA (within-day reactivity), as well as the relationship between daily stressors and next-day NA (next-day reactivity; affective spillover). In growth model analyses, the authors evaluated the predictive role of patients' NA reactivity in their early (Sessions 1-4) and late (Sessions 5-12) response to CT. Within-day NA reactivity did not predict early or late response to CT. However, next-day reactivity predicted early response to CT, such that patients who had greater NA spillover in response to negative events had a slower rate of symptom change during the first 4 sessions. Affective spillover did not influence later response to CT. The findings suggest that depressed patients who have difficulty bouncing back the next day from their NA reactions to a relative increase in daily negative events will respond less quickly to the early sessions of CT.

Cohn, Amy M.; Hunter-Reel, Dorian; Hagman, Brett T.; Mitchell, Jessica (2011):

Promoting behavior change from alcohol use through mobile technology: The future of ecological momentary assessment.

In: *Alcoholism: Clinical and Experimental Research* 35 (12), S. 2209–2215. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-27300-013&site=ehost-live;amycohn@usf.edu.

Abstract:

BACKGROUND:

Interactive and mobile technologies (i.e., smartphones such as Blackberries, iPhones, and palm-top computers) show promise as an efficacious and cost-effective means of communicating health-behavior risks, improving public health outcomes, and accelerating behavior change. The present study was conducted as a "needs assessment" to examine the current available mobile smartphone applications (e.g., apps) that utilize principles of ecological momentary assessment (EMA)-daily self-monitoring or near real-time self-assessment of alcohol-use behavior-to promote positive behavior change, alcohol harm reduction, psycho-education about alcohol use, or abstinence from alcohol.

METHODS:

Data were collected and analyzed from iTunes for Apple iPhone(©) . An inventory assessed the number of available apps that directly addressed alcohol use and consumption, alcohol treatment, or recovery, and whether these apps incorporated empirically based components of alcohol treatment.

RESULTS:

Findings showed that few apps addressed alcohol-use behavior change or recovery. Aside from tracking drinking consumption, a minority utilized empirically based components of alcohol treatment. Some apps claimed they could serve as an intervention; however, no empirical evidence was provided.

CONCLUSIONS:

More studies are needed to examine the efficacy of mobile technology in alcohol intervention studies. The large gap between availability of mobile apps and their use in alcohol treatment programs indicates several important future directions for research.

From Negative to Positive and Back Again: Polarized Affective and Relational Experience in Borderline Personality Disorder.

In: *J Abnorm.Psychol.* (0021-843X (Linking)). DOI: 10.1037/a0028502.

Abstract:

A core feature of borderline personality disorder (BPD) is the tendency to evaluate one's experience with extreme polarity (i.e., feeling all good or all bad; Beck, Freeman, & Davis, 2004; Kernberg, 1975; Linehan, 1993). In this investigation, we examined the polarity of within-person reports of experience in individuals with BPD and healthy adults over the course of a 21-day, experience-sampling diary. We applied multilevel modeling techniques (Rafaeli, Rogers, & Ravelle, 2007) to capture the within-person covariance of momentary reports of negative and positive features of experience, either affective or relational. Our data indicated significantly greater polarity in reports of affective and relational experiences in BPD that increased during heightened interpersonal stress. We also examined the association of affective and relational polarity to reports of impulsive behaviors (e.g., self-injury, substance use, etc.) and found evidence that increased polarity in reports of affective (in low-stress contexts) and relational experiences (in high-stress contexts) predicted increased rate of reports of impulsive behaviors. Together, these data present strong evidence for the role of polarized experiences in BPD, and have implications for the treatment of individuals with this disorder. Coleman, Karen J.; Rosenberg, Dori E.; Conway, Terry L.; Sallis, James F.; Saelens, Brian E.; Frank, Lawrence D.; Cain, Kelli (2008):

Physical activity, weight status, and neighborhood characteristics of dog walkers.

In: *Prev Med* 47 (3), S. 309–312.

Abstract:

OBJECTIVE:

This study examined how demographics, physical activity, weight status, and neighborhood characteristics varied among households with and without dogs.

METHOD:

Participants aged 20 to 65 years (n=2199, 52% male, 75% white, mean age=45) were recruited from 32 neighborhoods in the Seattle, WA and Baltimore, MD regions during 2002-2005. Dog ownership, dog walking, education, height, weight, and family income were self-reported. Minutes of moderate to vigorous physical activity (MVPA) were measured objectively by 7-day accelerometry.

RESULTS:

Dog walking was associated with a higher proportion of participants who met national recommendations for MVPA (53%) when compared to those who had but did not walk their dog (33%) and to non-dog owners (46%). There were significantly fewer obese dog walkers (17%) when compared to both owners who did not walk their dogs (28%) and non-owners (22%). Dog owners who walked their dogs were more likely to live in high-walkable neighborhoods when compared to dog owners who did not walk their dogs.

CONCLUSION:

Dog walking may promote physical activity and contribute to weight control. Dog walking appears to be a mechanism by which residents of high-walkable neighborhoods obtain their physical activity.

Colley, Rachel C.; Garriguet, Didier; Janssen, Ian; Craig, Cora L.; Clarke, Janine; Tremblay, Mark S. (2011):

Physical activity of Canadian adults: accelerometer results from the 2007 to 2009 Canadian Health Measures Survey.

In: *Health Rep* 22 (1), S. 7–14.

Abstract:

BACKGROUND: Rising obesity rates and declining fitness levels have increased interest in understanding what underlies these trends. This article presents the first directly measured data on physical activity and sedentary behaviour on a nationally representative sample of Canadians aged 20 to 79 years. DATA AND METHODS: Data are from the 2007 to 2009 Canadian Health Measures Survey (CHMS). Physical activity was measured using accelerometry. Data are presented as time spent in sedentary, light, moderate and vigorous intensity movement as well as steps accumulated per day. RESULTS: An estimated 15% of Canadian adults accumulate 150 minutes of moderate-to-vigorous physical activity (MVPA) per week; 5% accumulate 150 minutes per week as at least 30 minutes of MVPA on 5 or more days a week. Men are more active than women and MVPA declines with increasing age and adiposity. Canadian adults are sedentary for approximately 9.5 hours per day (69% of waking hours). Men accumulate an average of 9,500 steps per day and women, 8,400 steps per day. The 10,000-steps-per-day target is achieved by 35% of adults. INTERPRETATION: Before the CHMS, objective measures of physical activity and sedentary behaviour were not available for a representative sample of Canadians. The findings indicate that 85% of adults are not active enough to meet Canada's new physical activity recommendation.

Colley, Rachel C.; Harvey, Alysha; Grattan, Kimberly P.; Adamo, Kristi B. (2014):

Impact of accelerometer epoch length on physical activity and sedentary behaviour outcomes for preschool-aged children.

In: *Health Rep* 25 (1), S. 3–9.

Abstract:

BACKGROUND: The Canadian Health Measures Survey uses accelerometry to collect physical activity and sedentary behaviour data. Between cycles 2 and 3, a transition was made from 60-second to 15-second epochs in accelerometry data for children aged 3 to 5. This study examines the impact of epoch length on physical activity and sedentary behaviour outcomes. DATA AND METHODS: Twenty-nine children aged 3 to 5 wore two accelerometers at the same time, one initialized to collect data in 60-second epochs, and the other, in 15-second epochs. Comparisons between epoch settings were made for several physical activity variables. RESULTS: Compared with the 60-second epoch setting, the 15-second setting captured more moderate-to-vigorous physical activity (MVPA) and sedentary time, but fewer steps and less light and total physical activity. The correlation between epoch settings was high for all variables except steps. INTERPRETATION: The epoch length used in accelerometer data collection affects physical activity and sedentary behaviour data for preschool-aged children.

Physical activity, sedentary behaviour and sleep in Canadian children: parent-report versus direct measures and relative associations with health risk.

In: *Health Rep* 23 (2), S. 45–52. Online verfügbar unter PM:22866540.

Abstract:

BACKGROUND: The accurate measurement of time devoted to physical activity, sedentary pursuits and sleep is difficult and varies considerably between surveys. This has implications for population surveillance and understanding how these variables relate to health. METHODS: This sample of children (n = 878) was from the 2007 to 2009 Canadian Health Measures Survey. Moderate- to-vigorous physical activity (MVPA), sedentary behaviour and sleep duration were assessed using both a questionnaire and an accelerometer. This article compared parent-reported and directly measured physical activity, sedentary behaviour and sleep, and examined their associations, alone or in combination, with selected health markers in children aged 6 to 11. RESULTS: According to parent reports, the children in this study had an average of 105 minutes of MVPA, 2.5 hours of screen time and 9.7 hours of sleep per day; accelerometers recorded 63 minutes of MVPA, 7.6 hours of sedentary time and 10.1 hours of sleep per day. MVPA, measured by parent-report or accelerometry, was significantly associated with body mass index. In a regression model, directly measured MVPA and sleep were significantly associated with body mass index, and directly measured MVPA was significantly associated with waist circumference. Parent-reported screen time approached a significant association with body mass index. INTERPRETATION: Time estimates and associations with health markers varied between parent-reported and directly measured physical activity, sedentary behaviour and sleep in children. These differences are important to understand before the two measurement techniques can be used interchangeably in research and health surveillance

Collings, P. J.; Brage, S.; Ridgway, C. L.; Harvey, N. C.; Godfrey, K. M.; Inskip, H. M. et al. (2013):

Physical activity intensity, sedentary time, and body composition in preschoolers.

In: *Am J Clin.Nutr.* 97 (5), S. 1020–1028. DOI: 10.3945/ajcn.112.045088.

Abstract:

BACKGROUND: Detailed associations between physical activity (PA) subcomponents, sedentary time, and body composition in preschoolers remain unclear. OBJECTIVE: We examined the magnitude of associations between objectively measured PA subcomponents and sedentary time with body composition in 4-y-old children. DESIGN: We conducted a cross-sectional study in 398 preschool children recruited from the Southampton Women's Survey. PA was measured by using accelerometry, and body composition was measured by using dual-energy X-ray absorptiometry. Associations between light physical activity, moderate physical activity (MPA), vigorous physical activity (VPA), and moderate-to-vigorous physical activity (MVPA) intensity; sedentary time; and body composition were analyzed by using repeated-measures linear regression with adjustment for age, sex, birth weight, maternal education, maternal BMI, smoking during pregnancy, and sleep duration. Sedentary time and PA were also mutually adjusted for one another to determine whether they were independently related to adiposity. RESULTS: VPA was the only intensity of PA to exhibit strong inverse associations with both total adiposity [P < 0.001 for percentage of body fat and fat mass index (FMI)] and abdominal adiposity (P = 0.002 for trunk FMI). MVPA was inversely associated with total adiposity (P = 0.018 for percentage of body fat; P = 0.022 for FMI) but only because of the contribution of VPA, because MPA was unrelated to fatness (P >/= 0.077). No associations were shown between the time spent sedentary and body composition (P >/= 0.11). CONCLUSIONS: In preschoolers, the time spent in VPA is strongly and independently associated with lower adiposity. In contrast, the time spent sedentary and in low-to-moderate-intensity PA was unrelated to adiposity. These results indicate that efforts to challenge pediatric obesity may benefit from prioritizing VPA

Collins, R. Lorraine; Vincent, Paula C.; Yu, Jihnhee; Liu, Liu; Epstein, Leonard H. (2014):

A Behavioral Economic Approach to Assessing Demand for Marijuana.

In: *Exp Clin Psychopharmacol. DOI:* 10.1037/a0035318.

Abstract:

In the United States, marijuana is the most commonly used illicit drug. Its prevalence is growing, particularly among young adults. Behavioral economic indices of the relative reinforcing efficacy (RRE) of substances have been used to examine the appeal of licit (e.g., alcohol) and illicit (e.g., heroin) drugs. The present study is the first to use an experimental, simulated purchasing task to examine the RRE of marijuana. Young-adult (M age = 21.64 years) recreational marijuana users (N = 59) completed a computerized marijuana purchasing task designed to generate demand curves and the related RRE indices (e.g., intensity of demand-purchases at lowest price; Omax-max. spent on marijuana; Pmax-price at which marijuana expenditure is max). Participants "purchased" high-grade marijuana across 16 escalating prices that ranged from $0/free to $160/joint. They also provided 2 weeks of real-time, ecological momentary assessment reports on their marijuana use. The purchasing task generated multiple RRE indices. Consistent with research on other substances, the demand for marijuana was inelastic at lower prices but became elastic at higher prices, suggesting that increases in the price of marijuana could lessen its use. In regression analyses, the intensity of demand, Omax, and Pmax, and elasticity each accounted for significant variance in real-time marijuana use. These results provide support for the validity of a simulated marijuana purchasing task to examine marijuana's reinforcing efficacy. This study highlights the value of applying a behavioral economic framework to young-adult marijuana use and has

implications for prevention, treatment, and policies to regulate marijuana use. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Collip, D.; Habets, P.; Marcelis, M.; Gronenschild, E.; Lataster, T.; Lardinois, M. et al. (2012):

Hippocampal volume as marker of daily life stress sensitivity in psychosis.

In: *Psychol.Med.* (0033-2917 (Linking)), S. 1–11. DOI: 10.1017/S003329171200219X.

Abstract:

BACKGROUND: Reduced hippocampal size and increased stress sensitivity are associated with psychotic disorder and familial risk for psychosis. However, to what degree the hippocampus is implicated in daily life stress reactivity has not yet been examined. The current study investigated (i) whether familial risk (the contrast between controls, patients and siblings of patients) moderated the relationship between hippocampal volume (HV) and emotional daily stress reactivity and (ii) whether familial risk (the contrast between controls and siblings of patients) moderated the relationship between HV and cortisol daily stress reactivity. Method T1-weighted magnetic resonance imaging (MRI) scans were acquired from 20 patients with schizophrenia, 37 healthy siblings with familial risk for schizophrenia and 32 controls. Freesurfer 5.0.0 was used to measure HV. The experience sampling method (ESM), a structured momentary assessment technique, was used to assess emotional stress reactivity, that is the effect of momentary stress on momentary negative affect (NA). In addition, in the control and sibling groups, cortisol stress reactivity was assessed using momentary cortisol levels extracted from saliva. RESULTS: Multilevel linear regression analyses revealed a significant three-way interaction between group, HV and momentary stress in both the model of NA and the model of cortisol. Increased emotional stress reactivity was associated with smaller left HV in patients and larger total HV in controls. In line with the results in patients, siblings with small HV demonstrated increased emotional and cortisol stress reactivity compared to those with large HV. CONCLUSIONS: HV may index risk and possibly disease-related mechanisms underlying daily life stress reactivity in psychotic disorder

Collip, D.; Oorschot, M.; Thewissen, V.; van Os, J.; Bentall, R.; Myin-Germeys, I. (2011):

Social world interactions: how company connects to paranoia.

In: *Psychological Medicine* 41 (05), S. 911–921.

Abstract:

BACKGROUND:

Experimental studies have indicated that social contact, even when it is neutral, triggers paranoid thinking in people who score high on clinical or subclinical paranoia. We investigated whether contextual variables are predictive of momentary increases in the intensity of paranoid thinking in a sample of participants ranging across a psychometric paranoia continuum.

METHOD:

The sample (n=154) consisted of 30 currently paranoid patients, 34 currently non-paranoid patients, 15 remitted psychotic patients, 38 high-schizotypy participants, and 37 control subjects. Based on their total score on Fenigstein's Paranoia Scale (PS), three groups with different degrees of paranoia were defined. The Experience Sampling Method (ESM), a structured diary technique, was used to assess momentary social context, perceived social threat and paranoia in daily life.

RESULTS:

There were differences in the effect of social company on momentary levels of paranoia and perceived social threat across the range of trait paranoia. The low and medium paranoia groups reported higher levels of perceived social threat when they were with less-familiar compared to familiar individuals. The medium paranoia group reported more paranoia in less-familiar company. The high paranoia group reported no difference in the perception of social threat or momentary paranoia between familiar and unfamiliar contacts.

CONCLUSIONS:

Paranoid thinking is context dependent in individuals with medium or at-risk levels of trait paranoia. Perceived social threat seems to be context dependent in the low paranoia group. However, at high levels of trait paranoia, momentary paranoia and momentary perceived social threat become autonomous and independent of social reality.

COMT Val158Met–stress interaction in psychosis: Role of background psychosis risk.

In: *CNS Neuroscience & Therapeutics* 17 (6), S. 612–619. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-27773-006&site=ehost-live;i.germeys@sp.unimaas.nl.

Abstract:

BACKGROUND:

The interplay between the catechol-O-methyltransferase (COMT) Val158Met polymorphism and environmental stress may have etiological relevance for psychosis, but differential effects have been reported in healthy control and patient groups, suggesting that COMT Val158Met interactions with stress may be conditional on background genetic risk for psychotic disorder.

METHODS:

Patients with a nonaffective psychotic disorder (n = 86) and control participants (n = 109) were studied with the experience sampling method (a structured diary technique) in order to assess stress, negative affect and momentary psychotic symptoms in the flow of daily life.

RESULTS:

Multilevel analyses revealed significant three-way interactions between group status (patient or control), COMT genotype and stress in the model of negative affect ($\chi(2)(2) = 13.26$, $P < 0.01$) as well as in the model of momentary psychotic symptoms ($\chi(2)(2) = 6.92$, $P < 0.05$). Exploration of the three-way interaction revealed that in patients, COMT genotype moderated the association between stress and negative affect ($\chi(2)(4) = 11.50$, $P < 0.005$), as well as the association between stress and momentary psychosis ($\chi(2)(4) = 12.79$, $P < 0.005$). Met/Met genotype patients showed significantly increased psychotic and affective reactivity to stress in comparison to the Val/Met and Val/Val genotypes. In contrast, healthy controls did not display large or significant COMT Val158Met X stress interactions.

CONCLUSIONS:

Important differences exist in the effect of COMT Val158Met on stress reactivity, which may depend on background risk for psychotic disorder. Differential sensitivity to environmental stress occasioned by COMT Val158Met may be contingent on higher order interactions with genetic variation underlying psychotic disorder.

From epidemiology to daily life: Linking daily life stress reactivity to persistence of psychotic experiences in a longitudinal general population study.

In: *PLoS One* 8 (4). DOI: 10.1037/t21411-000;

Abstract:

Subclinical psychotic experiences at the level of the general population are common, forming an extended psychosis phenotype with clinical psychosis. Persistence of subclinical experiences is associated with transition to later mental disorder. Increased daily life stress reactivity is considered an endophenotype for psychotic disorders. We examined, in a longitudinal framework, whether baseline momentary assessment markers of stress reactivity would predict persistence of subclinical psychotic experiences over time. In a general population sample of female twins (N = 566), the Experience Sampling Method (ESM; repetitive random sampling of momentary emotions, psychotic experiences and context) was used to assess (emotional and psychotic) daily life stress reactivity. Persistence of subclinical psychotic experiences was based on the Community Assessment of Psychic Experiences (CAPE), assessed three times over 14 months post-baseline. It was investigated whether baseline daily life emotional and psychotic stress reactivity predicted persistence of psychotic experiences over time. Higher levels of emotional stress reactivity (a decrease in positive and an increase in negative affect in response to stress), and increased psychotic reactivity to daily stress was found in individuals with persistent psychotic experiences over time compared to individuals with transient psychotic experiences. The results suggest that markers of daily life stress reactivity may predict "macro-level" persistence of normally transient expression of psychotic liability over time. Linking daily life markers of altered reactivity in terms of emotions and psychotic experiences to longitudinal persistence of psychotic experiences, associated with increased risk of transition to overt mental disorder, may contribute to earlier and more accurate diagnosis of risk. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Positive emotions from social company in women with persisting subclinical psychosis: lessons from daily life.

In: *Acta Psychiatr.Scand.* (0001-690X (Linking)). DOI: 10.1111/acps.12151.

Abstract:

OBJECTIVE: Altered social reward functioning is associated with psychosis irrespective of stage and severity. Examining the role of social reward functioning prospectively in relation to psychotic experiences before these become persistent and potentially disabling can aid in elucidating social mechanisms that induce shifts toward more severe psychotic states, without the confounding effects of clinical disorder. METHOD: In a longitudinal general population sample (N = 566), the experience sampling method (repetitive random sampling of momentary emotions and social context) was used to assess daily life social functioning at baseline. Persistence of subclinical psychotic experiences was based on the Community Assessment of Psychic Experiences assessed three times over 14 months. Analyses examined to what degree i) social context and ii) appreciation thereof differentiated between those who did and did not develop persistent psychotic experiences. RESULTS: Although individuals with persistent psychotic experiences did not differ in overall level of positive effect, the amount of time spent alone or the level of social satisfaction compared to individuals without persistent psychotic experiences, they were more sensitive to the rewarding effects of social company. CONCLUSION: Alterations in social reward experience may form one of the mechanisms that precede the development of the extended psychosis phenotype over time

Collop, Nancy A. (2008):

Portable monitoring for the diagnosis of obstructive sleep apnea.

In: *Current opinion in pulmonary medicine* 14 (6), S. 525–529.

Abstract:

Purpose of review: The demand for expedient diagnosis of suspected obstructive sleep apnea (OSA) has increased due to improved awareness of sleep disorders. Polysomnography (PSG) is the current preferred diagnostic modality but is relatively inconvenient, expensive and inefficient. Portable monitoring has been developed and is widely used in countries outside the United States as an alternative approach. A portable monitor records fewer physiologic variables but is typically unattended and can be performed in the home.

Recent findings: Numerous portable monitor studies have been performed over the past two to three decades. The US government and medical societies have extensively reviewed this literature several times in an attempt to determine if portable monitoring should be more broadly used for diagnosing OSA. In March 2008, the US Centers for Medicare and Medicaid

Services released a statement allowing the use of portable monitoring to diagnose OSA and prescribe continuous positive airway pressure. This has potentially opened the door for more widespread use of these devices. This review will focus on the literature that has examined portable monitoring as a diagnostic tool for OSA.

Summary: It is anticipated that portable monitoring as a diagnostic modality for OSA will be used more frequently in the United States following the Centers for Medicare and Medicaid Services ruling. Physicians and others considering the use of portable monitors should thoroughly understand the advantages and limitations of this technology.

Fish meal supplementation and ambulatory blood pressure in patients with hypertension: relevance of baseline membrane fatty acid composition.

In: *Am J Hypertens* 27 (3), S. 471–481. DOI: 10.1093/ajh/hpt231.

Abstract:

BACKGROUND: Studies on fish oil effects on ambulatory blood pressure (ABP) are inconclusive. We evaluated fish effects on fatty acid composition of red blood cell (RBC) membrane and ABP values and tested the hypothesis that the starting membrane fatty acid composition affects the ability to incorporate additional polyunsaturated fatty acids (PUFA) and decrease blood pressure. METHODS: In 55 hypertensive patients, we measured RBC membrane fatty acid by gas chromatography and performed ABP monitoring. Patients received nutritional counseling and 3 weekly meals of trout rich in PUFA. In 42 patients, RBC membrane fatty acid and ABP were reassessed after 6 months. RESULTS: At baseline, the PUFA/saturated fatty acid (SFA) ratio of RBC membrane (PUFA/SFA) was inversely related to 24-hour, daytime, and nighttime systolic and pulse pressure, a relationship that was independent of covariables. At follow-up, the PUFA/SFA ratio increased in 20 (48%) of 42 patients. Patients with increased PUFA/SFA ratio at follow-up had lower baseline PUFA/SFA ratio than patients without such increase. Fish meal supplementation decreased 24-hour systolic and diastolic pressure only in patients who had increased PUFA/SFA ratio, a change that was more prominent during the nighttime. The change in PUFA/SFA was inversely and independently related to the change in 24-hour systolic and pulse pressure, and a logistic regression analysis indicated low baseline PUFA/SFA ratio as the only independent predictor of PUFA/SFA increase and blood pressure decrease. CONCLUSIONS: The ability of fish meals to increase membrane PUFA content and decrease blood pressure in hypertensive patients depends upon the starting membrane fatty acid composition.

Colvin, Peter J.; Mermelstein, Robin J. (2010):

Adolescents' smoking outcome expectancies and acute emotional responses following smoking.

In: *Nicotine & Tobacco Research* 12 (12), S. 1203–1210.

Abstract:

INTRODUCTION:

Magnitude of mood change following smoking may be an important reinforcing effect in smoking escalation in adolescent smokers. This study used ecological momentary assessments (EMA) of adolescent smokers' reports of mood during smoking events to examine (a) whether global reports of negative affect (NA) expectancies were associated with in-the-moment magnitude of negative and positive mood change following smoking, (b) the possibility of a reciprocal feedback loop between global NA expectancies and acute mood change following smoking, and (c) whether this relationship generalizes to other expectancies and mood change.

METHODS:

Participants were 234 9(th) and 10(th) graders (54% female) who recorded at least one smoking event during 7 days of EMA data collection.

RESULTS:

Global reports of NA expectancies were significantly associated with the in-the-moment magnitude of changes in mood following smoking. Specifically, higher NA expectancies were associated with greater decreases in negative and greater increases in positive mood. Additionally, mood change following smoking predicted changes in NA expectancies but only for adolescents who continued to smoke 6 months later. The reciprocal feedback loop between expectancies and mood change was only present in adolescent smokers who continued to smoke over time. Findings indicated that this relationship is specific to NA expectancies and negative and positive mood change.

CONCLUSIONS:

These results highlight the importance of considering NA expectancies and mood changes following smoking in adolescent smokers. Assessing expectancies about NA relief may provide an opportunity for identifying and intervening on adolescents who may be most at risk for continuing to smoke.

Comte, M.; Hobin, E.; Majumdar, S. R.; Plotnikoff, R. C.; Ball, G. D.; McGavock, J. (2013):

Patterns of weekday and weekend physical activity in youth in 2 Canadian provinces.

In: *Appl.Physiol Nutr.Metab* 38 (2), S. 115–119. DOI: 10.1139/apnm-2012-0100.

Abstract:

Few Canadian children are meeting physical activity (PA) guidelines for optimal growth and health. There is little information describing the patterns of PA among Canadian youth, so it is difficult to determine where the deficits occur. The purpose of this study was to identify subgroups of youth and windows of time characterized by low PA and high sedentary behaviour. We conducted a cross-sectional study of 626 youth (aged 10-15 years) in 2 Canadian provinces. The primary exposure variables included geographic setting (rural vs. urban), sex, and days of the week (weekend days vs. weekdays). The primary outcome measures were minutes of light PA, moderate to vigorous physical activity (MVPA), and sedentary behavior, assessed with accelerometry. Compared with weekdays, MVPA was approximately 30% lower on weekend days (55.8 +/- 23.0 min vs. 38.7 +/- 26.7 min; p < 0.001), whereas light PA was approximately 15% higher. Significantly more youth achieved an average of >60 min of MVPA on weekdays than on weekend days (46% vs. 22%; p < 0.001). Sex-specific differences in MVPA were more pronounced on weekdays than on weekend days (approximately 13 vs approximately 8 min per day; p < 0.01). Youth in rural settings achieved approximately 9 fewer minutes of MVPA daily than youth in urban settings (p < 0.001). In youth 10 to 15 years of age, daily MVPA is lower and light PA is higher on weekend days than on weekdays. Girls and students living in rural areas were particularly vulnerable to low levels of MVPA

Conen, David; Bamberg, Fabian (2008):

Noninvasive 24-h ambulatory blood pressure and cardiovascular disease: a systematic review and meta-analysis.

In: *J Hypertens* 26 (7), S. 1290–1299.

Abstract:

OBJECTIVE:

We systematically assessed the evidence regarding the association between noninvasive 24-h systolic blood pressure and incident cardiovascular events.

METHODS:

We searched PubMed, EMBASE, and the Cochrane Library through April 2007. Studies that prospectively followed at least 100 individuals for at least 1 year, and that reported at least one effect estimate of interest were included. Two independent investigators abstracted information on study design, subject characteristics, blood pressure measurements, outcome assessment, effect estimates, and adjustment for potential confounders.

RESULTS:

We identified 20 eligible articles based on 15 independent cohort studies. The association between 24-h systolic blood pressure and a combined cardiovascular endpoint was assessed in nine cohort studies, including 9299 participants who were followed up to 11.1 years and had 881 outcome events. The summary hazard ratio (95% confidence interval) per 10-mmHg increase of 24-h systolic blood pressure was 1.27 (1.18-1.38) (P < 0.001). Further adjustment for office blood pressure in four studies with 4975 participants and 499 outcome events provided a similar summary estimate [hazard ratio (95% confidence interval) per 10-mmHg increase of 24-systolic blood pressure 1.21 (1.10-1.33) (P < 0.001)]. Office blood pressure was usually assessed on a single occasion. We found no significant variability according to age, sex, population origin, baseline office blood pressure, follow-up time, diabetes, or study quality. There was a consistent association between 24-h systolic blood pressure and stroke, cardiovascular mortality, total mortality, and cardiac events with hazard ratio (95% confidence interval) per 10 mmHg increase of 24-h systolic blood pressure of 1.33 (1.22-1.44), 1.19 (1.13-1.26), 1.12 (1.07-1.17), and 1.17 (1.09-1.25), respectively.

CONCLUSION:

24-h systolic blood pressure is a strong predictor of cardiovascular events, providing prognostic information independent of conventional office blood pressure.

Conley, K. M.; Lehman, B. J. (2012):

Test anxiety and cardiovascular responses to daily academic stressors.

In: *Stress Health* 28 (1), S. 41–50. DOI: 10.1002/smi.1399.

Abstract:

Routine academic events may cause stress and produce temporary elevations in blood pressure. Students who experience test anxiety may be especially prone to cardiovascular activation in response to academic stress. This study drew on self-reported stress and ambulatory blood pressure measurements provided by 99 undergraduate participants (30% men, mean age=21 years) who participated over 4 days. Posture, activity level, recent consumption and the previous same-day reading were considered as covariates in a series of hierarchical linear models. Results indicate elevations in systolic blood pressure at times of acute academic stressors; neither diastolic blood pressure nor heart rate was linked with academic stress. In addition, those participants higher in test anxiety exhibited especially pronounced elevations in systolic blood pressure during times of acute academic stress. This research suggests that everyday academic stressors are linked with temporary increases in blood pressure and that test anxiety may contribute to these elevations. Test anxiety has implications for future academic and job success, and cardiovascular responses to everyday stress may contribute to health problems later in life

Connelly, Mark; Miller, Todd; Gerry, Gerry; Bickel, Jennifer (2010):

Electronic momentary assessment of weather changes as a trigger of headaches in children.

In: *Headache* 50 (5), S. 779–789. DOI: 10.1111/j.1526-4610.2009.01586.x.

Abstract:

BACKGROUND\r\nVariables that are thought to precipitate migraine or tension-type headache episodes in children hitherto have only been studied using retrospective reports. As such, there is little empirical evidence to support the actual predictive association between presumed headache triggers and actual headache occurrence in children.\r\nOBJECTIVE\r\nThe present study sought to determine if fluctuations in weather, a commonly reported headache trigger in children, predict increased likelihood of headache occurrence when evaluated using rigorous prospective methodology (\"electronic momentary assessment\").\r\nMETHODS\r\nTwenty-five children (21 girls, 4 boys) between the ages of 8-17 years attending a new patient neurology clinic appointment and having a diagnosis of chronic migraine, chronic tension-type, or episodic migraine headache (with or without aura) participated in the study. Children completed baseline measures on headache characteristics, presumed headache triggers, and mood and subsequently were trained in the use of electronic diaries to record information on headaches. Children then completed thrice daily diaries on handheld computers for a 2-week time period (42 assessments per child) while data on weather variables (temperature, dew point temperature, barometric pressure, humidity, precipitation, and sunlight) in the child's geographic location were recorded each time a diary was completed. Data were analyzed using multilevel models.\r\nRESULTS\r\nOf the weather variables, relative humidity and presence of precipitation were significantly predictive of new headache onset, with nearly a 3-fold increase in probability of headache occurrence during times of precipitation or elevated humidity in the child's area, b = 0.38, t(821) = 2.10, P = .04, and b = 0.02, t(821) = 2.81, P = .01, respectively. These associations remained after accounting for fluctuations in mood, and associations were not significantly stronger in children who at baseline thought that weather was a headache trigger for them. Changes in temperature, dew point temperature, barometric pressure, and sunlight were not significantly predictive of new headache episode occurrence in this sample.\r\nCONCLUSIONS\r\nResults of the present study lend some support to the belief commonly held by children with recurrent headaches that weather changes may contribute to headache onset. Although electronic momentary assessment methodology was found to be feasible in this population and to have the potential to identify specific headache triggers for children, it remains to be determined how best (or even whether) to incorporate this information into treatment recommendations.

Connelly, Kay; Ur Rehman Laghari, Khalil; Mokhtari, Mounir; Falk, Tiago H. (2014):

Approaches to Understanding the Impact of Technologies for Aging in Place: A Mini-Review.

In: *Gerontology. DOI:* 10.1159/000355644.

Abstract:

Background: There are many approaches to evaluating aging-in-place technologies. While there are standard measures for outcomes such as health and caregiver burden, which lend themselves to statistical analysis, researchers have a harder time identifying why a particular information and communication technology (ICT) intervention worked (or not). Objective: The

purpose of this paper is to review a variety of methods that can help answer these deeper questions of when people will utilize an ICT for aging in place, how they use it, and most importantly why. This review is sensitive to the special context of aging in place, which necessitates an evaluation that can explore the nuances of the experiences of older adults and their caregivers with the technology in order to fully understand the potential impact of ICTs to support aging in place. Methods: The authors searched both health (PubMed) and technology (ACM Digital Library) venues, reviewing 115 relevant papers that had an emphasis on understanding the use of aging-in-place technologies. This mini-review highlights a number of popular methods used in both the health and technology fields, including qualitative methods (e.g. interviews, focus groups, contextual observations, diaries, and cultural probes) and quantitative methods (e.g. surveys, the experience sampling method, and technology logs). Results: This review highlights that a single evaluation method often is not adequate for understanding why people adopt ICTs for aging in place. The review ends with two examples of multifaceted evaluations attempting to get at these deeper issues. Conclusion: There is no proscriptive formula for evaluating the intricate nuances of technology acceptance and use in the aging-in-place context. Researchers should carefully examine a wide range of evaluation techniques to select those that will provide the richest insights for their particular project. (c) 2014 S. Karger AG, Basel.

Conner, T. S.; Barrett, L. F. (2012):

Trends in ambulatory self-report: the role of momentary experience in psychosomatic medicine.

In: *Psychosom.Med.* 74 (4), S. 327–337. DOI: 10.1097/PSY.0b013e3182546f18.

Abstract:

In this article, we review the differences between momentary, retrospective, and trait self-report techniques and discuss the unique role that ambulatory reports of momentary experience play in psychosomatic medicine. After a brief historical review of self-report techniques, we discuss the latest perspective that links ambulatory self-reports to a qualitatively different conscious self-the "experiencing self"--which is functionally and neuroanatomically different from the "remembering" and "believing" selves measured through retrospective and trait questionnaires. The experiencing self functions to navigate current environments and is relatively more tied to the salience network and corporeal information from the body that regulates autonomic processes. As evidence, we review research showing that experiences measured through ambulatory assessment have stronger associations with cardiovascular reactivity, cortisol response, immune system function, and threat/reward biomarkers compared with memories or beliefs. By contrast, memories and beliefs play important roles in decision making and long-term planning, but they are less tied to bodily processes and more tied to default/long-term memory networks, which minimizes their sensitivity for certain research questions. We conclude with specific recommendations for using self-report questionnaires in psychosomatic medicine and suggest that intensive ambulatory assessment of experiences may provide greater sensitivity for connecting psychological with biologic processes

Conner, Tamlin S.; Brookie, Kate L.; Richardson, Aimee C.; Polak, Maria A. (2014):

On carrots and curiosity: Eating fruit and vegetables is associated with greater flourishing in daily life.

In: *Br J Health Psychol. DOI:* 10.1111/bjhp.12113.

Abstract:

OBJECTIVES: Our aim was to determine whether eating fruit and vegetables (FV) is associated with other markers of well-being beyond happiness and life satisfaction. Towards this aim, we tested whether FV consumption is associated with greater eudaemonic well-being - a state of flourishing characterized by feelings of engagement, meaning, and purpose in life. We also tested associations with two eudaemonic behaviours - curiosity and creativity. DESIGN: Daily diary study across 13 days (micro-longitudinal, correlational design). METHODS: A sample of 405 young adults (67% women; mean age 19.9 [SD 1.6] years) completed an Internet daily diary for 13 consecutive days. Each day, participants reported on their consumption of fruit, vegetables, sweets, and chips, as well as their eudaemonic well-being, curiosity, creativity, positive affect (PA), and negative affect. Between-person associations were analysed on aggregated data. Within-person associations were analysed using multilevel models controlling for weekday and weekend patterns. RESULTS: Fruit and vegetables consumption predicted greater eudaemonic well-being, curiosity, and creativity at the between- and within-person levels. Young adults who ate more FV reported higher average eudaemonic well-being, more intense feelings of curiosity, and greater creativity compared with young adults who ate less FV. On days when young adults ate more FV, they reported greater eudaemonic well-being, curiosity, and creativity compared with days when they ate less FV. FV consumption also predicted higher PA, which mostly did not account for the associations between FV and the other well-being variables. Few unhealthy foods (sweets, chips) were related to well-being except that consumption of sweets was associated with greater curiosity and PA at the within-person level. Lagged data analyses showed no carry-over effects of FV consumption onto next-day well-being (or vice versa). CONCLUSIONS: Although these

patterns are strictly correlational, this study provides the first evidence that FV consumption may be related to a broader range of well-being states that signal human flourishing in early adulthood. Statement of contribution What is already known on this subject? There is growing evidence that a diet rich in fruits and vegetables (FV) is related to greater happiness, life satisfaction, and positive affect. These associations are not entirely explained by demographic or health variables including socio-economic status, exercise, smoking, and body mass index (BMI). Recent experimental and daily diary research suggests that FV consumption may be a causal factor in promoting states of positive well-being. Research has examined the links between FV consumption and hedonic well-being - whether people feel good (vs. bad) and satisfied-but has not addressed links between FV consumption and eudaemonic well-being- whether people feel engaged and experience their lives as meaningful and purposeful. What does this study add? It provides the first evidence that eating FV is related to greater eudaemonic well-being in a naturalistic setting. Eating FV was also related to greater self-reported curiosity and creativity. FV consumption may underlie a broad range of experiences that signal flourishing. Future randomised controlled trials of FV should include measures of eudaemonic well-being as outcome variables.

Conrad, Ansgar; Wilhelm, Frank H.; Roth, Walton T.; Spiegel, David; Taylor, C. Barr (2008):

Circadian affective, cardiopulmonary, and cortisol variability in depressed and nondepressed individuals at risk for cardiovascular disease.

In: *Journal of Psychiatric Research* 42 (9), S. 769–777.

Abstract:

Depression is a risk factor for cardiovascular disease (CVD) perhaps mediated by hypothalamic-pituitary-adrenal (HPA) axis or vagal dysregulation. We investigated circadian mood variation and HPA-axis and autonomic function in older (55 years) depressed and nondepressed volunteers at risk for CVD by assessing diurnal positive and negative affect (PA, NA), cortisol, and cardiopulmonary variables in 46 moderately depressed and 19 nondepressed volunteers with elevated CVD risk. Participants sat quietly for 5-min periods (10:00, 12:00, 14:00, 17:00, 19:00, and 21:00), and then completed an electronic diary assessing PA and NA. Traditional and respiration-controlled heart rate variability (HRV) variables were computed for these periods as an index of vagal activity. Salivary cortisols were collected at waking, waking+30min, 12:00, 17:00, and 21:00h. Cortisol peaked in the early morning after waking, and gradually declined over the day, but did not differ between groups. PA was lower and NA was higher in the depressed group throughout the day. HRV did not differ between groups. Negative emotions were inversely related to respiratory sinus arrhythmia in nondepressed participants. We conclude that moderately depressed patients do not show abnormal HPA-axis function. Diurnal PA and NA distinguish depressed from nondepressed individuals at risk for CVD, while measures of vagal regulation, even when controlled for physical activity and respiratory confounds, do not. Diurnal mood variations of older individuals at risk for CVD differ from those reported for other groups and daily fluctuations in NA are not related to cardiac autonomic control in depressed individuals.

Conroy, David E.; Maher, Jaclyn P.; Elavsky, Steriani; Hyde, Amanda L.; Doerksen, Shawna E. (2013):

Sedentary Behavior as a Daily Process Regulated by Habits and Intentions.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-07737-001%26site%3dehost-live.

Abstract:

Objective: Sedentary behavior is a health risk but little is known about the motivational processes that regulate daily sedentary behavior. This study was designed to test a dual-process model of daily sedentary behavior, with an emphasis on the role of intentions and habits in regulating daily sedentary behavior. Method: College students (N = 128) self-reported on their habit strength for sitting and completed a 14-day ecological momentary assessment study that combined daily diaries for reporting motivation and behavior with ambulatory monitoring of sedentary behavior using accelerometers. Results: Less than half of the variance in daily sedentary behavior was attributable to between-person differences. People with stronger sedentary habits reported more sedentary behavior on average. People whose intentions for limiting sedentary behavior were stronger, on average, exhibited less self-reported sedentary behavior (and marginally less monitored sedentary behavior). Daily deviations in those intentions were negatively associated with changes in daily sedentary behavior (i.e., stronger than usual intentions to limit sedentary behavior were associated with reduced sedentary behavior). Sedentary behavior also varied within people as a function of concurrent physical activity, the day of week, and the day in the sequence of the monitoring period. Conclusions: Sedentary behavior was regulated by both automatic and controlled motivational processes. Interventions should target both of these motivational processes to facilitate and maintain behavior change. Links between sedentary behavior and daily deviations in intentions also indicate the need for ongoing efforts to support controlled motivational processes on a daily basis. Conroy, David E.; Ram, Nilam; Pincus, Aaron L.; Coffman, Donna L.; Lorek, Amy E.; Rebar, Amanda L.; Roche, Michael J. (2014):

Daily Physical Activity and Alcohol Use Across the Adult Lifespan.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-37740-001%26site%3dehost-live.

Abstract:

Objective: In contrast to proposals that physical activity (PA) can be a substitute for alcohol use, people who engage in greater overall PA generally consume more alcohol on average than less-active peers. Acknowledging that both PA and alcohol use vary considerably from day-to-day, this study evaluated whether established associations reflect daily behavioral coupling within-person, are an artifact of procedures that aggregate behavior over time, or both. Methods: A life span sample of 150 adults (aged 19–89 years) completed three 21-day measurement bursts of a daily diary study. At the end of each day, they reported on their PA and alcohol consumption. Data were analyzed in a negative binomial multilevel regression. Results: As expected, both behaviors exhibited limited between-person variation. After controlling for age, gender, and seasonal and social calendar influences, daily deviations in PA were significantly associated with daily total alcohol use. Once the within-person process linking PA and alcohol use was controlled, usual PA and total alcohol use were not associated. Conclusions: The established between-person association linking PA and alcohol use reflects the aggregation of a daily process that unfolds within-people over time. Further work is needed to identify mediators of this daily association and to evaluate causality, as well as to investigate these relations in high-risk samples. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Cook, I.; Alberts, M.; Lambert, E. V. (2012):

Influence of cut-points on patterns of accelerometry-measured free-living physical activity in rural and urban black South african women.

In: *J.Phys.Act.Health* 9 (2), S. 300–310. Online verfügbar unter PM:22368229.

Abstract:

BACKGROUND: We describe the effect of 2 different accelerometer cut-points on physical activity (PA) patterns in rural and urban black South African women. METHODS: Hip-mounted uni-axial accelerometers were worn for 6 to 7 days by rural (n = 272) and urban (n = 16) participants. Twenty-hour (4 AM to 12 AM) PA counts (cts) and volumes (min.day-1) were extracted: sedentary (SED, <100 cts.min-1), light (100-759 cts.min-1), moderate-1 (MOD1, 760-1951 cts.min-1), moderate-2 to vigorous (MOD2VG, >/=1952 cts.min-1), and bouts >/=10 min for >/=760 cts.min-1 (MOD1VGbt) and >/=1952 cts.min-1 (MOD2VGbt). RESULTS: Valid data were obtained from 263 rural women and 16 urban women. Total counts and average counts were higher (+80,399 cts.day-1, +98 cts.min-1.day-1) (P < .01), SED lower (-61 min.day-1, P = .0042), MOD1 higher (+65 min.day-1, P < .0001), and MOD1VGbt higher (+19 min.day-1, P = .0179) in rural women compared with urban women. Estimated adherence (>/=30 min.day-1 for 5 days.wk-1) was 1.4-fold higher in rural women than urban women for MOD-1VGbt, but 3.3-fold higher in urban women than rural women for MOD2VGbt. CONCLUSIONS: Rural women accumulate greater amounts of PA than urban women within a particular count band. Depending on which moderate PA cut-point was used to estimate PA public health adherence, rural women could be classified as less physically active than urban women

Cook, Jonathan E.; Arrow, Holly; Malle, Bertram F. (2011):

The effect of feeling stereotyped on social power and inhibition.

In: *Pers Soc Psychol Bull* 37 (2), S. 165–180. DOI: 10.1177/0146167210390389.

Abstract:

An experience sampling study examined the degree to which feeling stereotyped predicts feelings of low power and inhibition among stigmatized and nonstigmatized individuals. For 7 days, participants with a concealable (gay and lesbian), a visible (African American), or no identifiable stigma recorded feelings of being stereotyped, of powerlessness, and of inhibition immediately following social interactions. For members of all three groups, feeling stereotyped was associated with more inhibition, and this relation was partially mediated by feeling low in power. Although stigmatized participants reported feeling stereotyped more often than nonstigmatized participants, they reacted less strongly to the experience, consistent with the presence of buffering mechanisms developed by those living with stigma. African Americans appeared to buffer the impact of feeling stereotyped more effectively than gay and lesbian participants, an effect that was partly attributable to African Americans' higher identity centrality.

Friendship trumps ethnicity (but not sexual orientation): Comfort and discomfort in inter-group interactions.

In: *British Journal of Social Psychology* 51 (2), S. 273–289. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-15870-006&site=ehost-live;jecook@columbia.edu.

Abstract:

An experience sampling study tested the degree to which interactions with out-group members evoked negative affect and behavioural inhibition after controlling for level of friendship between partners. When friendship level was statistically controlled, neither White nor Black participants reported feeling more discomfort interacting with ethnic out-group members compared to ethnic in-group members. When partners differed in sexual orientation, friendship level had a less palliating effect. Controlling for friendship, both gay and straight men—but not women—felt more behaviourally inhibited when interacting with someone who differed in sexual orientation, and heterosexual participants of both genders continued to report more negative affect with gay and lesbian interaction partners. However, gay and lesbian participants reported similar levels of negative affect interacting with in-group (homosexual) and out-group (heterosexual) members after friendship level was controlled. Results suggest that much of the discomfort observed in inter-ethnic interactions may be attributable to lower levels of friendship with out-group partners. The discomfort generated by differences in sexual orientation, however, remains a more stubborn barrier to comfortable intergroup interactions. Cook, D. J.; Thompson, J. E.; Prinsen, S. K.; Dearani, J. A.; Deschamps, C. (2013):

Functional recovery in the elderly after major surgery: assessment of mobility recovery using wireless technology.

In: *Ann.Thorac.Surg.* 96 (3), S. 1057–1061. DOI: 10.1016/j.athoracsur.2013.05.092.

Abstract:

PURPOSE: Hospitalization and surgery in older patients often leads to a loss of strength, mobility, and functional capacity. We tested the hypothesis that wireless accelerometry could be used to measure mobility during hospital recovery after cardiac surgery. DESCRIPTION: We used an off-the-shelf fitness monitor to measure daily mobility in patients after surgery. Data were transmitted wirelessly, aggregated, and configured onto a provider-viewable dashboard. EVALUATION: Wireless monitoring of mobility after major surgery was easy and practical. There was a significant relationship between the number of steps taken in the early recovery period, length of stay, and dismissal disposition. CONCLUSIONS: Wireless monitoring of mobility after major surgery creates an opportunity for early identification and intervention in individual patients and could serve as a tool to evaluate and improve the process of care and to affect postdischarge outcomes

Cooper, Ashley R.; Page, Angie S.; Wheeler, Benedict W.; Hillsdon, Melvyn; Griew, Pippa; Jago, Russell (2010):

Patterns of GPS measured time outdoors after school and objective physical activity in English children: The PEACH project.

In: *Int J Behav Nutr Phys Act* 7. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31883-001%26site%3dehost-live;ashley.cooper@bris.ac.uk.

Abstract:

BACKGROUND:

Observational studies have shown a positive association between time outdoors and physical activity in children. Time outdoors may be a feasible intervention target to increase the physical activity of youth, but methods are required to accurately measure time spent outdoors in a range of locations and over a sustained period. The Global Positioning System (GPS) provides precise location data and can be used to identify when an individual is outdoors. The aim of this study was to investigate whether GPS data recorded outdoors were associated with objectively measured physical activity.

METHODS:

Participants were 1010 children (11.0 +/- 0.4 years) recruited from 23 urban primary schools in South West England, measured between September 2006 and July 2008. Physical activity was measured by accelerometry (Actigraph GT1M) and children wore a GPS receiver (Garmin Foretrex 201) after school on four weekdays to record time outdoors. Accelerometer and GPS data were

recorded at 10 second epochs and were combined to describe patterns of physical activity when both a GPS and accelerometer record were present (outdoors) and when there was accelerometer data only (indoors). ANOVA was used to investigate gender and seasonal differences in the patterns of outdoor and indoor physical activity, and linear regression was used to examine the cross-sectional associations between GPS-measured time outdoors and physical activity.

RESULTS:

GPS-measured time outdoors was a significant independent predictor of children's physical activity after adjustment for potential confounding factors. Physical activity was more than 2.5 fold higher outdoors than indoors (1345.8 +/- 907.3 vs 508.9 +/- 282.9 counts per minute; F = 783.2, p < .001). Overall, children recorded 41.7 +/- 46.1 minutes outdoors between 3.30 pm and 8.30 pm, with more time spent outdoors in the summer months (p < .001). There was no gender difference in time spent outdoors. Physical activity outdoors was higher in the summer than the winter (p < .001), whilst there was no seasonal variation in physical activity indoors.

CONCLUSIONS:

Duration of GPS recording is positively associated with objectively measured physical activity and is sensitive to seasonal differences. Minute by minute patterning of GPS and physical activity data is feasible and may be a useful tool to investigate environmental influences on children's physical activity and to identify opportunities for intervention.

Corder, Kirsten; Brage, Søren; Ekelund, Ulf (2007):

Accelerometers and pedometers: methodology and clinical application.

In: *Current Opinion in Clinical Nutrition & Metabolic Care* 10 (5), S. 597–603.

Abstract:

PURPOSE OF REVIEW:

The relationship between physical activity and health varies considerably, partly due to the difficulty of assessing physical activity accurately. This review examines recent literature on the validation of movement sensors to assess habitual physical activity. Recommendations are given for the use of movement sensors during free-living conditions and methods of data analysis and interpretation are discussed.

RECENT FINDINGS:

Recent progress in physical-activity research includes detailed comparative studies of different monitor brands. The move away from using linear-regression equations and the use of novel data-analysis strategies is increasing the accuracy with which energy expenditure can be estimated from accelerometry. New technologies, including the combination of accelerometry with the measurement of physiological parameters, have great potential for the increased accuracy of physical-activity assessment.

SUMMARY:

Accelerometry is able to adequately assess physical activity and its association with health outcomes but currently methods have limited accuracy for the estimation of free-living energy expenditure. Pedometers provide an inexpensive overall measure of physical activity but are unable to assess intensity, frequency and duration of activity or to estimate energy expenditure. Interpretation of monitor output is best kept as close to the measurement domain as possible.

Corder, Kirsten; Brage, Søren; Mattocks, Calum; Ness, Andy; Riddoch, Chris; Wareham, Nicholas J.; Ekelund, Ulf (2007):

Comparison of two methods to assess PAEE during six activities in children.

In: *Med Sci Sports Exerc* 39 (12), S. 2180–2188.

Abstract:

PURPOSE:

The purpose of this study was to compare the accuracy of physical activity energy expenditure (PAEE)-prediction models using accelerometry alone (ACC) and accelerometry combined with heart rate monitoring (HR+ACC) to estimate PAEE during six common activities in children (lying, sitting, slow and brisk walking, hop-scotch, running). Three PAEE-prediction models derived using the current data, and five previously published prediction models were cross-validated to estimate PAEE in this sample.

METHODS:

PAEE was assessed using ACC, HR+ACC, and indirect calorimetry during six activities in 145 children (12.4 +/- 0.2 yr). One ACC and two HR+ACC PAEE-prediction models were derived using linear regression on data from the current study. These three new

models were cross-validated using a jackknife approach, and a modified Bland-Altman method was used to assess the validity of all eight models.

RESULTS:

PAEE predictions using the one ACC and two HR+ACC models derived in the current study correlated strongly with measured values (RMSE = 97.3-118.0 J.min.kg). All five previously published models agreed well overall (RMSE = 115.6-245.3 J.min.kg), but systematic error was present for most of these, to a greater extent for ACC.

CONCLUSIONS:

ACC and HR+ACC can both be used to predict overall PAEE during these six activities in children; however, systematic error was present in all predictions. Although both ACC and HR+ACC provide accurate predictions of overall PAEE, according to the activities in this study, PAEE-prediction models using HR+ACC may be more accurate and widely applicable than those based on accelerometry alone.

Corder, Kirsten; Crespo, Noe C.; van Sluijs, Esther M. F.; Lopez, Nanette V.; Elder, John P. (2012):

Parent awareness of young children's physical activity.

In: *Prev Med* 55 (3), S. 201–205. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-24714-010%26site%3dehost-live;klc29@medschl.cam.ac.uk.

Abstract:

Objective: Parents who overestimate their child's physical activity (PA) level may not encourage their children to increase their PA. We assessed parental awareness of child PA, and investigated potential correlates of overestimation. Method: Child PA (accelerometer) and parent-classified child PA ['active'≥60 min/day vs. 'inactive' b60 min/ day moderate and vigorous PA (MVPA)] were measured over 7 days [n=329, 44% male, 39% Latino;mean (SD) 9.1 (0.7)years] in an obesity prevention study in San Diego (Project MOVE). Agreement between date-matched objective MVPA and parent-classified child PA was assessed; % days parental overestimation was the outcome variable. Associations between parental overestimation and potential correlates were investigated using three-level mixed-effects linear regression. Results: Children met the PA guidelines on 43% of days. Parents overestimated their children's PA on 75% of days when children were inactive. Most parents (80%) overestimated their child's PA on ≥1 measurement day. Parental support for child PA (transport, encouragement and participation with child) ($p<0.01$) was positively associated with higher overestimation. Parents of girls showed more overestimation than parents of boys ($p=0.04$). Conclusion: Most parents incorrectly classified their child as active when their child was inactive. Strategies addressing parental overestimation may be important in PA promotion. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Assessment of physical activity in youth.

In: *Journal of Applied Physiology* 105 (3), S. 977–987.

Abstract:

Despite much progress with physical activity assessment, the limitations concerning the accurate measurement of physical activity are often amplified in young people due to the cognitive, physiological, and biomechanical changes that occur during natural growth as well as a more intermittent pattern of habitual physical activity in youth compared with adults. This mini-review describes and compares methods to assess habitual physical activity in youth and discusses main issues regarding the use and interpretation of data collected with these techniques. Self-report instruments and movement sensing are currently the most frequently used methods for the assessment of physical activity in epidemiological research; others include heart rate monitoring and multisensor systems. Habitual energy expenditure can be estimated from these input measures with varying degree of uncertainty. Nonlinear modeling techniques, using accelerometry perhaps in combination with physiological parameters like heart rate or temperature, have the greatest potential for increasing the prediction accuracy of habitual physical activity energy expenditure. Although multisensor systems may be more accurate, this must be balanced against feasibility, a balance that shifts with technological and scientific advances and should be considered at the beginning of every new study.

Corder, Kirsten; van Sluijs, Esther Mf; Wright, Antony; Whincup, Peter; Wareham, Nicholas J.; Ekelund, Ulf (2009):

Is it possible to assess free-living physical activity and energy expenditure in young people by self-report?

In: *Am J Clin Nutr* 89 (3), S. 862–870.

Abstract:

BACKGROUND:

It is unclear whether it is possible to accurately estimate physical activity energy expenditure (PAEE) by self-report in youth.

OBJECTIVE:

We assessed the validity and reliability of 4 self-reports to assess PAEE and time spent at moderate and vigorous intensity physical activity (MVPA) over the previous week in British young people between 4 and 17 y of age.

DESIGN:

PAEE and MVPA were derived from the Children's Physical Activity Questionnaire, Youth Physical Activity Questionnaire, and Swedish Adolescent Physical Activity Questionnaire; a lifestyle score indicative of habitual activity was derived from the Child Heart and Health Study in England Questionnaire. These data were compared with criterion methods, PAEE, and MVPA derived from simultaneous measurements by doubly labeled water and accelerometry in 3 age groups: 4-5 y (n = 27), 12-13 y (n = 25), and 16-17 y (n = 24). Validity was assessed by using Spearman correlations and the Bland-Altman method, and reliability was assessed by using intraclass correlation coefficients.

RESULTS:

The strength of association between questionnaire and criterion methods varied (r = 0.09 to r = 0.46). Some questionnaires were able to accurately assess group-level PAEE and MVPA for some age groups, but the error was large for individual-level estimates throughout. Reliability of the Youth Physical Activity Questionnaire and Child Heart and Health Study in England Questionnaire was good (intraclass correlation coefficient: 0.64-0.92).

CONCLUSIONS:

Absolute PAEE and MVPA estimated from these self-reports were not valid on an individual level in young people, although some questionnaires appeared to rank individuals accurately. Age (the outcome of interest) and whether individual or group-level estimates are necessary will influence the best choice of self-report method when assessing physical activity in youth.

Corder, K.; van Sluijs, E M F; Steele, R. M.; Stephen, A. M.; Dunn, V.; Bamber, D. et al. (2011):

Breakfast consumption and physical activity in British adolescents.

In: *British Journal of Nutrition* 105 (2), S. 316–321. DOI: 10.1017/S0007114510003272.

Abstract:

Studies show an inverse relationship between breakfast frequency and weight gain. This may reflect poor eating habits generally and associated low physical activity (PA) or direct impacts of breakfast on mechanisms leading to lethargy and reduced PA. The relationship between breakfast frequency and PA is inconclusive. We aimed to determine whether breakfast frequency is associated with PA levels in British adolescents independent of body composition and socio-economic status (SES). Habitual breakfast frequency (self-report questionnaire) was assessed in 877 adolescents (43% male, age 14·5 (SD 0·5) years old). PA was measured over 5 d (accelerometry, average counts/ min; cpm). Associations between daily PA and breakfast frequency were assessed using linear regression adjusted for body fat percentage and SES. Effect modification by sex and associations with PA during the morning (06.00-12.00 hours) were explored. For boys, there were no significant associations between breakfast frequency and PA. For girls, less frequent breakfast consumption was significantly associated with lower PA (cpm) during the morning (occasional v. frequent b - 6·1 (95% CI - 11·1, -1·1), P = 0·017) when adjusted for body fat percentage and SES. There were no associations between PA and breakfast consumption over the whole day; however, for girls, less frequent breakfast consumption may be associated with lower PA levels during the morning, suggesting that breakfast consumption should perhaps be taken into consideration when aiming to promote PA in adolescent girls.

Cordier, Reinie; Brown, Nicole; Chen, Yu-Wei; Wilkes-Gillan, Sarah; Falkmer, Torbjorn (2014):

Piloting the use of experience sampling method to investigate the everyday social experiences of children with Asperger syndrome/high functioning autism.

In: *Dev Neurorehabil*, S. 1–8. DOI: 10.3109/17518423.2014.915244.

Abstract:

Abstract Objective: This pilot study explored the nature and quality of social experiences of children with Asperger Syndrome/High Functioning Autism (AS/HFA) through experience sampling method (ESM) while participating in everyday activities. Methods: ESM was used to identify the contexts and content of daily life experiences. Six children with AS/HFA (aged 8-12) wore an iPod Touch on seven consecutive days, while being signalled to complete a short survey. Results: Participants were in the company of others 88.3% of their waking time, spent 69.0% of their time with family and 3.8% with friends, but only conversed with others 26.8% of the time. Participants had more positive experiences and emotions when they were with friends compared with other company. Participating in leisure activities was associated with enjoyment, interest in the occasion, and having positive emotions. Conclusions: ESM was found to be helpful in identifying the nature and quality of social experiences of children with AS/HFA from their perspective.

Ambulatory monitoring in the diagnosis and management of obstructive sleep apnoea syndrome.

In: *Eur.Respir.Rev.* 22 (129), S. 312–324. DOI: 10.1183/09059180.00004213.

Abstract:

Obstructive sleep apnoea (OSA) is a highly prevalent disorder associated with complications such as arterial hypertension, cardiovascular diseases and traffic accidents. The resources allocated for OSA are insufficient and OSA is a significant public health problem. Portable recording devices have been developed for the detection of OSA syndrome and have proved capable of providing an equivalent diagnosis to in-laboratory polysomnography (PSG), at least in patients with a high pre-test probability of OSA syndrome. PSG becomes important in patients who have symptoms and certain comorbidities such as chronic obstructive pulmonary disease or stroke, as well as in patients with a clinical history suggesting a different sleep disorder. Continuous positive airway pressure is the most effective treatment in OSA. Ambulatory monitoring of the therapeutic modalities has been evaluated to enhance the care process and reduce costs compared to the conventional approach, without sacrificing efficiency. This review evaluates the role of portable monitoring devices in the diagnostic process of OSA and the search for alternative strategies based on ambulatory management protocols

FDA regulation of mobile health technologies.

In: *N Engl J Med* 371 (4), S. 372–379. DOI: 10.1056/NEJMhle1403384.

Abstract:

Mobile health ("mHealth") technologies that employ portable devices such as smartphones and tablets for medical purposes are rapidly transforming the medical profession. Yet adapting existing regulatory processes to ensure the safety and efficacy of this new set of products has proved challenging for the U.S. Food and Drug Administration (FDA). In this Article, we highlight issues encountered by the agency in applying its authority and its established approval and monitoring processes to this new genre of medical devices. After reviewing legislative proposals and recommendations by the FDA as to the appropriate scope of agency oversight of mHealth products, we present policy recommendations for updating the FDA's authority. We conclude that preserving the FDA's premarket and postmarket authority and providing the agency with additional funding and expertise provide a more promising solution than strictly limiting FDA's authority, which could impede the agency's ability to adapt to future innovation by tying it to existing products.

Cortinovis, Ilaria; Luraschi, Eugenia; Intini, Sara; Sessa, Marco; Fave, Antonella Delle (2011):

The daily experience of people with achondroplasia.

In: *Applied Psychology: Health and Well-Being* 3 (2), S. 207–227. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-12591-005%26site%3dehost-live;ilaria.cor@email.it.

Abstract:

This study aimed at investigating the daily experience of adults with achondroplasia. From the perspective of positive psychology, the experience reported in work, family, and relationships was analysed to detect resources and opportunities for social integration and personal growth. Participants were ten women and eight men, members of AISAC–the Italian Association for the Knowledge and Study of Achondroplasia. Following a mixed method approach, quantitative data gathered through the Experience Sampling Method provided information on daily activities and their associated experience, while qualitative data obtained through the Flow Questionnaire and Life Theme Questionnaire enabled us to explore optimal experience and associated activities, participants' present challenges and future goals. Results highlighted the role of work as a key resource to achieving well-being. Interactions with parents and siblings provided support and relaxation, while building one's own family emerged as a major future goal. Participants associated socialising with highly positive experiences of involvement and creativity; however, they reported spending a large percentage of time alone. Findings suggested that challenging and qualified work opportunities are crucial in promoting the personal growth and social integration of persons with achondroplasia. Promoting socialisation and removing social and communication barriers should be major issues for policy makers, health professionals, and associations. Courvoisier, Delphine S.; Eid, Michael; Lischetzke, Tanja; Schreiber, Walter H. (2010):

Psychometric properties of a computerized mobile phone method for assessing mood in daily life.

In: *Emotion* 10 (1), S. 115–124. DOI: 10.1037/a0017813.

Abstract:

Ecological momentary assessment is a method that is now largely used to study behavior and mood in the settings in which they naturally occur. It maximizes ecological validity and avoids the limitations of retrospective self-reports. Studies on the psychometric properties of scales administered via mobile phone ecological momentary assessment are lacking. Therefore, we collected data on a 4-item mood scale measuring well being on six occasions per day for 7 days (N = 307) and examined compliance rate across time, within day, and within week. Using specific latent state-trait structural equation models, we analyzed the degree to which interindividual mood differences on an occasion of measurement were because of (a) measurement error, (b) stable differences in mood level, and (c) occasion-specific differences. Results show good compliance (mean compliance: 74.9% of calls answered). Moreover, the scale showed good reliability (M = .82). Mood was mostly stable, especially the first 3 days of the week. It depended weakly albeit significantly on the previous assessment (autoregressive coefficient). In conclusion, computerized mobile phone assessment is an appropriate, easy-to-use, and promising method to measure mood.

Courvoisier, D. S.; Eid, M.; Lischetzke, T. (2012):

Compliance to a cell phone-based ecological momentary assessment study: The effect of time and personality characteristics.

In: *Psychol.Assess.* (1040-3590 (Linking)). DOI: 10.1037/a0026733.

Abstract:

Ecological momentary assessment (EMA) is a method that is now widely used to study behavior and mood in the settings in which they naturally occur. It maximizes ecological validity and avoids the limitations of retrospective self-reports. Compliance patterns across time have not been studied. Consistent compliance patterns could lead to data not missing at random and bias the results of subsequent analyses. In order to use modern statistical approaches for handling missing data, it is important to include variables predicting missing values into the statistical analysis. Therefore, these predictors have to be known and measured. The authors collected data on 3 four-item mood scales measuring well-being, wakefulness, and nervousness on 6 occasions per day for 7 days (N = 305) and examined compliance rate across time, within day, and within week. Results show good global compliance (mean compliance: 74.9% of calls answered). Compliance varied more within day than within week. Within day, it was lower for the first call of the day between 9 p.m. and 11 p.m. and higher for the call between 5 p.m. and 7 p.m. Within week, calls were equally answered across days of the week, but, as the study progressed, there was a slight drop in

compliance with a progressive decrease that was stronger for the first 2 calls. Compliance on the person level did not depend on personality or on satisfaction with life. Practical consequences of the results for conducting ambulatory assessment studies are discussed, and some recommendations are given. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Cousins, Jennifer C.; Whalen, Diana J.; Dahl, Ronald E.; Forbes, Erika E.; Olino, Thomas M.; Ryan, Neal D.; Silk, Jennifer S. (2011):

The bidirectional association between daytime affect and nighttime sleep in youth with anxiety and depression.

In: *Journal of Pediatric Psychology* 36 (9), S. 969–979. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24878-003&site=ehost-live;cousinsjc2@upmc.edu.

Abstract:

Objective: This study examines relationships between affect and sleep in youth with affective disorders using ecological momentary assessment (EMA). Methods: Participants included 94 youth, ages 8–16 (M = 11.73, 53% female) years with an anxiety disorder only (n = 23), primary major depressive disorder (with and without a secondary anxiety diagnoses; n = 42), and healthy controls (n = 29). A cell phone EMA protocol assessed affect and actigraphy measured sleep. Results: The patterns of bidirectional relationships between affect and sleep differed across diagnostic groups. Higher daytime positive affect and positive to negative affect ratios were associated with more time in bed during the subsequent night for youth with primary depression and less time in bed for youth with anxiety only. More time asleep was associated with more positive affect for both diagnostic groups the following day. Conclusions: This relationship may be important to consider in the treatment of youth affective disorders. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Coza, Aurel; Nigg, Benno M.; Fliri, Ladina (2010):

Quantification of soft-tissue vibrations in running: Accelerometry versus high-speed motion capture.

In: *Journal of applied biomechanics* 26, S. 367–372.

Abstract:

Soft-tissue vibrations can be used to quantify selected properties of human tissue and their response to impact. Vibrations are typically quantified using high-speed motion capture or accelerometry. The aim of this study was to compare the amplitude and frequency of soft-tissue vibrations during running when quantified by highspeed motion capture and accelerometry simultaneously. This study showed: (a) The estimated measurement errors for amplitude and frequency were of the same order of magnitude for both techniques. (b) There were no significant differences in the mean peak frequencies and peak amplitudes measured by the two methods. (c) The video method showed an inability to capture high frequency information. This study has shown that a tradeoff has to be made between the accuracy in amplitude and frequency when these methods are employed to quantify soft tissue vibrations in running.

A procedure for evaluating sensitivity to within-person change: can mood measures in diary studies detect change reliably?

In: *Pers Soc Psychol Bull* 32 (7), S. 917–929. DOI: 10.1177/0146167206287721.

Abstract:

The recent growth in diary and experience sampling research has increased research attention on how people change over time in natural settings. Often however, the measures in these studies were originally developed for studying between-person differences, and their sensitivity to within-person changes is usually unknown. Using a Generalizability Theory framework, the authors illustrate a procedure for developing reliable measures of change using a version of the Profile of Mood States (POMS; McNair, Lorr, & Droppleman, 1992) shortened for diary studies. Analyzing two data sets, one composed of 35 daily reports from 68 persons experiencing a stressful examination and another composed of daily reports from 164 persons over a typical 28-day period, we demonstrate that three-item measures of anxious mood, depressed mood, anger, fatigue, and vigor have appropriate reliability to detect within-person change processes.

Cranford, James A.; Tennen, Howard; Zucker, Robert A. (2010):

Feasibility of using interactive voice response to monitor daily drinking, moods, and relationship processes on a daily basis in alcoholic couples.

In: *Alcohol Clin Exp Res* 34 (3), S. 499–508. DOI: 10.1111/j.1530-0277.2009.01115.x.

Abstract:

BACKGROUND\r\nDaily process research on alcohol involvement has used paper-and-pencil and electronic data collection methods, but no studies have yet tested the feasibility of using Interactive Voice Response (IVR) technology to monitor drinking, affective, and social interactional processes among alcoholic (ALC) couples. This study tested the feasibility of using IVR with n = 54 ALC couples.\r\nMETHODS\r\nParticipants were n = 54 couples (probands who met criteria for a past 1-year alcohol use disorder and their partners) recruited from a substance abuse treatment center and the local community. Probands and their partners reported on their daily drinking, marital interactions, and moods once a day for 14 consecutive days using an IVR system. Probands and partners were on average 43.4 and 43.0 years old, respectively.\r\nRESULTS\r\nParticipants completed a total of 1,418 out of a possible 1,512 diary days for an overall compliance rate of 93.8%. ALC probands completed an average of 13.3 (1.0) diary reports, and partners completed an average of 13.2 (1.0) diary reports. On average, daily IVR calls lasted 7.8 (3.0) minutes for ALC probands and 7.6 (3.0) minutes for partners. Compliance was significantly lower on weekend days (Fridays and Saturdays) compared to other weekdays for probands and spouses. Although today's intoxication predicted tomorrow's noncompliance for probands but not spouses, the strongest predictor of proband's compliance was their spouse's compliance. Daily anxiety and marital conflict were associated with daily IVR nonresponse, which triggered automated reminder calls.\r\nCONCLUSIONS\r\nFindings supported that IVR is a useful method for collecting daily drinking, mood, and relationship process data from alcoholic couples. Probands' compliance is strongly associated with their partners' compliance, and automated IVR calls may facilitate compliance on high anxiety, high conflict days.

Increasing Self-Regulatory Energy Using an Internet-Based Training Application Delivered by Smartphone Technology.

In: *Cyberpsychol.Behav.Soc.Netw.* (2152-2723 (Electronic)). DOI: 10.1089/cyber.2013.0105.

Abstract:

Abstract Self-control resources can be defined in terms of "energy." Repeated attempts to override desires and impulses can result in a state of reduced self-control energy termed "ego depletion" leading to a reduced capacity to regulate future self-control behaviors effectively. Regular practice or "training" on self-control tasks may improve an individual's capacity to overcome ego depletion effectively. The current research tested the effectiveness of training using a novel Internet-based smartphone application to improve self-control and reduce ego depletion. In two experiments, participants were randomly assigned to either an experimental group, which received a daily program of self-control training using a modified Stroop-task Internet-based application delivered via smartphone to participants over a 4-week period, or a no-training control group. Participants assigned to the experimental group performed significantly better on post-training laboratory self-control tasks relative to participants in the control group. Findings support the hypothesized training effect on self-control and highlight the effectiveness of a novel Internet-based application delivered by smartphone as a practical means to administer and monitor a self-control training program. The smartphone training application has considerable advantages over other means to train self-control adopted in previous studies in that it has increased ecological validity and enables effective monitoring of compliance with the training program

Using mobile applications that combine self-report micro surveys to enhance GPS tracking data.

In: *The International Journal of Educational and Psychological Assessment* 11 (1), S. 55–74. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-28409-005%26site%3dehost-live;Claire.Omalley@nottingham.ac.uk;sarah.sharples@nottingham.ac.uk;jef@cs.nott.ac.uk;epzdg@exmail.nottingham.ac.uk;psxjc3@nottigham.ac.uk.

Abstract:

Investigating highly contextual behaviours, such as travel choices or health activities, can benefit from automated data capture using GPS, but also require self-report of actions and intentions. We present a case study of how event-based micro-surveys can be combined with GPS to understand car sharing behaviour. An opportunity sample of 24 participants took part in a seven-day study. At the start of each journey, participants used a smartphone-based application to provide basic self-report information about their journeys and their amenability to sharing. The application then tracked their journey giving a GPS trace for distance, time and duration. The combined micro-survey and GPS approach gave useful data relating whether journeys were shared, whether they could be shared, and some of the characteristics of those journeys. This supported exploratory analysis and hypothesis testing. However, usability of the application was a major consideration in the acceptability of the study, particularly with regards to the design of open questions. Also, the time sensitive nature of contextual behaviour means there is a trade-off between the depth of data captured by micro-survey, and survey completion. Overall, while we find there is empirical value in the combination of micro-survey and GPS, application usability, and appropriate design to reflect the behaviour under study are major factors in the success of this approach. A pilot study of electronic directly observed therapy to improve hydroxyurea adherence in pediatric patients with sickle-cell disease.

In: *Pediatr Blood Cancer. DOI:* 10.1002/pbc.24931.

Abstract:

BACKGROUND: Poor hydroxyurea (HU) adherence limits effective HU use in patients with sickle cell disease (SCD). Electronic directly observed therapy (DOT) may limit costs and achieve high HU adherence in children with SCD. This study aimed to determine if electronic DOT was feasible, acceptable, and could achieve >/=90% HU adherence. PROCEDURE: Children with SCD were recruited for this single institution, 6-month pilot study if they had been prescribed HU for >/=6 months and had daily access to a smartphone or computer. Participants submitted HU administration videos daily and received electronic reminder alerts, personalized feedback, and incentives to encourage adherence as part of electronic DOT. Primary outcomes were feasibility, participant satisfaction with electronic DOT, and HU adherence. Secondary outcomes included mean corpuscular volume (MCV), hemoglobin F percentage (HbF), and overall participant satisfaction with HU therapy. RESULTS: Of 15 enrolled participants, 14 completed the study. Satisfaction surveys showed electronic DOT reminded participants to take HU and could be completed in fewer than 5 minutes daily. Participants' median medication possession ratio at study entry improved from 0.75 (0.59-0.82) to 0.91 (0.85-1.00) (P = 0.02) at the end of the study. Overall median observed HU adherence with electronic DOT was 93.3%. Median MCV and HbF increased from 96.0 to107.2 (P = 0.009) and 10.5 to 11.4 (P = 0.03), respectively. CONCLUSIONS: This study demonstrates electronic DOT is feasible, acceptable, and can achieve high HU adherence. Further study is needed to confirm that electronic DOT can improve HU adherence and impact clinical outcomes in children with SCD. Pediatr Blood Cancer (c) 2014 Wiley Periodicals, Inc.

Crespo, C.; Aboy, M.; Fernandez, J. R.; Mojon, A. (2012):

Automatic identification of activity-rest periods based on actigraphy.

In: *Med.Biol.Eng Comput.* 50 (4), S. 329–340. DOI: 10.1007/s11517-012-0875-y.

Abstract:

We describe a novel algorithm for identification of activity/rest periods based on actigraphy signals designed to be used for a proper estimation of ambulatory blood pressure monitoring parameters. Automatic and accurate determination of activity/rest periods is critical in cardiovascular risk assessment applications including the evaluation of dipper versus non-dipper status. The algorithm is based on adaptive rank-order filters, rank-order decision logic, and morphological processing. The algorithm was validated on a database of 104 subjects including actigraphy signals for both the dominant and non-dominant hands (i.e., 208 actigraphy recordings). The algorithm achieved a mean performance above 94.0%, with an average number of 0.02 invalid transitions per 48 h

Crespo, Noe C.; Sallis, James F.; Conway, Terry L.; Saelens, Brian E.; Frank, Lawrence D. (2011):

Worksite physical activity policies and environments in relation to employee physical activity.

In: *Am J Health Promot* 25 (4), S. 264–271. DOI: 10.4278/ajhp.081112-QUAN-280.

Abstract:

PURPOSE\r\nExamine associations between worksite physical activity promotion strategies and employees' physical activity and sedentary behaviors.\r\nDESIGN\r\nCross-sectional.\r\nSETTING\r\nSeattle-King County, Washington and Baltimore, Maryland-Washington, D.C. regions.\r\nSUBJECTS\r\nAdults working outside the home (n = 1313). Mean age was 45 ± 10 years, 75.8% of participants were non-Hispanic white, 56% were male, and 51% had income ≥$70,000/year.\r\nMEASURES\r\nParticipants reported demographic characteristics and presence/absence of nine physical activity promotion environment and policy strategies in their work environment (e.g., showers, lockers, physical activity programs). A worksite physical activity promotion index was a tally of strategies. Total sedentary and moderate-to-vigorous physical activity (MVPA) min/d were objectively assessed via 7-day accelerometry. Total job-related physical activity minutes and recreational physical activity minutes were self-reported with the International Physical Activity Questionnaire.\r\nANALYSIS\r\nMixed-effects models and generalized estimating equations evaluated the association of the worksite promotion index with physical activity and sedentary behavior, adjusting for demographics.\r\nRESULTS\r\nA higher worksite promotion index was significantly associated with higher total sedentary behavior (β = 3.97), MVPA (β = 1.04), recreational physical activity (β = 1.1 and odds ratio = 1.39; away from work and at work, respectively) and negatively with job-related physical activity (β = .90).\r\nCONCLUSIONS\r\nMultiple worksite physical activity promotion strategies based on environmental supports and policies may increase recreational physical activity and should be evaluated in controlled trials. These findings are particularly important given the increasingly sedentary nature of employment.

Crisco, Joseph J.; Fiore, Russell; Beckwith, Jonathan G.; Chu, Jeffrey J.; Brolinson, Per Gunnar; Duma, Stefan et al. (2010):

Frequency and location of head impact exposures in individual collegiate football players.

In: *Journal of athletic training* 45 (6), S. 549.

Abstract:

CONTEXT:

Measuring head impact exposure is a critical step toward understanding the mechanism and prevention of sport-related mild traumatic brain (concussion) injury, as well as the possible effects of repeated subconcussive impacts.

OBJECTIVE:

To quantify the frequency and location of head impacts that individual players received in 1 season among 3 collegiate teams, between practice and game sessions, and among player positions.

DESIGN:

Cohort study.

SETTING:

Collegiate football field.

PATIENTS OR OTHER PARTICIPANTS:

One hundred eighty-eight players from 3 National Collegiate Athletic Association football teams.

INTERVENTION(S):

Participants wore football helmets instrumented with an accelerometer-based system during the 2007 fall season.

MAIN OUTCOME MEASURE(S):

The number of head impacts greater than 10 g and location of the impacts on the player's helmet were recorded and analyzed for trends and interactions among teams (A, B, or C), session types, and player positions using Kaplan-Meier survival curves.

RESULTS:

The total number of impacts players received was nonnormally distributed and varied by team, session type, and player position. The maximum number of head impacts for a single player on each team was 1022 (team A), 1412 (team B), and 1444 (team C). The median number of head impacts on each team was 4.8 (team A), 7.5 (team B), and 6.6 (team C) impacts per practice and 12.1 (team A), 14.6 (team B), and 16.3 (team C) impacts per game. Linemen and linebackers had the largest number of impacts

per practice and per game. Offensive linemen had a higher percentage of impacts to the front than to the back of the helmet, whereas quarterbacks had a higher percentage to the back than to the front of the helmet.

CONCLUSIONS:

The frequency of head impacts and the location on the helmet where the impacts occur are functions of player position and session type. These data provide a basis for quantifying specific head impact exposure for studies related to understanding the biomechanics and clinical aspects of concussion injury, as well as the possible effects of repeated subconcussive impacts in football.

Crooke, A. H.; Reid, S. C.; Kauer, S. D.; McKenzie, D. P.; Hearps, S. J.; Khor, A. S.; Forbes, A. B. (2013):

Temporal mood changes associated with different levels of adolescent drinking: Using mobile phones and experience sampling methods to explore motivations for adolescent alcohol use.

In: *Drug Alcohol Rev* (0959-5236 (Linking)). DOI: 10.1111/dar.12034.

Abstract:

INTRODUCTION AND AIMS: Alcohol use during adolescence is associated with the onset of alcohol use disorders, mental health disorders, substance abuse as well as socially and physically damaging behaviours, the effects of which last well into adulthood. Nevertheless, alcohol use remains prevalent in this population. Understanding motivations behind adolescent alcohol consumption may help in developing more appropriate and effective interventions. This study aims to increase this understanding by exploring the temporal relationship between mood and different levels of alcohol intake in a sample of young people. DESIGN AND METHODS: Forty-one secondary school students used a purpose-designed mobile phone application to monitor their daily mood and alcohol use for 20 random days within a 31 day period. Generalised estimating equations were used to examine the relationship between differing levels of alcohol consumption (light, intermediate and heavy) and positive and negative mood three days before and after drinking episodes. RESULTS: While there was no relationship between light and heavy drinking and positive mood, there was an increase in positive mood before and after the drinking event for those that drank intermediate amounts. No statistically significant relationships were found between negative mood and any of the three drinking categories. DISCUSSION AND CONCLUSION: Adolescents who drank in intermediate amounts on a single drinking occasion experienced an increase in positive mood over the three days leading up to and three days following a drinking event. These findings contribute to an understanding of the motivations that underpin adolescent alcohol use, which may help inform future interventions

Daily mood patterns and bulimic behaviors in the natural environment.

In: *Behav Res Ther* 47 (3), S. 181–188.

Abstract:

OBJECTIVE:

Negative affect has been purported to play an important role in the etiology and maintenance of bulimic behaviors. The objective of this study was to identify daily mood patterns in the natural environment exhibited by individuals with bulimia nervosa and to examine the relationship between these patterns and bulimic behaviors.

METHOD:

One hundred thirty-three women aged 18-55 meeting DSM-IV criteria for bulimia nervosa were recruited through clinical referrals and community advertisements. Ecological momentary assessment was used to collect multiple ratings of negative affect, binge eating and purging each day for a two-week period using palmtop computers. Latent growth mixture modeling was used to identify daily mood patterns.

RESULTS:

Nine distinct daily mood patterns were identified. The highest rates of binge eating and purging episodes occurred on days characterized by stable high negative affect or increasing negative affect over the course of the day.

CONCLUSIONS:

These findings support the conclusion that negative mood states are intimately tied to bulimic behaviors and may in fact precipitate such behavior.

Cuddy, John S.; Ham, Julie A.; Harger, Stephanie G.; Slivka, Dustin R.; Ruby, Brent C. (2008):

Effects of an electrolyte additive on hydration and drinking behavior during wildfire suppression.

In: *Wilderness Environ Med* 19 (3), S. 172–180.

Abstract:

OBJECTIVE:

The purpose of this study was to compare the effects of a water + electrolyte solution versus plain water on changes in drinking behaviors, hydration status, and body temperatures during wildfire suppression.

METHODS:

Eight participants consumed plain water, and eight participants consumed water plus an electrolyte additive during 15 hours of wildfire suppression. Participants wore a specially outfitted backpack hydration system equipped with a digital flow meter system affixed inline to measure drinking characteristics (drinking frequency and volume). Body weight and urine-specific gravity were collected pre- and postshift. Ambient, core, and skin temperatures were measured continuously using a wireless system. Work output was monitored using accelerometry.

RESULTS:

There were no differences between groups for body weight, drinking frequency, temperature data, activity, or urine-specific gravity (1.019 +/- 0.007 to 1.023 +/- 0.010 vs. 1.019 +/- 0.005 to 1.024 +/- 0.009 for water and water + electrolyte groups pre- and postshift, respectively; P < .05). There was a main effect for time for body weight, demonstrating an overall decrease (78.1 +/- 13.3 and 77.3 +/- 13.3 kg pre- and postshift, respectively; P < .05) across the work shift. The water group consumed more total fluid (main effect for treatment) than the water + electrolyte group (504 +/- 472 vs. 285 +/- 279 mL.h(-1) for the water and water + electrolyte groups, respectively; P < .05).

CONCLUSION:

The addition of an electrolyte mixture to plain water decreased the overall fluid consumption of the water + electrolyte group by 220 mL.h(-1) (3.3 L.d(-1)). Supplementing water with electrolytes can reduce the amount of fluid necessary to consume and transport during extended activity. This can minimize carrying excessive weight, possibly reducing fatigue during extended exercise.

Cuddy, J. S.; Reinert, A. R.; Hailes, W. S.; Slivka, D. R.; Ruby, B. C. (2013):

Accelerometry and salivary cortisol response during Air Force Special Tactics Officer selection.

In: *Extrem.Physiol Med.* 2 (1), S. 28. DOI: 10.1186/2046-7648-2-28.

Abstract:

BACKGROUND: Special Tactics Officer (STO) selection is conducted to select officers to enter the combat controller training pipeline. The aims were to determine physical activity patterns, estimate energy expenditure, and identify whether return and/or unsuccessful candidates demonstrated differences in cortisol responses compared to non-selected and/or first-time attendees. METHODS: Participants completed the STO selection, consisting of 5 days of physical and mental challenges. Participants were equipped with ActiCals(R), and saliva samples were collected throughout the STO selection. RESULTS: Average activity counts were 684 +/- 200 countsmin-1, with no group differences. Estimated energy expenditure was 4,105 +/- 451 kcalday-1. Cortisol was elevated following extended physical training but returned to baseline during rest. Return candidates had significantly lower cortisol responses compared to first-timers, 0.43 +/- 0.06 mugdl-1 versus 0.76 +/- 0.18 mugdl-1, respectively, p < 0.05. CONCLUSIONS: An individual's salivary cortisol response to the stresses incurred during the STO selection has the potential to be incorporated into the entire picture of a candidate's performance and ability to handle stress

Cullum, Jerry; O'Grady, Megan; Armeli, Stephen; Tennen, Howard (2012):

The role of context-specific norms and group size in alcohol consumption and compliance drinking during natural drinking events.

In: *Basic and Applied Social Psychology* 34 (4), S. 304–312. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-20494-002&site=ehost-live;tennen@nso1.uchc.edu.

Abstract:

We examined how group size and context-specific drinking norms corresponded to alcohol consumption and compliance with drinking offers using experience sampling methods. For 30 days, 397 college students reported daily on their alcohol consumption and social-context during natural social drinking events. Larger groups corresponded with greater alcohol consumption, but only when context-specific norms were high. Furthermore, larger groups increased compliance with drinking offers when norms were high but decreased compliance with drinking offers when norms were low. Thus, subtle features of the social-context may influence not only overall consumption behavior but also compliance with more overt forms of social influence. Home-based monitoring and assessment of Parkinson's disease.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 15 (1), S. 47–53. DOI: 10.1109/TITB.2010.2091142.

Abstract:

As a clinically complex neurodegenerative disease, Parkinson's disease (PD) requires regular assessment and close monitoring. In our current study, we have developed a home-based tool designed to monitor and assess peripheral motor symptoms. An evaluation of the tool was carried out over a period of ten weeks on ten people with idiopathic PD. Participants were asked to use the tool twice daily over four days, once when their medication was working at its best (\"on\" state) and once when it had worn off (\"off\" state). Results showed the ability of the data collected to distinguish the \"on\" and \"off\" state and also demonstrated statistically significant differences in timed assessments. It is anticipated that this tool could be used in the home environment as an early alert to a change in clinical condition or to monitor the effects of changes in prescribed medications used to manage PD.

Cuspidi, Cesare; Facchetti, Rita; Bombelli, Michele; Sala, Carla; Grassi, Guido; Mancia, Giuseppe (2014):

Accuracy and prognostic significance of electrocardiographic markers of left ventricular hypertrophy in a general population: findings from the Pressioni Arteriose Monitorate E Loro Associazioni population.

In: *J Hypertens* 32 (4), S. 921–928. DOI: 10.1097/HJH.0000000000000085.

Abstract:

AIM: : We assessed the value of three electrocardiographic (ECG) voltage criteria in detecting left ventricular hypertrophy (LVH) and in predicting cardiovascular events and all-cause mortality in the Pressioni Arteriose Monitorate E Loro Associazioni (PAMELA) population. METHODS: At entry, 1549 individuals (age 50 +/- 13 years, 50.5% men) underwent diagnostic tests including laboratory investigations, 24-h ambulatory blood pressure monitoring, and standard ECG and echocardiography. RESULTS: The sensitivity of ECG criteria for LVH was lowest for Sokolow-Lyon voltage (1.5 and 0.78%), intermediate for Cornell voltage (20.5 and 19.0%), and highest for RaVL wave amplitude (26.0 and 36.2%), independently of whether left ventricular mass was indexed to body surface area or height, respectively. After adjustment for age, sex, night-time SBP, low-density lipoprotein and high-density lipoprotein cholesterol, serum glucose, BMI, smoking, and previous cardiovascular events, only Cornell voltage index [hazard ratio for a 0.1 mV increase: 1.050, 95% confidence interval (CI): 1.017-1.083, P < 0.003] predicted an increased risk of cardiovascular events as well as all-cause mortality. Furthermore, when the categorical relationship between ECG-graphic LVH and cardiovascular outcomes was investigated in multiple models, only LVH identified by the Cornell voltage index remained an independent predictor of cardiovascular events (hazard ratio = 2.466, CI 1.459-4.168, P = 0.0008) and all-cause deaths (hazard ratio = 2.984, CI 1.380-6.449, P = 0.005). CONCLUSION: Despite the limited sensitivity of ECG voltage criteria in detecting LVH, our results show that Cornell voltage index may improve cardiovascular risk stratification in a general population independently of several confounding factors.

Cuspidi, Cesare; Facchetti, Rita; Bombelli, Michele; Sala, Carla; Grassi, Guido; Mancia, Giuseppe (2014):

Differential Value of Left Ventricular Mass Index and Wall Thickness in Predicting Cardiovascular Prognosis: Data From the PAMELA Population.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu019.

Abstract:

BACKGROUND: Data on the prognostic value of echocardiographic left ventricular (LV) hypertrophy (LVH) as defined by LV wall thickness rather than LV mass estimate are scarce and not univocal. Thus, we investigated the value of LV mass index, wall thickness, and relative wall thickness (RWT) in predicting cardiovascular events in the PAMELA population. METHODS: At entry 1,716 subjects underwent diagnostic tests, including laboratory investigations, 24-hour ambulatory blood pressure (BP) monitoring, and echocardiography. For the purpose of this analysis, all subjects were divided into quintiles of LV mass, LV mass/body surface area (BSA), LV mass/height2.7, interventricular septum (IVS), posterior wall (PW) thickness, IVS+PW thickness, and RWT. RESULTS: Over a follow-up of 148 months, 139 nonfatal or fatal cardiovascular events were documented. After adjustment for age, sex, BP, fasting blood glucose, total cholesterol, and use of antihypertensive drugs, only the subjects stratified in the highest quintiles of LV mass indexed to body surface area (BSA) or height2.7 exhibited a greater likelihood of incident cardiovascular disease (relative risk (RR) = 2.72, 95% confidence interval (CI) = 1.05-7.00, P = 0.03; RR = 4.83, 95% CI = 1.45-16.13, P = 0.01, respectively) as compared with the first quintile (reference group). The same was not true for the highest quintiles of IVS, PW thickness, IVS+PW thickness, and RWT. Similar findings were found when echocardiographic parameters were expressed as continuous variables. CONCLUSIONS: This study indicates that LV wall thickness, different from LV mass index, does not provide a reliable estimate of cardiovascular risk associated with LVH in a general population. From these data it is recommended that echocardiographic laboratories should provide a systematic estimate of LV mass index, which is a strong, independent predictor of incident cardiovascular disease.

Cuspidi, Cesare; Meani, Stefano; Lonati, Laura; Fusi, Veronica; Valerio, Cristiana; Sala, Carla et al. (2006):

Short-term reproducibility of a non-dipping pattern in type 2 diabetic hypertensive patients.

In: *J Hypertens* 24 (4), S. 647–653.

Abstract:

BACKGROUND:

Little information is available on the reproducibility of nocturnal variations in blood pressure in type 2 diabetic hypertensive patients.

OBJECTIVE:

We aimed to compare the intrasubject short-term reproducibility of a nocturnal non-dipping pattern and the prevalence of cardiac and extracardiac signs of target organ damage, in a group of type 2 diabetic hypertensive patients and in an age/gender-matched group of non-diabetic hypertensive subjects.

METHODS:

Thirty-six treated hypertensive patients with long-lasting type 2 diabetes (> 10 years duration) consecutively attending our hospital out-patient hypertension clinic (group I; mean age, 65 +/- 9 years), and 61 untreated non-diabetic subjects with grade 1 and grade 2 uncomplicated essential hypertension, matched for age and gender, and chosen from patients attending an outpatient clinic (group II; mean age, 65 +/- 5 years), were considered for this analysis. All patients underwent blood sampling for routine blood chemistry, 24-h urine collection for microalbuminuria, two 24-h periods of ambulatory blood pressure monitoring (ABPM) within a 4-week period, echocardiography, and carotid ultrasonography. A dipping pattern was defined as a greater than 10% reduction in the average systolic and diastolic blood pressure at night compared with average daytime values.

RESULTS:

A reproducible nocturnal dipping and non-dipping profile was found in 11 (30.6%) and 21 (58.3%) diabetic patients, respectively; while only in four (11.1%) patients was a variable dipping profile observed. Of the 23 patients with a non-dipping pattern during the first ABPM period, 21 (91.3%) also had this type of pattern during the second ABPM recording. In group II (non-diabetic hypertensive patients), 30 patients (49.2%, P < 0.05) had a dipping pattern, 13 patients (21.3%, P < 0.01) had a non-dipping profile pattern and 18 patients (29.5%, P < 0.01) had a variable dipping pattern. Of the 20 patients with a non-dipping pattern during the first ABPM period, 13 (65.0%) confirmed this type of pattern during the second ABPM recording. Finally, the prevalence of left ventricular hypertrophy (77.7 versus 41.4%, P < 0.01), carotid plaques (80.5 versus 38.3%, P < 0.01), carotid intima-media thickening (54.3 versus 44.0%, P < 0.05) and microalbuminuria (11.1 versus 2.0%, P < 0.01) was significantly higher in group I than in group II. According to a logistic regression analysis, diabetes, left ventricular hypertrophy and carotid plaques were the main independent predictors of the non-dipping (pattern in the overall population.

CONCLUSIONS:

These findings indicate that intrasubject variability of non-dipper pattern is lower in diabetic than in non-diabetic hypertensive patients, that classification of diabetic hypertensive patients as dipper or non-dipper on the basis of a single ABP recording is more reliable than in non-diabetic patients, and that the more frequent and reproducible non-dipping (pattern in diabetic patients is associated with a more prominent cardiac and extracardiac target organ damage.

Cuspidi, Cesare; Meani, Stefano; Valerio, Cristiana; Negri, Francesca; Sala, Carla; Maisaidi, Meilikemu et al. (2008):

Body mass index, nocturnal fall in blood pressure and organ damage in untreated essential hypertensive patients.

In: *Blood Press Monit* 13 (6), S. 318–324.

Abstract:

AIM:

We sought to investigate the relationship between body mass index (BMI) and parameters derived from 48-h ambulatory blood pressure monitoring (ABPM) as well as organ damage in human hypertension.

METHODS:

A total of 658 consecutive outpatients with grade 1 and 2 hypertension, never treated with antihypertensive medications underwent the following procedures: (i) routine examination, (ii) 24-h urine collection for microalbuminuria, (iii) ABPM over two 24-h periods within 4 weeks, (iv) echocardiography and (v) carotid ultrasonography. Each patient was classified as lean (BMI<25 kg/m2) or overweight/obese (> or =25 kg/m2) and according to the consistency of the dipping or nondipping status in the first and second ABPM period, as dipper (DD), nondipper and variable dipper.

RESULTS:

Mean 48-h, daytime and nighttime systolic BP or diastolic BP were superimposable in the lean (n=314) and overweight (n=344) group. Overweight patients had a reduced nocturnal BP drop compared with their lean counterparts; the prevalence of DD pattern, indeed, was 15% lower in the overweight group as a whole, with a 17% difference in men and 13% in women. The prevalence of left ventricular hypertrophy was higher in overweight than in lean patients (31.8 vs. 15.9% in men and 48.7 vs. 15.6% in women, P<0.01); this more pronounced cardiac involvement was associated with structural carotid alterations.

CONCLUSION:

This study, the first to investigate the relationship between BMI and nocturnal BP patterns as assessed by two ABPM sessions, shows that overweight hypertensive patients are more likely to have a reduced nocturnal fall in BP and a greater cardiac and extracardiac organ damage as compared with their lean counterparts despite a similar overall BP load.

da Silva, Vinicius Z M; Lima, Alexandra C.; Vargas, Fillippe T.; Cahalin, Lawrence P.; Arena, Ross; Cipriano, Gerson (2013):

Association between physical activity measurements and key parameters of cardiopulmonary exercise testing in patients with heart failure.

In: *Journal of cardiac failure* 19 (9), S. 635–640. DOI: 10.1016/j.cardfail.2013.08.002.

Abstract:

BACKGROUND\r\nA hallmark characteristic of heart failure (HF) is reduced physical activity (PA) patterns. The relationship between key cardiopulmonary exercise testing (CPX) variables and PA patterns has not been investigated. Therefore, we evaluated PA patterns in patients with ischemic HF and its relationship to peak oxygen consumption (VO2), the minute ventilation/carbon dioxide production (VE/VCO2) slope, and the oxygen uptake efficiency slope (OUES).\r\nMETHODS AND RESULTS\r\nSixteen patients with HF wore an accelerometer for six days to measure total steps/day as well as percentage of time at light, moderate, and vigorous PA. Symptom-limited CPX was performed on a treadmill using a ramping protocol. Total steps correlated with VO2 (r = 0.64 P < .05), the VE/VCO2 slope (r = -0.72; P < .05), and the OUES (0.63; P < .05). The percentage of time at light-intensity PA correlated with the VE/VCO2 slope (r = 0.58; P < .05) and the OUES (r = -0.51; P < .05). The percentage of time at vigorous-intensity PA correlated with peak VO2 (r = 0.55; P < .05) and the VE/VCO2 slope (r = -0.52; P < .05).\r\nCONCLUSIONS\r\nPA assessed by accelerometer is significantly associated with key CPX variables in patients with HF.

Citizen social science: a methodology to facilitate and evaluate workplace learning in continuing interprofessional education.

In: *J Interprof Care. DOI:* 10.3109/13561820.2013.874982.

Abstract:

Abstract Workplace learning in continuing interprofessional education (CIPE) can be difficult to facilitate and evaluate, which can create a number of challenges for this type of learning. This article presents an innovative method to foster and investigate

workplace learning in CIPE - citizen social science. Citizen social science involves clinicians as co-researchers in the systematic examination of social phenomena. When facilitated by an open-source online social networking platform, clinicians can participate via computer, smartphone, or tablet in ways that suit their needs and preferences. Furthermore, as co-researchers they can help to reveal the dynamic interplay that facilitates workplace learning in CIPE. Although yet to be tested, citizen social science offers four potential benefits: it recognises and accommodates the complexity of workplace learning in CIPE; it has the capacity to both foster and evaluate the phenomena; it can be used in situ, capturing and having direct relevance to the complexity of the workplace; and by advancing both theoretical and methodological debates on CIPE, it may reveal opportunities to improve and sustain workplace learning. By describing an example situated in the youth health sector, this article demonstrates how these benefits might be realised.

Ubiquitous health monitoring system for multiple users using a ZigBee and WLAN dual-network.

In: *Telemedicine and e-Health* 15 (9), S. 891–897.

Abstract:

A ubiquitous health monitoring system for multiple users was developed based on a ZigBee and wireless local area network (WLAN) dual-network. A compact biosignal monitoring unit (BMU) for measuring electrocardiogram (ECG), photoplethysmogram (PPG), and temperature was also developed. A single 8-bit microcontroller operated the BMU including most of digital filtering and wireless communication. The BMU with its case was reduced to 55 x 35 x 15 mm and 33 g. In routine use, vital signs of 6 bytes/sec (heart rate, temperature, pulse transit time) per each user were transmitted through a ZigBee module even though all the real-time data were recorded in a secure digital memory of the BMU. In an emergency or when need arises, a channel of a particular user was switched to another ZigBee module, called the emergency module, that sent all ECG and PPG waveforms in real time. Each emergency ZigBee module handled up to a few users. Data from multiple users were wirelessly received by the ZigBee receiver modules in a controller called ZigBee-WLAN gateway, where the ZigBee modules were connected to a WLAN module. This WLAN module sent all data wirelessly to a monitoring center. Operating the dual modes of ZigBee/WLAN utilized an advantage of ZigBee by handling multiple users with minimum power consumption, and overcame the ZigBee limitation of low data rate. This dual-network system for LAN is economically competitive and reliable.

Dagoo, Jesper; Asplund, Robert Persson; Bsenko, Helene Andersson; Hjerling, Sofia; Holmberg, Anna; Westh, Susanne et al. (2014):

Cognitive behavior therapy versus interpersonal psychotherapy for social anxiety disorder delivered via smartphone and computer: a randomized controlled trial.

In: *J Anxiety Disord* 28 (4), S. 410–417. DOI: 10.1016/j.janxdis.2014.02.003.

Abstract:

In this study, a previously evaluated guided Internet-based cognitive behavior therapy for social anxiety disorder (SAD) was adapted for mobile phone administration (mCBT). The treatment was compared with a guided self-help treatment based on interpersonal psychotherapy (mIPT). The treatment platform could be accessed through smartphones, tablet computers, and standard computers. A total of 52 participants were diagnosed with SAD and randomized to either mCBT (n=27) or mIPT (n=25). Measures were collected at pre-treatment, during the treatment, post-treatment and 3-month follow-up. On the primary outcome measure, the Liebowitz Social Anxiety Scale - self-rated, both groups showed statistically significant improvements. However, mCBT performed significantly better than mIPT (between group Cohen's d=0.64 in favor of mCBT). A larger proportion of the mCBT group was classified as responders at post-treatment (55.6% versus 8.0% in the mIPT group). We conclude that CBT for SAD can be delivered using modern information technology. IPT delivered as a guided self-help treatment may be less effective in this format.

Dalton, A.; Patel, S.; Chowdhury, A. R.; Welsh, M.; Pang, T.; Schachter, S. et al. (2012):

Development of a body sensor network to detect motor patterns of epileptic seizures.

In: *IEEE Trans.Biomed.Eng* 59 (11), S. 3204–3211. DOI: 10.1109/TBME.2012.2204990.

Abstract:

The objective of this study was the development of a remote monitoring system to monitor and detect simple motor seizures. Using accelerometer-based kinematic sensors, data were gathered from subjects undergoing medication titration at the Beth Israel Deaconess Medical Center. Over the course of the study, subjects repeatedly performed a predefined set of instrumental activities of daily living (iADLs). During the monitoring sessions, EEG and video data were also recorded and provided the gold standard for seizure detection. To distinguish seizure events from iADLs, we developed a template matching algorithm. Considering the unique signature of seizure events and the inherent temporal variability of seizure types across subjects, we incorporated a customized mass-spring template into the dynamic time warping algorithm. We then ported this algorithm onto a commercially available internet tablet and developed our body sensor network on the Mercury platform. We designed several policies on this platform to compare the tradeoffs between feature calculation, raw data transmission, and battery lifetime. From a dataset of 21 seizures, the sensitivity for our template matching algorithm was found to be 0.91 and specificity of 0.84. We achieved a battery lifetime of 10.5 h on the Mercury platform

Naturalistic monitoring of the affect-heart rate relationship: a day reconstruction study.

In: *Health Psychol* 29 (2), S. 186–195. DOI: 10.1037/a0017626.

Abstract:

OBJECTIVE\r\nProspective studies have linked negative affect with hypertension, cardiovascular disease, and mortality. This study aims to identify if cardiovascular activity in day-to-day settings is related to affect levels as assessed using the Day Reconstruction Method (Kahneman, Krueger, Schkade, Schwarz, & Stone, 2004).\r\nDESIGN\r\n186 people underwent baseline physiological testing and were monitored naturalistically for an entire day. Multilevel models were the principal analyses used.\r\nMAIN OUTCOME MEASURES\r\nWe utilized an online day reconstruction survey to produce a continuous account of affect, social interactions, and activity patterns during waking hours. Ambulatory heart rate (HR) was assessed during the same period. Personality, health behavior, consumption, self-reported activity, and baseline physiological characteristics were assessed to isolate the relationships between affect and HR.\r\nRESULTS\r\nNegative affect predicted an elevated ambulatory HR and tiredness predicted a lower HR. Associations between negative affectivity and increased cardiovascular reactivity were maintained after taking account of baseline physiological factors, health behavior, and personality.\r\nCONCLUSION\r\nNegative affect in everyday life is a reliable predictor of HR. Combining day reconstruction with psychophysiological and environmental monitoring is a minimally invasive method with promising interdisciplinary relevance.

Daniel, Karen D.; Kim, Grace Y.; Vassiliou, Christophoros C.; Galindo, Marilyn; Guimaraes, Alexander R.; Weissleder, Ralph et al. (2009):

Implantable diagnostic device for cancer monitoring.

In: *Biosensors and Bioelectronics* 24 (11), S. 3252–3257.

Abstract:

Biopsies provide required information to diagnose cancer but, because of their invasiveness, they are difficult to use for managing cancer therapy. The ability to repeatedly sample the local environment for tumor biomarker, chemotherapeutic agent, and tumor metabolite concentrations could improve early detection of metastasis and personalized therapy. Here we describe an implantable diagnostic device that senses the local in vivo environment. This device, which could be left behind during biopsy, uses a semi-permeable membrane to contain nanoparticle magnetic relaxation switches. A cell line secreting a model cancer biomarker produced ectopic tumors in mice. The transverse relaxation time (T2) of devices in tumor-bearing mice was 20 ± 10% lower than devices in control mice after 1 day by magnetic resonance imaging ($p < 0.01$). Short term applications for this device are numerous, including verification of successful tumor resection. This may represent the first continuous monitoring device for soluble cancer biomarkers in vivo.

Daniele Giansanti (2006):

Does centripetal acceleration affect trunk flexion monitoring by means of accelerometers?

In: *Physiol Meas* 27 (10), S. 999. Online verfügbar unter http://stacks.iop.org/0967-3334/27/i=10/a=006.

Abstract:

Micro electro-mechanical and NANO technologies are sensibly reducing circuit and geometrical errors in accelerometer sensors. These sensors are often used as portable inclinometer sensors for trunk flexion monitoring in clinical applications. In this case, the rotating trunk generates centripetal acceleration, an error source that technological efforts cannot eliminate. This study analysed the effect of this source for typical human monitoring conditions by simulations and clinical validation using a wearable device with rate gyroscopes and accelerometers (Giansanti and Maccioni 2005 Physiol. Meas. [/0967-3334/26/5/010] 26 689–705). Results showed that this error source did not affect long-term monitoring applications (Mathie et al [/0967-3334/25/2/r01] 2004 Physiol. Meas. 25 R1–R20) but in the short-term monitoring caused a mean angular error equal to 0.96° for the most critical single-task application represented by the sit-to-stand.

Daniels, Kevin (2013):

Job characteristics and problem-solving. In: Arnold B. Bakker und Kevin Daniels: A day in the life of a happy worker.

Hg. v. Arnold B. Bakker und Kevin Daniels. New York, NY US: Psychology Press (Current issues in work and organizational psychology), S. 58–71. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-02788-005%26site%3dehost-live.

Abstract:

(from the chapter) Many theories of job design treat job characteristics as stable, independent of the person performing the job, and as an "objective" determinant of workplace health, well-being, and performance. Drawing on the job crafting and coping literatures, in this chapter, I portray job characteristics as dynamic phenomena which are enacted by people for specific purposes. I show how this approach to job design can be used to help understand how some job characteristics can protect and enhance daily levels of well-being, learning, creativity, innovation, and cognitive performance through facilitating the generation and implementation of solutions to workplace problem-solving demands. Next, I will review how traditional approaches to job design have furthered our understanding of what makes for good and productive work. I will also review some of the unstated assumptions of this approach that are inherent to the methodologies used in this stream of literature. Following from this, I will examine some of the major principles from the emerging literature on job crafting. Together with some of the literature on coping, I will show how the literature on job design can be extended to examine how workers shape their work over the short-term for specific purposes. These purposes include solving problems at work. I will then outline how experience-sampling and diary methods can add to our understanding of job design and its consequences because they allow researchers to look at job design in a new way. Before concluding the chapter with implications for job design theories, I will review research that indicates the importance of examining how workers shape their work over the short-term for specific purposes. This research indicates implications for well-being and different facets of work performance, such as learning, creativity, innovation, and cognitive performance. Problem solving and well-being: Exploring the instrumental role of job control and social support.

In: *Journal of Management* 39 (4), S. 1016–1043. DOI: 10.1037/t00791-000;

Abstract:

Enacting social support and job control can enable effective problem solving and protect well-being. The authors operationalized social support used for problem solving as “discussing problems with others to solve problems” (DIS-SP) and job control used to solve problems as “changing aspects of work activities to solve problems” (CHA-SP). Analyses of experience sampling data (N = 191) revealed that DIS-SP was inversely associated with subsequent negative affect and that there were curvilinear relationships between CHA-SP and subsequent levels of negative affect, fatigue, and cognitive failure, such that only high levels of CHA-SP were associated with lower levels of negative affect, fatigue, and cognitive failure. Fatigue was inversely

associated with subsequent levels of DIS-SP and CHA-SP. Contrary to expectations, there was a positive association between cognitive failure and subsequent CHA-SP. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Daniels, Kevin; Glover, Jane; Mellor, Nadine (2014):

An experience sampling study of expressing affect, daily affective well-being, relationship quality, and perceived performance.

In: *Journal of Occupational and Organizational Psychology* 87 (4), S. 781–805. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-27147-001%26site%3dehost-live.

Abstract:

Few studies have directly examined the processes through which workers use job resources, such as job control and social support, to regulate affect. We focused on affective expression, which is a specific form of affect regulation. We investigated the extent to which workers used both job control and social support to express affect. Thirty-nine call centre workers provided data up to four times a day over five consecutive working days (number of observations = 272). Executing job control to allow workers to express affect was related to using social support to express affect. Workers' understanding of their personal goals mediated relationships between using social support to express affect and four outcomes (negative affect, positive affect, perceived performance, and quality of workplace relationships). Perceived empathy mediated relationships between using social support to express affect and three outcomes (negative affect, positive affect, and quality of workplace relationships). The findings indicated that (1) one job resource can be used to facilitate using another job resource for affect regulation and (2) different job resources may play different roles in conferring benefits from affective expression. Practitioner points· Jobs cannot be treated as static entities with fixed characteristics. Rather workers will use resources embedded in job design for specific purposes. · Job redesign interventions intended to enhance affective well-being need to take account of the social and cognitive processes that mediate the relationship between work and affective well-being. · Job redesign interventions need to integrate information about dynamic processes in which use of one job resource can enable use of another job resource. Daniels, Kevin; Wimalasiri, Varuni; Beesley, Nick; Cheyne, Alistair (2012):

Affective well-being and within-day beliefs about job demands' influence on work performance: An experience sampling study.

In: *Journal of Occupational and Organizational Psychology* 85 (4), S. 666–674. DOI: 10.1037/t18072-000;

Abstract:

Affective well-being is influenced by individuals' momentary beliefs concerning events' impact on goals. We examined within-day beliefs concerning problem-solving demands' adverse impact on an important work goal (work performance). Participants (N = 68) provided data up to four times per day for one working week. Hourly beliefs about problem-solving demands' adverse impact on performance were associated with end-of-hour anxious affect and inversely associated with end-of-hour motivated pleasant affect. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Dansie, Elizabeth J.; Turk, Dennis C.; Martin, Kathryn R.; van Domelen, Dane R.; Patel, Kushang V. (2014):

Association of Chronic Widespread Pain with Objectively Measured Physical Activity in Adults: Findings from the National Health and Nutrition Examination Survey.

In: *J Pain. DOI:* 10.1016/j.jpain.2014.01.489.

Abstract:

Chronic widespread pain (CWP) is a common and potentially debilitating disorder. Patterns of physical activity (PA) in adults with CWP have primarily been investigated using subjective, self-report measures. The current study sought to characterize PA among community-dwelling individuals with CWP, chronic regional pain (CRP), or no chronic pain (NCP) using objective measurements obtained via accelerometry in the 2003-2004 National Health and Nutrition Examination Survey (NHANES). Data from 3,952 participants ages 20 and older were analyzed to assess relationships between pain status and objective measurements of PA. Prevalence of CWP was 3.3% and 5.4% for men and women, respectively. In men and women, the average activity counts per minute (CPM) and time spent in moderate-to-vigorous PA were significantly lower for the CWP group than

for the NCP group. Interestingly, time spent in sedentary, light, and lifestyle activities were not associated with pain status. Statistical interaction tests indicated that the effects of chronic pain on CPM were stronger in men than in women. Despite recommendations for increased moderate-to-vigorous PA as a pain management strategy for CWP, results from this nationally representative study indicate that adults with CWP participate in less moderate-to-vigorous PA than individuals without chronic pain. PERSPECTIVE: Using objective measurement of physical activity in a nationally representative sample, this study demonstrates adults with chronic widespread pain participate in reduced daily and moderate-to-vigorous physical activity in comparison to people with no chronic pain. Findings indicate that clinicians should emphasize the importance of increasing PA in patients with CWP.

Alterations of blood pressure in type 1 diabetic children and adolescents.

In: *Pediatr Nephrol* 21 (5), S. 672–676.

Abstract:

The aim of this study was to assess the association between metabolic control, microalbuminuria, and diabetic nephropathy with ambulatory blood pressure monitoring (ABPM) in normotensive individuals with type 1 diabetes mellitus (DM). ABPM was undertaken in 68 normotensive type 1 diabetic patients with a mean age of 14.4±4.2 years. Microalbuminuria was diagnosed on the basis of a urinary albumin excretion rate grater than 20 µg/min in two of the three 24-h urine collections. Hypertension (HT) frequency was greater in the microalbuminuric patients than normoalbuminuric patients (54 vs 17.54%, p=0.05) with ABPM. Microalbuminuric patients had a higher diastolic pressure burden than normoalbuminuric patients. There were no differences in systolic and diastolic dips between the two groups. Diastolic pressure loads in all periods showed a significant correlation with duration of diabetes, mean HbA1c from the onset of diabetes, and level of microalbuminuria. Nocturnal dipping was reduced in 41.2% of the patients. In the normoalbuminuric group 41.1% and in the microalbuminuric group 63.6% were nondippers. Our data demonstrate higher 24-h and daytime diastolic blood pressure load and loss of nocturnal dip in type 1 diabetic adolescents and children. High diastolic blood pressure burden in diabetic patients could represent a risk for nephropathy.

Dasgupta, Kaberi; Joseph, Lawrence; Pilote, Louise; Strachan, Ian; Sigal, Ron J.; Chan, Cathy (2010):

Daily steps are low year-round and dip lower in fall/winter: findings from a longitudinal diabetes cohort.

In: *Cardiovasc Diabetol* 9 (1), S. 81.

Abstract:

BACKGROUND:

Higher walking levels lead to lower mortality in type 2 diabetes, but inclement weather may reduce walking. In this patient population, we conducted a longitudinal cohort study to objectively quantify seasonal variations both in walking and in two vascular risk factors associated with activity levels, hemoglobin A1C and blood pressure.

METHODS:

Between June 2006 and July 2009, volunteer type 2 diabetes patients in Montreal, Quebec, Canada underwent two weeks of pedometer measurement up to four times over a one year follow-up period (i.e. once/season). Pedometer viewing windows were concealed (snap-on cover and tamper proof seal). A1C, blood pressure, and anthropometric parameters were also assessed. Given similarities in measures for spring/summer and fall/winter, and because not all participants completed four assessments, spring and summer values were collapsed as were fall and winter values. Mean within-individual differences (95% confidence intervals) were computed for daily steps, A1C, and systolic and diastolic blood pressure, by subtracting spring/summer values from fall/winter values.

RESULTS:

Among 201 participants, 166 (82.6%) underwent at least one fall/winter and one spring/summer evaluation. Approximately half were women, the mean age was 62.4 years (SD 10.8), and the mean BMI was 30.1 kg/m2 (SD 5.7). Step counts averaged at a sedentary level in fall/winter (mean 4,901 steps/day, SD 2,464) and at a low active level in spring/summer (mean 5,659 steps/day, SD 2,611). There was a -758 (95% CI: -1,037 to -479) mean fall/winter to spring/summer within-individual difference. There were no significant differences in A1C or in anthropometric parameters. Systolic blood pressure was higher in fall/winter (mean 137 mm Hg, SD 16) than spring/summer (133 mm Hg, SD 14) with a mean difference of 4.0 mm Hg (95% CI: 2.3 to 5.7).

CONCLUSIONS:

Daily step counts in type 2 diabetes patients are low, dipping lower during fall/winter. In this medication-treated cohort, A1C was stable year-round but a fall/winter systolic blood pressure increase was detected. Our findings signal a need to develop strategies to help patients increase step counts year-round and prevent both reductions in step counts and increases in blood pressure during the fall and winter.

Detection of a Meal Using Continuous Glucose Monitoring Implications for an artificial β-cell.

In: *Diabetes Care* 31 (2), S. 295–300.

Abstract:

OBJECTIVE:

The purpose of this study was to introduce a novel meal detection algorithm (MDA) to be used as part of an artificial beta-cell that uses a continuous glucose monitor (CGM).

RESEARCH DESIGN AND METHODS:

We developed our MDA on a dataset of 26 meal events using records from 19 children aged 1-6 years who used the MiniMed CGMS Gold. We then applied this algorithm to CGM records from a DirecNet pilot study of the FreeStyle Navigator continuous glucose sensor. During a research center admission, breakfast insulin was withheld for 1 h, and discrete glucose levels were obtained every 10 min after the meal.

RESULTS:

Based on the Navigator readings, the MDA detected a meal at a mean time of 30 min from the onset of eating, at which time the mean serum glucose was 21 mg/dl above baseline (range 2-36 mg/dl), and >90% of meals were detected before the glucose had risen 40 mg/dl from baseline.

CONCLUSIONS:

The MDA will enable automated insulin dosing in response to meals, facilitating the development of an artificial pancreas.

David, James P. (1999):

Coping Efforts in Daily Life: Role of Big Five Traits and Problem Appraisals.

In: *J Personality* 67 (2), S. 265–294. DOI: 10.1111/1467-6494.00056.

Abstract:

The role of problem appraisal and Big Five traits in coping with bothersome daily events was investigated. Community-residing men completed diaries regarding stressful events and coping for eight consecutive days. Results of multi-level analyses indicated that lower perceived control over events was associated with greater reliance on distraction, catharsis, acceptance, seeking emotional social support, but less use of direct action. Stressor severity was positively associated with catharsis and religion, but negatively associated with acceptance. Neuroticism, Extraversion, Openness to experience, and Conscientiousness predicted coping strategy use. In addition, broad personality dimensions moderated relations between appraisals (perceived uncontrolability and severity) and coping strategy use. Although previous research implicated perceived control in coping, the present study suggests that both appraisals of stressor severity and individual differences in personality are also important determinants of coping strategy use at the daily level.

Davis, Jaimie N.; Tung, Amy; Chak, Salva S.; Ventura, Emily E.; Byrd-Williams, Courtney E.; Alexander, Katharine E. et al. (2009):

Aerobic and strength training reduces adiposity in overweight Latina adolescents.

In: *Med Sci Sports Exerc* 41 (7), S. 1494–1503. DOI: 10.1249/MSS.0b013e31819b6aea.

Abstract:

PURPOSE\r\nTo date, no study has examined the synergistic effects of a nutrition and combination of aerobic and strength training (CAST) on both adiposity and metabolic parameters in overweight Latina adolescent females. The goal was to assess if a 16-wk nutrition plus CAST pilot study had stronger effects on reducing adiposity and on improving glucose/insulin indices

compared with control (C), nutrition only (N), and a nutrition plus strength training (N + ST) groups.\r\nMETHODS\r\nIn a 16-wk randomized trial, 41 overweight Latina girls (15.2 +/- 1.1 yr) were randomly assigned to C (n = 7), N (n = 10), N + ST (n = 9), or N + CAST (n = 15). All intervention groups received modified carbohydrate nutrition classes (once a week), whereas the N + ST also received strength training (twice a week) and the N + CAST received a combination of strength and aerobic training (twice a week). The following were measured before and after intervention: strength by one repetition maximum, physical activity by the 7-d accelerometry and the 3-d physical activity recall, dietary intake by 3-d records, body composition by dual-energy x-ray absorptiometry (DEXA), glucose/insulin indices by oral glucose tolerance test, and intravenous glucose tolerance test with minimal modeling. Across intervention group, effects were tested using ANCOVA with post hoc pairwise comparisons.\r\nRESULTS\r\nThere were significant overall intervention effects for all adiposity measures (weight, body mass index [BMI], BMI z-scores, and DEXA total body fat), with a decrease of 3% in the N + CAST group compared with a 3% increase in the N + ST group (P < or = 0.05). There was also an intervention effect for fasting glucose with the N group increasing by 3% and the N + CAST group decreasing by 4% (P < or = 0.05).\r\nCONCLUSION\r\nThe CAST was more effective than nutrition alone or nutrition plus strength training for reducing multiple adiposity outcomes and fasting glucose in overweight Latina girls. However, further research investigating and identifying intervention approaches that improve both adiposity and insulin indices, particularly in high-risk populations, are warranted.

Davison, Kirsten Krahnstoever; Deane, Glenn D. (2010):

The consequence of encouraging girls to be active for weight loss.

In: *Soc Sci Med* 70 (4), S. 518–525. DOI: 10.1016/j.socscimed.2009.10.061.

Abstract:

The purpose of the study, conducted in Pennsylvania, USA, was to assess the prospective effect of parental encouragement of physical activity (PA) for weight loss on adolescent girls' concern about weight, Body Mass Index (BMI) and objectively-measured PA. Non-Hispanic White girls (N = 177) and their parents were assessed when girls were 9, 11, 13 and 15 years old. At each age, girls' concern about their weight, pubertal development, BMI, and dietary intake were measured along with mothers' and fathers' encouragement of PA for weight loss, modeling of PA, and logistic support for PA. At ages 13 and 15 years, girls' PA was assessed using accelerometry. At age 11, girls' PA was measured using a combination of self-report measures and a standardized assessment of cardiovascular fitness. Parents of obese girls reported the highest encouragement of PA for weight loss; however, girls from all weight categories were exposed to encouragement of PA for weight loss and showed similar age-related increases in parental encouragement. Encouragement of PA for weight loss was prospectively associated with higher concern about weight and higher BMI, independent of pre-existing levels of these constructs and covariates. Encouragement of PA for weight loss was not associated with girls' objectively-measured PA. Parental encouragement of PA for weight loss was therefore not an effective strategy in this sample. Findings are consistent with research on parental child feeding practices, where parental control has been linked with unintended negative dietary and psychosocial outcomes among children.

Davison, R. Richard; van Someren, Ken A.; Jones, Andrew M. (2009):

Physiological monitoring of the Olympic athlete.

In: *Journal of Sports Sciences* 27 (13), S. 1433–1442. DOI: 10.1080/02640410903045337.

Abstract:

As the winning margin in Olympic competition is so small, there is a continuous quest for improvements in the preparation of athletes at this standard. Therefore, even the smallest physiological improvements that result from modifications in training strategy, preparation regime or ergogenic aids are potentially useful. Unfortunately, there is a lack of research data on elite competitors, which limits our interpretation of current literature to the elite sporting environment. This places extra responsibility on the physiologist to carefully consider the most appropriate physiological variables to monitor, the best protocols to assess those variables, and the accurate interpretation of the test results. In this paper, we address the key issues of ecological validity, measurement error, and interpretation for the most commonly monitored physiological variables. Where appropriate, we also indicate areas that would benefit from further research.

Dayer, L.; Heldenbrand, S.; Anderson, P.; Gubbins, P. O.; Martin, B. C. (2013):

Smartphone medication adherence apps: potential benefits to patients and providers.

In: *J Am Pharm.Assoc.(2003.)* 53 (2), S. 172–181. DOI: 10.1331/JAPhA.2013.12202.

Abstract:

OBJECTIVES: To provide an overview of medication adherence, discuss the potential for smartphone medication adherence applications (adherence apps) to improve medication nonadherence, evaluate features of adherence apps across operating systems (OSs), and identify future opportunities and barriers facing adherence apps. PRACTICE DESCRIPTION: Medication nonadherence is a common, complex, and costly problem that contributes to poor treatment outcomes and consumes health care resources. Nonadherence is difficult to measure precisely, and interventions to mitigate it have been largely unsuccessful. PRACTICE INNOVATION: Using smartphone adherence apps represents a novel approach to improving adherence. This readily available technology offers many features that can be designed to help patients and health care providers improve medication-taking behavior. MAIN OUTCOME MEASURES: Currently available apps were identified from the three main smartphone OSs (Apple, Android, and Blackberry). In addition, desirable features for adherence apps were identified and ranked by perceived importance to user desirability using a three-point rating system: 1, modest; 2, moderate; or 3, high. The 10 highest-rated apps were installed and subjected to user testing to assess app attributes using a standard medication regimen. RESULTS 160 adherence apps were identified and ranked. These apps were most prevalent for the Android OS. Adherence apps with advanced functionality were more prevalent on the Apple iPhone OS. Among all apps, MyMedSchedule, MyMeds, and RxmindMe rated the highest because of their basic medication reminder features coupled with their enhanced levels of functionality. CONCLUSION: Despite being untested, medication apps represent a possible strategy that pharmacists can recommend to nonadherent patients and incorporate into their practice

De, Groot S.; Nieuwenhuizen, M. G. (2013):

Validity and reliability of measuring activities, movement intensity and energy expenditure with the DynaPort MoveMonitor.

In: *Med Eng Phys* (1350-4533 (Linking)). DOI: 10.1016/j.medengphy.2013.04.004.

Abstract:

The purpose of this study was to evaluate the validity and reliability of assessing activities, movement intensity (MI) and energy expenditure (EE) measured by accelerometry. 28 Able-bodied participants performed standardized tasks while an accelerometer was worn and oxygen uptake was measured. After uploading the accelerometer data to the manufacturer's website, a report was received that gave minute-by-minute MI and EE of the performed activities. Validity was assessed by comparing reported activities and EE with the actual performed activities and calculated EE from the oxygen uptake, and by testing whether MI differed between walking velocities and cycling resistances. Reliability was assessed by performing the protocol twice. Except for standing (classified predominantly (82%) as sitting), most activities were categorized mainly correctly (93-100%). A difference in MI was detected between walking speeds but not between cycling resistances. EE was overestimated for walking (ICC=0.54) and underestimated for cycling (ICC=0.03). Reliability of MI was high (ICC=0.91) but reliability for the relative time spent in activities or the step count was weak to moderate. In conclusion, most activities were categorized correctly, MI seemed to be valid and reliable but reliability is low for relative time spent in activities and EE cannot be estimated well

De, Nazelle A.; Seto, E.; Donaire-Gonzalez, D.; Mendez, M.; Matamala, J.; Nieuwenhuijsen, M. J.; Jerrett, M. (2013):

Improving estimates of air pollution exposure through ubiquitous sensing technologies.

In: *Environ.Pollut.* 176 (0269-7491 (Linking)), S. 92–99. DOI: 10.1016/j.envpol.2012.12.032.

Abstract:

Traditional methods of exposure assessment in epidemiological studies often fail to integrate important information on activity patterns, which may lead to bias, loss of statistical power, or both in health effects estimates. Novel sensing technologies integrated with mobile phones offer potential to reduce exposure measurement error. We sought to demonstrate the usability and relevance of the CalFit smartphone technology to track person-level time, geographic location, and physical activity patterns for improved air pollution exposure assessment. We deployed CalFit-equipped smartphones in a free-living population of 36 subjects in Barcelona, Spain. Information obtained on physical activity and geographic location was linked to space-time air pollution mapping. We found that information from CalFit could substantially alter exposure estimates. For instance, on average travel activities accounted for 6% of people's time and 24% of their daily inhaled NO. Due to the large number of mobile phone users, this technology potentially provides an unobtrusive means of enhancing epidemiologic exposure data at low cost

Debrot, A.; Schoebi, D.; Perrez, M.; Horn, A. B. (2013):

Touch as an interpersonal emotion regulation process in couples' daily lives: the mediating role of psychological intimacy.

In: *Pers.Soc.Psychol.Bull* 39 (10), S. 1373–1385. DOI: 10.1177/0146167213497592.

Abstract:

Interpersonal touch seems to promote physical health through its effects on stress-sensitive parameters. However, less is known about the psychological effects of touch. The present study investigates associations between touch and romantic partners' affective state in daily life. We hypothesized that this association is established by promoting the recipient's experience of intimacy. Both partners of 102 dating couples completed an electronic diary 4 times a day during 1 week. Multilevel analyses revealed that touch was associated with enhanced affect in the partner. This association was mediated by the partner's psychological intimacy. Touch was also associated with intimacy and positive affect in the actor. Finally, participants who were touched more often during the diary study week reported better psychological well-being 6 months later. This study provides evidence that intimate partners benefit from touch on a psychological level, conveying a sense of strengthened bonds between them that enhances affect and well-being

Debusscher, Jonas; Hofmans, Joeri; Fruyt, Filip (2014):

The Curvilinear Relationship between State Neuroticism and Momentary Task Performance.

In: *PLoS One* 9 (9), S. e106989. DOI: 10.1371/journal.pone.0106989.

Abstract:

A daily diary and two experience sampling studies were carried out to investigate curvilinearity of the within-person relationship between state neuroticism and task performance, as well as the moderating effects of within-person variation in momentary job demands (i.e., work pressure and task complexity). In one, results showed that under high work pressure, the state neuroticism-task performance relationship was best described by an exponentially decreasing curve, whereas an inverted U-shaped curve was found for tasks low in work pressure, while in another study, a similar trend was visible for task complexity. In the final study, the state neuroticism-momentary task performance relationship was a linear one, and this relationship was moderated by momentary task complexity. Together, results from all three studies showed that it is important to take into account the moderating effects of momentary job demands because within-person variation in job demands affects the way in which state neuroticism relates to momentary levels of task performance. Specifically, we found that experiencing low levels of state neuroticism may be most beneficial in high demanding tasks, whereas more moderate levels of state neuroticism are optimal under low momentary job demands.

Decelis, Andrew; Jago, Russell; Fox, Kenneth R. (2014):

Objectively assessed physical activity and weight status in Maltese 11-12 year-olds.

In: *Eur J Sport Sci* 14 Suppl 1, S. S257-66. DOI: 10.1080/17461391.2012.691113.

Abstract:

The objectives of the study were to identify levels of physical activity and sedentary time and assess how they differ by weight status in Maltese boys and girls. Participants were 234 Maltese children aged 11-12 years, of which 187 (80%) provided complete data. Physical activity was assessed using accelerometry and weight status determined through gender-specific age-adjusted Body mass index (BMI). Self-reported mode of transport to school, TV and computer time, gaming and mobile phone use were assessed by questionnaire. Total physical activity was generally very low and significantly lower for girls than boys at all times on weekdays and on weekends till 7 pm. Overweight and obesity prevalence was 27% and 18.6%, respectively. Differences in overall physical activity were observed between non-overweight, and overweight and obese boys (p=0.003). Differences in moderate to vigorous intensity physical activity (MVPA) in boys were significant across all weight categories (p=0.001) and in girls (p=0.020) between the overweight (27.6 min), the non-overweight (26.4 min) and the obese (18.9 min). For weekdays, mean physical activity differences (p=0.013) were observed between non-overweight (515.5 cpm) and obese boys (416.4 cpm). Differences in MVPA were found (p=0.038) between non-overweight (4.4 min) and obese boys in the 6 am-3 pm period. Differences were also found between overweight (13.2 min) and obese girls (8.1 min) (p=0.024) in that period. On weekends, mean physical activity differences were found between non-overweight and overweight boys from 8 am-7 pm but not for girls. Physical activity levels in this sample were very low when compared to recommended levels, while the prevalence of overweight and obesity and sedentary time were high. Girls are significantly less active than boys throughout the week. Activity level differences and patterning across the day and week were related to weight status with obese children showing markedly less activity. These

results suggest that we need to provide more opportunities for overweight and obese children to be active throughout the week, with a particular emphasis on physical activity during school hours.

Dechering, Dirk G.; van der Steen, Marijke S; Adiyaman, Ahmet; Thijs, Lutgarde; Deinum, Jaap; Li, Yan et al. (2008):

Reproducibility of the ambulatory arterial stiffness index in hypertensive patients.

In: *J Hypertens* 26 (10), S. 1993–2000. DOI: 10.1097/HJH.0b013e328309ee4c.

Abstract:

BACKGROUND\r\nWe studied the repeatability of the ambulatory arterial stiffness index (AASI), which can be computed from 24-h blood pressure (BP) recordings as unity minus the regression slope of diastolic on systolic BP.\r\nMETHODS\r\nOne hundred and fifty-two hypertensive outpatients recruited in Nijmegen (mean age = 46.2 years; 76.3% with systolic and diastolic hypertension) and 145 patients enrolled in the Systolic Hypertension in Europe (Syst-Eur) trial (71.0 years) underwent 24-h BP monitoring at a median interval of 8 and 31 days, respectively. We used the repeatability coefficient, which is twice the SD of the within-participant differences between repeat recordings, and expressed it as a percentage of four times the SD of the mean of the paired measurements.\r\nRESULTS\r\nMean AASI (crude or derived by time-weighted or robust regression) and 24-h pulse pressure (PP) were similar on repeat recordings in both cohorts. In Nijmegen patients, repeatability coefficients of AASI and PP were approximately 50%. In Syst-Eur trial patients, repeatability coefficient was approximately 60% for AASI and approximately 40% for PP. For comparison, repeatability coefficients for 24-h systolic and diastolic BP were approximately 30%. Differences in AASI between paired recordings were correlated with differences in the goodness of fit (r2) of the AASI regression line as well as with differences in the night-to-day BP ratio. However, in sensitivity analyses stratified for type of hypertension, r2, or dipping status, repeatability coefficients for AASI did not widely depart from 50 to 60% range.\r\nCONCLUSION\r\nEstimates of mean AASI were not different between repeat recordings, and repeatability coefficients were within the 50-60% range.

Dedert, E. A.; Dennis, P. A.; Swinkels, C. M.; Calhoun, P. S.; Dennis, M. F.; Beckham, J. C. (2013):

Ecological Momentary Assessment of Posttraumatic Stress Disorder Symptoms During a Smoking Quit Attempt.

In: *Nicotine.Tob.Res.* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt167.

Abstract:

INTRODUCTION: Smokers with posttraumatic stress disorder (PTSD) tend to lapse more quickly following a quit attempt, which might be explained by changes in PTSD symptoms during a quit attempt. The present study examines changes in PTSD symptoms, negative affect, and craving before and during a quit attempt. METHODS: Participants in this study were 52 smokers with PTSD who completed random-alarm ecological momentary assessments of PTSD symptoms, negative affect, cigarette craving, and smoking behavior throughout a prequit phase of ad-hoc smoking, a phase of abstinence from smoking, and a postlapse phase. RESULTS: Relative to the prequit phase, the abstinent phase was marked by decreases in PTSD reexperiencing, avoidance, and numbing clusters (ps </= .01). The odds of PTSD symptom or negative affect variability from one reading in the ecological momentary assessment (EMA)to the next reading was decreased in PTSD reexperiencing, avoidance, and numbing clusters (ps </= .02). Smoking cravings were also mildly decreased in the abstinent and postlapse phases (ps < .01), although some cravings in both phases were rated at the maximum intensity. Increased craving was predicted by the previous EMA reading of PTSD symptoms. CONCLUSIONS: Results suggested that smoking abstinence is not associated with exacerbation of PTSD symptoms, but PTSD symptoms during abstinence were related to craving levels during the quit attempt

Dehart, Tracy; Pelham, Brett W. (2007):

Fluctuations in state implicit self-esteem in response to daily negative events.

In: *Journal of Experimental Social Psychology* 43 (1), S. 157–165.

Abstract:

A repeated assessment study examined changes in state implicit self-esteem after negative events. Multilevel analyses revealed that trait explicit self-esteem and self-concept clarity moderated the within-person association between daily negative events and state implicit self-esteem. People with low trait explicit self-esteem or low self-concept clarity experienced decreases in state implicit self-esteem when they experienced negative life events. In contrast, for people with high trait explicit self-esteem or high self-concept clarity, state implicit self-esteem remained stable after negative events. In addition, changes in state implicit self-

esteem remained significant after controlling for state explicit self-esteem and daily negative affect. This study is the first to study changes in implicit self-esteem in the context of daily life events.

Deja, G.; Borowiec, M.; Fendler, W.; Pietrzak, I.; Szadkowska, A.; MacHnica, L. et al. (2014):

Non-dipping and arterial hypertension depend on clinical factors rather than on genetic variability of ACE and RGS2 genes in patients with type 1 diabetes.

In: *Acta Diabetol. DOI:* 10.1007/s00592-014-0568-0.

Abstract:

The aim of our study was to characterize the association of clinical and genetic risk factors such as: ACE genotype (rs17997552, rs1800764, rs4459609) and RGS2 (rs2746071) with the development of hypertension (HT) and non-dipping phenomenon in patients with type 1 diabetes mellitus (T1DM). A total of 238 adolescents and young adults with T1DM-103 females and 135 males, aged 8-30 years (mean 17.35 +/- 5.2) with diabetes duration 1-26 years (mean 7.72 +/- 6.2), with mean HbA1c (IFCC) 58 +/- 15 mmol/mmol-were subjected to 24-h ambulatory blood pressure measurements (ABPM). The results of the ABPM were analyzed in association with the polymorphisms of ACE and RGS2 genes and clinical data of patients. HT was recognized in 65 (27 %) and non-dipping in 111 (46.63 %) patients. In the multivariate analysis of factors predisposing to HT, the variables that remained significant were the following: male sex (OR 1.62; 95 % CI 1.171-2.250), non-dipping (OR 1.40; 95 % CI 1.03-1.90) and total cholesterol level (OR 1.01; 95 % CI 1.005-1.021). The only factor influencing non-dipping was the duration of diabetes-OR 1.09 (95 % CI 1.04-1.14). The patients displaying non-dipping have a twice increased risk of development of HT (OR 2.17; 95 % CI 1.21-3.89). There was no association between disturbances of blood pressure (BP) and genotypes of ACE: rs17997552, rs1800764, rs4459609 and RGS2: rs2746071. Clinical rather than genetic risk factors seem to be connected with BP disturbances in young patients with T1DM. Although we have identified representative groups of HT versus non-HT and dipping versus non-dipping subjects, the effect of genetic predisposition to the development of higher BP is too weak to be statistically significant.

Estimation and visualization of sagittal kinematics of lower limbs orientation using body-fixed sensors.

In: *Biomedical Engineering, IEEE Transactions on* 53 (7), S. 1385–1393.

Abstract:

A new method of estimating lower limbs orientations using a combination of accelerometers and gyroscopes is presented. The model is based on estimating the accelerations of ankle and knee joints by placing virtual sensors at the centers of rotation. The proposed technique considers human locomotion and biomechanical constraints, and provides a solution to fusing the data of gyroscopes and accelerometers that yields stable and drift-free estimates of segment orientation. The method was validated by measuring lower limb motions of eight subjects, walking at three different speeds, and comparing the results with a reference motion measurement system. The results are very close to those of the reference system presenting very small errors (Shank: rms = 1.0, Thigh: rms = 1.6 degrees) and excellent correlation coefficients (Shank: r = 0.999, Thigh: r = 0.998). Technically, the proposed ambulatory system is portable, easily mountable, and can be used for long-term monitoring without hindrance to natural activities. Finally, a gait analysis tool was designed to visualize the motion data as synthetic skeletons performing the same actions as the subjects.

Del Rosario, Michael B.; Wang, Kejia; Wang, Jingjing; Liu, Ying; Brodie, Matthew; Delbaere, Kim et al. (2014):

A comparison of activity classification in younger and older cohorts using a smartphone.

In: *Physiol Meas* 35 (11), S. 2269–2286. DOI: 10.1088/0967-3334/35/11/2269.

Abstract:

Automatic recognition of human activity is useful as a means of estimating energy expenditure and has potential for use in fall detection and prediction. The emergence of the smartphone as a ubiquitous device presents an opportunity to utilize its embedded sensors, computational power and data connectivity as a platform for continuous health monitoring. In the study described herein, 37 older people (83.9 +/- 3.4 years) performed a series of activities of daily living (ADLs) while a smartphone (containing a triaxial accelerometer, triaxial gyroscope and barometric pressure sensor) was placed in the front pocket of their trousers. These results are compared to a similar trial conducted previously in which 20 young people (21.9 +/- 1.65 years) were

asked to perform the same ADLs using the same smartphone (again in the front pocket of their trousers).In each trial, the participants were asked to perform several activities (standing, sitting, lying, walking on level ground, up and down staircases, and riding an elevator up and down) in a free-living environment. During each acquisition session, the internal sensor signals were recorded and subsequently used to develop activity classifiers based on a decision tree algorithm that classified ADL in epochs of ~1.25 s. When training and testing with the younger cohort, using a leave-one-out cross validation procedure, a total classification sensitivity of 80.9% +/- 9.57% ([Formula: see text] = 0.75 +/- 0.12) was obtained. Retraining and testing on the older cohort, again using cross validation, gives a comparable total class sensitivity of 82.0% +/- 8.88% ([Formula: see text] =0.74 +/- 0.12).When trained with the younger group and tested on the older group, a total class sensitivity of 69.2% +/- 24.8% (95% confidence interval [69.6%, 70.6%]) and [Formula: see text] = 0.60 +/- 0.27 (95% confidence interval [0.58, 0.59]) was obtained. When trained on the older group and tested on the younger group, a total class sensitivity of 80.5% +/- 6.80% (95% confidence interval [79.0%, 80.6%]) and [Formula: see text] = 0.74 +/- 0.08 (95% confidence interval [0.73, 0.75]) was obtained.An instance of the decision tree classifier developed was implemented on the smartphone as a software application. It was capable of performing real-time activity classification for a period of 17 h on a single battery charge, illustrating that smartphone technology provides a viable platform on which to perform long-term activity monitoring.

Delaney, Angela; Pellizzari, Margaret; Speiser, Phyllis W.; Frank, Graeme R. (2009):

Pitfalls in the measurement of the nocturnal blood pressure dip in adolescents with type 1 diabetes.

In: *Diabetes Care* 32 (1), S. 165–168. DOI: 10.2337/dc08-1319.

Abstract:

OBJECTIVE\r\nThe purpose of this study was to screen adolescents with type 1 diabetes using ambulatory blood pressure monitoring (ABPM) to 1) test the hypothesis that using a preset sleep time results in an overdiagnosis of abnormal nocturnal dipping in systolic blood pressure and 2) assess the reproducibility of an abnormal nocturnal systolic blood pressure dip.\r\nRESEARCH DESIGN AND METHODS\r\nFor aim 1, ABPM from 53 adolescent patients with type 1 diabetes was reviewed. Nocturnal dips in systolic blood pressure calculated by actual sleep time were compared with those from a preset sleep time. For aim 2, blood pressure monitoring from 98 patients using actual reported sleep time was reviewed. Reproducibility of the nocturnal dip in systolic blood pressure was assessed in a subset of \"nondippers.\"\r\nRESULTS\r\nFor aim 1, the actual mean +/- SE decline in nocturnal systolic blood pressure was 11.6 +/- 4.7%, whereas the mean decline in nocturnal systolic blood pressure calculated using the preset sleep time was 8.8 +/- 4.9% (P < 0.0001). For aim 2, 64% of patients had a normal nocturnal decline in systolic blood pressure (14.9 +/- 3.1% mmHg), whereas 36% had an abnormal dip (5.7 +/- 2.8% mmHg). Repeat ABPM performed in 22 of the 35 nondippers revealed that only 36% had abnormal systolic dipping confirmed on the repeat ABPM.\r\nCONCLUSIONS\r\nThe use of actual reported sleep time is required to accurately determine the nocturnal dip in systolic blood pressure. Repeating ABPM in nondippers is essential to confirm this abnormality.

Delfino, Ralph J.; Gillen, Daniel L.; Tjoa, Thomas; Staimer, Norbert; Polidori, Andrea; Arhami, Mohammad et al. (2010):

Electrocardiographic ST-segment depression and exposure to traffic-related aerosols in elderly subjects with coronary artery disease.

In: *Environmental health perspectives* 119 (2).

Abstract:

BACKGROUND:

Air pollutants have not been associated with ambulatory electrocardiographic evidence of ST-segment depression ≥ 1 mm (probable cardiac ischemia). We previously found that markers of primary (combustion-related) organic aerosols and gases were positively associated with circulating biomarkers of inflammation and ambulatory blood pressure in the present cohort panel study of elderly subjects with coronary artery disease.

OBJECTIVES:

We specifically aimed to evaluate whether exposure markers of primary organic aerosols and ultrafine particles were more strongly associated with ST-segment depression of ≥ 1 mm than were secondary organic aerosols or PM2.5 (particulate matter with aerodynamic diameter ≤ 2.5 μm) mass.

METHODS:

We evaluated relations of air pollutants to ambulatory electrocardiographic evidence of cardiac ischemia over 10 days in 38 subjects without ST depression on baseline electrocardiographs. Exposures were measured outdoors in retirement communities in the Los Angeles basin, including daily size-fractionated particle mass and hourly markers of primary and secondary organic

aerosols and gases. Generalized estimating equations were used to estimate odds of hourly ST-segment depression (≥ 1 mm) from hourly air pollution exposures and to estimate relative rates of daily counts of ST-segment depression from daily average exposures, controlling for potential confounders.

RESULTS:

We found significant positive associations of hourly ST-segment depression with markers of combustion-related aerosols and gases averaged 1-hr through 3-4 days, but not secondary (photochemically aged) organic aerosols or ozone. The odds ratio per interquartile increase in 2-day average primary organic carbon (5.2 µg/m3) was 15.4 (95% confidence interval, 3.5-68.2). Daily counts of ST-segment depression were consistently associated with primary combustion markers and 2-day average quasi-ultrafine particles < 0.25 µm.

CONCLUSIONS:

Results suggest that exposure to quasi-ultrafine particles and combustion-related pollutants (predominantly from traffic) increase the risk of myocardial ischemia, coherent with our previous findings for systemic inflammation and blood pressure.

Dellava, Jocilyn E.; Hoffman, Daniel J. (2009):

Validity of resting energy expenditure estimated by an activity monitor compared to indirect calorimetry.

In: *British Journal of Nutrition* 102 (1), S. 155–159. DOI: 10.1017/S0007114508143537.

Abstract:

The use of activity monitors (triaxial accelerometers) to estimate total energy expenditure in kilocalories is dependent on the estimation of resting energy expenditure (REE). However, the REE estimated by activity monitors has not been validated against more precise techniques, such as indirect calorimetry (IC). Therefore, the objective of the present study was to compare REE estimated by the Actical activity monitor (ActMon) to that measured by IC and standard prediction equations of REE. Fifty healthy adults between 18 and 43 years of age were measured for weight and percentage of body fat using a digital scale and bioelectrical impedance. The REE estimated by the ActMon was only 129 kJ/d higher, but not statistically different (P>0.05), than the REE measured with IC. Using multiple linear regression, there was a positive relationship for men, but not for women, between fat mass (kg) and percentage of body fat and the difference in REE estimated by the ActMon compared to IC (P < 0.001). Therefore, in the cohort studied, the use of an activity monitor to estimate REE is valid when compared to IC, but not to a standard prediction equation of REE.

Dellon, E. S.; Irani, A. M.; Hill, M. R.; Hirano, I. (2013):

Development and field testing of a novel patient-reported outcome measure of dysphagia in patients with eosinophilic esophagitis.

In: *Aliment.Pharmacol.Ther.* 38 (6), S. 634–642. DOI: 10.1111/apt.12413.

Abstract:

BACKGROUND: Dysphagia is the hallmark of eosinophilic esophagitis (EoE), but no validated dysphagia instruments in this population exist. AIM: To develop and field test a patient-reported outcome (PRO) for dysphagia in subjects with EoE. METHODS: This was a multi-centre/multi-phase prospective study. The first phase developed a dysphagia questionnaire using qualitative methods. The second phase was a 30-day field trial to test the instrument and assess content validity. Adolescents and adults with EoE, active symptoms of dysphagia and oesophageal eosinophilia (>/=15 eosinophils per high-power field) were enrolled. Solid-food-avoidance days, dysphagia days and actions taken to get relief were recorded. A dysphagia score was calculated and compared to the Straumann Dysphagia Instrument (SDI). RESULTS: Ten adolescents and 10 adults were included in the first phase and the Dysphagia Symptom Questionnaire (DSQ), a three-item daily electronic diary, was developed. In the second phase, 35 subjects finished the field trial (18 adults, 17 adolescents, mean age 24, 54% male, 95% white, 54% currently on topical corticosteroids). The median number of dysphagia days per week was 2 for adolescents vs. 4 for adults (P < 0.001), and 2 for those on topical steroids vs. 4 for those not on topical steroids (P < 0.001). The DSQ score strongly correlated with the number of dysphagia days (R = 0.96; P < 0.001) and the SDI (R = 0.77; P < 0.001). CONCLUSIONS: The DSQ, a three-question patient-reported outcome, was successfully developed and field tested. The DSQ had content validity and the score accurately measured dysphagia frequency and intensity. The Dysphagia Symptom Questionnaire is suitable for use in clinical trials of EoE patients with dysphagia

Demiralp, E.; Thompson, R. J.; Mata, J.; Jaeggi, S. M.; Buschkuehl, M.; Barrett, L. F. et al. (2012):

Feeling blue or turquoise? Emotional differentiation in major depressive disorder.

In: *Psychol.Sci.* 23 (11), S. 1410–1416. DOI: 10.1177/0956797612444903.

Abstract:

Some individuals have very specific and differentiated emotional experiences, such as anger, shame, excitement, and happiness, whereas others have more general affective experiences of pleasure or discomfort that are not as highly differentiated. Considering that individuals with major depressive disorder (MDD) have cognitive deficits for negative information, we predicted that people with MDD would have less differentiated negative emotional experiences than would healthy people. To test this hypothesis, we assessed participants' emotional experiences using a 7-day experience-sampling protocol. Depression was assessed using structured clinical interviews and the Beck Depression Inventory-II. As predicted, individuals with MDD had less differentiated emotional experiences than did healthy participants, but only for negative emotions. These differences were above and beyond the effects of emotional intensity and variability

Dencker, M.; Thorsson, O.; Karlsson, M. K.; Lindén, C.; Wollmer, P.; Andersen, L. B. (2009):

Objectively measured daily physical activity related to cardiac size in young children.

In: *Scandinavian Journal of Medicine & Science in Sports* 19 (5), S. 664–668. DOI: 10.1111/j.1600-0838.2008.00842.x.

Abstract:

Training studies in children have suggested that endurance training can give enlargement of cardiac dimensions. This relationship has not been studied on a population-based level in young children with objective methods. A cross-sectional study was made of 248 children (140 boys and 108 girls), aged 8-11 years, from a population-based cohort. Left ventricular end-diastolic diameter (LVDD) and left atrial end-systolic diameter (LA) were measured with echocardiography and indexed for body surface area (BSA). Physical activity was assessed by accelerometry, and the duration of vigorous physical activity per day (VPA) was calculated. Acceptable accelerometer and echocardiography measurements were obtained in 228 children (boys=127, girls=101). Univariate correlations between VPA and LVDD were indexed for BSA in boys ($r=0.27$, $P<0.05$) and in girls ($r=0.10$, NS). Multiple regression analysis showed that independent factors for LVDD, indexed for BSA for boys, were age and VPA. LA indexed for BSA was not related to physical activity variables in either gender. No clear relationship exists between cardiac size and daily physical activity in children aged 8-11 years. This suggests that significant cardiac remodelling due to volume exposure secondary to a high amount of physical activity begins later in life.

Deng, Xinmei; Sang, Biao; Luan, Ziyan (2013):

Up- and down-regulation of daily emotion: an experience sampling study of Chinese adolescents' regulatory tendency and effects.

In: *Psychol Rep* 113 (2), S. 552–565.

Abstract:

The present study examined Chinese adolescents' emotion regulatory tendency and its effect, using an Experience Sampling Method. Participants comprised 72 Chinese adolescents (M age = 15.2 yr., SD = 1.7; 36 girls). Momentary emotional experience and regulation was assessed up to 5 or 6 times each day for two weeks. Results showed that participants tended to use up-regulation when they experienced positive emotion and habitually regulated their negative emotion by down-regulation. Also, adolescents who utilized down-regulation in a certain sampling moment reported higher positive emotion at the subsequent sampling moment. Moreover, adolescents who utilized down-regulation more frequently reported higher positive emotion at the subsequent sampling moment. Overall, down-regulation seemed to be a more adaptive regulatory strategy than up-regulation in Chinese adolescents' emotional lives.

Denissen, Jaap J. A.; Butalid, Ligaya; Penke, Lars; van Aken, Marcel A G (2008):

The effects of weather on daily mood: a multilevel approach.

In: *Emotion* 8 (5), S. 662–667. DOI: 10.1037/a0013497.

Abstract:

The present study examines the effects of six weather parameters (temperature, wind power, sunlight, precipitation, air pressure, and photoperiod) on mood (positive affect, negative affect, and tiredness). Data were gathered from an online diary study (N = 1,233), linked to weather station data, and analyzed by means of multilevel analysis. Multivariate and univariate analyses enabled distinction between unique and shared effects. The results revealed main effects of temperature, wind power, and sunlight on negative affect. Sunlight had a main effect on tiredness and mediated the effects of precipitation and air pressure on tiredness. In terms of explained variance, however, the average effect of weather on mood was only small, though significant random variation was found across individuals, especially regarding the effect of photoperiod. However, these individual differences in weather sensitivity could not be explained by the Five Factor Model personality traits, gender, or age.

Dennis, Michael L.; Scott, Christy K.; Funk, Rodney R.; Nicholson, Lisa (2014):

A Pilot Study to Examine the Feasibility and Potential Effectiveness of Using Smartphones to Provide Recovery Support for Adolescents.

In: *Subst Abus*, S. 0. DOI: 10.1080/08897077.2014.970323.

Abstract:

ABSTRACT. Background: Smartphone applications can potentially provide recovery monitoring and support in real-time, real-life contexts. Study aims included determining feasibility of: a) Adolescents completing ecological momentary assessments (EMA) and utilizing phone-based ecological momentary interventions (EMI); and b) Using EMA and EMI data to predict substance use in the subsequent week. Methods: Twenty-nine adolescents were recruited at discharge from residential treatment, regardless of their discharge status or length of stay. During the 6-week pilot, youth were prompted to complete an EMA at 6 random times per day and were provided access to a suite of recovery support EMI. Youth completed 87% of the 5,580 EMAs. Based on use in the next 7 days, EMA observations were classified into 3 risk groups: "Current Use" in the past 30 minutes (3% of observations), "Unrecognized Risk" (42%), or "Recognized Risk" (55%). All youth had observations in 2 or more risk groups and 38%, in all three. Youth accessed an EMI on-average 162 times each week. Results: Participants were: 31% female, 48% African American, 21% Caucasian, 7% Hispanic, 24% Mixed/Other, average age 16.6 years. During the 90 days prior to entering treatment, youth reported using alcohol (38%), marijuana (41%), and other drugs (7%). When compared to the "Recognized Risk" group's use in the following week (31%), both the "Unrecognized Risk" (50%, OR = 2.08) and "Current Use" (96%, OR = 50.30) groups reported significantly higher rates of use in the next week. When an EMI was accessed 2 or more times within the hour following an EMA, the rate of using during the next week was significantly lower than when EMIs were not accessed (32% vs. 43%, OR = 0.62). Conclusions: Results demonstrate the feasibility of using smartphones for recovery monitoring and support with adolescents, with potential to reduce use.

Dennison, L.; Morrison, L.; Conway, G.; Yardley, L. (2013):

Opportunities and challenges for smartphone applications in supporting health behavior change: qualitative study.

In: *J Med Internet Res* 15 (4), S. e86. DOI: 10.2196/jmir.2583.

Abstract:

BACKGROUND: There is increasing interest from academics and clinicians in harnessing smartphone applications (apps) as a means of delivering behavioral interventions for health. Despite the growing availability of a range of health-related apps on the market, academic research on the development and evaluation of such apps is in the relatively early stages. A few existing studies have explored the views of various populations on using mobile phones for health-related issues and some studies are beginning to report user feedback on specific apps. However, there remains little in depth research on users' (and potential users') experiences and views on a wide range of features and technologies that apps are, or will soon be, capable of. In particular, research on young adults is lacking, which is an unfortunate omission considering that this group comprises of a good number of mobile technology adoptors. OBJECTIVE: The current study sought to explore young adults' perspectives on apps related to health behavior change. It sought their experiences and views of features that might support health behavior change and issues that contribute to interest in and willingness to use such apps. METHODS: Four focus groups were conducted with 19 students and staff at a University in the United Kingdom. Participants included 13 females and 6 males with a mean age of 23.79 (SD 7.89). The focus group discussions centred on participants' experiences of using smartphone apps to support a healthy lifestyle, and their interest in and feelings about features and capabilities of such apps. The focus groups were recorded, transcribed, and analyzed using inductive thematic analysis. RESULTS: Study findings suggested that young, currently healthy adults have some interest in apps that attempt to support health-related behavior change. Accuracy and legitimacy, security, effort required, and immediate effects on mood emerged as important influences on app usage. The ability to record and track behavior and goals and the ability to acquire advice and information "on the go" were valued. Context-sensing capabilities and

social media features tended to be considered unnecessary and off-putting. CONCLUSIONS: This study provided insight into the opportunities and challenges involved in delivering health-related behavioral interventions through smartphone apps. The findings suggested a number of valued features and characteristics that app developers may wish to consider when creating health behavior apps. Findings also highlighted several major challenges that appeared to need further consideration and research to ensure the development of effective and well-accepted behavior change apps

Depp, Colin A.; Ceglowski, Jenni; Wang, Vicki C.; Yaghouti, Faraz; Mausbach, Brent T.; Thompson, Wesley K.; Granholm, Eric L. (2014):

Augmenting psychoeducation with a mobile intervention for bipolar disorder: A randomized controlled trial.

In: *J Affect Disord* 174C, S. 23–30. DOI: 10.1016/j.jad.2014.10.053.

Abstract:

BACKGROUND: Psychosocial interventions for bipolar disorder are frequently unavailable and resource intensive. Mobile technology may improve access to evidence-based interventions and may increase their efficacy. We evaluated the feasibility, acceptability and efficacy of an augmentative mobile ecological momentary intervention targeting self-management of mood symptoms. METHODS: This was a randomized single-blind controlled trial with 82 consumers diagnosed with bipolar disorder who completed a four-session psychoeducational intervention and were assigned to 10 weeks of either: 1) mobile device delivered interactive intervention linking patient-reported mood states with personalized self-management strategies, or 2) paper-and-pencil mood monitoring. Participants were assessed at baseline, 6 weeks (mid-point), 12 weeks (post-treatment), and 24 weeks (follow up) with clinician-rated depression and mania scales and self-reported functioning. RESULTS: Retention at 12 weeks was 93% and both conditions were associated with high satisfaction. Compared to the paper-and-pencil condition, participants in the augmented mobile intervention condition showed significantly greater reductions in depressive symptoms at 6 and 12 weeks (Cohens d for both were d=0.48). However, these effects were not maintained at 24-weeks follow up. Conditions did not differ significantly in the impact on manic symptoms or functional impairment. LIMITATIONS: This was not a definitive trial and was not powered to detect moderators and mediators. CONCLUSIONS: Automated mobile-phone intervention is feasible, acceptable, and may enhance the impact of brief psychoeducation on depressive symptoms in bipolar disorder. However, sustainment of gains from symptom self-management mobile interventions, once stopped, may be limited.

Depp, Colin A.; Mausbach, Brent; Granholm, Eric; Cardenas, Veronica; Ben-Zeev, Dror; Patterson, Thomas L. et al. (2010):

Mobile interventions for severe mental illness: design and preliminary data from three approaches.

In: *The Journal of nervous and mental disease* 198 (10), S. 715.

Abstract:

Mobile devices can be used to deliver psychosocial interventions, yet there is little prior application in severe mental illness. We provide the rationale, design, and preliminary data from 3 ongoing clinical trials of mobile interventions developed for bipolar disorder or schizophrenia. Project 1 used a personal digital assistant to prompt engagement in personalized self-management behaviors based on real-time data. Project 2 employed experience sampling through text messages to facilitate case management. Project 3 was built on group functional skills training for schizophrenia by incorporating between-session mobile phone contacts with therapists. Preliminary findings were of minimal participant attrition, and no broken devices; yet, several operational and technical barriers needed to be addressed. Adherence was similar to that reported in nonpsychiatric populations, with high participant satisfaction. Therefore, mobile devices seem feasible and acceptable in augmenting psychosocial interventions for severe mental illness, with future research in establishing efficacy, cost effectiveness, and ethical and safety protocols.

Smartphone Medical Applications for Women's Health: What Is the Evidence-Base and Feedback?

In: *Int J Telemed Appl* 2013, S. 782074. DOI: 10.1155/2013/782074.

Abstract:

Background. Smartphone medical applications have a major role to play in women's health with their roles being very broad, ranging from improving health behaviours to undertaking personalised tests. Objective(s). Using Medline, Web of Knowledge, and the PRISMA guidelines 15 randomized controlled trials (RCTs) were identified, with mobile interventions being tested on 1603 females, in relation to key aspects of health. Using a similar systematic approach an iPhone database search identified 47 applications (apps) developed to improve women's health. Findings. Ten RCTs used text messaging or app interventions to support weight loss, with significant improvements being observed in eight studies. For other aspects of women's health RCTs are needed to determine possible health benefits. iPhone store data analysis identified that a substantial number of women's health apps did not have star ratings or feedback comments (68 and 49 per cent, resp.), raising concerns about their validity. Conclusion. Peer-review systems, supporting statements of evidence, or certification standards would be beneficial in maintaining the quality and credibility of future health-focused apps. Patient groups should also ideally be involved in the development and testing of mobile medical apps.

Smartphone use, work–home interference, and burnout: A diary study on the role of recovery.

In: *Applied Psychology* 63 (3), S. 411–440. DOI: 10.1037/t10797-000.

Abstract:

This diary study examines the impact of daily recovery experiences on daily work–home interference (WHI) and daily burnout symptoms within a group of smartphone users. A total of 69 employees using smartphones on the initiative of their employer completed a diary questionnaire on five successive workdays (N = 293 data points). We hypothesised that particularly for intensive smartphone users it would be important to engage in activities fostering psychological detachment and relaxation in order to reduce the risk of WHI. We predicted that smartphone use would be positively related to WHI. Finally, we predicted that the positive relationship between WHI and state levels of burnout would be stronger for intensive smartphone users. Overall, the results of multi-level analyses supported these hypotheses. The findings emphasise the importance of a clear organisational policy regarding smartphone use during after-work hours. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

A diary study on work-related smartphone use, psychological detachment and exhaustion: examining the role of the perceived segmentation norm.

In: *J Occup Health Psychol* 19 (1), S. 74–84. DOI: 10.1037/a0035076.

Abstract:

In this diary study, we examined the associations between daily work-related smartphone use and daily psychological detachment and daily work-related exhaustion within a group of smartphone owners. In addition, we studied the role of the perceived segmentation norm at the workplace as a moderator of the link between work-related smartphone use and detachment. A total of 70 employees using smartphones on initiative of their employer completed a diary questionnaire on 4 successive workdays (N = 268 data points). We hypothesized that work-related smartphone use is negatively related to psychological detachment and that psychological detachment, in turn, is negatively related to work-related exhaustion. Finally, we expected that especially employees who perceive a high segmentation norm at their workplace have difficulties to psychologically detach from work on days that they use their smartphone more intensively. Overall, the results of multilevel analyses supported these hypotheses. The findings emphasize the importance of a clear organizational policy regarding work-related smartphone use outside of work hours.

Derogatis, L. R.; Komer, L.; Katz, M.; Moreau, M.; Kimura, T.; Garcia, M. et al. (2012):

Treatment of Hypoactive Sexual Desire Disorder in Premenopausal Women: Efficacy of Flibanserin in the VIOLET Study.

In: *J.Sex Med.* 9 (4), S. 1074–1085. DOI: 10.1111/j.1743-6109.2011.02626.x.

Abstract:

Introduction. Hypoactive Sexual Desire Disorder (HSDD) is the most common form of Female Sexual Dysfunction and is characterized by low sexual desire that causes distress. Aim. The aim of this study was to assess the efficacy and safety of flibanserin, a postsynaptic 5-HT(1A) agonist/5-HT(2A) antagonist, in premenopausal women with HSDD. Methods. North American premenopausal women with HSDD were randomized to 24 weeks' treatment with placebo (N = 295), flibanserin 50 mg (N = 295), or flibanserin 100 mg (N = 290), once daily at bedtime. Main Outcome Measures. Coprimary endpoints were change from baseline to study end in number of satisfying sexual events (SSE) and sexual desire score measured daily using an electronic diary (eDiary). Secondary endpoints included change from baseline to study end in Female Sexual Function Index (FSFI) desire domain and total scores, Female Sexual Distress Scale-Revised (FSDS-R) Item 13 and total scores, and Patient's Global Impression of Improvement. Results. Flibanserin 50 mg and 100 mg led to increases in SSE ($P < 0.05$ and $P < 0.01$ vs. placebo, respectively). There was a numerical trend toward improvement in eDiary desire score on flibanserin 100 mg, but statistical significance was not reached ($P = 0.07$ vs. placebo). FSFI desire domain and total scores increased with both flibanserin regimens ($P < 0.05$). FSDS-R total and Item 13 scores decreased with flibanserin 100 mg ($P < 0.001$), indicating reduced sexual distress. More women receiving flibanserin 50 mg and 100 mg considered their HSDD to have improved than women receiving placebo (39.6% and 50.0% vs. 30.3%, respectively) ($P < 0.05$). Conclusion. In premenopausal women with HSDD, flibanserin 50 mg and 100 mg once daily at bedtime were well tolerated and associated with statistically significant improvements in SSE, sexual desire (FSFI desire domain score but not eDiary desire score) and overall sexual function, and reduction of sexual distress, vs. placebo. Desantis, Amy S.; Adam, Emma K.; Doane, Leah D.; Mineka, Susan; Zinbarg, Richard E.; Craske, Michelle G. (2007):

Racial/ethnic differences in cortisol diurnal rhythms in a community sample of adolescents.

In: *Journal of Adolescent Health* 41 (1), S. 3–13.

Abstract:

PURPOSE:

To identify potential physiological pathways to racial disparities in health outcomes, this study uses cortisol data collected from a community sample of 255 adolescents to examine whether there are racial/ethnic differences in cortisol slopes and levels across the waking day in naturalistic settings.

METHODS:

This study uses salivary cortisol data (sampled five times per day over 3 days) to examine racial/ethnic differences in diurnal cortisol rhythms, while covarying the presence of major depressive disorder and chronic and episodic life stress (assessed by structured interviews), momentary negative emotion (reported in diaries completed with cortisol samples), and socioeconomic status, sleep, and health variables (assessed by questionnaire) previously found to be associated with cortisol levels.

RESULTS:

African-American and Hispanic youth were found to have flatter cortisol slopes across the waking day than their Caucasian counterparts. Differences are due to higher bedtime cortisol levels among Hispanics and to both lower wakeup and higher bedtime levels among African-Americans. Although higher levels of negative emotion were associated with flatter diurnal rhythms, the socioenvironmental factors examined failed to explain the observed racial/ethnic differences in diurnal cortisol rhythms.

CONCLUSIONS:

Significantly flatter diurnal cortisol slopes were found among African American and Hispanic adolescents, a pattern which has been related to negative health consequences. Further research is needed to examine how early these differences emerge and to identify their developmental origins. Although genetic contributions are possible, greater prenatal stress exposure, low birth weight, adverse early childhood experiences, experiences with racism or discrimination, and lifetime history of chronic stress are all reasonable psychosocial hypotheses to pursue.

Desantis, Amy S.; Adam, Emma K.; Mendelsohn, Kathryn A.; Doane, Leah D. (2010):

Concordance between self-reported and objective wakeup times in ambulatory salivary cortisol research.

In: *International Journal of Behavioral Medicine* 17 (1), S. 74–78. DOI: 10.1007/s12529-009-9053-5.

Abstract:

BACKGROUND\r\nHypothalamic-pituitary-adrenal (HPA) axis functioning has implications for physical and mental health. One important indicator of HPA axis functioning, the salivary cortisol awakening response (CAR), is sensitive to whether participants provide their samples at the requested times after waking.\r\nPURPOSE\r\nTo examine the extent to which adolescents report morning wakeup times accurately, test the impact of inaccurate waketime reporting on compliance with a salivary cortisol sampling protocol designed to estimate the CAR, and to examine the implications of non-compliance for CAR estimates.\r\nMETHOD\r\nIn a sample of 91 late adolescents, objective waketimes determined using actigraphy were compared to self-reported waketimes. Associations between accuracy of waketimes and compliance with requested morning cortisol sampling timings (wakeup and 30 min post-awakening) were examined, as were implications of non-compliance for the size of the CAR.\r\nRESULTS\r\nIn terms of accuracy, 72% of self-reported waketimes were within 5 min and 90% were within 15 min of objective waketimes. Individuals who were more than 5 min discrepant in their waketime reporting, however, had a 90% decrease in their likelihood of being compliant-taking both morning cortisol samples within the requested time frames after waking. However, CARs were significantly lower only among individuals whose subjective and objective waketimes differed by more than 15 min.\r\nCONCLUSIONS\r\nSelf-reported waketimes were reasonably accurate when compared to objective estimates of time of waking. When available, however, estimates of compliance are improved by knowledge of objective waketimes, resulting in increased accuracy of CAR estimates.

Devito Dabbs, Annette; Dew, Mary Amanda; Myers, Brad; Begey, Alex; Hawkins, Robert; Ren, Dianxu et al. (2009):

Evaluation of a hand-held, computer-based intervention to promote early self-care behaviors after lung transplant.

In: *Clinical transplantation* 23 (4), S. 537–545. DOI: 10.1111/j.1399-0012.2009.00992.x.

Abstract:

BACKGROUND\r\nLung transplant recipients are expected to perform self-care behaviors to maximize transplant-related health outcomes. Despite high non-adherence rates in performing these self-care behaviors, and the dire clinical consequences of such non-adherence, interventions are lacking. Pocket Personal Assistant for Tracking Health (Pocket PATH) is a hand-held device developed for patients to record health data, review data trends, and report condition changes to the transplant team.\r\nMETHODS\r\nA pilot trial was conducted to compare self-care agency, self-care behaviors, and health-related quality of life (HRQOL) between recipients randomized to use Pocket PATH (n = 15) vs. standard care (n = 15) for the first two months following hospital discharge after lung transplantation.\r\nRESULTS\r\nBaseline characteristics were equivalent across groups. Patients in the Pocket PATH group showed significantly higher ratings of self-care agency, performed self-care behaviors at significantly higher rates, and reported significantly better HRQOL than standard care controls.\r\nCONCLUSION\r\nPocket PATH is more efficacious than standard care in promoting early self-care agency, self-care behaviors, and HRQOL in lung recipients. A large-scale randomized controlled trial is needed to test the impact of Pocket PATH on long-term self-care behaviors.

Testing social-cognitive theory to explain physical activity change in adolescent girls from low-income communities.

In: *Res Q Exerc Sport* 84 (4), S. 483–491.

Abstract:

PURPOSE: The aim of this study was to test the hypothesized structural paths in Bandura's social-cognitive theory (SCT) model on adolescent girls' physical activity following a 12-month physical activity and dietary intervention to prevent obesity. METHOD: We conducted a 12-month follow-up study of 235 adolescent girls (M(age) = 13.2 years, SD = 0.4) from 12 secondary schools located in low-income communities. At baseline, participants completed SCT scales related to physical activity (i.e., self-efficacy, intention, parental support, and outcome expectations). At baseline and 12-month follow-up (postintervention), participants wore accelerometers for 7 days. Structural equation modeling was used to determine if Time 1 measures predicted physical activity at 12-month follow-up after adjusting for baseline activity. RESULTS: The model explained 28% and 34% of the variance

in physical activity and intention, respectively. Model fit indexes indicated the data were a good fit to the model; however, only self-efficacy was associated with physical activity at 12 months. There was no support for intention or outcome expectations as proximal determinants of behavior. Self-efficacy was associated with outcome expectations and parental support; however, only outcome expectations predicted intention. CONCLUSIONS: Current findings indicate a large proportion of the variance for physical activity and intention remains unexplained and that the proposed pathways in the SCT model were not fully supported. Future model testing may need to consider augmentation or integration of theoretical models, which may include ecological components if we are to advance our understanding of physical activity behavior in this subgroup of the adolescent population.

Dhingra, Lara K.; Homel, Peter; Grossman, Bella; Chen, Jack; Scharaga, Elyssa; Calamita, Steven et al. (2014):

Ecological momentary assessment of smoking behavior in persistent pain patients.

In: *Clin J Pain* 30 (3), S. 205–213. DOI: 10.1037/t04175-000;

Abstract:

Objectives: Smoking is associated with chronic pain and pain-related functional impairment. Some studies suggest that pain activates smoking urges and others suggest that smoking is analgesic. We evaluated these associations using ecological momentary assessment, a method for real-time measurement of health-related phenomena. Methods: For 1 week, 36 chronic pain patients who smoked a mean of 17.5 (SD = 9.4) cigarettes per day completed multiple daily assessments on a handheld computer. Results: The sample included 67% women and 39% whites; 67% had back pain, with an average (SD) worst pain severity during the past week of 8.6 (1.5) on a 0 to 10 numeric rating scale. Patients completed an average (SD) of 44 (24) random assessments. At each assessment, the patient recorded pain “right now” on a 0 to 10 scale, whether he/she was “about to smoke,” and if he/she had “just smoked in the past 30 minutes,” pain before smoking. After controlling for other significant correlates of pain, patients who were about to smoke had more pain than at other times (M [SD] = 6.5 [2.3] vs. 5.2 [2.4]; P < 0.01), but pain before and after smoking was not different (M [SD] = 6.1 [2.2] vs. 5.9 [2.3]; P = 0.18). Discussion: These findings support the hypothesis that smoking behavior is triggered by pain, but smoking is not analgesic. Future studies should clarify potential explanatory mechanisms for this pain-related trigger and evaluate tailored cessation strategies for pain patients. Diabetes Research in Children Network Study Group (2007):

Continuous glucose monitoring in children with type 1 diabetes.

In: *J Pediatr* 151 (4), S. 388–393.

Abstract:

OBJECTIVE:

To examine the feasibility of daily use of a continuous glucose monitor, the FreeStyle Navigator Continuous Glucose Monitoring System ("Navigator"), in children with type 1 diabetes (T1D).

STUDY DESIGN:

After a masked Navigator was used for 4 to 7 days to establish a baseline level of glycemic control, 30 insulin pump users with T1D (average age 11.2 years) were asked to use the Navigator daily for 13 weeks.

RESULTS:

Subjects averaged 149 h/wk of Navigator use during the first 4 weeks, which decreased slightly to 134 h/wk during weeks 9 to 13 (P = .006). Mean hemoglobin A1c improved from 7.1% at baseline to 6.8% at 13 weeks (P = .02), and the percentage of glucose values between 71 and 180 mg/dL increased from 52% to 60% (P = .01). Subjects and parents reported high satisfaction with the Navigator on the Continuous Glucose Monitor Satisfaction Scale. Two subjects had severe skin reactions related to sensor mount adhesive.

CONCLUSION:

This study indicates that incorporating real-time continuous glucose monitoring into the daily treatment of children with T1D is feasible. The results provide a compelling rationale for conducting a randomized trial of daily use of a continuous glucose monitor in children with T1D.

Diana, C.; Cristina, B.; Azucena, G. P.; Luis, F.; Ignacio, M. (2012):

Experience-sampling methodology with a mobile device in fibromyalgia.

In: *Int.J Telemed.Appl.* 2012 (1687-6415 (Linking)), S. 162673. DOI: 10.1155/2012/162673.

Abstract:

This work describes the usability studies conducted in the development of an experience-sampling methodology (ESM) system running in a mobile device. The goal of the system is to improve the accuracy and ecology in gathering daily self-report data in individuals suffering a chronic pain condition, fibromyalgia. The usability studies showed that the developed software to conduct ESM with mobile devices (smartphones, cell phones) can be successfully used by individuals with fibromyalgia of different ages and with low level of expertise in the use of information and communication technologies. 100% of users completed the tasks successfully, although some have completely illiterate. Also there seems to be a clear difference in the way of interaction obtained in the two studies carried out

Diener, Ed; Tay, Louis (2013):

Review of the day reconstruction method (drm).

In: *Social Indicators Research*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-07637-001%26site%3dehost-live;ediener@illinois.edu.

Abstract:

The Day Reconstruction Method (DRM) for assessing daily experience and subjective well-being is reviewed. The DRM is a promising method as it assesses feelings within situations and activities, and therefore goes beyond asking who is happy to asking when they are happy. The technique might be less burdensome on respondents than experience-sampling, and might reduce memory biases that are inherent in global recall of feelings. However, evidence for the validity and reliability of the DRM is limited and is not entirely supportive. Research is needed on the psychometrics of the DRM, for example by comparing it to mobile phone assessments and other forms of experience-sampling, as well as to global reports of feelings in situations. Conceptual issues with computing overall subjective well-being by weighting a respondent's activity scores by the time spent in them are discussed. Despite the promises of the DRM, the many unresolved issues with it and the alternative of using on-line electronic experience-sampling techniques suggest that more research is needed before the value of the DRM is established. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Detection of walking periods and number of steps in older adults and patients with Parkinson's disease: accuracy of a pedometer and an accelerometry-based method.

In: *Age and ageing* 37 (4), S. 436–441.

Abstract:

The aim of this study was to examine if walking periods and number of steps can accurately be detected by a single small body-fixed device in older adults and patients with Parkinson's disease (PD). Results of an accelerometry-based method (DynaPort MicroMod) and a pedometer (Yamax Digi-Walker SW-200) worn on each hip were evaluated against video observation. Twenty older adults and 32 PD patients walked straight-line trajectories at different speeds, of different lengths and while doing secondary tasks in an indoor hallway. Accuracy of the instruments was expressed as absolute percentage error (older adults versus PD patients). Based on the video observation, a total of 236.8 min of gait duration and 24,713 steps were assessed. The DynaPort method predominantly overestimated gait duration (10.7 versus 11.1%) and underestimated the number of steps (7.4 versus 6.9%). Accuracy decreased significantly as walking distance decreased. Number of steps were also mainly underestimated by the pedometers, the left Yamax (6.8 versus 11.1%) being more accurate than the right Yamax (11.1 versus 16.3%). Step counting of both pedometers was significantly less accurate for short trajectories (3 or 5 m) and as walking pace decreased. It is concluded that the Yamax pedometer can be reliably used for this study population when walking at sufficiently high gait speeds (>1.0 m/s). The accelerometry-based method is less speed-dependent and proved to be more appropriate in the PD patients for walking trajectories of 5 m or more.

Experience-sampling and event-sampling research. In: Arnold B. Bakker und Kevin Daniels: A day in the life of a happy worker.

Hg. v. Arnold B. Bakker und Kevin Daniels. New York, NY US: Psychology Press (Current issues in work and organizational psychology), S. 85–99. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-02788-007%26site%3dehost-live.

Abstract:

(from the chapter) In recent years, an emerging focus on studying within-person processes and phenomena has started to complement traditional between-person research streams that explain how and why construct scores co-vary among individuals (Ilies, Schwind, & Heller, 2007; Ilies et al., 2010). Recent innovations and improvements in technological, analytical, and conceptual areas have helped the field expand rapidly, spurring a greatly increased interest in this research approach. One of the most important of these innovations has been the introduction of the Experience-Sampling Method (ESM; Larson & Csikszentmihalyi, 1983). ESM, in broad terms, aims to utilize a multiple measurement schedule over a set period of time in order to explain fluctuations in episodic experiences (e.g. affective states) and the dynamic antecedents and outcomes of these fluctuations. More specifically, ESM approaches include using a random- or fixed-event or signal-contingent schedule in order to measure the dependent and independent variables at multiple points during an individual's day, typically over a period of multiple days. Data from ESM designs are then commonly used as input in within-person or cross-level multivariate, mediational, or moderational multilevel regression models, using statistical techniques such as Hierarchical Linear Modeling (Raudenbush & Bryk, 2002). In order to contribute to this emerging stream of research, this chapter aims to outline and discuss the basic features of ESM and to examine the advantages and disadvantages of implementing these features in ESM research designs. Moreover, we provide illustrative examples of various types of these designs. We also provide suggestions for future research utilizing ESM in various ways to examine within-person research questions. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (chapter)

Taking fatigue seriously, II: variability in fatigue levels in cancer patients.

In: *Psychosomatics* 48 (3), S. 247–252.

Abstract:

Fatigue is a common and distressing complaint of cancer patients. It is typically measured with symptom inventories that reflect the patient's experience over the previous days or weeks. This study examined short-term variation in fatigue levels in a heterogeneous group of cancer patients over a 3-day period to examine the feasibility of such repeated assessments and to characterize the extent and pattern of fatigue symptoms in cancer patients. Thirty-four cancer outpatients with diverse malignancies wore a prototype fatigue watch monitor for three consecutive 24-hour periods and provided fatigue ratings every hour while awake for the 3 days. Patients completed an average of 40 self-reports over 72 hours. These reports revealed a diurnal variation in fatigue, with increasing levels in the evening. The reports also revealed considerable differences across individuals and within individuals in terms of fatigue ratings. Multiple ratings of fatigue within short periods of time can be obtained and reveal that fatigue levels are quite variable, even within an individual. Cancer patients experience their fatigue as "moderate to extreme" 33% of the time.

Ding, H.; Karunanithi, M.; Duncan, M.; Ireland, D.; Noakes, M.; Hooker, C. (2013):

A mobile phone enabled health promotion program for middle-aged males.

In: *Conf.Proc.IEEE Eng Med.Biol.Soc.* 2013 (1557-170X (Linking)), S. 1173–1176. DOI: 10.1109/EMBC.2013.6609715.

Abstract:

The prevalence of chronic diseases among middle aged males outweigh their female counterparts in developed countries. To prevent this, delivery of health promotion programs targeting lifestyle modifications of physical activity and nutrition in middle-aged males has been essential, but often difficult. ManUp health promotion program was a recent initiative that uses current advances in information and communication technology (ICT) to reach the middle-aged males. One of the key components of the ICT approach was the development of smartphone application to enable middle-aged men to uptake the program with their own mobile phone. The smart phone application was aimed at providing varied level of challenges towards physical activity and healthy eating behavior, with interactive and motivational feedback SMS messages. The ManUp program was recently

implemented and trialed in a randomized control trial in Gladstone and Rockhampton, Queens. This paper describes the components of the smart phone application integrated within the ManUp health promotion program

Dinger, Mary K.; Behrens, Timothy K. (2006):

Accelerometer-determined physical activity of free-living college students.

In: *Med Sci Sports Exerc* 38 (4), S. 774–779.

Abstract:

PURPOSE:

This study was conducted to provide descriptive data of accelerometer-determined ambulatory physical activity in a sample of free-living college students and to examine college students' ambulatory physical activity patterns.

METHODS:

All participants (245 females, age = 19.9 +/- 1.6 yr, body mass index (BMI) = 22.9 +/- 3.3 kg x m(-2); 209 males, age = 20.2 +/- 2.0 yr, BMI = 25.2 +/- 4.0 kg x m(-2)) wore an accelerometer for seven consecutive days. Accumulated physical activity (ct.d, ct x min(-1) x d(-1), and min x d(-1) spent at different intensities) and minutes per day spent in moderate or vigorous physical activity in sessions of at least 10 min were analyzed to describe the physical activity of the sample and examine physical activity patterns.

RESULTS:

The entire sample accumulated 362,750.1 +/- 112,824.1 ct x d(-1) (males = 383,787.2 +/- 112,001.3 vs females = 344,804.1 +/- 110,619.5 ct x d(-1), P < 0.01) and 46.7 +/- 18.9 min x d(-1) in moderate physical activity (males = 51.7 +/- 19.8 vs females = 42.5 +/- 17.0 min x d(-1), P < 0.01). They were more active on weekdays than weekend days (P < 0.05), and they spent 13.6 +/- 12.7 min x d(-1) (males = 13.2 +/- 12.0 vs females = 13.8 +/- 13.3, P > 0.05) in moderate or vigorous physical activity sessions of at least 10 min.

CONCLUSION:

Participants in this study accumulated a moderate amount of physical activity on most weekdays. Most participants, however, were not meeting the current moderate physical activity recommendation when moderate or vigorous physical activity sessions of at least 10 min were examined.

Direito, Artur; Pfaeffli Dale, Leila; Shields, Emma; Dobson, Rosie; Whittaker, Robyn; Maddison, Ralph (2014):

Do physical activity and dietary smartphone applications incorporate evidence-based behaviour change techniques?

In: *BMC Public Health* 14 (1), S. 646. DOI: 10.1186/1471-2458-14-646.

Abstract:

BACKGROUND: There has been a recent proliferation in the development of smartphone applications (apps) aimed at modifying various health behaviours. While interventions that incorporate behaviour change techniques (BCTs) have been associated with greater effectiveness, it is not clear to what extent smartphone apps incorporate such techniques. The purpose of this study was to investigate the presence of BCTs in physical activity and dietary apps and determine how reliably the taxonomy checklist can be used to identify BCTs in smartphone apps. METHODS: The top-20 paid and top-20 free physical activity and/or dietary behaviour apps from the New Zealand Apple App Store Health & Fitness category were downloaded to an iPhone. Four independent raters user-tested and coded each app for the presence/absence of BCTs using the taxonomy of behaviour change techniques (26 BCTs in total). The number of BCTs included in the 40 apps was calculated. Krippendorff's alpha was used to evaluate interrater reliability for each of the 26 BCTs. RESULTS: Apps included an average of 8.1 (range 2-18) techniques, the number being slightly higher for paid (M = 9.7, range 2-18) than free apps (M = 6.6, range 3-14). The most frequently included BCTs were "provide instruction" (83% of the apps), "set graded tasks" (70%), and "prompt self-monitoring" (60%). Techniques such as "teach to use prompts/cues", "agree on behavioural contract", "relapse prevention" and "time management" were not present in the apps reviewed. Interrater reliability coefficients ranged from 0.1 to 0.9 (Mean 0.6, SD = 0.2). CONCLUSIONS: Presence of BCTs varied by app type and price; however, BCTs associated with increased intervention effectiveness were in general more common in paid apps. The taxonomy checklist can be used by independent raters to reliably identify BCTs in physical activity and dietary behaviour smartphone apps.

Dlesk, A.; Kamensky, G.; Stefanik, M.; Kuzma, M.; Pernicky, M. (2014):

Treatment efficiency of resistant hypertension in cardiologist's office.

In: *Bratisl Lek Listy* 115 (1), S. 25–29.

Abstract:

BACKGROUND: The target values of blood pressure have not been achieved in our population of patients sufficiently. The most difficult is a control of patients with resistant hypertension. We do not have data about efficiency treatment of these patients today. OBJECTIVES: The aim of our study was to assess current treatment status and by antihypertensive treatment modification we tried to reach an adequate blood pressure control. METHODS: Fifty two patients suffering from resistant hypertension 2-3 degree ESC/ESH with high cardiovascular risk have been observed. Reaching of the target blood pressure values was verified by 24-hour ambulatory blood pressure monitoring. RESULTS: The target blood pressure values were achieved in 50 % of patients during 18 months. We noticed a statistically significant difference ($p<0.001$) in a decrease of casual and 24-hour ambulatory blood pressure in the group of controlled hypertensive patients in comparison with a group where blood pressure did not decrease sufficiently. In case of 50 % patients, the target blood pressure values have not been reached in spite of more antihypertensive drugs and a higher dose. CONCLUSION: Adequately and systematically controlled patients were treated less intensively in comparison with an inadequately controlled group. 24-hour blood pressure monitoring analysis confirmed correction of the patological diurnal rhythm mostly in adequate blood pressure controlled group. In this group, we have noticed a statistically significant decrease of blood urea and creatinin levels and albumin/creatinin ratio in urine. Resistant hypertension needs multi-faceted approach with consistent control of all comorbidities in a case of problematic blood pressure control (Tab. 6, Fig. 1, Ref. 21).

Doane, Leah D.; Adam, Emma K. (2010):

Loneliness and cortisol: momentary, day-to-day, and trait associations.

In: *Psychoneuroendocrinology* 35 (3), S. 430–441. DOI: 10.1016/j.psyneuen.2009.08.005.

Abstract:

In attempts to understand the social determinants of health, strong associations have been found between measures of loneliness, physiological stress processes, and physical and mental health outcomes. Feelings of loneliness are hypothesized to have implications for physiological stress processes, including activity of the hypothalamic-pituitary-adrenal (HPA) axis. In a community sample of young adults, multilevel modeling was used to examine whether trait and state feelings of loneliness were related to changes in levels of the stress-sensitive hormone cortisol, and whether the associations between loneliness and cortisol were mediated or moderated by the presence of concurrent depression or high levels of chronic life stress. Results indicated that trait loneliness was associated with a flattening of the diurnal cortisol rhythm. In addition, both daily and momentary state variations in loneliness were related to cortisol. Prior day feelings of loneliness were associated with an increased cortisol awakening response the next morning and momentary experiences of loneliness during the day were associated with momentary increases in cortisol among youth who also had high chronic interpersonal stress. Results were significant after covarying current depression, both chronic and momentary reports of stress, and medical and lifestyle covariates. This study expanded on prior work by investigating and revealing three different time courses of association between loneliness and HPA axis activity in young adults: trait, daily and momentary.

Doane, Leah D.; Zeiders, Katharine H. (2013):

Contextual moderators of momentary cortisol and negative affect in adolescents' daily lives.

In: *Journal of Adolescent Health*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-43456-001%26site%3dehost-live.

Abstract:

PURPOSE: To use an ecological momentary assessment design to examine the links between momentary negative affect and cortisol in a sample of adolescents preparing to transition to college. Guided by a risk and resilience framework, we also explored whether important ecological factors, perceived discrimination and social support, moderated the momentary associations between negative affect and youths' cortisol. METHODS: Adolescents (N = 77) provided salivary samples and diary reports of affect and experiences five times a day over 3 days. They also completed self-report questionnaires on perceived discrimination and social support from family and friends. RESULTS: Within-person increases in momentary negative affect were associated with increases in cortisol. Perceived discrimination and social support from friends moderated this association.

Adolescents who reported average and high levels of perceived discrimination experienced exaggerated cortisol responses to negative affect, whereas adolescents who reported low levels of perceived discrimination did not experience significant reactivity to negative affect. In contrast, adolescents who reported high levels of social support from friends experienced attenuated cortisol responses to negative affect compared with adolescents who reported average or low levels of social support from friends. CONCLUSIONS: This study contributes to our understanding of youths' daily socioemotional experiences and physiological reactivity by identifying how perceived discrimination and social support from friends amplified and attenuated, respectively, the effects of negative affect on cortisol reactivity. Examining these processes within adolescents' naturalistic environments advances our understanding of the moderating role of ecological characteristics in adolescents' everyday lives. Dobkin, B. H.; Xu, X.; Batalin, M.; Thomas, S.; Kaiser, W. (2011):

Reliability and validity of bilateral ankle accelerometer algorithms for activity recognition and walking speed after stroke.

In: *Stroke* 42 (8), S. 2246–2250. DOI: 10.1161/STROKEAHA.110.611095.

Abstract:

BACKGROUND AND PURPOSE: Outcome measures of mobility for large stroke trials are limited to timed walks for short distances in a laboratory, step counters and ordinal scales of disability and quality of life. Continuous monitoring and outcome measurements of the type and quantity of activity in the community would provide direct data about daily performance, including compliance with exercise and skills practice during routine care and clinical trials. METHODS: Twelve adults with impaired ambulation from hemiparetic stroke and 6 healthy controls wore triaxial accelerometers on their ankles. Walking speed for repeated outdoor walks was determined by machine-learning algorithms and compared to a stopwatch calculation of speed for distances not known to the algorithm. The reliability of recognizing walking, exercise, and cycling by the algorithms was compared to activity logs. RESULTS: A high correlation was found between stopwatch-measured outdoor walking speed and algorithm-calculated speed (Pearson coefficient, 0.98; P=0.001) and for repeated measures of algorithm-derived walking speed (P=0.01). Bouts of walking >5 steps, variations in walking speed, cycling, stair climbing, and leg exercises were correctly identified during a day in the community. Compared to healthy subjects, those with stroke were, as expected, more sedentary and slower, and their gait revealed high paretic-to-unaffected leg swing ratios. CONCLUSIONS: Test-retest reliability and concurrent and construct validity are high for activity pattern-recognition Bayesian algorithms developed from inertial sensors. This ratio scale data can provide real-world monitoring and outcome measurements of lower extremity activities and walking speed for stroke and rehabilitation studies

A comparison of affect ratings obtained with ecological momentary assessment and the day reconstruction method.

In: *Social Indicators Research* 99 (2), S. 269–283.

Abstract:

Measurement of affective states in everyday life is of fundamental importance in many types of quality of life, health, and psychological research. Ecological momentary assessment (EMA) is the recognized method of choice, but the respondent burden can be high. The day reconstruction method (DRM) was developed by Kahneman and colleagues (Science, 2004, 306, 1776-1780) to assess affect, activities and time use in everyday life. We sought to validate DRM affect ratings by comparison with contemporaneous EMA ratings in a sample of 94 working women monitored over work and leisure days. Six EMA ratings of happiness, tiredness, stress, and anger/frustration were obtained over each 24 h period, and were compared with DRM ratings for the same hour, recorded retrospectively at the end of the day. Similar profiles of affect intensity were recorded with the two techniques. The between-person correlations adjusted for attenuation ranged from 0.58 (stress, working day) to 0.90 (happiness, leisure day). The strength of associations was not related to age, educational attainment, or depressed mood. We conclude that the DRM provides reasonably reliable estimates both of the intensity of affect and variations in affect over the day, so is a valuable instrument for the measurement of everyday experience in health and social research.

Doherty, Sean T.; Lemieux, Christopher J.; Canally, Culum (2014):

Tracking human activity and well-being in natural environments using wearable sensors and experience sampling.

In: *Soc Sci Med* 106, S. 83–92. DOI: 10.1016/j.socscimed.2014.01.048.

Abstract:

A growing range of studies have begun to document the health and well-being benefits associated with contact with nature. Most studies rely on generalized self-reports following engagement in the natural environment. The actual in-situ experience during contact with nature, and the environmental features and factors that evoke health benefits have remained relatively unexplored. Smartphones offer a new opportunity to monitor and interact with human subjects during everyday life using techniques such as Experience Sampling Methods (ESM) that involve repeated self-reports of experiences as they occur in-situ. Additionally, embedded sensors in smartphones such as Global Positioning Systems (GPS) and accelerometers can accurately trace human activities. This paper explores how these techniques can be combined to comprehensively explore the perceived health and well-being impacts of contact with nature. Custom software was developed to passively track GPS and accelerometer data, and actively prompt subjects to complete an ESM survey at regular intervals throughout their visit to a provincial park in Ontario, Canada. The ESM survey includes nine scale questions concerning moods and emotions, followed by a series of open-ended experiential questions that subjects provide recorded audio responses to. Pilot test results are used to illustrate the nature, quantity and quality of data obtained. Participant activities were clearly evident from GPS maps, including especially walking, cycling and sedate activities. From the ESM surveys, participants reported an average of 25 words per question, taking an average of 15 s to record them. Further qualitative analysis revealed that participants were willing to provide considerable insights into their experiences and perceived health impacts. The combination of passive and interactive techniques is sure to make larger studies of this type more affordable and less burdensome in the future, further enhancing the ability to understand how contact with nature enhances health and well-being.

Doherty, S. T.; Oh, P. (2012):

A multi-sensor monitoring system of human physiology and daily activities.

In: *Telemed.J.E.Health* 18 (3), S. 185–192. DOI: 10.1089/tmj.2011.0138.

Abstract:

OBJECTIVE: To present the design and pilot test results of a continuous multi-sensor monitoring system of real-world physiological conditions and daily life (activities, travel, exercise, and food consumption), culminating in a Web-based graphical decision-support interface. MATERIALS AND METHODS: The system includes a set of wearable sensors wirelessly connected to a "smartphone" with a continuously running software application that compresses and transmits the data to a central server. Sensors include a Global Positioning System (GPS) receiver, electrocardiogram (ECG), three-axis accelerometer, and continuous blood glucose monitor. A food/medicine diary and prompted recall activity diary were also used. The pilot test involved 40 type 2 diabetic patients monitored over a 72-h period. RESULTS: All but three subjects were successfully monitored for the full study period. Smartphones proved to be an effective hub for managing multiple streams of data but required attention to data compression and battery consumption issues. ECG, accelerometer, and blood glucose devices performed adequately as long as subjects wore them. GPS tracking for a full day was feasible, although significant efforts are needed to impute missing data. Activity detection algorithms were successful in identifying activities and trip modes but could benefit by incorporating accelerometer data. The prompted recall diary was an effective tool for augmenting algorithm results, although subjects reported some difficulties with it. The food and medicine diary was completed fully, although end times and medicine dosages were occasionally missing. CONCLUSIONS: The unique combination of sensors holds promise for increasing accuracy and reducing burden associated with collecting individual-level activity and physiological data under real-world conditions, but significant data processing issues remain. Such data will provide new opportunities to explore the impacts of human geography and daily lifestyle on health at a fine spatial/temporal scale

Dolan, Eamon; Li, Yan; Thijs, Lutgarde; McCormack, Patricia; Staessen, Jan A.; O'Brien, Eoin; Stanton, Alice (2006):

Ambulatory arterial stiffness index: rationale and methodology.

In: *Blood Press Monit* 11 (2), S. 103–105.

Abstract:

OBJECTIVES:

Increased arterial stiffness is associated with the development of cardiovascular disease and may even predict its development at an early stage. Increased pulse pressure is seen as a marker of increased arterial stiffness and can be readily measured by

ambulatory blood pressure monitoring. We propose another surrogate measure of arterial stiffness derived from ambulatory blood pressure monitoring that may predict cardiovascular mortality over and above pulse pressure, namely, the dynamic relationship between diastolic and systolic blood pressure over 24 h--the ambulatory arterial stiffness index.

METHODS:

Using all blood pressure readings over the 24-h period from 11 291 (5965 women; mean age 54.6 years) patients referred for ambulatory blood pressure monitoring to a blood pressure clinic, diastolic blood pressure was plotted against systolic blood pressure, and the regression slope was calculated; ambulatory arterial stiffness index was defined as one minus this regression slope.

RESULTS:

Both ambulatory arterial stiffness index and pulse pressure were higher in women (0.42 vs. 0.40 and 57.0 vs. 55.3 mmHg, respectively). For the entire group, the correlation between ambulatory arterial stiffness index and pulse pressure was 0.5.

CONCLUSIONS:

Ambulatory arterial stiffness index is a new measure that is readily available from ambulatory blood pressure monitoring and may provide added prognostic information for cardiovascular outcome.

Dolezsar, Cynthia M.; McGrath, Jennifer J.; Herzig, Alyssa J. M.; Miller, Sydney B. (2014):

Perceived racial discrimination and hypertension: a comprehensive systematic review.

In: *Health Psychol* 33 (1), S. 20–34. DOI: 10.1037/a0033718.

Abstract:

OBJECTIVE: Discrimination is posited to underlie racial disparities in hypertension. Extant literature suggests a possible association between racial discrimination and blood pressure, although inconsistent findings have been reported. The aim of this comprehensive systematic review was to quantitatively evaluate the association between perceived racial discrimination with hypertensive status and systolic, diastolic, and ambulatory blood pressure. METHOD: Electronic database search of PubMed and PsycINFO (keywords: blood pressure/hypertension/diastolic/systolic, racism/discrimination/prejudice/unfair treatment) was combined with descendancy and ascendancy approaches. Forty-four articles (N = 32,651) met inclusion criteria. Articles were coded for demographics, hypertensive diagnosis, blood pressure measurement, discrimination measure and constructs, study quality, and effect sizes. RESULTS: Random effects meta-analytic models were tested based on Fisher's Z, the derived common effect size metric. Overall, perceived racial discrimination was associated with hypertensive status, Zhypertension = 0.048, 95% CI [.013, .087], but not with resting blood pressure, Zsystolic = 0.011, 95% CI [-.006, .031], Zdiastolic = .016, 95% CI [-.006, .034]. Moderators that strengthened the relation included sex (male), race (Black), age (older), education (lower), and hypertensive status. Perceived discrimination was most strongly associated with nighttime ambulatory blood pressure, especially among Blacks. CONCLUSIONS: Despite methodological limitations in the existing literature, there was a small, significant association between perceived discrimination and hypertension. Future studies should consider ambulatory nighttime blood pressure, which may more accurately capture daily variation attributable to experienced racial discrimination. Perceived discrimination may partly explain racial health disparities.

Domene, Pablo A.; Easton, Chris (2014):

Combined triaxial accelerometry and heart rate telemetry for the physiological characterization of latin dance in non-professional adults.

In: *J Dance Med Sci* 18 (1), S. 29–36. DOI: 10.12678/1089-313X.18.1.29.

Abstract:

The purpose of this study was to value calibrate, cross-validate, and determine the reliability of a combined triaxial accelerometry and heart rate telemetry technique for characterizing the physiological and physical activity parameters of Latin dance. Twenty-two non-professional adult Latin dancers attended two laboratory-based dance trials each. After familiarization and a standardized warm-up, a multi-stage (3 x 5-minute) incremental (based on song tempo) Afro-Cuban salsa choreography was performed while following a video displayed on a projection screen. Data were collected with a portable indirect calorimeter, a heart rate telemeter, and wrist-, hip-, and ankle-mounted ActiGraph GT3X+ accelerometers. Prediction equations for energy expenditure and step count were value calibrated using forced entry multiple regression and cross-validated using a delete-one jackknife approach with additional Bland-Altman analysis. The average dance intensity reached 6.09 +/- 0.96 kcal/kg/h and demanded 45.9 +/- 11.3% of the heart rate reserve. Predictive ability of the derived models was satisfactory, where R(2) = 0.80; SEE = 0.44 kcal/kg/h and R(2) = 0.74; SEE = 3 step/min for energy expenditure and step count, respectively. Dependent t-tests indicated no differences between predicted and measured values for both energy expenditure (t65 = -0.25, p

= 0.80) and step count (t65 = -0.89, p = 0.38). The 95% limits of agreement for energy expenditure and step count were -0.98 to 0.95 kcal/kg/h and -7 to 7 step/min, respectively. Latin dance to salsa music elicits physiological responses representative of moderate to vigorous physical activity, and a wrist-worn accelerometer with simultaneous heart rate measurement constitutes a valid and reliable technique for the prediction of energy expenditure and step count during Latin dance.

Donaire-Gonzalez, David; Nazelle, Audrey; Seto, Edmund; Mendez, Michelle; Nieuwenhuijsen, Mark J.; Jerrett, Michael (2013):

Comparison of physical activity measures using mobile phone-based CalFit and actigraph.

In: *J Med Internet Res* 15 (6), S. 67–77. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-26855-006%26site%3dehost-live;mnieuwenhuijsen@creal.cat.

Abstract:

Background: Epidemiological studies on physical activity often lack inexpensive, objective, valid, and reproducible tools for measuring physical activity levels of participants. Novel sensing technologies built into smartphones offer the potential to fill this gap. Objective: We sought to validate estimates of physical activity and determine the usability for large population-based studies of the smartphone-based CalFit software. Methods: A sample of 36 participants from Barcelona, Spain, wore a smartphone with CalFit software and an Actigraph GT3X accelerometer for 5 days. The ease of use (usability) and physical activity measures from both devices were compared, including vertical axis counts (VT) and duration and energy expenditure predictions for light, moderate, and vigorous intensity from Freedson's algorithm. Statistical analyses included (1) Kruskal-Wallis rank sum test for usability measures, (2) Spearman correlation and linear regression for VT counts, (3) concordance correlation coefficient (CCC), and (4) Bland-Altman plots for duration and energy expenditure measures. Results: Approximately 64% (23/36) of participants were women. Mean age was 31 years (SD 8) and mean body mass index was 22 kg/m-^{2} (SD 2). In total, 25/36 (69%) participants recorded at least 3 days with at least 10 recorded hours of physical activity using CalFit. The linear association and correlations for VT counts were high (adjusted R-^{2} = 0.85; correlation coefficient .932, 95% CI 0.931-0.933). CCCs showed high agreement for duration and energy expenditure measures (from 0.83 to 0.91). Conclusions: The CalFit system had lower usability than the Actigraph GT3X because the application lacked a means to turn itself on each time the smartphone was powered on. The CalFit system may provide valid estimates to quantify and classify physical activity. CalFit may prove to be more cost-effective and easily deployed for large-scale population health studies than other specialized instruments because cell phones are already carried by many people. Dong, Hui; Jiang, Xiongjing; Liang, Tuo; Zou, Yubao; Guan, Ting; Peng, Meng et al. (2014):

One-year outcomes of percutaneous renal denervation for the treatment of resistant hypertension: the first Chinese experience.

In: *Chin Med J (Engl)* 127 (6), S. 1003–1007.

Abstract:

BACKGROUND: As a novel device-based approach targeting the renal sympathetic nerves, percutaneous renal denervation (RDN) has been shown to be effective and safe for reducing blood pressure. However, while considerable data on RDN have been obtained from Western populations, there is limited findings from East Asian populations. The purpose of this study was to evaluate one-year outcomes of RDN for the treatment of resistant hypertension in Chinese patients. METHODS: Between February and August 2012, 14 patients (mean age 39+/-8 years, 10 males) with resistant hypertension underwent successful RDN at the Fuwai Hospital. All 14 patients were followed up at 1, 3, 6 and 12 months post-procedure. Blood pressure, use of antihypertensive agents, renal function, and complications were investigated. RESULTS: Baseline values included mean office blood pressure of 164/103+/-14/10 mmHg, mean 3.9+/-0.6 anti-hypertensive agents, and an estimated glomerular filtration rate of (79+/-19) mlxmin(-1)x1.73 m(-2). Office blood pressure after the procedure was reduced by -14/-10, -17/-11, -21/-12, and -24/-14 mmHg at 1, 3, 6, and 12 months respectively, and the reduction of the number of antihypertensive agents at the above corresponding time points was -1.3, -1.5, -1.7 and -1.8 respectively (all P < 0.001). The mean reduction of 24-hour ambulatory blood pressure was similar to the reduction of office blood pressure at the four corresponding time points. Renal function did not significantly change at any time point (all P > 0.05). No clinical complications were observed at 12-month follow-up. CONCLUSION: This study showed that RDN seems to be effective in reducing blood pressure of Chinese patients with resistant hypertension, with minimal adverse events at 12-month follow-up.

Dopp, R. R.; Mooney, A. J.; Armitage, R.; King, C. (2012):

Exercise for adolescents with depressive disorders: a feasibility study.

In: *Depress.Res Treat.* 2012 (2090-1321 (Linking)), S. 257472. DOI: 10.1155/2012/257472.

Abstract:

Objectives. Adolescence is associated with increased depressive symptoms and decreased aerobic exercise, yet the relationship between exercise and clinical depression among adolescents requires further examination. This study assessed the feasibility of a 12-week intervention designed to increase exercise for adolescents with depressive disorders: Will a teenager with depression exercise? Methods. Participants were 13 adolescents with depression reporting low levels of aerobic exercise. They completed a 12-week intervention (15 supervised exercise sessions and 21 independent sessions). Exercise was measured through the aerobic exercise Questionnaire, actigraphy, and heart-rate monitoring. Depression was measured with the Children's Depression Rating Scale, Revised, and Quick Inventory of Depressive Symptomatology, Self-Report. Results. All participants who started the intervention completed the protocol, attending all supervised exercise sessions. Actigraphy verified 81% adherence to the protocol's independent sessions. Analysis of secondary outcomes showed a significant increase in exercise levels and a significant decrease in depression severity. Initially, ten participants were overweight or obese, and three were healthy weight. After 12 weeks of exercise, the number of participants in the healthy-weight category doubled. Conclusions. Adolescents suffering from depression can complete a rigorous protocol requiring structured increases in aerobic exercise. Participants showed significant increases in exercise, and significant decreases in depressive symptoms

Dores, Helder; Sousa Almeida, Manuel; Araujo Goncalves, Pedro; Branco, Patricia; Gaspar, Augusta; Sousa, Henrique et al. (2014):

Renal denervation in patients with resistant hypertension: 6-month results.

In: *Rev Port Cardiol. DOI:* 10.1016/j.repc.2013.09.008.

Abstract:

INTRODUCTION: The increase of activation of sympathetic nervous system has a central role in the pathophysiology of hypertension (HT). Catheter-based renal denervation (RDN) was recently developed for the treatment of resistant HT. AIM: To evaluate the safety and efficacy of RDN in HT reduction at 6-months in patients with resistant HT. METHODS: Prospective registry of patients with essential resistant HT, submitted to RDN between July-2011 and May-2013. The efficacy of RDN was defined as >/=10mmHg reduction in office systolic blood pressure (SBP), 6-months after the intervention. RESULTS: In a resistant HT outpatient clinic, 177 consecutive patients were evaluated, of whom 34 were submitted to RDN (age 62.7+/-7.6 years old; 50,0% male). There were no vascular complications, namely of the access or the renal arteries. Of the 22 patients with complete 6-months follow-up, the response rate was 81.8% (n=18). The mean office SBP reduction was 22mmHg (174+/-23 vs. 152+/-22mmHg; p <0.001) and diastolic 9mmHg (89+/-16 vs. 80+/-11mmHg; p=0.006). The number of antihypertensive drugs (5.5+/-1.0 vs. 4.6+/-1.1; p=0.010) and pharmacological classes (5.4+/-0.7 vs. 4.6+/-1,1; p=0.009) were also significantly reduced. Among the 24h ambulatory blood pressure monitoring and echocardiographic parameters analysed, there were a significantly reduction in the percentage of diastolic load (45+/-29 vs. 27+/-26%; p=0.049) and in the left ventricular mass index (174+/-56 vs. 158+/-60g/m2; p=0.014). CONCLUSION: In this cohort of patients with resistant HT submitted to RDN, this intervention was safe and effective, with a significant blood pressure reduction at 6 months follow-up.

Accelerometer-Measured Versus Self-reported Physical Activity in College Students: Implications for Research and Practice.

In: *J Am Coll Health* 62 (3), S. 204–212. DOI: 10.1080/07448481.2013.877018.

Abstract:

Abstract Objective: To determine the level of moderate-vigorous-intensity physical activity (MVPA) assessed via self-report and accelerometer in the college population, and to examine intrapersonal and contextual variables associated with physical activity (PA). Participants: Participants were 77 college students at a university in the northwest sampled between January 2011 and December 2011. Methods: Participants completed a validated self-report measure of PA and measures of athletic identity and benefits and barriers to exercise. Participants' PA levels were assessed for 2 weeks via accelerometry. Results: Participants' estimations of their time spent engaged in MVPA were significantly higher when measured via self-report versus accelerometry. Stronger athletic identity, perceived social benefits and barriers, and time-effort barriers were related to PA levels. Conclusions: Estimation of college students' level of PA may require interpretation of data from different measurement methods, as self-report and accelerometry generate different estimations of PA in college students who may be even less active than previously believed.

Results of a pilot test of a self-administered smartphone-based treatment system for alcohol use disorders: Usability and early outcomes.

In: *Substance Abuse* 35 (2), S. 168–175. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-21230-014%26site%3dehost-live.

Abstract:

ABSTRACT. Background: This paper provides results from a pilot study focused on assessing early-stage effectiveness and usability of a smartphone-based intervention system that provides a stand-alone, self-administered intervention option, the Location-Based Monitoring and Intervention for Alcohol Use Disorders (LBMI-A). The LBMI-A provided numerous features for intervening with ongoing drinking, craving, connection with supportive others, managing life problems, high-risk location alerting, and activity scheduling. Methods: Twenty-eight participants, ranging in age from 22 to 45, who met criteria for an alcohol use disorder used an LBMI-A–enabled smartphone for 6 weeks. Results: Participants indicated the LBMI-A intervention modules were helpful in highlighting alcohol use patterns. Tools related to managing alcohol craving, monitoring consumption, and identifying triggers to drink were rated by participants as particularly helpful. Participants also demonstrated significant reductions in hazardous alcohol use while using the system (56% of days spent hazardously drinking at baseline vs. 25% while using the LBMI-A) and drinks per day diminished by 52%. Conclusions: Implications for system improvement as well as suggestions for designing ecological momentary assessment and intervention systems for substance use disorders are discussed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Measuring slope to improve energy expenditure estimates during field-based activities.

In: *Appl.Physiol Nutr.Metab* 38 (3), S. 352–356. DOI: 10.1139/apnm-2012-0223.

Abstract:

This technical note describes methods to improve activity energy expenditure estimates by using a multi-sensor board (MSB) to measure slope. Ten adults walked over a 4-km (2.5-mile) course wearing an MSB and mobile calorimeter. Energy expenditure was estimated using accelerometry alone (base) and 4 methods to measure slope. The barometer and global positioning system methods improved accuracy by 11% from the base ($p < 0.05$) to 86% overall. Measuring slope using the MSB improves energy expenditure estimates during field-based activities

Neighborhood park use by children: use of accelerometry and global positioning systems.

In: *Am J Prev Med* 46 (2), S. 136–142. DOI: 10.1016/j.amepre.2013.10.009.

Abstract:

BACKGROUND: Although having a greater number of neighborhood parks may be associated with greater overall physical activity in children, information is lacking about the extent to which children actually use parks for physical activity. PURPOSE: This study combined accelerometer, GPS, GIS, and self-report methods to examine neighborhood park availability, perceived proximity, and use for physical activity in children. METHODS: Low- to middle-income children (aged 8-14 years) (n=135) from suburban communities in Southern California wore an Actigraph accelerometer and GlobalSat BT-335 GPS device across 7 days to measure physical activity and park use, respectively. ArcGIS identified parks within a 500-m residential buffer of children's homes. Parents reported perceptions of neighborhood park proximity through the Neighborhood Environment Walkability Survey (NEWS). Data were collected from March 2009 to December 2010, and analyzed in 2013. RESULTS: Fifty-four percent of families lived within 500 m of a park. Of these children, GPS data indicated that 16% used it more than 15 minutes and an additional 11% of children used it between 5 and 15 minutes during the 7-day study period. The odds of extended park use (>15 minutes) increased fourfold when the distance between home and the nearest neighborhood park decreased by 100 m. Additionally, the odds of any park use (>5 minutes) doubled when moving from the 25th to the 75th percentile for park greenness/vegetation density. CONCLUSIONS: Although children's use of neighborhood parks was generally low, it increased substantially when parks were closer to children's homes and had greater vegetation density.

Development of a smartphone application to measure physical activity using sensor-assisted self-report.

In: *Front Public Health* 2, S. 12. DOI: 10.3389/fpubh.2014.00012.

Abstract:

Introduction: Despite the known advantages of objective physical activity monitors (e.g., accelerometers), these devices have high rates of non-wear, which leads to missing data. Objective activity monitors are also unable to capture valuable contextual information about behavior. Adolescents recruited into physical activity surveillance and intervention studies will increasingly have smartphones, which are miniature computers with built-in motion sensors. Methods: This paper describes the design and development of a smartphone application ("app") called Mobile Teen that combines objective and self-report assessment strategies through (1) sensor-informed context-sensitive ecological momentary assessment (CS-EMA) and (2) sensor-assisted end-of-day recall. Results: The Mobile Teen app uses the mobile phone's built-in motion sensor to automatically detect likely bouts of phone non-wear, sedentary behavior, and physical activity. The app then uses transitions between these inferred states to trigger CS-EMA self-report surveys measuring the type, purpose, and context of activity in real-time. The end of the day recall component of the Mobile Teen app allows users to interactively review and label their own physical activity data each evening using visual cues from automatically detected major activity transitions from the phone's built-in motion sensors. Major activity transitions are identified by the app, which cues the user to label that "chunk," or period, of time using activity categories. Conclusion: Sensor-driven CS-EMA and end-of-day recall smartphone apps can be used to augment physical activity data collected by objective activity monitors, filling in gaps during non-wear bouts and providing additional real-time data on environmental, social, and emotional correlates of behavior. Smartphone apps such as these have potential for affordable deployment in large-scale epidemiological and intervention studies.

Dunton, Genevieve F.; Huh, Jimi; Leventhal, Adam M.; Riggs, Nathaniel; Hedeker, Donald; Spruijt-Metz, Donna; Pentz, Mary Ann (2014):

Momentary assessment of affect, physical feeling states, and physical activity in children.

In: *Health Psychol* 33 (3), S. 255–263. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-16576-001%26site%3dehost-live.

Abstract:

Objective: Most research on the interplay of affective and physical feelings states with physical activity in children has been conducted under laboratory conditions and fails to capture intraindividual covariation. The current study used Ecological Momentary Assessment (EMA) to bidirectionally examine how affective and physical feeling states are related to objectively

measured physical activity taking place in naturalistic settings during the course of children's everyday lives. Methods: Children (N = 119, ages 9–13 years, 52% male, 32% Hispanic) completed 8 days of EMA monitoring, which measured positive affect (PA), negative affect (NA), feeling tired, and feeling energetic up to 7 times per day. EMA responses were time-matched to accelerometer assessed moderate-to-vigorous physical activity (MVPA) in the 30 min before and after each EMA survey. Results: Higher ratings of feeling energetic and lower ratings of feeling tired were associated with more MVPA in the 30 min after the EMA prompt. More MVPA in the 30 min before the EMA prompt was associated with higher ratings of PA and feeling energetic and lower ratings of NA. Between-subjects analyses indicated that mean hourly leisure-time MVPA was associated with less intraindividual variability in PA and NA. Conclusions: Physical feeling states predict subsequent physical activity levels, which in turn, predict subsequent affective states in children. Active children demonstrated higher positive and negative emotional stability. Although the strength of these associations were of modest magnitude and their clinical relevance is unclear, understanding the antecedents to and consequences of physical activity may have theoretical and practical implications for the maintenance and promotion of physical activity and psychological well-being in children. Dunton, G. F.; Intille, S. S.; Wolch, J.; Pentz, M. A. (2012):

Investigating the impact of a smart growth community on the contexts of children's physical activity using Ecological Momentary Assessment.

In: *Health Place* 18 (1), S. 76–84. DOI: 10.1016/j.healthplace.2011.07.007.

Abstract:

This quasi-experimental research used Ecological Momentary Assessment with electronic surveys delivered through mobile phones to determine whether children change the type of contexts (i.e., settings) where they engage in physical activity after a recent move to a smart growth (SG) community in the U.S. as compared to children living in conventional low-to-medium density U.S. suburban communities (controls). SG vs. control children engaged in a greater proportion of physical activity bouts with friends, a few blocks from home, and at locations to which they walked. Over six months, the proportion of physical activity bouts reported at home (indoors) and in high traffic locations decreased among SG but not control children. Six-month increases in daily moderate-to-vigorous physical activity did not significantly differ by group. Children might have altered the type of contexts where they engage in physical activity after moving to SG communities, yet more time may be necessary for these changes to impact overall physical activity

Dunton, G. F.; Kawabata, K.; Intille, S.; Wolch, J.; Pentz, M. A. (2012):

Assessing the social and physical contexts of children's leisure-time physical activity: an ecological momentary assessment study.

In: *Am.J.Health Promot.* 26 (3), S. 135–142. DOI: 10.4278/ajhp.100211-QUAN-43.

Abstract:

PURPOSE: To use Ecological Momentary Assessment with mobile phones to describe where and with whom children's leisure-time physical activity occurs. DESIGN: Repeated assessments across 4 days (Friday-Monday) during nonschool time (20 total). SETTING: Chino, California, and surrounding communities. SUBJECTS: Primarily low to middle income children (N =121; aged 9-13 years; x =11.0 years, SD =1.2 years; 52% male, 38% Hispanic/Latino). MEASURES: Electronic surveys measured current activity (e.g., active play/sports/exercise, watching TV/movies), social company (e.g., family, friends, alone), physical location (e.g., home, outdoors, school), and other perceived contextual features (e.g., safety, traffic, vegetation, distance from home). Analysis . Multilevel linear and multinomial logistic regression. RESULTS: Most of children's physical activity occurred outdoors (away from home) (42%), followed by at home (indoors) (30%), front/backyard (at home) (8%), someone else's house (8%), at a gym/recreation center (3%), and other locations (9%). Children's physical activity took place most often with multiple categories of people together (e.g., friends and family) (39%), followed by family members only (32%), alone (15%), and with friends only (13%). Age, weight status, income, and racial/ethnic differences in physical activity contexts were observed. CONCLUSIONS: The most frequently reported contexts for children's leisure time physical activity were outdoors and with family members and friends together

Dunton, Genevieve F.; Liao, Yue; Intille, Stephen; Wolch, Jennifer; Pentz, Mary Ann (2011):

Physical and social contextual influences on children's leisure-time physical activity: an ecological momentary assessment study.

In: *J Phys Act Health* 8 (1), S. S103.

Abstract:

BACKGROUND:

This study used real-time electronic surveys delivered through mobile phones, known as Ecological Momentary Assessment (EMA), to determine whether level and experience of leisure-time physical activity differ across children's physical and social contexts.

METHODS:

Children (N = 121; ages 9 to 13 years; 52% male, 32% Hispanic/Latino) participated in 4 days (Fri.-Mon.) of EMA during nonschool time. Electronic surveys (20 total) assessed primary activity (eg, active play/sports/exercise), physical location (eg, home, outdoors), social context (eg, friends, alone), current mood (positive and negative affect), and enjoyment. Responses were time-matched to the number of steps and minutes of moderate-to-vigorous physical activity (MVPA; measured by accelerometer) in the 30 minutes before each survey.

RESULTS:

Mean steps and MVPA were greater outdoors than at home or at someone else's house (all P < .05). Steps were greater with multiple categories of company (eg, friends and family together) than with family members only or alone (all P < .05). Enjoyment was greater outdoors than at home or someone else's house (all P < .05). Negative affect was greater when alone and with family only than friends only (all P < .05).

CONCLUSION:

Results describing the value of outdoor and social settings could inform context-specific interventions in this age group.

Momentary assessment of adults' physical activity and sedentary behavior: feasibility and validity.

In: *Front Psychol* 3 (1664-1078 (Electronic)), S. 260. DOI: 10.3389/fpsyg.2012.00260.

Abstract:

Introduction: Mobile phones are ubiquitous and easy to use, and thus have the capacity to collect real-time data from large numbers of people. Research tested the feasibility and validity of an Ecological Momentary Assessment (EMA) self-report protocol using electronic surveys on mobile phones to assess adults' physical activity and sedentary behaviors. Methods: Adults (N = 110; 73% female, 30% Hispanic, 62% overweight/obese) completed a 4-day signal-contingent EMA protocol (Saturday-Tuesday) with eight surveys randomly spaced throughout each day. EMA items assessed current activity (e.g., Watching TV/Movies, Reading/Computer, Physical Activity/Exercise). EMA responses were time-matched to minutes of moderate-to-vigorous physical activity (MVPA) and sedentary activity (SA) measured by accelerometer immediately before and after each EMA prompt. Results: Unanswered EMA prompts had greater MVPA (+/-15 min) than answered EMA prompts (p = 0.029) for under/normal weight participants, indicating that activity level might influence the likelihood of responding. The 15-min. intervals before versus after the EMA-reported physical activity (n = 296 occasions) did not differ in MVPA (p > 0.05), suggesting that prompting did not disrupt physical activity. SA decreased after EMA-reported sedentary behavior (n = 904 occasions; p < 0.05) for overweight and obese participants. As compared with other activities, EMA-reported physical activity and sedentary behavior had significantly greater MVPA and SA, respectively, in the +/-15 min of the EMA prompt (ps < 0.001), providing evidence for criterion validity. Conclusion: Findings generally support the acceptability and validity of a 4-day signal-contingent EMA protocol using mobile phones to measure physical activity and sedentary behavior in adults. However, some MVPA may be missed among underweight and normal weight individuals

Dzierzewski, Joseph M.; Fung, Constance H.; Jouldjian, Stella; Alessi, Cathy A.; Irwin, Michael R.; Martin, Jennifer L. (2014):

Decrease in daytime sleeping is associated with improvement in cognition after hospital discharge in older adults.

In: *J Am Geriatr Soc* 62 (1), S. 47–53.

Abstract:

OBJECTIVES: To examine the relationship between changes in objectively assessed sleep and global cognitive functioning from inpatient postacute rehabilitation to 6-month follow-up. DESIGN: Secondary analysis of two prospective, longitudinal studies. SETTING: Inpatient rehabilitation units at a Veterans Affairs Medical Center. PARTICIPANTS: Older adults (mean age 73.8 +/- 9.4) undergoing inpatient rehabilitation (n = 192). MEASUREMENTS: All participants completed 7 nights and days of ambulatory sleep monitoring using wrist actigraphy (yielding an estimate of nighttime wakefulness and daytime sleep) and the Mini-Mental State Examination (MMSE) during a postacute inpatient rehabilitation stay and 6 months after discharge. The 5-item Geriatric Depression Scale, Geriatric Pain Measure, and Cumulative Illness Rating Scale for Geriatrics were completed during inpatient rehabilitation. RESULTS: Growth curve modeling (controlling for baseline age, education, sex, body mass index, depression, pain, and comorbidity burden) revealed that individuals whose amount of daytime sleep decreased from inpatient postacute rehabilitation to 6-month follow-up also experienced improvements in MMSE score (beta = -0.01, t(80 = -3.22, P = .002)). Change in nighttime wakefulness was not a significant predictor of change in MMSE score. CONCLUSION: Older adults whose daytime sleeping decreased after hospital discharge also experienced improvements in cognitive functioning at 6 month follow-up. As such, daytime sleep may represent a promising candidate for targeted interventions aimed at promoting cognitive recovery after hospital discharge.

Ebenfeld, Lara; Kleine Stegemann, Stefan; Lehr, Dirk; Ebert, David Daniel; Jazaieri, Hooria; van Ballegooijen, Wouter et al. (2014):

Efficacy of a hybrid online training for panic symptoms and agoraphobia: study protocol for a randomized controlled trial.

In: *Trials* 15, S. 427. DOI: 10.1186/1745-6215-15-427.

Abstract:

BACKGROUND: Recently, internet-based interventions have been proposed as effective treatments for people with panic disorder (PD). However, little is known about the clinical effects of integrating mobile technology into these interventions. Because users carry their smartphones with them throughout the day, we hypothesize that this technology can be used to significantly support individuals with monitoring and overcoming their PD symptoms. The aim of the present study is to evaluate the efficacy and cost-effectiveness of a newly developed hybrid intervention that combines internet/PC with smartphone delivery to treat the symptoms of PD. The intervention is based on cognitive behavioral therapy and consists of six modules over a total of six weeks. METHODS/DESIGN: A two-arm randomized controlled trial (RCT) will be conducted to evaluate the effects of a hybrid online training module for PD. Based on a power calculation (d =0.60; 1-beta of 80%; alpha =0.05), 90 participants with mild to moderate panic symptoms with or without agoraphobia (as assessed by the Panic and Agoraphobia Scale) will be recruited from the general population and randomly assigned to either the intervention group or a six-month waitlist control group. The primary outcome measure will be the severity of panic symptoms. Secondary outcomes will include depression, quality of life, and an observer-based rating of panic severity. Furthermore, data regarding acceptance and the usability of the smartphone app will be assessed. Assessments will take place at baseline as well as eight weeks, three months, and six months after randomization. Moreover, a cost-effectiveness analysis will be performed from a societal perspective. Data will be analyzed on an intention-to-treat basis and per protocol. DISCUSSION: To our knowledge, this RCT is one of the first to examine the efficacy of a hybrid online training for adult PD. This study seeks to contribute to the emerging field of hybrid online training. If the intervention is efficacious, then research on this hybrid online training should be extended. The cost-effectiveness analysis will also indicate whether online training is an economical tool for treating PD among adults. TRIAL REGISTRATION: German Clinical Trial Register: DRKS00005223 (registered on 15 August 2013).

Ebner-Priemer, Ulrich W.; Eid, Michael; Kleindienst, Nikolaus; Stabenow, Simon; Trull, Timothy J. (2009):

Analytic strategies for understanding affective (in)stability and other dynamic processes in psychopathology.

In: *Journal of Abnormal Psychology* 118 (1), S. 195–202. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2009-01738-010&site=ehost-live;ulrich.ebner-priemer@zi-mannheim.de.

Abstract:

The dynamics of psychopathological symptoms as a topic of research has been neglected for some time, likely because of the inability of cross-sectional and retrospective reports to uncover the ebb and flow of symptoms. Data gathered with the experience sampling method (ESM) enable researchers to study symptom variability and instability over time as well as the dynamic interplay between the environment, personal experiences, and psychopathological symptoms. ESM data can illuminate these dynamic processes, if time is both considered and integrated into (a) the research question itself, (b) the assessment or sampling method, and (c) the data analytic strategy. The authors highlight the complexity of assessing affective instability and

unstable interpersonal relationships and explore sampling and analytic methods. Finally, they propose guidelines for future investigations. For the assessment of affective instability, the authors endorse the use of time-contingent recordings and of instability indices that address temporal dependency. For the assessment of unstable interpersonal relationships, they advocate the use of event-contingent recordings and separate analyses within and across dyads. Ebner-Priemer, U. W.; Koudela, S.; Mutz, G.; Kanning, M. (2012):

Interactive Multimodal Ambulatory Monitoring to Investigate the Association between Physical Activity and Affect.

In: *Front Psychol* 3 (1664-1078 (Electronic)), S. 596. DOI: 10.3389/fpsyg.2012.00596.

Abstract:

Although there is a wealth of evidence that physical activity has positive effects on psychological health, a large proportion of people are inactive. Data regarding counts, steps, and movement patterns are limited in their ability to explain why people remain inactive. We propose that multimodal ambulatory monitoring, which combines the assessment of physical activity with the assessment of psychological variables, helps to elucidate real world physical activity. Whereas physical activity can be monitored continuously, psychological variables can only be assessed at discrete intervals, such as every hour. Moreover, the assessment of psychological variables must be linked to the activity of interest. For example, if an inactive and overweight person is physically active once a week, psychological variables should be assessed during this episode. Linking the assessment of psychological variables to episodes of an activity of interest can be achieved with interactive monitoring. The primary aim of our interactive multimodal ambulatory monitoring approach was to intentionally increase the number of e-diary assessments during "active" episodes. We developed and tested an interactive monitoring algorithm that continuously monitors physical activity in everyday life. When predefined thresholds are surpassed, the algorithm triggers a signal for participants to answer questions in their electronic diary. Using data from 70 participants wearing an accelerative device for 24 h each, we found that our algorithm quadrupled the frequency of e-diary assessments during the activity episodes of interest compared to random sampling. Multimodal interactive ambulatory monitoring appears to be a promising approach to enhancing our understanding of real world physical activity and movement

A valence-dependent group-specific recall bias of retrospective self-reports: a study of borderline personality disorder in everyday life.

In: *The Journal of nervous and mental disease* 194 (10), S. 774–779. DOI: 10.1097/01.nmd.0000239900.46595.72.

Abstract:

Recall is an active reconstruction process likely to distort past experiences. This distortion, known as recall bias, seems to manifest itself differently in sick and healthy people. A recall bias has been documented in several disorders, but never investigated in borderline personality disorder (BPD). To determine recall bias in BPD, we assessed momentary and retrospective ratings of specific emotions in 50 patients with BPD and 50 healthy controls (HCs), using the methodology of 24-hour ambulatory monitoring. Our data reveal a group-specific valence-dependent recall bias of retrospective self-report, indicated by a different overall recall pattern in HCs and BPD. BPD patients show an overall negative recall pattern, whereas HCs show a positive recall pattern. A traditional questionnaire approach does not distinguish between symptoms of the disorder and recall bias, although the pathological mechanisms underlying them as well as the appropriate treatment strategies may be different.

Distress and affective dysregulation in patients with borderline personality disorder: a psychophysiological ambulatory monitoring study.

In: *The Journal of nervous and mental disease* 196 (4), S. 314–320.

Abstract:

Borderline personality disorder (BPD) is characterized by enduring psychological distress and affective dysregulation. Several models have linked both phenomena, but are lacking empirical support. To investigate the relation between psychological

distress and components of affective dysregulation (especially inability to label emotions, conflictive emotions, and physiological hyperarousal), we repeatedly assessed these components using a 24-hour ambulatory monitoring approach in a group of 50 BPD patients and 50 healthy controls. Hierarchical linear model analyses identified a clear relation between inability to label emotions and distress in the BPD group ($p = 0.0009$) but not across all subjects ($p = 0.6492$). Conflictive emotions were related to psychological distress in both groups ($p < 0.0001$). This relation is, however, most pertinent to the BPD group who experienced conflicting emotions more frequently. Physiological arousal (heart rate) was related to distress in both groups. Our empirical findings emphasize training in labeling emotions and distress tolerance interventions in treatment for BPD.

Ebner-Priemer, Ulrich W.; Trull, Timothy J. (2009):

Ambulatory assessment: an innovative and promising approach for clinical psychology.

In: *European Psychologist* 14 (2), S. 109–119.

Abstract:

Convergent experimental data, autobiographical studies, and investigations on daily life have all demonstrated that gathering information retrospectively is a highly dubious methodology. Retrospection is subject to multiple systematic distortions (i.e., affective valence effect, mood congruent memory effect, duration neglect; peak end rule) as it is based on (often biased) storage and recollection of memories of the original experience or the behavior that are of interest. The method of choice to circumvent these biases is the use of electronic diaries to collect self-reported symptoms, behaviors, or physiological processes in real time. Different terms have been used for this kind of methodology: ambulatory assessment, ecological momentary assessment, experience sampling method, and real-time data capture. Even though the terms differ, they have in common the use of computer-assisted methodology to assess self-reported symptoms, behaviors, or physiological processes, while the participant undergoes normal daily activities. In this review we discuss the main features and advantages of ambulatory assessment regarding clinical psychology and psychiatry: (a) the use of realtime assessment to circumvent biased recollection, (b) assessment in real life to enhance generalizability, (c) repeated assessment to investigate within person processes, (d) multimodal assessment, including psychological, physiological and behavioral data, (e) the opportunity to assess and investigate context-specific relationships, and (f) the possibility of giving feedback in real time. Using prototypic examples from the literature of clinical psychology and psychiatry, we demonstrate that ambulatory assessment can answer specific research questions better than laboratory or questionnaire studies.

Ebner-Priemer, Ulrich W.; Trull, Timothy J. (2009):

Ecological momentary assessment of mood disorders and mood dysregulation.

In: *Psychological Assessment* 21 (4), S. 463.

Abstract:

In this review, we discuss ecological momentary assessment (EMA) studies on mood disorders and mood dysregulation, illustrating 6 major benefits of the EMA approach to clinical assessment: (a) Real-time assessments increase accuracy and minimize retrospective bias; (b) repeated assessments can reveal dynamic processes; (c) multimodal assessments can integrate psychological, physiological, and behavioral data; (d) setting- or context-specific relationships of symptoms or behaviors can be identified; (e) interactive feedback can be provided in real time; and (f) assessments in real-life situations enhance generalizability. In the context of mood disorders and mood dysregulation, we demonstrate that EMA can address specific research questions better than laboratory or questionnaire studies. However, before clinicians and researchers can fully realize these benefits, sets of standardized e-diary questionnaires and time sampling protocols must be developed that are reliable, valid, and sensitive to change.

Ebner-Priemer, Ulrich W.; Welch, Stacy S.; Grossman, Paul; Reisch, Thomas; Linehan, Marsha M.; Bohus, Martin (2007):

Psychophysiological ambulatory assessment of affective dysregulation in borderline personality disorder.

In: *Psychiatry Res* 150 (3), S. 265–275.

Abstract:

Many experts now believe that pervasive problems in affect regulation constitute the central area of dysfunction in borderline personality disorder (BPD). However, data is sparse and inconclusive. We hypothesized that patients with BPD, in contrast to healthy gender and nationality-matched controls, show a higher frequency and intensity of self-reported emotions, altered

physiological indices of emotions, more complex emotions and greater problems in identifying specific emotions. We took a 24-hour psychophysiological ambulatory monitoring approach to investigate affect regulation during everyday life in 50 patients with BPD and in 50 healthy controls. To provide a typical and unmanipulated sample, we included only patients who were currently in treatment and did not alter their medication schedule. BPD patients reported more negative emotions, fewer positive emotions, and a greater intensity of negative emotions. A subgroup of non-medicated BPD patients manifested higher values of additional heart rate. Additional heart rate is that part of a heart rate increase that does not directly result from metabolic activity, and is used as an indicator of emotional reactivity. Borderline participants were more likely to report the concurrent presence of more than one emotion, and those patients who just started treatment in particular had greater problems in identifying specific emotions. Our findings during naturalistic ambulatory assessment support emotional dysregulation in BPD as defined by the biosocial theory of [Linehan, M.M., 1993. Cognitive–Behavioral Treatment of Borderline Personality Disorder. The Guildford Press, New York.] and suggest the potential utility for evaluating treatment outcome.

Edgar, Christopher; McRorie, Margaret; Sneddon, Ian (2012):

Emotional intelligence, personality and the decoding of non-verbal expressions of emotion.

In: *Personality and Individual Differences* 52 (3), S. 295–300. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-29798-010&site=ehost-live;i.sneddon@qub.ac.uk;m.mcrorie@qub.ac.uk;cedgar07@qub.ac.uk.

Abstract:

Previous research has highlighted theoretical and empirical links between measures of both personality and trait emotional intelligence (EI), and the ability to decode facial expressions of emotion. Research has also found that the posed, static characteristics of the photographic stimuli used to explore these links affects the decoding process and differentiates them from the natural expressions they represent. This undermines the ecological validity of established trait-emotion decoding relationships. This study addresses these methodological shortcomings by testing relationships between the reliability of participant ratings of dynamic, spontaneously elicited expressions of emotion with personality and trait EI. Fifty participants completed personality and self-report EI questionnaires, and used a computer-logging program to continuously rate change in emotional intensity expressed in video clips. Each clip was rated twice to obtain an intra-rater reliability score. The results provide limited support for links between both trait EI and personality variables and how reliably we decode natural expressions of emotion. Limitations and future directions are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Trait anxiety and trait anger measured by ecological momentary assessment and their correspondence with traditional trait questionnaires.

In: *J.Res.Pers.* 47 (6). DOI: 10.1016/j.jrp.2013.08.005.

Abstract:

Ecological momentary assessments (EMA) of anxiety and anger/hostility were obtained every 25-30 minutes over two 24-hour periods, separated by a median of 6 months, from 165 employees at a university in the Northeast. We used a multilevel trait-state-error structural equation model to estimate: (1) the proportion of variance in EMA anxiety and anger/hostility attributable to stable trait-like individual differences; (2) the correspondence between these trait-like components of EMA anxiety and anger/hostility and traditional questionnaire measures of each construct; and (3) the test-retest correlation between two 24-hour averages obtained several months apart. After adjustment for measurement error, more than half the total variance in EMA reports of anxiety and anger/hostility is attributable to stable trait-like individual differences; however, the trait-like component of each construct is only modestly correlated with questionnaire measures of that construct. The 6-month "test-retest" correlations of latent variables representing the true 24-hour EMA average anxiety and average anger are quite high (r >/= 0.83).

This study represents the longest follow-up period over which EMA-based estimates of traits have been examined. The results suggest that although the trait component (individual differences) of EMA momentary ratings of anxiety and anger is larger than the state component, traditional self-report questionnaires of trait anxiety and anger correspond only weakly with EMA-defined traits

Edwards, Andy G.; Hill, James O.; Byrnes, William C.; Browning, Raymond C. (2010):

Accuracy of optimized branched algorithms to assess activity-specific physical activity energy expenditure.

In: *Med Sci Sports Exerc* 42 (4), S. 672–682. DOI: 10.1249/MSS.0b013e3181bd196d.

Abstract:

PURPOSE\r\nTo assess the activity-specific accuracy achievable by branched algorithm (BA) analysis of simulated daily living physical activity energy expenditure (PAEE) within a sedentary population.\r\nMETHODS\r\nSedentary men (n = 8) and women (n = 8) first performed a treadmill calibration protocol, during which HR, accelerometry (ACC), and PAEE were measured in 1-min epochs. From these data, HR-PAEE and ACC-PAEE regressions were constructed and used in each of six analytic models to predict PAEE from ACC and HR data collected during a subsequent simulated daily living protocol. Criterion PAEE was measured during both protocols via indirect calorimetry. The accuracy achieved by each model was assessed by the root mean square of the difference between model-predicted daily living PAEE and the criterion daily living PAEE (expressed here as percent of mean daily living PAEE).\r\nRESULTS\r\nAcross the range of activities, an unconstrained post hoc-optimized BA best predicted criterion PAEE. Estimates using individual calibration were generally more accurate than those using group calibration (14% vs 16% error, respectively). These analyses also performed well within each of the six daily living activities, but systematic errors appeared for several of those activities, which may be explained by an inability of the algorithm to simultaneously accommodate a heterogeneous range of activities. Analyses between mean square error by subject and activity suggest that optimization involving minimization of root mean square for total daily living PAEE is associated with decreased error between subjects but increased error between activities.\r\nCONCLUSIONS\r\nThe performance of post hoc-optimized BA may be limited by heterogeneity in the daily living activities being performed.

Edwards, Lloyd J.; Simpson, Sean L. (2014):

An analysis of 24-h ambulatory blood pressure monitoring data using orthonormal polynomials in the linear mixed model.

In: *Blood Press Monit. DOI:* 10.1097/MBP.0000000000000039.

Abstract:

BACKGROUND: The use of 24-h ambulatory blood pressure monitoring (ABPM) in clinical practice and observational epidemiological studies has grown considerably in the past 25 years. ABPM is a very effective technique for assessing biological, environmental, and drug effects on blood pressure. OBJECTIVES: In order to enhance the effectiveness of ABPM for clinical and observational research studies using analytical and graphical results, developing alternative data analysis approaches using modern statistical techniques are important. METHODS: The linear mixed model for the analysis of longitudinal data is particularly well suited for the estimation of, inference about, and interpretation of both population (mean) and subject-specific trajectories for ABPM data. We propose using a linear mixed model with orthonormal polynomials across time in both the fixed and random effects to analyze ABPM data. RESULTS: We demonstrate the proposed analysis technique using data from the Dietary Approaches to Stop Hypertension (DASH) study, a multicenter, randomized, parallel arm feeding study that tested the effects of dietary patterns on blood pressure. CONCLUSION: The linear mixed model is relatively easy to implement (given the complexity of the technique) using available software, allows for straightforward testing of multiple hypotheses, and the results can be presented to research clinicians using both graphical and tabular displays. Using orthonormal polynomials provides the ability to model the nonlinear trajectories of each subject with the same complexity as the mean model (fixed effects).

Ambulatory but Sedentary: Impact on Cognition and the Rest–Activity Rhythm in Nursing Home Residents With Dementia.

In: *The Journals of Gerontology Series B: Psychological Sciences and Social Sciences* 63 (5), S. P279-P287.

Abstract:

Physical activity has been positively associated with cognition and the rest-activity rhythm. In the present study, nursing staff classified ambulatory nursing home residents with moderate dementia either as active (n=42) or as sedentary (n=34). We assessed the rest-activity rhythm by means of actigraphy, and we administered neuropsychological tests to assess cognitive functioning. Compared with the group that was considered sedentary, the group that was considered active had a significantly better rest-activity rhythm, indicating agreement between nursing staff classifications and data gathered by the actigraph. Cognitive function was related neither to active-sedentary classification nor to actigraph measures. Similar ambulatory nursing home residents with dementia may show considerable differences in their level of daily physical activity and in their rest-activity rhythm, but the precise relationship among all variables requires further investigation.

Eguchi, Kazuo; Ishikawa, Joji; Hoshide, Satoshi; Pickering, Thomas G.; Schwartz, Joseph E.; Shimada, Kazuyuki; Kario, Kazuomi (2009):

Night time blood pressure variability is a strong predictor for cardiovascular events in patients with type 2 diabetes.

In: *Am J Hypertens* 22 (1), S. 46–51. DOI: 10.1038/ajh.2008.294.

Abstract:

BACKGROUND\r\nWe aimed this study to test the hypothesis that short-term blood pressure (BP) variability and abnormal patterns of diurnal BP variation, evaluated by ambulatory BP (ABP), predicts risk of incident cardiovascular disease (CVD) in patients with type 2 diabetes (T2DM).\r\nMETHODS\r\nABP monitoring (ABPM) was performed in 300 patients with uncomplicated T2DM without known CVD and without BP medications, who were followed for 54 +/- 20 months. The relationships of different measures of BP variability, the presence of abnormal patterns of diurnal BP variation (nondipper, riser, or morning BP surge) and the standard deviations of awake and asleep ABP were determined. Cox proportional hazards models were used to estimate hazard ratios (HRs) and their 95% confidence intervals (CIs) before and after controlling for various covariates.\r\nRESULTS\r\nThe mean age was 67.8 +/- 9.6 years, 48% were male, 253 (84%) had a diagnosis of hypertension, and the mean of the standard deviations of awake systolic BP/diastolic BP (SBP/DBP) were 18 +/- 6/11 +/- 4 mm Hg, and those of sleep SBP/DBP were 13 +/- 5/9 +/- 3 mm Hg. During follow-up, there were 29 cardiovascular events. In multivariable analyses, the standard deviations of sleep SBP (HR = 1.08; 95% CI, 1.01-1.16, P < 0.05) and sleep DBP (HR = 1.13; 1.04-1.23, P < 0.01) were independently associated with incident CVD. Neither the nondipper and riser patterns nor the morning BP surge were associated with incident CVD events independently of clinic and 24-h BP levels.\r\nCONCLUSIONS\r\nAbnormal diurnal BP variation was not a predictor of CVD in patients with T2DM. Night time BP variability was an independent predictor of future incidence of CVD, suggesting that this measure could reflect pathophysiology of T2DM.

Eguchi, Kazuo; Kuruvilla, Sujith; Ogedegbe, Gbenga; Gerin, William; Schwartz, Joseph E.; Pickering, Thomas G. (2009):

What is the optimal interval between successive home blood pressure readings using an automated oscillometric device?

In: *J Hypertens* 27 (6), S. 1172.

Abstract:

OBJECTIVES:

To clarify whether a shorter interval between three successive home blood pressure (HBP) readings (10 s vs. 1 min) taken twice a day gives a better prediction of the average 24-h BP and better patient compliance.

DESIGN:

We enrolled 56 patients from a hypertension clinic (mean age: 60 +/- 14 years; 54% female patients). The study consisted of three clinic visits, with two 4-week periods of self-monitoring of HBP between them, and a 24-h ambulatory BP monitoring at the second visit. Using a crossover design, with order randomized, the oscillometric HBP device (HEM-5001) could be programmed to take three consecutive readings at either 10-s or 1-min intervals, each of which was done for 4 weeks. Patients were asked to measure three HBP readings in the morning and evening. All the readings were stored in the memory of the monitors.

RESULTS:

The analyses were performed using the second-third HBP readings. The average systolic BP/diastolic BP for the 10-s and 1-min intervals at home were 136.1 +/- 15.8/77.5 +/- 9.5 and 133.2 +/- 15.5/76.9 +/- 9.3 mmHg (P = 0.001/0.19 for the differences in systolic BP and diastolic BP), respectively. The 1-min BP readings were significantly closer to the average of awake ambulatory BP

(131 +/- 14/79 +/- 10 mmHg) than the 10-s interval readings. There was no significant difference in patients' compliance in taking adequate numbers of readings at the different time intervals.

CONCLUSION:

The 1-min interval between HBP readings gave a closer agreement with the daytime average BP than the 10-s interval.

Eguchi, Kazuo; Pickering, Thomas G.; Hoshide, Satoshi; Ishikawa, Joji; Ishikawa, Shizukiyo; Schwartz, Joseph E. et al. (2008):

Ambulatory blood pressure is a better marker than clinic blood pressure in predicting cardiovascular events in patients with/without type 2 diabetes.

In: *Am J Hypertens* 21 (4), S. 443–450.

Abstract:

Background The prognostic significance of ambulatory blood pressure (ABP) has not been established in patients with type 2 diabetes (T2DM).

Methods In order to clarify the impact of ABP on cardiovascular prognosis in patients with or without T2DM, we performed ABP monitoring (ABPM) in 1,268 subjects recruited from nine sites in Japan, who were being evaluated for hypertension. The mean age of the patients was 70.4 ± 9.9 years, and 301 of them had diabetes. The patients were followed up for 50 ± 23 months. We investigated the relation between incidence of cardiovascular diseases (CVDs) and different measures of ABP, including three categories of awake systolic blood pressure (SBP <135, 135–150, and >150 mm Hg), sleep SBP (<120, 120–135, and >135 mm Hg), and dipping trends in nocturnal blood pressure (BP) (dippers, nondippers, and risers). Cox regression models were used in order to control for classic risk factors.

Results Higher awake and sleep SBPs predicted higher incidence of CVD in patients with and without diabetes. In multivariable analyses, elevated SBPs while awake and asleep predicted increased risk of CVD more accurately than clinic BP did, in both groups of patients. The relationships between ABP level and CVD were similar in both groups. In Kaplan–Meier analyses, the incidence of CVD in nondippers was similar to that in dippers, but risers experienced the highest risk of CVD in both groups ($P < 0.01$). The riser pattern was associated with a ∼150% increase in risk of CVD, in both groups.

Conclusions These findings suggest that ABPM is a better predictor of cardiovascular risk than clinic BP, and that this holds true for patients with or without T2DM.

Eguchi, Kazuo; Pickering, Thomas G.; Schwartz, Joseph E.; Hoshide, Satoshi; Ishikawa, Joji; Ishikawa, Shizukiyo et al. (2008):

Short sleep duration as an independent predictor of cardiovascular events in Japanese patients with hypertension.

In: *Archives of internal medicine* 168 (20), S. 2225–2231. DOI: 10.1001/archinte.168.20.2225.

Abstract:

BACKGROUND\r\nIt is not known whether short duration of sleep is a predictor of future cardiovascular events in patients with hypertension.\r\nMETHODS\r\nTo test the hypothesis that short duration of sleep is independently associated with incident cardiovascular diseases (CVD), we performed ambulatory blood pressure (BP) monitoring in 1255 subjects with hypertension (mean [SD] age, 70.4 [9.9] years) and followed them for a mean period of 50 (23) months. Short sleep duration was defined as less than 7.5 hours (20th percentile). Multivariable Cox hazard models predicting CVD events were used to estimate the adjusted hazard ratio and 95% confidence interval (CI) for short sleep duration. A riser pattern was defined when mean nighttime systolic BP exceeded daytime systolic BP. The end point was a cardiovascular event: stroke, fatal or nonfatal myocardial infarction (MI), and sudden cardiac death.\r\nRESULTS\r\nIn multivariable analyses, short duration of sleep (<7.5 hours) was associated with incident CVD (hazard ratio [HR], 1.68; 95% CI, 1.06-2.66; P = .03). A synergistic interaction was observed between short sleep duration and the riser pattern (P = .09). When subjects were classified according to their sleep time and a riser vs nonriser pattern, the group with shorter sleep duration plus the riser pattern had a substantially and significantly higher incidence of CVD than the group with predominant normal sleep duration plus the nonriser pattern (HR, 4.43; 95% CI, 2.09-9.39; P < .001), independent of covariates.\r\nCONCLUSIONS\r\nShort duration of sleep is associated with incident CVD risk and the combination of the riser pattern and short duration of sleep that is most strongly predictive of future CVD, independent of ambulatory BP levels. Physicians should inquire about sleep duration in the risk assessment of patients with hypertension.

Eid, Michael; Courvoisier, Delphine S.; Lischetzke, Tanja (2012):

Structural equation modeling of ambulatory assessment data. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 384–406. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-021%26site%3dehost-live.

Abstract:

(from the chapter) From a methodological point of view, the major aim of ambulatory assessment is the measurement of variability over time. If behavior and feelings did not fluctuate over time, ambulatory assessment would be a waste of money because a single measurement would be sufficient for assessing an individual's behavior or experience. However, not every fluctuation of scores over time indicates that the state of an individual really changes. Fluctuations in scores can just be due to measurement error. Because measurement errors cannot be avoided in the social and behavioral sciences, fluctuations of scores over time are at least partly due to measurement error. The crucial question then is to what degree behavior and feelings are really variable and how error-free states can be measured. Moreover, in order to detect the situational influences on behavior and experiences, the measurement of error-free, occasion-specific variables that can be related to situational characteristics is necessary. Structural equation modeling allows researchers to separate measurement error from true individual scores and is able to distinguish between variability that is due to unsystematic measurement error, and variability that reflects systematic influences of situations and time. Moreover, structural equation modeling offers the possibility to calculate coefficients that indicate the psychometric properties of measures, such as their reliability, stability, and variability. An introduction into structural equation modeling in general is given, for example, by Kline (2010) and Schumacker and Lomax (2010). In this chapter we show how structural equation modeling can be used for ambulatory assessment. We start with models for a single day. We first introduce general models of longitudinal analysis and show how these models can be adapted to the situation of individually varying times of observation. Then we extend this modeling approach to multiple days, focusing on models that are appropriate to analyze interindividual differences. Finally, we show how these models can be used to estimate scores of intraindividual variability. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Eiholzer, Urs; Meinhardt, Udo; Rousson, Valentin; Petrò, Renato; Schlumpf, Michael; Fusch, Gerhard et al. (2008):

Association between short sleeping hours and physical activity in boys playing ice hockey.

In: *J Pediatr* 153 (5), S. 640-5, 645.e1. DOI: 10.1016/j.jpeds.2008.05.015.

Abstract:

OBJECTIVES\r\nTo determine physical activity in healthy boys and how physical activity relates to training and daily awake hours.\r\nSTUDY DESIGN\r\nIn 66 boys (5 to 15 years) affiliated with an ice-hockey club, we measured total daily energy expenditure (TDEE, doubly-labeled water) and basal metabolic rate (ventilated-hood method). Physical activity energy expenditure for the whole day (DAEE), during training, and during spontaneous physical activity was measured by accelerometry and activity protocols. Univariate (UA) and multivariate (MA) correlation analysis was applied.\r\nRESULTS\r\nPhysical activity level, DAEE, and TDEE for prepubertal (2.0 and 2.2 Mcal/d) and pubertal (bone age >or=13 years; 1.8 and 2.8 Mcal/d) boys were matched to literature data from normal boys of equal age. In prepubertal boys DAEE correlated positively with awake hours (r(UA) = 0.55, r(MA) = 0.39, P < .01). In pubertal boys this correlation was not significant, the slopes between the 2 groups being significantly different (P = .025). In prepubertal boys spontaneous physical activity expenditure correlated significantly positively with training activity expenditure (r(UA) = 0.72, r(MA) = 0.52, P < .001).\r\nCONCLUSION\r\nContrary to findings in adults, where short sleepers had lower physical activity and intensive training was negatively compensated reducing spontaneous physical activity, in physically active prepubertal boys, total daily and spontaneous physical activity relate positively to awake hours and training; suggesting child-specific control of physical activity.

Eissa, Mona A. H.; Meininger, Janet C.; Nguyen, Thong Q.; Chan, Wenyaw (2007):

The relationship of ambulatory blood pressure to physical activity in a tri-ethnic population of obese and nonobese adolescents.

In: *Am J Hypertens* 20 (2), S. 140–147.

Abstract:

BACKGROUND:

The association between physical activity (PA) and ambulatory blood pressure (ABP) is documented in adults. This association and factors that may modify it, such as obesity, have not been reported in adolescents. The aims of this study were to determine the association of PA with ABP in 11- to 16-year-old adolescents, and to examine the modifying effects of obesity and other factors.

METHODS:

Data on 24-h ABP and PA were obtained from 374 adolescents using the wrist actigraph. Correlations between average PA for every 5-min interval preceding each BP measurement and ABP were calculated during the awake period. Mixed-effects models were used with ABP variables as separate, dependent variables. In addition to PA scores for 5 min preceding each BP, body mass index (BMI) z-score and other variables were added to the models as covariates and as interaction terms with activity.

RESULTS:

Correlations of PA for 5 min preceding BP measurements were 0.22 and 0.25 for systolic blood pressure (SBP) and diastolic blood pressure (DBP) respectively. In mixed-effects analysis, each 1-unit increase in PA was associated with an increase in SBP of 0.02 mm Hg, in DBP of 0.01 mm Hg, and in HR of 0.02 beat/min ($P < .0001$). The association of BP with PA was significantly less for those with higher BMI z-scores (SBP, $P < .001$, DBP, $P = .027$). The associations of PA with SBP and HR were modified by sexual maturation status of the adolescents.

CONCLUSIONS:

This study found that PA is associated with ABP measurements. These associations are modified by obesity status and other variables. Recognizing these associations may improve the interpretation of ABP measurements.

Ekelund, Ulf; Brage, Soren; Griffin, Simon J.; Wareham, Nicholas J. (2009):

Objectively measured moderate-and vigorous-intensity physical activity but not sedentary time predicts insulin resistance in high-risk individuals.

In: *Diabetes Care* 32 (6), S. 1081–1086.

Abstract:

OBJECTIVE:

Low levels of physical activity appear to be associated with insulin resistance. However, the detailed associations of these complex relationships remain elusive. We examined the prospective associations between self-reported TV viewing time, objectively measured time spent sedentary, at light-intensity activity, and at moderate- and vigorous-intensity physical activity (MVPA) with insulin resistance.

RESEARCH DESIGN AND METHODS:

In 192 individuals (81 men and 111 women) with a family history of type 2 diabetes, we measured physical activity and anthropometric and metabolic variables at baseline and after 1 year of follow-up in the ProActive UK trial. Physical activity was measured objectively by accelerometry. Insulin resistance was expressed as fasting insulin and the homeostasis model assessment score (HOMA-IR).

RESULTS:

Baseline MVPA was a significant predictor of fasting insulin at follow-up (beta = -0.004 [95% CI -0.007 to -0.0001], $P = 0.022$), and the association approached significance for HOMA-IR (beta = -0.003 [-0.007 to 0.000002], $P = 0.052$), independent of time spent sedentary, at light-intensity activity, sex, age, smoking status, waist circumference, and self-reported TV viewing. Time spent sedentary and at light-intensity activity were not significantly associated with insulin resistance. The change in MVPA between baseline and follow-up was inversely related to fasting insulin (beta = -0.003 [-0.007 to -0.0003], $P = 0.032$) and the HOMA-IR score (beta = -0.004 [-0.008 to -0.001], $P = 0.015$) at follow-up, after adjustment for baseline phenotype in addition to the same confounders as above.

CONCLUSIONS:

These results highlight the importance of promoting moderate-intensity activity such as brisk walking for improving insulin sensitivity and possibly other metabolic risk factors to prevent type 2 diabetes.

Ekelund, Ulf; Griffin, Simon J.; Wareham, Nicholas J. (2007):

Physical activity and metabolic risk in individuals with a family history of type 2 diabetes.

In: *Diabetes Care* 30 (2), S. 337–342.

Abstract:

OBJECTIVE—We sought to examine the independent associations between different dimensions of physical activity with intermediary and clustered metabolic risk factors in overweight individuals with an increased risk of type 2 diabetes to inform future preventive action.

RESEARCH DESIGN AND METHODS—We measured total body movement and five other subcomponents of physical activity by accelerometry in 258 adults (aged 30–50 years) with a family history of type 2 diabetes. We estimated aerobic fitness from an incremental treadmill exercise test. We measured body composition by bioimpedance and waist circumference, blood pressure, fasting triglycerides, HDL cholesterol, glucose, and insulin with standard methods. We constructed a standardized continuously distributed variable for clustered risk.

RESULTS—Total body movement (counts · day−1) was significantly and independently associated with three of six risk factors (fasting triglycerides, insulin, and HDL) and with clustered metabolic risk (P = 0.004) after adjustment for age, sex, and obesity. Time spent at moderate- and vigorous-intensity physical activity (MPVA) was independently associated with clustered metabolic risk (P = 0.03). Five- and 10-min bouts of MVPA, time spent sedentary, time spent at light-intensity activity, and aerobic fitness were not significantly related with clustered risk after adjustment for confounding factors.

CONCLUSIONS—Total body movement is associated with intermediary phenotypic risk factors for cardiovascular disease and metabolic disease and with clustered metabolic risk independent of aerobic fitness and obesity. Increasing the total amount of physical activity in sedentary and overweight individuals may have beneficial effects on metabolic risk factors.

Ekelund, U.; Luan, J.; Sherar, L. B.; Esliger, D. W.; Griew, P.; Cooper, A. (2012):

Moderate to vigorous physical activity and sedentary time and cardiometabolic risk factors in children and adolescents.

In: *JAMA* 307 (7), S. 704–712. DOI: 10.1001/jama.2012.156.

Abstract:

CONTEXT: Sparse data exist on the combined associations between physical activity and sedentary time with cardiometabolic risk factors in healthy children. OBJECTIVE: To examine the independent and combined associations between objectively measured time in moderate- to vigorous-intensity physical activity (MVPA) and sedentary time with cardiometabolic risk factors. DESIGN, SETTING, AND PARTICIPANTS: Pooled data from 14 studies between 1998 and 2009 comprising 20 871 children (aged 4-18 years) from the International Children's Accelerometry Database. Time spent in MVPA and sedentary time were measured using accelerometry after reanalyzing raw data. The independent associations between time in MVPA and sedentary time, with outcomes, were examined using meta-analysis. Participants were stratified by tertiles of MVPA and sedentary time. MAIN OUTCOME MEASURES: Waist circumference, systolic blood pressure, fasting triglycerides, high-density lipoprotein cholesterol, and insulin. RESULTS: Times (mean [SD] min/d) accumulated by children in MVPA and being sedentary were 30 (21) and 354 (96), respectively. Time in MVPA was significantly associated with all cardiometabolic outcomes independent of sex, age, monitor wear time, time spent sedentary, and waist circumference (when not the outcome). Sedentary time was not associated with any outcome independent of time in MVPA. In the combined analyses, higher levels of MVPA were associated with better cardiometabolic risk factors across tertiles of sedentary time. The differences in outcomes between higher and lower MVPA were greater with lower sedentary time. Mean differences in waist circumference between the bottom and top tertiles of MVPA were 5.6 cm (95% CI, 4.8-6.4 cm) for high sedentary time and 3.6 cm (95% CI, 2.8-4.3 cm) for low sedentary time. Mean differences in systolic blood pressure for high and low sedentary time were 0.7 mm Hg (95% CI, -0.07 to 1.6) and 2.5 mm Hg (95% CI, 1.7-3.3), and for high-density lipoprotein cholesterol, differences were -2.6 mg/dL (95% CI, -1.4 to -3.9) and -4.5 mg/dL (95% CI, -3.3 to -5.6), respectively. Geometric mean differences for insulin and triglycerides showed similar variation. Those in the top tertile of MVPA accumulated more than 35 minutes per day in this intensity level compared with fewer than 18 minutes per day for those in the bottom tertile. In prospective analyses (N = 6413 at 2.1 years' follow-up), MVPA and sedentary time were not associated with waist circumference at follow-up, but a higher waist circumference at baseline was associated with higher amounts of sedentary time at follow-up. CONCLUSION: Higher MVPA time by children and adolescents was associated with better cardiometabolic risk factors regardless of the amount of sedentary time

Mobile applications for diabetes self-management: status and potential.

In: *J Diabetes Sci Technol* 7 (1), S. 247–262. Online verfügbar unter PM:23439183.

Abstract:

BACKGROUND: Advancements in smartphone technology coupled with the proliferation of data connectivity has resulted in increased interest and unprecedented growth in mobile applications for diabetes self-management. The objective of this article

is to determine, in a systematic review, whether diabetes applications have been helping patients with type 1 or type 2 diabetes self-manage their condition and to identify issues necessary for large-scale adoption of such interventions. METHODS: The review covers commercial applications available on the Apple App Store (as a representative of commercially available applications) and articles published in relevant databases covering a period from January 1995 to August 2012. The review included all applications supporting any diabetes self-management task where the patient is the primary actor. RESULTS: Available applications support self-management tasks such as physical exercise, insulin dosage or medication, blood glucose testing, and diet. Other support tasks considered include decision support, notification/alert, tagging of input data, and integration with social media. The review points to the potential for mobile applications to have a positive impact on diabetes self-management. Analysis indicates that application usage is associated with improved attitudes favorable to diabetes self-management. Limitations of the applications include lack of personalized feedback; usability issues, particularly the ease of data entry; and integration with patients and electronic health records. CONCLUSIONS: Research into the adoption and use of user-centered and sociotechnical design principles is needed to improve usability, perceived usefulness, and, ultimately, adoption of the technology. Proliferation and efficacy of interventions involving mobile applications will benefit from a holistic approach that takes into account patients' expectations and providers' needs

Elkins, Sara R.; Moore, Todd M.; McNulty, James K.; Kivisto, Aaron J.; Handsel, Vanessa A. (2012):

Electronic Diary Assessment of the Temporal Association Between Proximal Anger and Intimate Partner Violence Perpetration.

In: *Psychology of Violence*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-28089-001%26site%3dehost-live.

Abstract:

Objective: The temporal association between proximal anger and intimate partner violence (IPV) perpetration was examined using electronic daily diary assessment methodology. In addition, relevant demographic and relational variables were examined as potential moderators of the association between anger and IPV perpetration. Method: Participants were 184 men and women in dating relationships who completed daily surveys reporting anger and IPV for a period of 2 months. Results: Increases in proximal anger were associated with greater odds of psychological (2.78), physical (2.38), and sexual aggression perpetration (2.27). Analyses also demonstrated a quadratic relationship for psychological aggression and proximal anger, such that increased anger was more strongly associated with psychological aggression when anger was relatively low versus higher in the first place. Moderators of the relationship between proximal anger and IPV perpetration included age and length of relationship. Conclusions: These data are the first to provide evidence for the temporal relationship between anger and IPV perpetration. Data support electronic diary assessment as an effective way to assess moment-to-moment partner interactions, increase participant compliance, and minimize retrospective recall bias. Electronic diary assessment may also hold promise for the creation of intervention programs that address proximal anger in conjunction with distal variables that increase risk for IPV perpetration. Emaus, Aina; Degerstrøm, Jorid; Wilsgaard, Tom; Hansen, Bjørge Herman; Dieli-Conwright, Christina M.; Furberg, Anne-Sofie et al. (2010):

Does a variation in self-reported physical activity reflect variation in objectively measured physical activity, resting heart rate, and physical fitness? Results from the Tromsø study.

In: *Scandinavian journal of public health* 38 (5 suppl), S. 105–118.

Abstract:

AIMS:

To study the association between self-reported physical activity (PA) and objectively measured PA, resting heart rate, and physical fitness.

METHODS:

During 2007-08, 5017 men and 5607 women aged 30-69 years attended the sixth survey of the Tromsø study. Self-reported PA during leisure-time and work were assessed and resting heart rate was measured. In a sub-study, the activity study, PA (Actigraph LLC) and physical fitness (VO_2(max)) were objectively measured among 313 healthy men and women aged 40-44 years.

RESULTS:

Self-reported leisure PA was significantly correlated with VO_2(max) (ml/kg/min) (women 0.40, $p < 0.001$, men 0.44 $p < 0.001$) and moderate-to-vigorous PA (>2000 counts/min) (women 0.28, $p < 0.01$, men 0.25, $p < 0.01$). The intra-class correlation coefficient between self-reported leisure PA and overall PA (counts/min) measured by accelerometer was 0.62 (95% CI 0.51, 0.71) for women and 0.59 (95% CI 0.47, 0.69) for men, and for VO_2(max) the intra-class correlation coefficient was 0.86 (95% CI 0.81, 0.90) for both sexes. Among all participants, an inverse dose-response relationship was observed between self-reported leisure PA and resting heart rate for both men and women ($p < 0.0001$). More women than men met the international recommendations of 10,000 step counts/day (27% vs. 22%) and the recommendation of at least 30 minutes/day of moderate-to-vigorous intensities (30% vs. 22 %).

CONCLUSIONS:

The Tromsø physical activity questionnaire has acceptable validity and provides valid estimates of high-intensity leisure activity. However, these results underscore the need for collecting objectively PA measurements in large epidemiological studies.

Engel, Scott G.; Kahler, Kirsten A.; Lystad, Chad M.; Crosby, Ross D.; Simonich, Heather K.; Wonderlich, Stephen A. et al. (2009):

Eating behavior in obese BED, obese non-BED, and non-obese control participants: a naturalistic study.

In: *Behav Res Ther* 47 (10), S. 897–900. DOI: 10.1016/j.brat.2009.06.018.

Abstract:

Laboratory studies have shown considerable differences between the eating behavior, particularly binge eating behavior, of participants with and without binge eating disorder (BED). However, these findings were not replicated in two field experiments employing ecological momentary assessment (EMA) in which obese BED and obese non-BED participants reported comparable binge eating behavior. In the current study, we examined differences in binge eating with an innovative assessment scheme employing both EMA and a standardized computer-based dietary recall program to avoid some of the limitations of past laboratory and field research. Obese BED, obese non-BED, and non-obese control participants reported significant differences in eating patterns, loss of control, overeating, and binge eating behavior. Of particular importance was the finding that BED participants engaged in more overeating and more binge eating episodes than non-BED participants. These findings suggest that the use of EMA in combination with dietary recall may be a relatively objective and useful approach to assessing binge eating behavior. The findings further suggest that individuals with BED are observably different from those without the disorder, which may have implications for eating disorder diagnoses in DSM-V.

Descriptive experience sampling: What is it good for?

In: *Journal of Consciousness Studies* 18 (1), S. 130–149. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-20325-008&site=ehost-live;pcarruth@umd.edu;marke@umd.edu.

Abstract:

Comments on the book Describing inner experience? Proponent meets skeptic by Russell T. Hurlburt and Eric Schwitzgebel (see record 2007-14525-000). We defend the reliability of Hurlburt's Descriptive Experience Sampling method against some of Schwitzgebel's attacks. But we agree with Schwitzgebel that the method could be used much more widely than it has been, helping to answer questions about the nature and structure of consciousness in addition to cataloguing the latter's contents. We sketch a number of potential lines of further enquiry.

Understanding Patterns of Young Children's Physical Activity After School - It's all About Context: A Cross-Sectional Study.

In: *J Phys Act Health. DOI:* 10.1123/jpah.2013-0153.

Abstract:

BACKGROUND: To promote healthy lifestyles, we need to understand more about the patterns of children's activities after school. METHODS: Twenty 5-7 year old children and their parents participated in this study. Parents used 'real-time' diaries to

report children's activities and contextual information at three randomly selected times per day, over 4 school days. Reporting was repeated after 13 weeks. Simultaneously children wore Actical accelerometers. RESULTS: Approximately 300 simultaneous accelerometer measurements and diary entries were compared. Despite a large range, mean physical activity levels were highest when children engaged in activities generally considered as "active" and lowest for doing "nothing". However, the range within activities was very large; some children who reported TV/screen time accumulated high accelerometry counts and conversely, some children were practically sedentary during organized sports. Children spent most (78%) of their after school time indoors, but the children were significantly more active outdoors than indoors (t(74.8) = 5.0, p<.001). CONCLUSIONS: Accelerometer data in conjunction with real-time diaries provide a more complete understanding of the value of outdoor play in increasing movement opportunities for children's after school activities.

Young Children's After-School Activities - There's More to it Than Screen Time: A Cross-Sectional Study of Young Primary School Children.

In: *J Phys Act Health. DOI:* 10.1123/jpah.2013-0075.

Abstract:

BACKGROUND: Children can spend substantial amounts of leisure time in sedentary activities, dominated by TV/screen time. However, objective real-time measurement of activities after school among young school children is seldom described. METHODS: School children (n=246, aged 5-7 years, mean 6.0) randomly selected from 14 schools across Sydney, Australia and their parents were recruited. Parents used a real-time objective measure (Experience Sampling Method, ESM) to record children's activities, and whether they were indoors or outdoors at three random times each day after school. Data were collected across four week days in each of two weeks separated by 13 weeks. RESULTS: Results based on 2940 responses from 214 child-parent dyads showed that 25% of behaviour involved physical activity; 51% was spent in sedentary activities; and 22% TV/screen time. Most instances (81%) occurred indoors. CONCLUSION: Despite a high proportion of TV/screen time, children were also engaged in a range of other sedentary and physically active pursuits after school. Hence TV/screen time is not a suitable proxy for all sedentary behaviour, and it is important to gather information on other non-screen based sedentary and physically active behaviors. Future research is warranted to further investigate after-school activities in young primary school children.

Fluctuation of flow and affect in everyday life: A second look at the paradox of work.

In: *Journal of Happiness Studies*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-43115-001%26site%3dehost-live.

Abstract:

Studies with the Experience Sampling Method (ESM) have shown that individuals experience more flow at work than at leisure. This indicates that people enjoy working but paradoxically at the same time leisure activities are preferred (“paradox of work”). We took a second look at the paradox of work by measuring flow directly, including affect measures, and differentiating between active and passive leisure activities. We also adopted a dynamical approach based on the idea that the transitions of experiences has to be taken into account to get the total picture. For the period of 1 week, data of 100 employees with different professions were collected with the ESM (in total 4,504 measurements). In accordance with existing work, we found that flow was high during work. It was slightly (albeit significantly) higher than during active leisure activities and considerably higher than during passive leisure activities. At the same time, negative activation was low during passive and active leisure activities and lower than during work and vice versa for valence (happiness). Thus, leisure activities do have a positive affective quality that could explain why people prefer leisure to work. Regarding the dynamical approach, we tested whether flow during work would lead to higher valence in leisure but could not support this assumption. We discussed the findings and made suggestions for future research. In an additional analysis, we reveal that perceived outcome experience could partially explain why work and leisure experience differed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Historical lines and an overview of current research on flow. In: Stefan Engeser (Hg.): Advances in flow research.

New York, NY US: Springer Science + Business Media, S. 1–22. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-09605-001&site=ehost-live;schiepe-tiska@tum.de;engeser@uni-n-trier.de.

Abstract:

(from the chapter) This chapter introduces the flow concept by listing the components of flow as provided by Csikszentmihalyi. We will show that these components constitute the widely shared definitional ground of researchers in the field, with only minor variation between research groups and time periods. Next, we try to clarify some lingering ambiguities regarding the components of flow, and then talk about flow as an optimal experience as well as discussing flow and happiness. Subsequently, we trace the history of flow. We take time to describe the beginnings of flow research by Csikszentmihalyi and a similar research program by Rheinberg in Germany. Following the description of flow and qualitative analyses, the quantitative method of the experience sampling method (ESM), which has greatly influenced research on flow, will be presented. Creativity and well-being remain an important part of flow research and will be considered here, but flow research has entered many other areas, spanning from a strong emphasis on sport, learning, and flow at work to the emerging research on flow in teams and social interaction or psychophysiological correlates of flow. Finally, we complete this chapter by exploring methodological aspects of the research on flow. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Ecological momentary assessment of maternal cortisol profiles over a multiple-day period predicts the length of human gestation.

In: *Psychosomatic Medicine* 73 (6), S. 469–474. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-26306-006&site=ehost-live;pwadhwa@uci.edu;sentring@uci.edu.

Abstract:

Objective: Biobehavioral models of prenatal stress highlight the importance of the stress-related hormone cortisol. However, the association between maternal cortisol levels and the length of human gestation requires further investigation because most previous studies have relied on one-time cortisol measures assessed at varying gestational ages. This study assessed whether ecological momentary assessment (EMA) of cortisol sampling improves the ability to predict the length of human gestation. In addition, associations between EMA-based measures of psychological state (negative affect) with cortisol levels during pregnancy were assessed. Methods: For a 4-day period, 25 healthy pregnant women (mean gestational age at assessment = 23.4 [standard deviation = 9.1] weeks) collected seven salivary samples per day for the assessment of cortisol and provided a rating of negative affect every waking hour using an electronic diary. Results: Higher salivary cortisol concentrations at awakening and throughout the day (p = .001), as well as a flatter cortisol response to awakening (p = .005), were associated with shorter length of gestation. Women who delivered an infant at 36 weeks of gestations had 13% higher salivary cortisol levels at awakening than women who delivered an infant at 41 weeks of gestation. The EMA-based measure of negative affect was associated with higher cortisol throughout the day (p = .006) but not to gestational length (p = .641). The one-time measure of cortisol was not associated with length of gestation, and traditional retrospective recall measures of negative affect were not associated with cortisol. Conclusions: Our findings support the ecological validity of repeated ambulatory assessments of cortisol in pregnancy and their ability to improve the prediction of adverse birth outcomes. Epler, Amee J.; Tomko, Rachel L.; Piasecki, Thomas M.; Wood, Phillip K.; Sher, Kenneth J.; Shiffman, Saul; Heath, Andrew C. (2014):

Does Hangover Influence the Time to Next Drink? An Investigation Using Ecological Momentary Assessment.

In: *Alcohol Clin Exp Res. DOI:* 10.1111/acer.12386.

Abstract:

BACKGROUND: Measures of hangover are associated with current and future problematic alcohol use. At present, it is not known whether these associations reflect any direct influence of hangover events on near-term drinking behaviors. The current study aimed to determine whether hangover following a drinking episode influences time to next drink (TTND) and, if so, to

determine the direction of this effect and identify any moderating personal or contextual factors. METHODS: Community-recruited, frequent drinkers oversampled for current smoking (N = 386) carried electronic diaries for 21 days, reporting on drinking behaviors and other experiences. Survival analysis was used to model data from 2,276 drinking episodes, including 463 episodes that were followed by self-reported hangover in morning diary entries. RESULTS: When tested as the sole predictor in a survival model, hangover was associated with increased TTND. The median survival time was approximately 6 hours longer after episodes with hangovers compared to those without. In a multivariate model, hangover was only significant in the presence of interaction effects involving craving at the end of the index drinking episode and the occurrence of financial stressors. Additional predictors of TTND in the final multivariate model included age, lifetime alcohol use disorder diagnosis, typical drinking frequency, day of the week, and morning reports of craving, negative affect, and stressors after the index episode. There was no association between morning reports of hangover and contemporaneous diary ratings of likelihood of drinking later the same day. CONCLUSIONS: The findings suggest that hangover has, at best, a modest or inconsistent influence on the timing of subsequent alcohol use among frequent drinkers.

Tobacco, cocaine, and heroin: Craving and use during daily life.

In: *Addict Behav* 35 (4), S. 318–324. DOI: 10.1016/j.addbeh.2009.11.003.

Abstract:

BACKGROUND\r\nRelationships among tobacco smoking, tobacco craving, and other drug use and craving may have treatment implications in polydrug-dependent individuals.\r\nMETHODS\r\nWe conducted the first ecological momentary assessment (EMA) study to investigate how smoking is related to other drug use and craving during daily life. For up to 20 weeks, 106 methadone-maintained outpatients carried PalmPilots (PDAs). They reported their craving, mood, behaviors, environment, and cigarette-smoking status in 2 to 5 random-prompt entries/day and initiated PDA entries when they used cocaine or heroin or had a discrete episode of craving for cocaine or heroin.\r\nRESULTS\r\nSmoking frequency increased linearly with random-prompt ratings of tobacco craving, cocaine craving, and craving for both cocaine and heroin. Smoking frequency was greater during discrete episodes of cocaine use and craving than during random-prompt reports of low craving for cocaine. This pattern was also significant for dual cocaine and heroin use and craving. Smoking and tobacco craving were each considerably reduced during periods of urine-verified abstinence from cocaine, and there was a (nonsignificant) tendency for morning smoking to be especially reduced during those periods.\r\nCONCLUSIONS\r\nThis EMA study confirms that smoking and tobacco craving are strongly associated with the use of and craving for cocaine and heroin. Together with prior findings, our data suggest that tobacco and cocaine may each increase craving for (and likelihood of continued use of) themselves and each other. Treatment for tobacco dependence should probably be offered concurrently with (rather than only after) initiation of treatment for other substance-use disorders.

Daily life hour by hour, with and without cocaine: an ecological momentary assessment study.

In: *Psychopharmacology* 211 (2), S. 223–232. DOI: 10.1007/s00213-010-1884-x.

Abstract:

RATIONALE\r\nEffects of an intervention cannot be understood without precise knowledge of the baseline behavior on which the intervention is superimposed. For misusers of illicit drugs, patterns of daily activities and moods have not been studied in a way that is amenable to statistical aggregation.\r\nOBJECTIVE\r\nThe aim of the study was to compare hour-by-hour daily

activities in cocaine-dependent outpatients during urine-verified periods of use and abstinence.\r\nMETHODS\r\nIn a cohort design, a volunteer sample of 112 methadone-maintained cocaine- and heroin-abusing outpatients provided ecological momentary assessment (EMA) data on handheld computers for 10,781 person-days. EMA responses to questions about current location, activities, companions, moods, and recent exposure to putative drug-use triggers were compared across periods of use and abstinence using SAS Proc Glimmix (for binary outcomes) and Proc Mixed (for continuous outcomes).\r\nRESULTS\r\nPeriods of cocaine use were associated with idle, solitary, affectively negative afternoons but, unexpectedly, were also associated with a greater likelihood of early-morning or late-evening work. The whole-day concomitants of cocaine use were often distinct from the acute predecessors of use seen in prior analyses from the same sample. Several measures of negative mood increased during abstinence.\r\nCONCLUSIONS\r\nWeeks of cocaine use and abstinence in outpatients are associated with distinct patterns of mood and behavior; the detailed hourly data reported here should help inform treatment interventions aimed at changing daily activities. The findings also argue against the contention that cocaine abstinence symptoms decrease monotonically from the day of cessation.

Epstein, D. H.; Preston, K. L. (2012):

TGI Monday?: drug-dependent outpatients report lower stress and more happiness at work than elsewhere.

In: *Am.J Addict.* 21 (3), S. 189–198. DOI: 10.1111/j.1521-0391.2012.00230.x.

Abstract:

In the general population, experience-sampling studies show that work is the aspect of daily life most associated with momentary unhappiness and a desire to be elsewhere. We assessed whether this holds true for urban outpatients in treatment for heroin and cocaine dependence. In a 25-week natural-history study, 79 employed methadone-maintained misusers of heroin and cocaine carried electronic diaries on which mood and behavior were assessed up to five times per day. Being at work was associated with lower stress, greater happiness, and lower drug craving. Work accounted for 14% of the variance in stress, 30% of the variance in happiness, and 50% of the variance in cocaine craving. Participants with skilled jobs reported more positive and less negative mood states (and lower cocaine craving) at all times compared to participants with semi/unskilled jobs, although the latter reported greater mood improvement at work. In all participants, mood improvements occurred specifically in the presence of coworkers (not other companions). Our seemingly unusual findings might be specific to substance-disorder patients (for whom work may be a respite from drug-using companions), but might also hold for other urban dwellers of similar socioeconomic backgrounds (for whom work may be a respite from environmental stressors)

Epstein, D. H.; Tyburski, M.; Craig, I. M.; Phillips, K. A.; Jobes, M. L.; Vahabzadeh, M. et al. (2014):

Real-time tracking of neighborhood surroundings and mood in urban drug misusers: Application of a new method to study behavior in its geographical context.

In: *Drug Alcohol Depend* 134 (0376-8716 (Linking)), S. 22–29. DOI: 10.1016/j.drugalcdep.2013.09.007.

Abstract:

BACKGROUND: Maladaptive behaviors may be more fully understood and efficiently prevented by ambulatory tools that assess people's ongoing experience in the context of their environment. METHODS: To demonstrate new field-deployable methods for assessing mood and behavior as a function of neighborhood surroundings (geographical momentary assessment; GMA), we collected time-stamped GPS data and ecological momentary assessment (EMA) ratings of mood, stress, and drug craving over 16 weeks at randomly prompted times during the waking hours of opioid-dependent polydrug users receiving methadone maintenance. Locations of EMA entries and participants' travel tracks calculated for the 12 before each EMA entry were mapped. Associations between subjective ratings and objective environmental ratings were evaluated at the whole neighborhood and 12-h track levels. RESULTS: Participants (N=27) were compliant with GMA data collection; 3711 randomly prompted EMA entries were matched to specific locations. At the neighborhood level, physical disorder was negatively correlated with negative mood, stress, and heroin and cocaine craving (ps<.0001-.0335); drug activity was negatively correlated with stress, heroin and cocaine craving (ps .0009-.0134). Similar relationships were found for the environments around respondents' tracks in the 12h preceding EMA entries. CONCLUSIONS: The results support the feasibility of GMA. The relationships between neighborhood characteristics and participants' reports were counterintuitive and counter-hypothesized, and challenge some assumptions about how ostensibly stressful environments are associated with lived experience and how such environments ultimately impair health. GMA methodology may have applications for development of individual- or neighborhood-level interventions

Epstein, David H.; Willner-Reid, Jessica; Vahabzadeh, Massoud; Mezghanni, Mustapha; Lin, Jia-Ling; Preston, Kenzie L. (2009):

Real-time electronic diary reports of cue exposure and mood in the hours before cocaine and heroin craving and use.

In: *Archives of General Psychiatry* 66 (1), S. 88–94. DOI: 10.1001/archgenpsychiatry.2008.509.

Abstract:

CONTEXT\r\nIn ecological momentary assessment (EMA), participants electronically report their activities and moods in their daily environments in real time, enabling a truly prospective approach to the study of acute precipitants of behavioral events. Ecological momentary assessment has greatly enhanced the study of tobacco addiction, but its use has rarely been attempted in individuals with cocaine or heroin addiction.\r\nOBJECTIVE\r\nTo prospectively monitor the acute daily life precipitants of craving for and use of cocaine and heroin.\r\nDESIGN\r\nCohort study.\r\nPARTICIPANTS\r\nA volunteer sample of 114 cocaine- and heroin-abusing outpatients who were being treated with methadone provided EMA data on handheld electronic devices for 14 918 person-days (mean, 130.9; range, 6-189 days per participant). Of these outpatients, a total of 102 (63 men, 39 women) provided acute precraving and/or preuse data and were thus included in the present analyses.\r\nMAIN OUTCOME MEASURES\r\nChanges in reports of mood and exposure to 12 putative drug-use triggers at random intervals during the 5 hours preceding each self-reported episode of drug craving or use, analyzed via repeated-measures logistic regression (generalized linear mixed models).\r\nRESULTS\r\nDuring the 5 hours preceding cocaine use or heroin craving, most of the 12 putative triggers showed linear increases. Cocaine use was most robustly associated with increases in participants reporting that they \"saw [the] drug\" (P < .001), were \"tempted to use out of the blue\" (P < .001), \"wanted to see what would happen if I used\" (P < .001), and were in a good mood (P < .001). Heroin craving was most robustly associated with increases in reports of feeling sad (P < .001) or angry (P = .01). Cocaine craving and heroin use showed few reliable associations with any of the putative triggers assessed.\r\nCONCLUSIONS\r\nThese findings confirm that polydrug-abusing individuals can provide behavioral data in their daily environments using handheld electronic devices and that those data can reveal orderly patterns, including prospectively detectable harbingers of craving and use, which may differ across drugs.

Ernst, M. E.; Sezate, G. S.; Lin, W.; Weber, C. A.; Dawson, J. D.; Carter, B. L.; Bergus, G. R. (2011):

Indication-specific 6-h systolic blood pressure thresholds can approximate 24-h determination of blood pressure control.

In: *J Hum Hypertens* 25 (4), S. 250–255. DOI: 10.1038/jhh.2010.66.

Abstract:

Ambulatory blood pressure monitoring (ABPM) is an accurate method for evaluating hypertension, yet its use in clinical practice may be limited by availability, cost and patient inconvenience. The objective of this study was to investigate the ability of a 6-h ABPM window to predict blood pressure control, judging by that of the full 24-h ABPM session across several clinical indications in a cohort of 486 patients referred for ABPM. Sensitivities and specificities of the 6-h systolic blood pressure mean to accurately classify patients as hypertensive were determined using a fixed reference point of 130 mm Hg for the 24-h mean. For four common indications, in which ABPM was ordered, prediction tables were constructed varying the thresholds for the 6-h mean to find the optimal value that best predicted the 24-h hypertensive status as determined from the full 24-h interval. Using a threshold of 137 mm Hg for the indications of borderline hypertension, evaluation of current antihypertensive regimen and suspected white-coat hypertension, sensitivity and specificity ranged from 0.83-0.88 to 0.80-0.88, respectively, for the ability of 6-h ABPM to correctly categorize hypertensive status. Using 133 mm Hg as the threshold for treatment resistance resulted in a sensitivity and specificity of 0.93 and 0.83, respectively. We conclude that a shortened ABPM session of 6 h can be used to accurately classify blood pressure as controlled or not, based on the results of a 24-h session. The optimal 6-h threshold for comparison depends upon indication for referral.

Ernst, Michael E.; Weber, Cynthia A.; Dawson, Jeffrey D.; O'Connor, Michelle A.; Lin, Wenjiao; Carter, Barry L.; Bergus, George R. (2008):

How well does a shortened time interval characterize results of a full ambulatory blood pressure monitoring session?

In: *The Journal of Clinical Hypertension* 10 (6), S. 431–435.

Abstract:

Ambulatory blood pressure monitoring (ABPM) is useful in evaluating cardiovascular risk but requires significant time. The authors examined how closely shortened time intervals correlate with the systolic blood pressure (BP) determined from a full 24-

hour ABPM session in 1004 ABPM recordings. After excluding the first hour, Pearson correlations performed for the mean systolic BP of the subsequent 3-, 5-, and 7-hour periods (4, 6, and 8 hours total) with the entire, and remainder of the session, demonstrated greatest improvement in correlation when the session is increased from 4 to 6 hours. Bland-Altman analysis of the 6-hour time period revealed a mean difference of 5.41 mm Hg compared with the full session mean. The authors conclude that 6-hour ABPM can approximate the overall mean BP obtained from full 24-hour ABPM. However, shortened sessions do not characterize the influence of circadian variation on the 24-hour mean BP and may overestimate the 24-hour BP levels.

Evans, C. C.; Hanke, T. A.; Zielke, D.; Keller, S.; Ruroede, K. (2012):

Monitoring community mobility with global positioning system technology after a stroke: a case study.

In: *J Neurol.Phys.Ther.* 36 (2), S. 68–78. DOI: 10.1097/NPT.0b013e318256511a.

Abstract:

BACKGROUND: Stroke survivors often experience difficulty returning to activities and places they deem important to their social, leisure, and occupational aspirations. The extent to which stroke survivors return to community mobility and their ability to navigate and access locations they deem meaningful have not been objectively measured. PURPOSE: We used global positioning system technology (GPSt) to measure the community mobility of a person poststroke, and assess the relationship between GPSt measures and clinical measures of mobility. METHODS: : The participant was a 56-year-old man who sustained a right pontine stroke. At discharge from rehabilitation, his Six-Minute Walk Test distance was 73 m. He was fitted with a GPS unit and an accelerometer attached to a single belt and instructed to wear the devices at all times when out of bed. After identifying 10 locations that were important to his goals, he was monitored for 5 separate 1-week periods, on the first, fifth, and ninth weeks and at 6 and 12 months after discharge. RESULTS: During the first 10 weeks, he averaged 7.6 target visits (70%) and 26.7 trips per week. At 1 year, his Six-Minute Walk distance score was 287.5 m. Accelerometry data revealed that he remained primarily sedentary. Target visits and trips per week did not change substantially over the course of 1 year, and compliance wearing the GPS unit was variable. CONCLUSIONS: Given the limited correlation in gait speed and distance with target attainment and trips, these outcomes likely measure different constructs for this subject. GPSt may offer insights into participation for stroke survivors following rehabilitation

Evenson, Kelly R. (2011):

Towards an Understanding of Change in Physical Activity from Pregnancy Through Postpartum.

In: *Psychology of Sport and Exercise* 12 (1), S. 36–45. DOI: 10.1016/j.psychsport.2010.04.010.

Abstract:

OBJECTIVE: The purpose of this paper was to describe the rationale, data collection, and proposed analyses for examination of mediators of change in physical activity from pregnancy to postpartum among a cohort of pregnant women. METHOD: The Pregnancy Infection and Nutrition 3 (PIN3) Study enrolled 2006 pregnant women into the cohort from 2001 to 2005. All women lived in central North Carolina upon enrollment. Physical activity was assessed using a self-reported one week recall, measured twice during pregnancy and once each at 3- and 12-months postpartum. On a subset of women, one-week accelerometer measures were also collected during the two postpartum time periods. Potential mediators (intrapersonal, interpersonal, community) were collected during pregnancy and postpartum through interviews and take home questionnaires. RESULTS: To assess mediation of physical activity among our cohort, we will first describe change in physical activity and the mediators, as well as their associations, through pregnancy into the postpartum period. Following this, the product of coefficients approach will be applied to examine whether each measure had indirect effects on change in physical activity. Each individual level mediator will be examined one at a time and across the time points in which it was available. The Sobel standard error approximation formula will be used to test for significance of the mediation effect. CONCLUSIONS: This study will provide evidence to develop appropriate interventions targeted at physical activity and will help focus efforts on the appropriate time periods between pregnancy and postpartum.

Evenson, Kelly R.; Calhoun, Kathryn C.; Herring, Amy H.; Pritchard, David; Wen, Fang; Steiner, Anne Z. (2014):

Association of physical activity in the past year and immediately after in vitro fertilization on pregnancy.

In: *Fertil Steril* 101 (4), S. 1047-1054.e5. DOI: 10.1016/j.fertnstert.2013.12.041.

Abstract:

OBJECTIVE: To estimate the association of physical activity on in vitro fertilization (IVF). DESIGN: Prospective cohort study. SETTING: Academic infertility clinic. PATIENT(S): Women (n = 121) undergoing nondonor IVF embryo transfer (fresh or frozen). INTERVENTION(S): The women completed a questionnaire on past year physical activity and wore an accelerometer from embryo transfer to serum pregnancy testing. MAIN OUTCOME MEASURE(S): Implantation, intrauterine gestation, and live birth. RESULT(S): Based on self-reported past year physical activity, the adjusted odds of intrauterine gestation was higher among those that had higher continuous active living (odds ratio [OR] 1.96, 95% confidence interval [CI] 1.09-3.50), sports/exercise (OR 1.48, CI 1.02-2.15), and total activity (OR 1.52, 95%CI 1.15-2.01) indices. After embryo transfer, women did almost no vigorous activity (median 0 min/d) as measured by the accelerometer. More of their time was spent in light activity (median 3.0 h/d) and sedentary behaviors (median 9.3 h/d). Accelerometer-measured physical activity and sedentary behavior after embryo transfer were not associated with any IVF outcome. CONCLUSION(S): An active lifestyle in the preceding year favorably impacted the IVF outcome. After embryo transfer, women engaged in mostly light physical activity and sedentary behaviors; therefore, the impact of vigorous physical activity on implantation could not be determined.

Evenson, K. R.; Wen, F.; Hillier, A.; Cohen, D. A. (2013):

Assessing the Contribution of Parks to Physical Activity using GPS and Accelerometry.

In: *Med Sci Sports Exerc* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e318293330e.

Abstract:

Purpose: Parks offer a free option for physical activity in many communities. How much time people spend using parks and the contribution that parks makes to their physical activity is not known. This study describes patterns of park use and physical activity among a diverse adult sample.Methods: From five US states, 238 adults enrolled in or near 31 study parks. Participants wore a global positioning system (GPS) monitor (Qstarz BT-Q1000X) and an ActiGraph accelerometer (GT1M) concurrently for three weeks. Parks were mapped from local and national park shape files. Park visits and travel to and from the parks were derived from the objective data.Results: Participants visited parks a median of 2.3 times/week and park visits lasted a median of 42.0 minutes. Overall, participants engaged in a median of 21.7 minutes/day of moderate activity and 0.1 minutes/day of vigorous activity, with an average of 8.2% of all moderate and 9.4% of all vigorous activity occurring within the parks. Among those with at least one park visit (n=218), counts per minute, moderate, moderate to vigorous physical activity (MVPA), number and time in MVPA bouts/day, and sedentary behavior were all higher on days when a park was visited compared to days when a park was not visited. Considering several definitions of active travel, walking or bicycling to and from the park added an additional 3.7 to 6.6 mean minutes of MVPA per park visit.Conclusion: Parks contributed as a place and destination for physical activity, but were underutilized. One of the next steps in this line of inquiry is to understand characteristics of parks used more often as a place and destination for physical activity

Evering, Richard M. H.; T+Nis, Thijs M.; Vollenbroek-Hutten, Miriam M. R. (2011):

Deviations in daily physical activity patterns in patients with the chronic fatigue syndrome: A case control study.

In: *Journal of Psychosomatic Research* 71 (3), S. 129–135. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-18163-007&site=ehost-live;r.evering@rrd.nl.

Abstract:

Objectives: Deviations in daily physical activity patterns may play an important role in the development and maintenance of fatigue in the chronic fatigue syndrome (CFS). The aim of this study is to gain insight into the objective daily physical activity pattern of patients with CFS in comparison with healthy controls. The secondary objective is studying the awareness in performing physical activities. Methods: The objective daily physical activity pattern was measured with a tri-axial accelerometer in 35 patients with CFS and in 35 age- and gender-matched healthy controls. The objective daily physical activity level and distribution of physical activities at low, medium and high intensity levels during the day were measured. Moreover, variability in performing physical activities within and between subjects was computed. Subjective ratings of self-reported daily physical activity levels were assessed at a visual analog scale. Results: CFS patients were significantly less physically active in the

afternoon and evening, and spent fewer activities at high intensity levels and more at low intensity levels. Moreover, CFS patients showed more variability in their own physical activity pattern during the afternoon. The heterogeneity in the physical activity pattern between subjects within the CFS and control group did not differ. Finally, CFS patients were more aware about their daily physical activity level than healthy controls. Conclusion: CFS patients showed deviations in the objectively measured daily physical activity pattern. Future research should elucidate the relation between impaired balances in daily physical activity patterns and fatigue severity in CFS. Ewart, C. K.; Elder, G. J.; Smyth, J. M. (2011):

How Implicit Motives and Everyday Self-Regulatory Abilities Shape Cardiovascular Risk in Youth.

In: *Ann Behav Med* (0883-6612 (Linking)). DOI: 10.1007/s12160-011-9336-3.

Abstract:

BACKGROUND AND PURPOSE: Tested hypotheses from social action theory that (a) implicit and explicit measures of agonistic (social control) motives and transcendence (self-control) motives differentially predict cardiovascular risk; and (b) implicit motives interact with everyday self-regulation behaviors to magnify risk. METHODS: Implicit/explicit agonistic/transcendence motives were assessed in a multi-ethnic sample of 64 high school students with the Social Competence Interview (SCI). Everyday self-regulation was assessed with teacher ratings of internalizing, externalizing, and self-control behaviors. Ambulatory blood pressure and daily activities were measured over 48 h. RESULTS: Study hypotheses were supported: implicit goals predicted blood pressure levels but explicit self-reported coping goals did not; self-regulation indices did not predict blood pressure directly but interacted with implicit agonistic/transcendence motives to identify individuals at greatest risk (all p </= 0.05). CONCLUSIONS: Assessment of implicit motives by SCI, and everyday self-regulation by teachers may improve identification of youth at risk for cardiovascular disease

Faber, Gert S.; Kingma, Idsart; Bruijn, Sjoerd M.; van Dieën, Jaap H. (2009):

Optimal inertial sensor location for ambulatory measurement of trunk inclination.

In: *Journal of biomechanics* 42 (14), S. 2406–2409. DOI: 10.1016/j.jbiomech.2009.06.024.

Abstract:

Trunk inclination (TI) is used often to quantify back loading in ergonomic workplace evaluation. The aim of the present study was to determine whether TI can be obtained using a single inertial sensor (IS) on the back, and to determine the optimal IS location on the back for the estimation of TI. Gold standard TI, the angle between the vertical and the line connecting the L5/S1 joint and the trunk centre of mass, was measured using an optoelectronic system. Ten subjects performed experimental trials, each consisting of a symmetric and an asymmetric lifting task, and of a left-right lateral flexion movement. Trials were repeated and, in between trials, the IS was shifted in small steps from a location on the thorax towards a location on the sacrum. Optimal IS location was defined as the IS location with minimum root-mean-square (RMS) error between the gold standard TI and the IS TI. Averaged over subjects, the optimal IS location for symmetric and asymmetric lifting was at about 25% of the distance from the midpoint between the posterior superior iliac spines (MPSIS) to the C7 spinous process. The RMS error at this location, averaged over subjects, was 4.6+/-2.9 degrees. For the left-right lateral flexion task, the optimal IS location was at about 30% of the MPSIS to C7 distance. Because in most activities of daily living, pure lateral flexion does not occur often, it is recommended place the IS at 25% of the distance from the MPSIS to C7.

Emotional impulsivity in children with adhd associated with comorbid—not adhd—symptomatology.

In: *Journal of Psychopathology and Behavioral Assessment*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-20449-001%26site%3dehost-live.

Abstract:

Children with ADHD often demonstrate sudden and intense shifts in both positive and negative affect. This study examined the role of diagnostic status on emotional impulsivity in children utilizing ecological momentary assessment (EMA). Parents of 64 8–

12 year old children (15 ADHD-only; 27 ADHD-comorbid; 22 control) completed a diagnostic structured interview and then an EMA protocol, rating the child's affect thrice daily for 28 days. Analysis of covariance (ANCOVA) suggested that children with ADHD and a comorbid disorder demonstrated significantly more EMA-derived emotional impulsivity than children with ADHD only and control children. No difference was found between children with ADHD only and control children. This study suggested that children with ADHD demonstrate significantly higher levels of emotional impulsivity than control children only in the presence of a comorbid disorder. Fagard, R. H.; Thijs, L.; Staessen, J. A.; Clement, D. L.; Buyzere, M. L.; Bacquer, D. A. (2009):

Night-day blood pressure ratio and dipping pattern as predictors of death and cardiovascular events in hypertension.

In: *J Hum Hypertens* 23 (10), S. 645–653. DOI: 10.1038/jhh.2009.9.

Abstract:

Our objective was to assess the prognostic significance of the night-time dipping pattern and the night-day blood pressure (BP) ratio for mortality and cardiovascular events in hypertensive patients without major cardiovascular disease at baseline. We performed a meta-analysis on individual data of 3468 patients from four prospective studies performed in Europe. Age of the subjects averaged 61+/-13 years; 45% were men and 61% were under antihypertensive treatment at the time of ambulatory BP monitoring. The night-day BP ratio and 24-h BP averaged, respectively, 0.907+/-0.085/0.866+/-0.095 and 138.1+/-16.4/82.3+/-11.0 mm Hg. Total follow-up time amounted to 23 164 patient-years. We used multivariable Cox regression analysis to assess the outcome of reverse dippers, non-dippers and extreme dippers vs dippers, and to assess the hazard ratios associated with 1 standard deviation higher night-day BP ratio. In comparison with dippers, and with adjustment for confounders and 24-h BP, the incidence of cardiovascular events was worse in reverse dippers (P<or=0.05), whereas mortality was lower in extreme dippers (P<or=0.01); outcome was similar in non-dippers and dippers. The systolic night-day BP ratio independently predicted all-cause mortality and cardiovascular events (P<or=0.001), which persisted after additional adjustment for 24-h BP (P<or=0.05); appropriate interaction terms indicated that the results were similar in men and women, in younger and older patients and in treated and untreated patients. In conclusion, the dipping pattern and the night-day BP ratio significantly and independently predict mortality and cardiovascular events in hypertensive patients without history of major cardiovascular disease, even after adjustment for 24-h BP.

The effect of job strain on nighttime blood pressure dipping among men and women with high blood pressure.

In: *Scand.J.Work Environ.Health* (0355-3140 (Linking)). DOI: 10.5271/sjweh.3294.

Abstract:

OBJECTIVES: Blunted nighttime blood pressure dipping is an established cardiovascular risk factor. This study examined the effect of job strain on nighttime blood pressure dipping among men and women with high blood pressure. METHODS: The sample consisted of 122 blue- and white collar workers (men=72, women=50). The Job Content Questionnaire was used to measure job psychological demands, job control, and social support. The ratio of job demands to job control was used to assess job strain. Nighttime blood pressure dipping was evaluated from 24-hour ambulatory blood pressure monitoring performed on three workdays. RESULTS: Men with high job strain had a 5.4 mm Hg higher sleep systolic blood pressure (P=0.03) and 3.5 mm Hg higher sleep pulse pressure (P=0.02) compared to men with low job strain. Men with high job strain had a smaller fall in systolic blood pressure and pulse pressure from awake to sleep state than those with low job strain (P<0.05). Hierarchical analyses showed that job strain was an independent determinant of systolic blood pressure dipping (P=0.03) among men after adjusting for ethnicity, body mass index, anxiety and depression symptoms, current smoking status, and alcohol consumption. Further exploratory analyses indicated that job control was the salient component of job strain associated with blood pressure dipping (P=0.03). CONCLUSIONS: High job strain is associated with a blunting of the normal diurnal variation in blood pressure and pulse pressure, which may contribute to the relationship between job strain and cardiovascular disease

Fanciullo, Gilbert J.; Cravero, Joseph P.; Mudge, Bridget O.; McHugo, Gregory J.; Baird, John C. (2007):

Development of a new computer method to assess children's pain.

In: *Pain Medicine* 8 (s3), S. 121–128.

Abstract:

OBJECTIVE:

The primary objective of this study was to determine initial psychometric properties and feasibility of a new Computer Face Scale for measuring pediatric pain. Drawbacks to current measurement tools include a lack of continuous variables, suboptimal mode of implementation, and difficulty interpreting results. A computer method of pediatric pain measurement is presented that addresses these problems. Basic psychometric properties, feasibility, and children's preference when compared with Wong-Baker Faces Scale were determined.

METHODS:

Fifty-four hospitalized, pediatric inpatients were tested using both the Computer Face Scale and the Wong-Baker Faces Scale. An additional 30 children (not hospitalized) were tested using only the Computer Face Scale.

RESULTS:

Both hospitalized and nonhospitalized children between the ages of 3 and 17 years of age are able to use the Computer Face Scale to express relative amounts of pain/hurt and happiness. The Computer Face Scale shows acceptable psychometric properties and is preferred by most children.

CONCLUSIONS:

The Computer Face Scale offers advantages over traditional pediatric pain measurement tools. The opportunity for real time review, electronic and time-stamped recording, electronic display, and temporal comparisons of reports affords the potential for improvement in pediatric pain assessment and treatment.

SQUID: Sensorized shirt with smartphone interface for exercise monitoring and home rehabilitation.

In: *IEEE Int.Conf.Rehabil.Robot.* 2013 (1945-7898 (Linking)), S. 1–6. DOI: 10.1109/ICORR.2013.6650451.

Abstract:

Stroke is a leading cause of serious long-term disability in the United States. There is a need for new technological adjuncts to expedite patients' scheduled discharge from hospital and pursue rehabilitation procedure at home. SQUID is a low-cost, smart shirt that incorporates a six-channel electromyography (EMG) and heart rate data acquisition module to deliver objective audiovisual and haptic biofeedback to the patient. The sensorized shirt is interfaced with a smartphone application, for the subject's usage at home, as well as the online database, for the therapist's remote supervision from hospital. A single healthy subject was recruited to investigate the system functionality during improperly performed exercise. The system can potentially be used in automated, remote monitoring of variety of physical therapy exercises, rooted in strength or coordination training of specific muscle groups

Farsang, Csaba (2014):

Efficacy and Tolerability of Fixed-Dose Combination of Perindopril/Indapamide in Type 2 Diabetes Mellitus: PICASSO Trial.

In: *Adv Ther* 31 (3), S. 333–344. DOI: 10.1007/s12325-014-0107-y.

Abstract:

BACKGROUND: Hypertension and type 2 diabetes mellitus (T2DM) synergistically deteriorate the vascular environment, making blood pressure reduction challenging, and substantially increasing cardiovascular risk. METHODS: In the real-life, open-label, observational, PICASSO study, 9,257 hypertensive patients unsuccessfully treated with antihypertensives were switched to fixed-dose combination of perindopril 10 mg/indapamide 2.5 mg. In this subgroup analysis, we analyzed changes in blood pressure and laboratory parameters of 2,762 hypertensive patients with T2DM or pre-diabetes. RESULTS: After 3 months of treatment, significant decreases in office blood pressure were noted in the whole cohort (-27.0 +/- 14.8/-12.7 +/- 9.8 mmHg; $p < 0.001$). Significant decreases were also recorded in patients with grade 1 hypertension (19.2 +/- 10.0/-9.4 +/- 7.9 mmHg), grade 2 (29.2 +/- 10.9/-13.3 +/- 8.7 mmHg) and grade 3 (-45.1 +/- 15.4/-21.5 +/- 11.2 mmHg). Significant decreases in ambulatory blood pressure were also noted ($n = 93$). In patients previously treated with angiotensin-converting enzyme inhibitor +/- hydrochlorothiazide or angiotensin receptor blocker +/- hydrochlorothiazide, mean 24-h blood pressure decreased by 23.4 +/- 13.9/11.5 +/- 9.7 and 22.3 +/- 8.7/10.4 +/- 13.2 mmHg, respectively ($p < 0.001$). Treatment was well tolerated and the switch to treatment with perindopril/indapamide was associated with improvements in laboratory parameters. CONCLUSIONS: Data from

this diabetes subgroup analysis suggest that fixed combination of perindopril 10 mg/indapamide 2.5 mg should be routinely considered for the treatment of hypertension in diabetic patients who are unsuccessfully managed with other antihypertensive medications.

Faulkner, H. J.; Arima, H.; Mohamed, A. (2012):

Latency to first interictal epileptiform discharge in epilepsy with outpatient ambulatory EEG.

In: *Clin.Neurophysiol.* (1388-2457 (Linking)). DOI: 10.1016/j.clinph.2012.01.023.

Abstract:

OBJECTIVE: The diagnosis and classification of epilepsy often relies upon the demonstration of interictal epileptiform discharges (IEDs). Routine 20-min EEG recording has low sensitivity, with multiple EEGs increasing sensitivity to a maximum of 77% (Doppelbauer et al., 1993). An alternate strategy is the use of prolonged continuous EEG; however, there are no data on the average latency to first IED with ambulatory monitoring. METHODS: In this retrospective study we reviewed 180 consecutive patients with epilepsy referred to a Specialist Epilepsy Unit who had undergone 96h outpatient ambulatory EEGs, without medication withdrawal, where IEDs were recorded. Latency to, and factors affecting first IED were analysed. RESULTS: Median latency to first IED was 316min, (interquartile range 70-772min, n=180). IEDs were recorded in 44% of patients within 4h, 58% within 8h, 85% within 24h and 95% within 48h. Recording for the full 96h period revealed only 5% further IEDs. Multivariate analysis showed the latencies to IEDs with generalised epilepsies were shorter than with focal epilepsies ($p<0.0001$). CONCLUSIONS: In 95% of patients showing scalp IEDs a 48h recording was sufficient for electro-clinical classification in this study. SIGNIFICANCE: Our data are the first to show the latency to recording interictal epileptiform discharges with prolonged outpatient EEG monitoring. These data are important in guiding diagnostic practice in Specialist Epilepsy Services

Faurholt-Jepsen, M.; Faurholt-Jepsen, D.; Range, N.; Praygod, G.; Jeremiah, K.; Aabye, M. G. et al. (2013):

The use of combined heart rate response and accelerometry to assess the level and predictors of physical activity in tuberculosis patients in Tanzania.

In: *Epidemiol.Infect.* (0950-2688 (Linking)), S. 1–9. DOI: 10.1017/S0950268813002070.

Abstract:

SUMMARY We assessed the role of tuberculosis (TB) disease and HIV infection on the level of physical activity. A combined heart rate and movement sensor was used to assess habitual physical activity in TB patients and non-TB controls. The association between sputum-negative TB, sputum-positive TB, HIV and physical activity estimates were assessed in multivariable linear regression models adjusted for age, sex, haemoglobin and alpha-1-acid glycoprotein (AGP). Sputum-positive [eB 0.43, 95% confidence interval (CI) 0.29-0.64] and sputum-negative (eB 0.67, 95% CI 0.47-0.94) TB as well as HIV infection (eB 0.59, 95% CI 0.46-0.75) were associated with reduced activity compared to controls. Anaemia accounted for a substantial part of the effects of HIV, while elevated AGP primarily mediated the TB effect. The level of physical activity is highly influenced by TB and HIV, and mainly mediated through anaemia of infection and associated with elevated acute phase response

Faurholt-Jepsen, Daniel; Hansen, Kristina Beck; van Hees, Vincent T.; Christensen, Line Brinch; Girma, Tsinuel; Friis, Henrik; Brage, Soren (2014):

Children Treated for Severe Acute Malnutrition Experience a Rapid Increase in Physical Activity a Few Days after Admission.

In: *J Pediatr. DOI:* 10.1016/j.jpeds.2014.02.014.

Abstract:

OBJECTIVE: To assess physical activity at admission and during recovery from severe acute malnutrition. STUDY DESIGN: Ethiopian children who were admitted with severe acute malnutrition received a clinical examination each week to monitor their recovery during rehabilitation. Using accelerometry (24 h/d for 5 consecutive days) at admission and again after 10 days of rehabilitation, we assessed the level and changes of physical activity. RESULTS: Among 13 children included, the mean (SD) age was 31.1 months (15.5). At baseline, the day-night activity difference was relatively small, whereas the level of activity had substantially increased at follow-up. The diurnal mean acceleration level was significantly greater at follow-up for wrist (1158.8 vs 541.4 counts per minute, $P = .003$) but not hip movements (204.1 vs 141.5, $P = .261$). During daytime (6 a.m. to 10 p.m.), hip

activity increased by 38% from baseline to follow-up (eB 1.38, 95% CI 1.17-1.62), and wrist activity more than doubled (eB 2.50, 95% CI 2.17-2.87). CONCLUSION: The level of physical activity among children with severe acute malnutrition is very low but increases rapidly during recovery. Accelerometry may be a useful approach in the recovery phase as an indicator of early improvement.

Faurholt-Jepsen, M.; Vinberg, M.; Christensen, E. M.; Frost, M.; Bardram, J.; Kessing, L. V. (2013):

Daily electronic self-monitoring of subjective and objective symptoms in bipolar disorder--the MONARCA trial protocol (MONitoring, treAtment and pRediCtion of bipolAr disorder episodes): a randomised controlled single-blind trial.

In: *BMJ Open* 3 (7). DOI: 10.1136/bmjopen-2013-003353.

Abstract:

INTRODUCTION: Electronic self-monitoring of affective symptoms using cell phones is suggested as a practical and inexpensive way to monitor illness activity and identify early signs of affective symptoms. It has never been tested in a randomised clinical trial whether electronic self-monitoring improves outcomes in bipolar disorder. We are conducting a trial testing the effect of using a Smartphone for self-monitoring in bipolar disorder. METHODS: We developed the MONARCA application for Android-based Smartphones, allowing patients suffering from bipolar disorder to do daily self-monitoring-including an interactive feedback loop between patients and clinicians through a web-based interface. The effect of the application was tested in a parallel-group, single-blind randomised controlled trial so far including 78 patients suffering from bipolar disorder in the age group 18-60 years who were given the use of a Smartphone with the MONARCA application (intervention group) or to the use of a cell phone without the application (placebo group) during a 6-month study period. The study was carried out from September 2011. The outcomes were changes in affective symptoms (primary), social functioning, perceived stress, self-rated depressive and manic symptoms, quality of life, adherence to medication, stress and cognitive functioning (secondary and tertiary). ANALYSIS: Recruitment is ongoing. ETHICS: Ethical permission has been obtained. DISSEMINATION: Positive, neutral and negative findings of the study will be published. REGISTRATION DETAILS: The trial is approved by the Regional Ethics Committee in The Capital Region of Denmark (H-2-2011-056) and The Danish Data Protection Agency (2013-41-1710). The trial is registered at ClinicalTrials.gov as NCT01446406

Faurholt-Jepsen, Maria; Vinberg, Maj; Frost, Mads; Christensen, Ellen; Bardram, Jakob; Kessing, Lars (2014):

Daily electronic monitoring of subjective and objective measures of illness activity in bipolar disorder using smartphones inverted question mark the MONARCA II trial protocol: a randomized controlled single-blind parallel-group trial.

In: *BMC Psychiatry* 14 (1), S. 309. DOI: 10.1186/s12888-014-0309-5.

Abstract:

BackgroundPatients with bipolar disorder often show decreased adherence with mood stabilizers and frequently interventions on prodromal depressive and manic symptoms are delayed.Recently, the MONARCA I randomized controlled trial investigated the effect of electronic self-monitoring on smartphones on depressive and manic symptoms. The findings suggested that patients using the MONARCA system had more sustained depressive symptoms than patients using a smartphone for normal communicative purposes, but had fewer manic symptoms during the trial. It is likely that the ability of these self-monitored measures to detect prodromal symptoms of depression and mania may be insufficient compared to automatically generated objective data on measures of illness activity such as phone usage, social activity, physical activity, and mobility. The Monsenso system, for smartphones integrating subjective and objective measures of illness activity was developed and will be tested in the present trial.MethodsThe MONARCA II trial uses a randomized controlled single-blind parallel-group design. Patients with bipolar disorder according to ICD-10 who previously have been treated at the Copenhagen Clinic for Affective Disorder, Denmark are included and randomized to either daily use of the Monsenso system including an feedback loop between patients and clinicians (the intervention group) or to the use of a smartphone for normal communicative purposes (the control group) for a 9-months trial period. The trial was started in September 2014 and recruitment is ongoing. The outcomes are: differences in depressive and manic symptoms; rate of depressive and manic episodes (primary); automatically generated objective data on measures of illness activity; number of days hospitalized; psychosocial functioning (secondary); perceived stress; quality of life; self-rated depressive symptoms; self-rated manic symptoms; recovery; empowerment and adherence to medication (tertiary) between the intervention group and the control group during the trial. Ethical permission has been obtained. Positive, neutral and negative findings will be published.DiscussionIf the system is effective in reducing depressive and/or manic symptoms (and other symptoms of bipolar disorder) and the rate of episodes, there will be basis for extending the use to the treatment of

bipolar disorder in general and in larger scale.Trial registrationClinicalTrials.gov NCT02221336. Registered 26th of September 2014.

Favela, Jesus; Tentori, Monica; Gonzalez, Victor M. (2010):

Ecological validity and pervasiveness in the evaluation of ubiquitous computing technologies for health care.

In: *Intl. Journal of Human–Computer Interaction* 26 (5), S. 414–444.

Abstract:

The difficulties associated with the evaluation of ubiquitous computing (Ubicomp) technologies increase in application domains such as hospitals, where human life can be at risk, privacy of personal records is paramount, and labor is costly and highly distributed across space and time. For the last 6 years numerous Ubicomp technologies in support of hospital work have been created and pilot-tested. In this article, the lessons learned from these evaluations are discussed, using two criteria to classify them. The first criterion is ecological validity, namely, the extent to which the evaluation is conducted under realistic conditions. Alternatives range from controlled experiments to in situ evaluations. The article argues in particular for the advantages of intermediate approaches, which is referred to as in silico and in replica. The second criterion relates to the degree of integration of the technology with the environment, which is referred to as its pervasiveness. The evaluation grid that comes out of this exercise highlights the importance of ecological validity in evaluating ambient computing technology that supports the activities conducted in complex health care settings such as hospitals. This provides a framework for evaluating Ubihealth, which can be used to select appropriate techniques as a function of the technological and environmental complexity as well as to devise novel evaluation techniques.

Favre, J.; Aissaoui, R.; Jolles, B. M.; Guise, J. A.; Aminian, K. (2009):

Functional calibration procedure for 3D knee joint angle description using inertial sensors.

In: *Journal of biomechanics* 42 (14), S. 2330–2335. DOI: 10.1016/j.jbiomech.2009.06.025.

Abstract:

Measurement of three-dimensional (3D) knee joint angle outside a laboratory is of benefit in clinical examination and therapeutic treatment comparison. Although several motion capture devices exist, there is a need for an ambulatory system that could be used in routine practice. Up-to-date, inertial measurement units (IMUs) have proven to be suitable for unconstrained measurement of knee joint differential orientation. Nevertheless, this differential orientation should be converted into three reliable and clinically interpretable angles. Thus, the aim of this study was to propose a new calibration procedure adapted for the joint coordinate system (JCS), which required only IMUs data. The repeatability of the calibration procedure, as well as the errors in the measurement of 3D knee angle during gait in comparison to a reference system were assessed on eight healthy subjects. The new procedure relying on active and passive movements reported a high repeatability of the mean values (offset<1 degrees) and angular patterns (SD<0.3 degrees and CMC>0.9). In comparison to the reference system, this functional procedure showed high precision (SD<2 degrees and CC>0.75) and moderate accuracy (between 4.0 degrees and 8.1 degrees) for the three knee angle. The combination of the inertial-based system with the functional calibration procedure proposed here resulted in a promising tool for the measurement of 3D knee joint angle. Moreover, this method could be adapted to measure other complex joint, such as ankle or elbow.

Fay, Doris; Sonnentag, Sabine (2012):

Within-person fluctuations of proactive behavior: How affect and experienced competence regulate work behavior.

In: *Human Performance* 25 (1), S. 72–93. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-04563-004&site=ehost-live;doris.fay@uni-potsdam.de.

Abstract:

This article studies proactive work behavior from a within-person perspective. Building on the broaden-and-build model and the mood-as-information approach, we hypothesized that negative trait affect and positive state affect predict the relative time

spent on proactive behavior. Furthermore, based on self-determination theory we argued that persons want to feel competent and that proactive behavior is one way to experience competence. In an experience-sampling study, 52 employees responded to surveys 3 times a day for 5 days. Hierarchical linear modeling confirmed the hypotheses on trait and state affect. Analyses furthermore showed that although a higher level of experienced competence at core task activities was associated with a subsequent increase in time spent on these activities, low experienced competence predicted an increase in time spent on proactive behavior. Fazio, Patrik; Granieri, Gino; Casetta, Ilaria; Cesnik, Edward; Mazzacane, Sante; Caliandro, Pietro et al. (2013):

Gait measures with a triaxial accelerometer among patients with neurological impairment.

In: *Neurological Sciences* 34 (4), S. 435–440. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-12493-003%26site%3dehost-live;patrik.fazio@unife.it.

Abstract:

The purpose of the present study is to evaluate accelerometric parameters of gait in different neurological conditions with pathological gait impairment compared to healthy subjects. We studied 17 patients affected by Parkinson's disease, 24 with ataxic gait due to different diseases and 24 healthy subjects supplied with a triaxial accelerometer with a portable datalogger which measures acceleration and deceleration on an anterior-posterior, mediolateral and vertical plane at an approximate level of the center of mass (back sacral localization) and in other two positions (sternal and frontal sacral region) during a steady-state walking. Analyses of the basic accelerometric parameters associated with a jerk analysis allowed us to differentiate between the population groups. We observed a significant reduction of acceleration parameters in neurological patients when compared with healthy subjects, with a reduction of the mean acceleration of 0.30 m/s(2) for ataxic and 0.64 m/s(2) for parkinsonian patients (t test, $p < 0.01$). The root-mean square of the accelerations was used to quantify the attenuations of accelerations. This study suggests that a triaxial accelerometer is a good practical and an economic tool for assessing the alteration of perambulation. Moreover, it is plausible to use these data to obtain objective parameters in the evaluation of the progression of the disease and the efficacy of therapeutic tools.

Feinstein, Justin S.; Adolphs, Ralph; Damasio, Antonio; Tranel, Daniel (2011):

The human amygdala and the induction and experience of fear.

In: *Current biology* 21 (1), S. 34–38.

Abstract:

Although clinical observations suggest that humans with amygdala damage have abnormal fear reactions and a reduced experience of fear, these impressions have not been systematically investigated. To address this gap, we conducted a new study in a rare human patient, SM, who has focal bilateral amygdala lesions. To provoke fear in SM, we exposed her to live snakes and spiders, took her on a tour of a haunted house, and showed her emotionally evocative films. On no occasion did SM exhibit fear, and she never endorsed feeling more than minimal levels of fear. Likewise, across a large battery of self-report questionnaires, 3 months of real-life experience sampling, and a life history replete with traumatic events, SM repeatedly demonstrated an absence of overt fear manifestations and an overall impoverished experience of fear. Despite her lack of fear, SM is able to exhibit other basic emotions and experience the respective feelings. The findings support the conclusion that the human amygdala plays a pivotal role in triggering a state of fear and that the absence of such a state precludes the experience of fear itself.

Felício, João S.; Pacheco, Juliana T.; Ferreira, Sandra R.; Plavnik, Frida; Moisés, Valdir A.; Kohlmann, Oswaldo et al. (2006):

Hyperglycemia and nocturnal systolic blood pressure are associated with left ventricular hypertrophy and diastolic dysfunction in hypertensive diabetic patients.

In: *Cardiovascular diabetology* 5, S. 19. DOI: 10.1186/1475-2840-5-19.

Abstract:

BACKGROUND\r\nThe aim of this study was to determine if hypertensive type 2 diabetic patients, when compared to patients with essential hypertension have an increased left ventricular mass index (LVMI) and a worse diastolic function, and if this fact

would be related to 24-h pressoric levels changes.\r\nMETHODS\r\nNinety-one hypertensive patients with type 2 diabetes mellitus (DM) (group-1 [G1]), 59 essential hypertensive patients (group-2 [G2]) and 26 healthy controls (group-3 [G3]) were submitted to 24-h Ambulatory Blood Pressure Monitoring (ABPM) and echocardiography (ECHO) with Doppler. We calculated an average of fasting blood glucose (AFBG) values of G1 from the previous 4.2 years and a glycemic control index (GCI) (percentual of FBG above 200 mg/dl).\r\nRESULTS\r\nG1 and G2 did not differ on average of diurnal systolic and diastolic BP. However, G1 presented worse diastolic function and a higher average of nocturnal systolic BP (NSBP) and LVMI (NSBP = 132 +/- 18 vs 124 +/- 14 mmHg; P < 0.05 and LVMI = 103 +/- 27 vs 89 +/- 17 g/m2; P < 0.05, respectively). In G1, LVMI correlated with NSBP (r = 0.37; P < 0.001) and GCI (r = 0.29; P < 0.05) while NSBP correlated with GCI (r = 0.27; P < 0.05) and AFBG (r = 0.30; P < 0.01). When G1 was divided in tertiles according to NSBP, the subgroup with NSBP> or =140 mmHg showed a higher risk of LVH. Diabetics with NSBP> or =140 mmHg and AFBG>165 mg/dl showed an additional risk of LVH (P < 0.05; odds ratio = 11). In multivariate regression, both GCI and NSBP were independent predictors of LVMI in G1.\r\nCONCLUSION\r\nThis study suggests that hyperglycemia and higher NSBP levels should be responsible for an increased prevalence of LVH in hypertensive patients with Type 2 DM.

Classification of a known sequence of motions and postures from accelerometry data using adapted Gaussian mixture models.

In: *Physiol Meas* 27 (10), S. 935. Online verfügbar unter http://stacks.iop.org/0967-3334/27/i=10/a=001.

Abstract:

Accelerometry shows promise in providing an inexpensive but effective means of long-term ambulatory monitoring of elderly patients. The accurate classification of everyday movements should allow such a monitoring system to exhibit greater 'intelligence', improving its ability to detect and predict falls by forming a more specific picture of the activities of a person and thereby allowing more accurate tracking of the health parameters associated with those activities. With this in mind, this study aims to develop more robust and effective methods for the classification of postures and motions from data obtained using a single, waist-mounted, triaxial accelerometer; in particular, aiming to improve the flexibility and generality of the monitoring system, making it better able to detect and identify short-duration movements and more adaptable to a specific person or device. Two movement classification methods were investigated: a rule-based Heuristic system and a Gaussian mixture model (GMM)-based system. A novel time-domain feature extraction method is proposed for the GMM system to allow better detection of short-duration movements. A method for adapting the GMMs to compensate for the problem of limited user-specific training data is also proposed and investigated. Classification performance was considered in relation to data gathered in an unsupervised, directed routine conducted in a three-month field trial involving six elderly subjects. The GMM system was found to achieve a mean accuracy of 91.3%, distinguishing between three postures (sitting, standing and lying) and five movements (sit-to-stand, stand-to-sit, lie-to-stand, stand-to-lie and walking), compared to 71.1% achieved by the Heuristic system. The adaptation method was found to offer a mean accuracy of 92.2%; a relative improvement of 20.2% over tests without subject-specific data and 4.5% over tests using only a limited amount of subject-specific data. While limited to a restricted subset of possible motions and postures, these results provide a significant step in the search for a more robust and accurate ambulatory classification system.

Take two apps and call me in the morning.

In: *Hosp Pharm* 48 (8), S. 703–704. DOI: 10.1310/hpj4808-703.

Abstract:

The pace of change in the world of information technology is remarkable at times. The role of the smartphone has rapidly been evolving into that of a health care tool, which has a variety of uses for providers and patients. In this installment, we provide our perspectives on the role of the smartphone and its associated apps.

Ferguson, Stuart G.; Shiffman, Saul (2011):

Using the methods of ecological momentary assessment in substance dependence research--smoking cessation as a case study.

In: *Subst Use Misuse* 46 (1), S. 87–95. DOI: 10.3109/10826084.2011.521399.

Abstract:

Ecological momentary assessment (EMA) is the name applied to any of a range of research methodologies that aim to assess participants in near real time as they go about their regular day-to-day activities. Such methods have particular utility for studying drug use and drug dependence. Using the area of nicotine dependence as a case study, this review highlights how EMA can be used to build upon the findings from more traditional research methods to enhance our understanding of drug use. Particular attention is given to the role that advances in technology have played in the adoption of EMA in drug dependence research.

Does reducing withdrawal severity mediate nicotine patch efficacy? A randomized clinical trial.

In: *Journal of Consulting and Clinical Psychology* 74 (6), S. 1153–1161. DOI: 10.1037/0022-006X.74.6.1153.

Abstract:

Nicotine replacement therapy (NRT) repeatedly has been shown to improve smoking treatment outcome. The major mechanism posited for this improvement in outcome is that NRT reduces nicotine craving and withdrawal. The authors tested this hypothesized mechanism of action using real-time data on craving and withdrawal, collected by ecological momentary assessments administered on a palm-top computer. Smokers (N = 324) were randomized to receive either active high-dose (35 mg) 24-hr patches or placebo. Increases in positive affect and decreases in craving, negative affect, and attention disturbance severity were related to lower risk of lapsing. Although NRT treatment did significantly decrease withdrawal and craving severity, these reductions only partially accounted for NRT's impact on time to first lapse: The results from a mediation analysis showed that the hazard ratio for NRT, when controlling for withdrawal and craving severity, was only a third to a half lower than the uncontrolled hazard ratio for NRT alone. This suggests that other mechanisms for the effectiveness of NRT need to be examined.

Examining the Benefits of Learning Based on an Audience Response System When Confronting Emergency Situations.

In: *Comput Inform Nurs. DOI:* 10.1097/CIN.0000000000000053.

Abstract:

This article presents an empirical study on the effectiveness of the use of an audience response system called SIstema De Respuesta inmediata de la Audiencia on a nursing course. A total of 130students of mixed gender, age, and computer experience and educational background on a third-year course in nursing administration and management participated in the study. The benefits of an audience response system as regards learning how to confront emergency situations were studied. The innovative aspect of the proposal is twofold: (1) the use of a smartphone to respond to the questions and (2) the analysis of the students' response time when confronting critical situations while managing nursing resources. A positive impact on the students' performance was revealed in their final assessments. Our findings show that SIstema De Respuesta inmediata de la Audiencia increases student participation and aids in identifying and correcting misconceptions. The students found SIstema De Respuesta inmediata de la Audiencia to be very motivating and wanted it to be used in additional lectures. Further research is required to study the effectiveness of SIstema De Respuesta inmediata de la Audiencia for it to be widely used in other disciplines.

Cloud computing for context-aware enhanced m-Health services.

In: *Methods Mol Biol* 1246, S. 147–155. DOI: 10.1007/978-1-4939-1985-7_10.

Abstract:

m-Health services are increasing its presence in our lives due to the high penetration of new smartphone devices. This new scenario proposes new challenges in terms of information accessibility that require new paradigms which enable the new applications to access the data in a continuous and ubiquitous way, ensuring the privacy required depending on the kind of data accessed. This paper proposes an architecture based on cloud computing paradigms in order to empower new m-Health applications to enrich their results by providing secure access to user data.

Fialho, Guilherme; Cavichio, Luciano; Povoa, Rui; Pimenta, João (2006):

Effects of 24-h shift work in the emergency room on ambulatory blood pressure monitoring values of medical residents.

In: *Am J Hypertens* 19 (10), S. 1005–1009. DOI: 10.1016/j.amjhyper.2006.03.007.

Abstract:

BACKGROUND\r\nMedical residency is marked by long work hours and shift work. The acute effects of these factors on the blood pressure (BP) of medical residents have not been adequately evaluated.\r\nMETHODS\r\nA total of 61 medical residents underwent to ambulatory blood pressure monitoring (ABPM) during a 24-h shift work in the emergency room (ER) and during a common working day.\r\nRESULTS\r\nBoth mean 24-h systolic and diastolic BP (DBP) and mean diastolic BP readings during sleep were higher during the 24-h shift work in the ER than during common working day (117 v 113 mm Hg, P < .05; 73 v 69 mm Hg, P < .05; and 61 v 58 mm Hg, P < .05, respectively). Abnormally high mean BP readings were more frequent during the 24-h shift work in the ER than in common working day (19 v 8, P < .05). Pressure load, nocturnal BP fall and pulse pressure values were similar in these two different working situations.\r\nCONCLUSION\r\nWorking in the ER on a 24-h shift leads to abnormal BP behavior in medical residents, thus suggesting that this type of work may be a risk factor for cardiovascular disease.

Finan, Patrick Hamilton (2012):

Genetic influences on the dynamics of pain and affect in fibromyalgia.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (12-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99120-470&site=ehost-live.

Abstract:

Fibromyalgia (FM) is a chronic musculoskeletal disorder characterized by widespread pain, fatigue, and a variety of other comorbid physiological and psychological characteristics, including a deficit of positive affect. Recently, the focus of research on the pathophysiology of FM has considered the role of a number of genomic variants. In the current manuscript, case-control analyses did not support the hypothesis that FM patients would differ from other chronic pain groups in catechol-O-methyltransferase (COMT) and mu-opioid receptor (OPRM1) genotype. However, evidence is provided in support of the hypothesis that functional single nucleotide polymorphisms on the COMT and OPRM1 genes would be associated with risk and resilience, respectively, in a dual processing model of pain-related positive affective regulation in FM. Forty-six female patients with a physician-confirmed diagnosis of FM completed an electronic diary that included once-daily assessments of positive affect and soft tissue pain. Multilevel modeling yielded a significant gene X environment interaction, such that individuals with met/met genotype on COMT experienced a greater decline in positive affect as daily pain increased than did either val/met or val/val individuals. A gene X environment interaction for OPRM1 also emerged, indicating that individuals with at least one asp allele were more resilient to elevations in daily pain than those homozygous for the asn allele. In sum, the findings offer researchers ample reason to further investigate the contribution of the catecholamine and opioid systems, and their associated genomic variants, to the still poorly understood experience of FM. Finan, P. H.; Tennen, H.; Thoemmes, F.; Zautra, A. J.; Davis, M. C. (2012):

Ambulatory monitoring in the genetics of psychosomatic medicine.

In: *Psychosom.Med.* 74 (4), S. 349–355. DOI: 10.1097/PSY.0b013e3182544a74.

Abstract:

Psychosomatic disorders are composed of an array of psychological, biologic, and environmental features. The existing evidence points to a role for genetic factors in explaining individual differences in the development and maintenance of a variety of disorders, but studies to date have not shown consistent and replicable effects. As such, the attempt to uncover individual differences in the expression of psychosomatic disorders as a function of genetic architecture requires careful attention to their phenotypic architecture or the various intermediate phenotypes that make up a heterogeneous disorder. Ambulatory monitoring offers a novel approach to measuring time-variant and situation-dependent intermediate phenotypes. Recent examples of the use of ambulatory monitoring in genetic studies of stress reactivity, chronic pain, alcohol use disorders, and psychosocial resilience are reviewed in an effort to highlight the benefits of ambulatory monitoring for genetic study designs

Finan, Patrick H.; Zautra, Alex J.; Davis, Mary C.; Lemery-Chalfant, Kathryn; Covault, Jonathan; Tennen, Howard (2010):

Genetic influences on the dynamics of pain and affect in fibromyalgia.

In: *Health Psychol* 29 (2), S. 134–142. DOI: 10.1037/a0018647.

Abstract:

OBJECTIVE\r\nThe purpose of the present investigation was to determine if variation in the catechol-O-methyltransferase (COMT) and mu-opioid receptor (OPRM1) genes is associated with pain-related positive affective regulation in fibromyalgia (FM).\r\nDESIGN\r\nForty-six female patients with FM completed an electronic diary that included daily assessments of positive affect and pain. Between- and within-person analyses were conducted with multilevel modeling.\r\nMAIN OUTCOME MEASURE\r\nDaily positive affect was the primary outcome measure.\r\nRESULTS\r\nAnalyses revealed a significant gene x experience interaction for COMT, such that individuals with met/met genotype experienced a greater decline in positive affect on days when pain was elevated than did either val/met or val/val individuals. This finding supports a role for catecholamines in positive affective reactivity to FM pain. A gene x experience interaction for OPRM1 also emerged, indicating that individuals with at least one asp allele maintained greater positive affect despite elevations in daily pain than those homozygous for the asn allele. This finding may be explained by the asp allele's role in reward processing.\r\nCONCLUSIONS\r\nTogether, the findings offer researchers ample reason to further investigate the contribution of the catecholamine and opioid systems, and their associated genomic variants, to the still poorly understood experience of FM.

Finan, Patrick H.; Zautra, Alex J.; Davis, Mary C.; Lemery-Chalfant, Kathryn; Covault, Jonathan; Tennen, Howard (2011):

COMT moderates the relation of daily maladaptive coping and pain in fibromyalgia.

In: *Pain* 152 (2), S. 300–307. DOI: 10.1016/j.pain.2010.10.024.

Abstract:

Forty-five women with fibromyalgia (FM) engaged in a 30-day electronic diary assessment, recording daily ratings of pain and 2 forms of maladaptive coping: pain catastrophizing and pain attention. Participants were genotyped for the val158met single nucleotide polymorphism (rs4680) in the catechol-O-methyltransferase (COMT) gene. COMT genotype moderated the daily relations of both maladaptive coping processes and pain. FM women with the homozygous met/met genotype evidenced more pain on days when pain catastrophizing was elevated relative to heterozygous and homozygous val158 carriers. FM women with the homozygous met/met genotype evidenced more pain on days when pain attention was elevated relative to those with the homozygous val/val genotype. Evidence is presented to suggest that these are independent effects. The findings provide multimeasure and multimethod support for genetic moderation of a maladaptive coping and pain process, which has been previously characterized in a sample of postoperative shoulder pain patients. Further, the findings advance our understanding of the role of COMT in FM, suggesting that genetic variation in the val158met polymorphism may affect FM pain through pathways of pain-related cognition.

Motor activity and depression severity in adolescent outpatients.

In: *Neuropsychobiology* 61 (1), S. 33–40. DOI: 10.1159/000262178.

Abstract:

OBJECTIVES\r\nThe present study investigated the association between motor activity and severity of depression in 6 depressed adolescent outpatients.\r\nMETHOD\r\nMotor activity was assessed by actigraphy and the severity of depression was assessed weekly using the CDRS-R. The levels of motor activity were analyzed by considering activity parameters.\r\nRESULTS\r\nAmong

the parameters of motor activity studied, the mean total activity, the mean 24-hour activity levels, the mean waking activity, and the mean activity level between 12:00 and 18:00 h were inversely correlated with severity of depression. The means of the 10 most active hours tended toward a negative correlation with the depressive severity score.\r\nCONCLUSION\r\nThe results seem to suggest an association between motor activity level and severity of depression in adolescents. Nevertheless, in order to reach a more conclusive understanding, it would be necessary to replicate this study using a larger number of individuals as well as a longer observation period.

Sleep patterns and sleepiness among young students: A longitudinal study before and after admission as trainees and apprentices.

In: *Chronobiol Int*, S. 1–8. DOI: 10.3109/07420528.2014.993765.

Abstract:

In developing countries, youngsters start to work during the high school years. Several studies have shown the difficulties associated with double shift, i.e. to work and study concomitantly, and its negative health consequences. Work and study time, as social synchronizers, have significant effects on the sleep-wake cycle (SWC). The purpose of this study was to evaluate sleep patterns and sleepiness in young students before and after entering the workforce as apprentices or trainees. Participants were 40 adolescents (26 males), 15-18 years old (mean = 15.8 years old) engaged in a first-job program at a non-governmental organization (NGO) while attending evening high school in the outskirts of the city of Sao Paulo, Brazil. The participants wore actigraphs (Ambulatory Monitoring, Inc.) and registered subjective sleepiness on KSS (Karolinska Sleepiness Scale) along 7 consecutive days, before and after admission to the job. Descriptive analyses were performed, and the variables were tested by means of the t-test and repeated measures ANOVA taking factors day of the week and time of the day into consideration. The participants' sleep duration on weekdays exhibited significant difference before and after starting work ($F = 4.55$; $p = 0.04$); the mean sleep duration was 492 min (SD = 44 min) before admission to the job to decrease to 405 min (SD = 58 min) after starting work. The mid-sleep time exhibited significant difference on weekdays before and after starting work (04:57 h; SD = 45 min versus 03:30 h; SD = 54 min; $F = 4.91$; $p = 0.03$). Finally, also sleepiness on weekdays ($F = 6.41$; $p = 0.04$) and at the waking time ($F = 10.75$; $p < 0.01$) exhibited significant difference before and after admission to the job. This article emphasizes the fact that social synchronizers like working during the day and studying in the evening changed the participants' SWC and were associated with sleep restriction. Brazilian governmental incentives notwithstanding, simultaneous performance of several activities by young workers should be considered as an occupational health hazard. Employment policies targeting young workers should take the dual shift - study and work - and its effects on the sleep-wake cycle into account.

Fisher, Steve R.; Galloway, Rebecca V.; Kuo, Yong-Fang; Graham, James E.; Ottenbacher, Kenneth J.; Ostir, Glenn V.; Goodwin, James S. (2011):

Pilot study examining the association between ambulatory activity and falls among hospitalized older adults.

In: *Arch Phys Med Rehabil* 92 (12), S. 2090–2092. DOI: 10.1016/j.apmr.2011.06.022.

Abstract:

OBJECTIVE\r\nTo examine the ambulatory activity of older patients who had a documented fall during hospitalization for acute illness.\r\nDESIGN\r\nA retrospective case-control design was used in a pilot study of patients (n=10; ≥65y) who had a documented fall during their hospital stay and matched controls (n=25) who did not fall.\r\nSETTING\r\nAcute care medical/surgical unit.\r\nPARTICIPANTS\r\nMen and women 65 years and older who wore a step activity monitor while hospitalized.\r\nINTERVENTIONS\r\nNot applicable.\r\nMAIN OUTCOME MEASURES\r\nFall incidents during the hospital stay were documented by the nurse in a standardized patient safety event report in accordance with hospital policy. The number of steps per 24-hour interval, time spent walking, and total number of activity episodes were determined for patients and controls.\r\nRESULTS\r\nOn average ± SD, patients who fell took 480.3 ± 432.2 steps per hospital day, spent 53.8 ± 36.9 minutes

walking, and engaged in 25.8 ± 16.9 episodes of activity. Mean daily steps, time spent walking, and number of activity episodes for patients who did not fall were 680.1 ± 876.0, 50.1 ± 58.6, and 21.6 ± 23.8, respectively. Logistic regression results indicated no association between the fall outcome and mean daily steps (odds ratio=.95; 95% confidence interval, 0.84-1.06).\r\nCONCLUSIONS\r\nAmbulatory activity among patients who fell varied widely. Mean daily steps, time spent walking, and number of episodes of activity were comparable with matched controls who did not fall. Patient falls were more likely to be associated with cognitive and hospital environmental factors than actual amount of walking.

Fisher, C. D.; Minbashian, A.; Beckmann, N.; Wood, R. E. (2013):

Task appraisals, emotions, and performance goal orientation.

In: *J Appl.Psychol.* 98 (2), S. 364–373. DOI: 10.1037/a0031260.

Abstract:

We predict real-time fluctuations in employees' positive and negative emotions from concurrent appraisals of the immediate task situation and individual differences in performance goal orientation. Task confidence, task importance, positive emotions, and negative emotions were assessed 5 times per day for 3 weeks in an experience sampling study of 135 managers. At the within-person level, appraisals of task confidence, task importance, and their interaction predicted momentary positive and negative emotions as hypothesized. Dispositional performance goal orientation was expected to moderate emotional reactivity to appraisals of task confidence and task importance. The hypothesized relationships were significant in the case of appraisals of task importance. Those high on performance goal orientation reacted to appraisals of task importance with stronger negative and weaker positive emotions than those low on performance goal orientation. Using experience sampling methodology in organizational behavior.

In: *J. Organiz. Behav.* 33 (7), S. 865–877. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-25717-001%26site%3dehost-live;Cynthia.

Abstract:

Experience sampling methodology and daily diary (ESM/DD) research elicits repeated reports of immediate or very recent experiences from the same sample of people for several days or weeks. Experience sampling and diary methods were almost unheard of in organizational research 15 years ago, but the past decade has seen a rapid rise in their use. These methods are helpful in studying dynamic within-person processes involving affect, behavior, interpersonal interactions, work events, and other transient workplace phenomena over time. Assessing cross-level effects of traits or other stable features on within-person processes and reactivity is also possible with ESM/DD data. We provide an introduction to issues in designing and carrying out an ESM/DD study, including data collection choices and schedules, measures, technology, training and motivation of participants, and analysis of multilevel data. We offer best practice recommendations and refer readers to further resources for additional detail on conducting and analyzing ESM/DD research. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Fitzgerald-Dejean, Donna M.; Rubin, Scott S.; Carson, Russell L. (2012):

An application of the experience sampling method to the study of aphasia: A case report.

In: *Aphasiology* 26 (2), S. 234–251. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-29295-007&site=ehost-live;dfitzgeralddejean@cox.net.

Abstract:

Background: Researchers stress that functional health and psychological well-being are important aspects of quality of life in the investigation of individuals with aphasia. Employed in the social sciences, the experience sampling method (ESM) has begun to shed light on deviations in participants' momentary responses to behavioural contingencies in naturalistic environments. Applications of ESM have demonstrated value in monitoring within-participant variations in mood, psychopathology, and treatment outcomes while minimising the effect of memory bias. Additionally, the application of ESM in psychological cognitive-behavioural therapy and occupational therapy (OT) research reportedly appeared to contribute to treatment success. A time-

based, fixed-schedule sampling application of ESM was used in this study to attain self-reports throughout an aphasia treatment programme. Aims: The current investigation introduced the ESM paradigm to the study of aphasia and piloted its use in measuring psychoemotional variables in an individual with chronic aphasia participating in an intensive treatment regime. Methods & Procedures: Repeated ESM probes were administered during a university-based treatment programme to measure the daily responses of a 75-year-old participant with a moderate-to-severe communicative impairment secondary to a cerebral vascular accident (CVA). A total of 20 brief ESM probes were cued by clinicians at four fixed times per day, 5 days a week during a 35-hour a week, 6-week programme. Probes conducted throughout each day used a 5-point Likert scale to query participant response to psychoemotional variables perceived happiness, perceived tiredness, perceived stress, and perceived communication satisfaction. Outcomes & Results: Findings revealed that the participant with aphasia was able to respond to a 5-point Likert scale administered with a personal data assistant (PDA) with 100% compliance when cued by clinicians that it was time to complete the ESM probe (464 responses across 29 days). The internal validity of internal states used in this study is supported by the strong negative correlation found with perceived happiness between both perceived tiredness ($p < .01$) and perceived stress ($p < .01$), as well as the positive correlation found between the negative states of perceived tiredness and perceived stress ($p < .01$). Conclusions: This initial success of ESM implementation in this case study of aphasia treatment suggests that further explorations are needed in the application of ESM in aphasia research. Personality research. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 525–538. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-029%26site%3dehost-live.

Abstract:

(from the chapter) Experience sampling methodology (ESM) is a method that allows for repeated measurement of behavior states within the context of individuals' everyday lives. Our purpose in this chapter is to articulate the kinds of conceptual questions about personality that ESM and other daily methods are uniquely suited to address. Because of its ability to assess what is actually happening in the moment, on multiple occasions, ESM opens up new questions about the trait-behavior relationship and the manifestation, the dynamics, and the inner workings of personality. In other words, how much and in what ways do people's traits influence behavior? How do people's personalities and behavior vary across occasions and time? How do people's traits function, and according to which internal processes? Although ESM has contributed a great deal of understanding to the connection between relationship variables and behavior (Gable, Gosnell, & Prok, this volume), and affective traits and experienced affect (e.g., Augustine & Larsen, this volume), we wish to locate this chapter more centrally in the conceptual domain of personality by articulating five specific conceptual questions that are relevant to personality and are addressable by ESM. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

The relevance of big five trait content in behavior to subjective authenticity: do high levels of within-person behavioral variability undermine or enable authenticity achievement?

In: *J Personality* 78 (4), S. 1353–1382. DOI: 10.1111/j.1467-6494.2010.00653.x.

Abstract:

Individuals vary their behavior from moment to moment a great deal, often acting \"out of character\" for their traits. This article investigates the consequences for authenticity. We compared 2 hypotheses-trait consistency, that individuals feel most authentic when acting in a way consistent with their traits; and state-content significance, that some ways of acting feel more authentic because of their content and consequences, regardless of the actor's corresponding traits. Three studies using experience-sampling methodology in laboratory and natural settings, with participants ages 18-51, strongly supported the state-content significance hypothesis and did not support the trait-consistency hypothesis. Authenticity was consistently associated with acting highly extraverted, agreeable, conscientious, emotionally stable, and intellectual, regardless of the actor's traits. Discussion focuses on possible implications for within-person variability in behavior and for the nature of the self-concept.

Evaluation of a Smartphone-based audio-biofeedback system for improving balance in older adults - A pilot study.

In: *Conf.Proc.IEEE Eng Med.Biol.Soc.* 2013 (1557-170X (Linking)), S. 1198–1201. DOI: 10.1109/EMBC.2013.6609721.

Abstract:

This study was designed to assess the effectiveness of a Smartphone-based audio-biofeedback (ABF) system for improving balance in older adults. This so-called "iBalance-ABF" system that we recetly developed is "all-inclusive" in the sense that its three main components of a balance prosthesis, (i) the sensory input unit, (ii) the processing unit, and (iii) the sensory output unit, are entirely embedded into the Smartphone. The underlying principle of this system is to supply the user with supplementary information about the medial-lateral (ML) trunk tilt relative to a predetermined adjustable "dead zone" through sound generation in earphones. Six healthy older adults voluntarily participated in this pilot study. Eyes closed, they were asked to stand upright and to sway as little as possible in two (parallel and tandem) stance conditions executed without and with the use of the iBalance-ABF system. Results showed that, without any visual information, the use of the Smartphone-based ABF allowed the older healthy adults to significantly decrease their ML trunk sway in the tandem stance posture and to mitigate the destabilizing effect induced by this particular stance. Although an extended study including a larger number of participants is needed to confirm these data, the present results are encouraging. They do suggest that Smartphone-based ABF system could be used for balance training and rehabilitation therapy in older adults

Floro, Joshua Nicholas (2012):

Reduced regulation of negative emotion with escalations in smoking behavior during high school: A dose-response effect.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (11-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99100-084&site=ehost-live.

Abstract:

Recent research suggests that cigarette smoking is associated with developing externalizing and internalizing psychological disorders. Because reduced emotion regulation is also associated with developing externalizing and internalizing disorders, and because cigarette smoking and nicotine addiction are theorized to interfere with emotion regulation processes, the association between cigarette smoking and psychological disorders may be mediated by reduced emotion regulation. This is the first study to examine the relationship between escalations in cigarette smoking behavior and emotion regulation. In a secondary analysis of electronic diary data from a multi-cohort, longitudinal observation study of high school students, the present study tested whether cigarette smoking was associated with reduced regulation of anger, sadness, anxiety, and happiness. Semiannually across the 4 high school years, students completed electronic diaries during 4 consecutive days. For each of these 4-day waves, smoking status was categorized as nonsmoking, infrequent smoking, or light-to-moderate smoking behavior. Daily emotion regulation was measured by area under the curve (AUC) and then averaged over a 4-day monitoring wave. AUC is a composite measure of emotion intensity, lability, and duration. A total of 178 male (55.6%) and female (44.4%) participants were included. Within-subject testing of the relationship between escalations in cigarette smoking behavior and 4-day wave measures of emotion regulation was done through repeated measures logistic regression modeling (Proc Genmod, SAS). Through forward selecting, stepwise model building, the present study attempted to control for sex, age, and freshman year externalizing and internalizing levels. Escalations in cigarette smoking behavior were associated with reductions in regulation of anger and sadness. A similar trend was found for anxiety but not at a statistically significant level. Escalations in cigarette smoking behavior were not associated with reductions in regulation of happiness. These findings indicate that adolescents become less adept at regulating their negative emotions as they progress in cigarette smoking behavior from nonsmoking to light-to-moderate smoking. These smoking-related reductions in regulation of negative emotion occur at subclinical levels of nicotine addiction. Further, these smoking-related reductions in regulation of negative emotion may put adolescents at risk for developing externalizing and internalizing disorders such as conduct disorder or depression, respectively. It's not just the television: survey analysis of sedentary behaviour in New Zealand young people.

In: *Int J Behav Nutr Phys Act* 8 (1479-5868 (Linking)), S. 132. DOI: 10.1186/1479-5868-8-132.

Abstract:

ABSTRACT: BACKGROUND: Sedentary behaviour has been linked with adverse health outcomes in young people; however, the nature and context of being sedentary is poorly understood. Accurate quantification and description of sedentary behaviour using population-level data is required. The aim of this research was to describe sedentary behaviour among New Zealand (NZ) youth and examine whether sedentary behaviour differs by Body Mass Index (BMI) status in this population. METHODS: A national representative cross-sectional survey of young people aged 5-24 years (n = 2,503) was conducted in 2008-2009. Data from this survey, which included subjectively (recall diary; n = 1,309) and objectively (accelerometry; n = 960) measured sedentary behaviour for participants aged 10-18 years were analysed using survey weighted methods. RESULTS: Participants self-reported spending on average 521 minutes per day (standard error [SE] 5.29) in total sedentary behaviour, 181 minutes per day (SE 3.91) in screen-based sedentary activities (e.g., television and video games), and 340 minutes per day (SE 5.22) in other non-screen sedentary behaviours (e.g., school, passive transport and self-care). Accelerometer-measured total sedentary behaviour was on average 420 minutes per day (SE 4.26), or 53% (SE 0.42%) of monitored time. There were no statistically significant differences in time spent in sedentary behaviour among overweight, obese and healthy/underweight young people. CONCLUSIONS: Both subjective and objective methods indicate that NZ youth spend much of their waking time being sedentary. No relationships were found between sedentary behaviour and BMI status. These findings extend previous research by describing engagement in specific sedentary activities, as well as quantifying the behaviour using an objective method. Differences in what aspects of sedentary behaviour the two methods are capturing are discussed. This research highlights the potential for future interventions to target specific sedentary behaviours or demographic groups

Fonareva, Irina; Amen, Alexandra M.; Ellingson, Roger M.; Oken, Barry S. (2012):

Differences in stress-related ratings between research center and home environments in dementia caregivers using ecological momentary assessment.

In: *International Psychogeriatrics* 24 (1), S. 90–98. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-30506-011&site=ehost-live;oken@ohsu.edu.

Abstract:

BACKGROUND:

Clinicians and researchers working with dementia caregivers typically assess caregiver stress in a clinic or research center, but caregivers' stress is rooted at home where they provide care. This study aimed to compare ratings of stress-related measures obtained in research settings and in the home using ecological momentary assessment (EMA).

METHODS:

EMA of 18 caregivers (mean age 66.4 years ±7.8; 89% females) and 23 non-caregivers (mean age 66.4 years ±7.9; 87% females) was implemented using a personal digital assistant. Subjects rated their perceived stress, fatigue, coping with current situation, mindfulness, and situational demand once in the research center and again at 3-4 semi-random points during a day at home. The data from several assessments conducted at home were averaged for statistical analyses and compared with the data collected in the research center.

RESULTS:

The testing environment had a differential effect on caregivers and non-caregivers for the ratings of perceived stress ($p < 0.01$) and situational demand ($p = 0.01$). When tested in the research center, ratings for all measures were similar between groups, but when tested at home, caregivers rated their perceived stress as higher than non-caregivers ($p = 0.02$). Overall, caregivers reported higher perceived stress at home than in the research center ($p = 0.02$), and non-caregivers reported greater situational demand in the research center than at home ($p < 0.01$).

CONCLUSIONS:

The assessment method and environment affect stress-related outcomes. Evaluating participants in their natural environment provides a more sensitive measure of stress-related outcomes. EMA provides a convenient way to gather data when evaluating dementia caregivers.

A robust classification scheme for detection of food intake through non-invasive monitoring of chewing.

In: *Conf.Proc.IEEE Eng Med.Biol.Soc.* 2012 (1557-170X (Linking)), S. 4891–4894. DOI: 10.1109/EMBC.2012.6347090.

Abstract:

Automatic methods for food intake detection are needed to objectively monitor ingestive behavior of individuals in a free living environment. In this study, a pattern recognition system was developed for detection of food intake through the classification of jaw motion. A total of 7 subjects participated in laboratory experiments that involved several activities of daily living: talking, walking, reading, resting and food intake while being instrumented with a wearable jaw motion sensor. Inclusion of such activities provided a high variability to the sensor signal and thus challenged the classification task. A forward feature selection process decided on the most appropriate set of features to represent the chewing signal. Linear and RBF Support Vector Machine (SVM) classifiers were evaluated to find the most suitable classifier that can generalize the high variability of the input signal. Results showed that an average accuracy of 90.52% can be obtained using Linear SVM with a time resolution of 15 sec

How do feelings influence effort? An empirical study of entrepreneurs' affect and venture effort.

In: *J Appl Psychol* 94 (4), S. 1086–1094. DOI: 10.1037/a0015599.

Abstract:

How do feelings influence the effort of entrepreneurs? To obtain data on this issue, the authors implemented experience sampling methodology in which 46 entrepreneurs used cell phones to provide reports on their affect, future temporal focus, and venture effort twice daily for 24 days. Drawing on the affect-as-information theory, the study found that entrepreneurs' negative affect directly predicts entrepreneurs' effort toward tasks that are required immediately. Results were consistent for within-day and next-day time lags. Extending the theory, the study found that positive affect predicts venture effort beyond what is immediately required and that this relationship is mediated by future temporal focus. The mediating effects were significant only for next-day outcomes. Implications of findings on the nature of the affect-effort relationship for different time lags are discussed.

Parenting stress, salivary biomarkers, and ambulatory blood pressure: A comparison between mothers and fathers of children with autism spectrum disorders.

In: *Journal of Autism and Developmental Disorders*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-42907-001%26site%3dehost-live.

Abstract:

Parents of children with autism spectrum disorders (ASD) may experience higher levels of stress and health problems than parents of children with typical development. However, most research has focused on mothers, with emphasis on parent-reported stress and wellbeing. This study compared parenting responsibility, distress, anxiety, depression, cortisol, alpha-amylase, and cardiovascular activity between 19 mother–father dyads of children with ASD. Mothers reported higher parenting responsibility, distress, anxiety, and depression than fathers, while fathers had higher blood pressure and heart rate variability. Mothers and fathers had lower than average morning cortisol levels, suggesting stress effects on the hypothalamic–pituitary–adrenal-axis. Parents of children with ASD may benefit from routine health screening (particularly adrenal and cardiovascular function) and referral for stress reduction interventions or supports. Appearance investment and everyday interpersonal functioning: An experience sampling study.

In: *Psychology of Women Quarterly* 34 (3), S. 380–393.

Abstract:

Several studies have shown that body satisfaction affects interpersonal functioning. However, few have studied the specific interpersonal correlates of another important body image dimension, appearance investment—that is, the importance a woman

places on appearance. We used an experience sampling design with PDA (personal digital assistant) devices to assess how 92 college women's appearance investment is related to perceptions of everyday social interactions and to investigate the association of these perceptions with mood and self-esteem. For 1 week, participants completed electronic diaries of their mood, self-esteem, and perceptions of one-on-one interactions. High appearance investment was associated with a stronger relationship between perceived communion of the interaction and negative mood and self-esteem. Notably, highly appearance-invested women did not report differences in average momentary levels of perceived communion or agency in interactions, negative mood, or self-esteem when compared to women with lower appearance investment. In contrast, women with low body satisfaction reported lower average perceptions of communion and self-esteem as well as higher average negative mood compared to women with higher body satisfaction, but no relationships among perceptions and self-esteem and mood were found. Thus, self-esteem and negative mood in women high in appearance investment might be contingent on perceptions of communion in interactions, even though they appear to have average levels of mood and self-esteem in general. This mood and self-esteem contingency could predispose appearance-invested women to psychological distress or eating pathology.

Forbes, E. E.; Stepp, S. D.; Dahl, R. E.; Ryan, N. D.; Whalen, D.; Axelson, D. A. et al. (2012):

Real-world affect and social context as predictors of treatment response in child and adolescent depression and anxiety: an ecological momentary assessment study.

In: *J.Child Adolesc.Psychopharmacol.* 22 (1), S. 37–47. DOI: 10.1089/cap.2011.0085.

Abstract:

OBJECTIVE: Response to treatment in child and adolescent affective disorders is variable, with limited ability of any one treatment to improve outcome across patients. Unfortunately, we know little about the factors that explain this variability in treatment response. Individual differences in the social and affective dynamics of daily life could help to elucidate the characteristics of youth who respond to treatment. METHODS: We used ecological momentary assessment of negative affect, positive affect, and companions in natural settings over 4 days in a sample of young people with depressive and anxiety disorders who participated in an 8-week open trial of cognitive behavioral therapy (CBT), selective serotonin reuptake inhibitors (SSRIs), or a combination of the two. Clinicians rated participants' clinical severity at five time points, and participants reported their symptoms before and after treatment. Latent growth curve models were used to predict rate of change in clinical severity from pretreatment affect in natural settings. RESULTS: Participants with high positive affect (PA), low negative affect (NA), and a high PA:NA ratio at baseline had lower severity, depressive symptoms, and anxiety symptoms at the end of treatment. Lower posttreatment symptoms were associated with spending more time with fathers and less time with peers before treatment. Although baseline affect was not associated with initial symptom severity, high NA and low PA:NA at baseline were related to slower rate of decline of severity during treatment. When baseline symptoms were included in models, NA and PA:NA predicted rate of decline in severity during treatment, whereas self-reported depressive and anxiety symptoms at baseline did not. CONCLUSION: A more typical profile of baseline affective functioning in natural settings-that is, lower NA and higher PA-and time with fathers, could provide a foundation for treatment response in children and adolescents. Affective and social dynamics in natural settings could ultimately help investigate which young people might benefit from current treatments

Forbush, Kelsie T.; Hunt, Tyler K. (2014):

Characterization of eating patterns among individuals with eating disorders: What is the state of the plate?

In: *Physiol Behav. DOI:* 10.1016/j.physbeh.2014.02.045.

Abstract:

Eating disorders will affect approximately 18 million individuals in the United States at some point in their lives, and are associated with significant psychological distress, psychosocial and quality-of-life impairment, medical morbidity, and mortality. Although aberrant eating behaviors play a central role in diagnostic definitions for eating disorders, much remains to be learned about eating patterns, diet quality, and energy balance among individuals with eating pathology. The goal of the current paper was to systematically review and integrate findings from published research studies characterizing the eating behaviors of individuals with eating disorders, including findings from both descriptive and laboratory-based research. We also describe results from studies using ecological momentary assessment - a methodology that assesses individuals' behaviors in their natural environment as they occurring, which may reduce retrospective recall bias, and provide improved ability to prospectively assess the temporal ordering of changes in multiple eating behaviors over time. We conclude with suggestions for future research, including the need for additional studies to test for differences in eating patterns among different demographic groups of individuals with eating disorders, and the need for new, more objective, assessment tools.

Utility and Efficacy of a Smartphone Application to Enhance the Learning and Behavior Goals of Traditional Cardiac Rehabilitation: A FEASIBILITY STUDY.

In: *J Cardiopulm Rehabil Prev. DOI:* 10.1097/HCR.0000000000000058.

Abstract:

PURPOSE:: Most eligible patients do not participate in traditional clinic-based cardiac rehabilitation (CR) despite well-established benefits. Novel approaches to overcome logistic obstacles and increase efficiencies of learning, behavior modification, and exercise surveillance may increase CR participation. In an observational study, the feasibility and utility of a mobile smartphone application for CR, Heart Coach (HC), were assessed as part of standard care. Ultimately, innovative CR models incorporating HC may facilitate better CR usage and value. METHODS:: Twenty-six patients enrolled in CR installed HC. Over the next 30 days, they were prompted by HC to complete a daily "task list" that included medications, walking, education (text and videos), and surveys. Cardiac rehabilitation providers monitored each patient's progress through a HC-based Web dashboard and also sent them personalized feedback and support. Completion of the tasks and feedback (qualitative and quantitative) from patients and clinicians were tracked. RESULTS:: Patients engaged with HC 90% of days during the study period, with uniformly favorable impact on compliance and adherence. Eighty-three percent of patients reported a positive/very positive HC experience. Providers reported that HC enhanced their provision of therapy by improving communication, clinical insight, patient participation, and program efficiency. CONCLUSIONS:: Integrating a mobile care delivery platform into CR was feasible, safe, and agreeable to patients and clinicians. It enhanced patient perceptions of CR care and physician perceptions of the CR caregiving process. Mobile-enabled technologies hold promise to extend the quality and reach of CR, and to better achieve contemporary accountable care goals.

Fox, K. R.; Hillsdon, M.; Sharp, D.; Cooper, A. R.; Coulson, J. C.; Davis, M. et al. (2011):

Neighbourhood deprivation and physical activity in UK older adults.

In: *Health & Place* 17 (2), S. 633–640. DOI: 10.1016/j.healthplace.2011.01.002.

Abstract:

The benefits of regular physical activity for older adults are now well-established but this group remain the least active sector of the population. In this paper, the association between levels of neighbourhood deprivation and physical activity was assessed. A sample of 125 males with a mean age of 77.5 (±5.6) years, and 115 females with a mean age of age 78.6 (±8.6) underwent 7-day accelerometry, a physical performance battery, and completed a daily journeys log. Univariate associations between physical activity parameters and level of deprivation of neighbourhood were extinguished in regression models controlling for age, gender, and level of educational attainment. Age, gender, educational attainment, body mass index, physical function, and frequency of journeys from the home explained between 50% and 54% of variance in activity parameters. These results suggest the importance of strategies to help older adults maintain physical function, healthy weight, and remain active in their communities.

Fox, Kennethr.; Stathi, Afroditi; McKenna, Jim; Davis, Markg. (2007):

Physical activity and mental well-being in older people participating in the Better Ageing Project.

In: *Eur J Appl Physiol* 100 (5), S. 591–602. DOI: 10.1007/s00421-007-0392-0.

Abstract:

Increasing evidence suggests that physical activity can prevent some aspects of mental illness in older people such as depression, dementia and Alzheimer's disease. Additionally, limited research has shown that engagement in structured exercise can improve aspects of psychological well-being such as mood and self-perceptions in older adults. However, the relationship between incidental daily activity such as walking or time spent sedentary, with psychological well-being has not been investigated. The Better Ageing Project provided an opportunity to assess well-being and quality of life using standardised questionnaires with 176 adults aged 70 and over. Accelerometry was used to objectively assess daily energy expended in physical activity at different levels of intensity. In addition, an assessment of the impact of the 12-month Better Ageing structured group exercise programme was assessed through questionnaires and interviews. Total daily physical activity energy expenditure (joules/day) and amount of time spent in activity of at least moderate intensity were weakly related (r = 0.20-0.28) to quality of life, subjective well-being and physical self-perceptions. Time spent sedentary (min/day) was weakly and negatively related to several mental health indicators. The quantitative data showed only minor psychological benefits of the exercise

intervention. In contrast, interviews with 27 research participants and 4 exercise leaders suggested that important improvements in perceived function and social benefits had been experienced.

Francis, Shelby L.; Letuchy, Elena M.; Levy, Steven M.; Janz, Kathleen F. (2014):

Sustained effects of physical activity on bone health: Iowa Bone Development Study.

In: *Bone* 63C, S. 95–100. DOI: 10.1016/j.bone.2014.03.004.

Abstract:

Studies of youth athletics and interventions have shown some maintenance of bone mineral content (BMC; g) after cessation of training, but less is known about sustained effects of everyday physical activity (PA). Using a prospective cohort, this report examined potential effects of childhood PA on adolescent BMC. Participants (N=156 boys, 170 girls) had exams at ages 5, 13, and 15. Body size and maturity were determined using anthropometry. Moderate-to-vigorous-intensity PA (MVPA) and vigorous-intensity PA (Vigorous PA) were measured using accelerometry. BMC of the spine and hip was measured using dual-energy X-ray absorptiometry. Mixed regression models tested whether PA at age 5 affected BMC at ages 13 and 15 after adjustment for age (year), height (cm), weight (kg), maturity (pre-peak height velocity or post), and activity level (min/day). Analysis was repeated to control for age 5 BMC. On average, boys participated in 59, 52, and 38min of MVPA and 13, 17, and 11min of Vigorous PA at ages 5, 13, and 15, respectively. MVPA (beta=0.799) and Vigorous PA (beta=1.338) at age 5 predicted later spine BMC ($p<0.05$). MVPA (beta=0.480) at age 5 predicted hip BMC. Girls participated in 47, 33, and 26min of MVPA and 10, 9 and 7min of Vigorous PA at ages 5, 13, and 15, respectively. Neither MVPA nor Vigorous PA predicted later spine BMC. MVPA (beta=0.302) at age 5 predicted hip BMC. After controlling for BMC at age 5 as well as the other covariates, the effect of MVPA (beta=0.695) and Vigorous PA (beta=1.079) at age 5 remained significant for boys at the spine. For girls, neither MVPA nor Vigorous PA at age 5 predicted spine or hip BMC. Children's early PA appears to have a modest effect on adolescent BMC at the critical regions of spine and hip; benefits may be greater for geometric changes, which future studies should include.

Franklin, M. S.; Mrazek, M. D.; Anderson, C. L.; Smallwood, J.; Kingstone, A.; Schooler, J. W. (2013):

The silver lining of a mind in the clouds: interesting musings are associated with positive mood while mind-wandering.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 583. DOI: 10.3389/fpsyg.2013.00583.

Abstract:

The negative effects of mind-wandering on performance and mood have been widely documented. In a recent well-cited study, Killingsworth and Gilbert (2010) conducted a large experience sampling study revealing that all off-task episodes, regardless of content, have equal to or lower happiness ratings, than on-task episodes. We present data from a similarly implemented experience sampling study with additional mind-wandering content categories. Our results largely conform to those of the Killingsworth and Gilbert (2010) study, with mind-wandering generally being associated with a more negative mood. However, subsequent analyses reveal situations in which a more positive mood is reported after being off-task. Specifically when off-task episodes are rated for interest, the high interest episodes are associated with an increase in positive mood compared to all on-task episodes. These findings both identify a situation in which mind-wandering may have positive effects on mood, and suggest the possible benefits of encouraging individuals to shift their off-task musings to the topics they find most engaging

Tracking Distraction: The Relationship Between Mind-Wandering, Meta-Awareness, and ADHD Symptomatology.

In: *J Atten Disord. DOI:* 10.1177/1087054714543494.

Abstract:

OBJECTIVE: Although earlier work has shown a link between mind-wandering and ADHD symptoms, this relationship has not been further investigated by taking into account recent advances in mind-wandering research. METHOD: The present study provides a comprehensive assessment of the relationship between mind-wandering and ADHD symptomatology in an adult community sample (N = 105, 71 females, M age = 23.1) using laboratory measures and experience sampling during daily life. RESULTS: Mind-wandering and detrimental mind-wandering were positively associated with ADHD symptoms. Meta-awareness

of mind-wandering mediated the relationship between ADHD symptomatology and detrimental mind-wandering, suggesting that some of the negative consequences can be ameliorated by strategies that facilitate meta-awareness. Interestingly, participants with low ADHD scores showed a positive relationship between detrimental mind-wandering and useful mind-wandering; however, participants with high ADHD scores failed to engage in this type of "strategic" mind-wandering. CONCLUSION: These results provide new insights into the relationship between ADHD symptomatology and mind-wandering that could have important clinical implications.

Franklin, S. S.; Thijs, L.; Hansen, T. W.; Li, Y.; Boggia, J.; Kikuya, M. et al. (2012):

Significance of white-coat hypertension in older persons with isolated systolic hypertension: a meta-analysis using the International Database on Ambulatory Blood Pressure Monitoring in Relation to Cardiovascular Outcomes population.

In: *Hypertension* 59 (3), S. 564–571. DOI: 10.1161/HYPERTENSIONAHA.111.180653.

Abstract:

The significance of white-coat hypertension in older persons with isolated systolic hypertension remains poorly understood. We analyzed subjects from the population-based 11-country International Database on Ambulatory Blood Pressure Monitoring in Relation to Cardiovascular Outcomes database who had daytime ambulatory blood pressure (BP; ABP) and conventional BP (CBP) measurements. After excluding persons with diastolic hypertension by CBP (>/=90 mm Hg) or by daytime ABP (>/=85 mm Hg), a history of cardiovascular disease, and persons <18 years of age, the present analysis totaled 7295 persons, of whom 1593 had isolated systolic hypertension. During a median follow-up of 10.6 years, there was a total of 655 fatal and nonfatal cardiovascular events. The analyses were stratified by treatment status. In untreated subjects, those with white-coat hypertension (CBP >/=140/<90 mm Hg and ABP <135/<85 mm Hg) and subjects with normal BP (CBP <140/<90 mm Hg and ABP <135/<85 mm Hg) were at similar risk (adjusted hazard rate: 1.17 [95% CI: 0.87-1.57]; P=0.29). Furthermore, in treated subjects with isolated systolic hypertension, the cardiovascular risk was similar in elevated conventional and normal daytime systolic BP as compared with those with normal conventional and normal daytime BPs (adjusted hazard rate: 1.10 [95% CI: 0.79-1.53]; P=0.57). However, both treated isolated systolic hypertension subjects with white-coat hypertension (adjusted hazard rate: 2.00; [95% CI: 1.43-2.79]; P<0.0001) and treated subjects with normal BP (adjusted hazard rate: 1.98 [95% CI: 1.49-2.62]; P<0.0001) were at higher risk as compared with untreated normotensive subjects. In conclusion, subjects with sustained hypertension who have their ABP normalized on antihypertensive therapy but with residual white-coat effect by CBP measurement have an entity that we have termed, "treated normalized hypertension." Therefore, one should be cautious in applying the term "white-coat hypertension" to persons receiving antihypertensive treatment

Franks, A. M.; Schmidt, J. M.; McCain, K. R.; Fraer, M. (2012):

Comparison of the effects of energy drink versus caffeine supplementation on indices of 24-hour ambulatory blood pressure.

In: *Ann.Pharmacother.* 46 (2), S. 192–199. DOI: 10.1345/aph.1Q555.

Abstract:

BACKGROUND: Cardiovascular events associated with energy drink consumption have been reported, but few data exist to delineate the hemodynamic effects of energy drinks. OBJECTIVE: To compare the effects of an energy drink versus caffeine supplementation on blood pressure (BP) indices as measured by 24-hour ambulatory BP monitoring (ABPM). METHODS: Healthy, nonsmoking, normotensive volunteers (aged 18-45 years) taking no medications were enrolled in a single-center, open-label, 2-period crossover pilot study. During each study period, subjects received either an energy drink (Red Bull Energy Drink, each dose containing 80 mg of caffeine and 1000 mg of taurine in an 8.3-oz serving) or a control (compounded caffeine solution, each dose containing 80 mg of caffeine solution in 8 oz of bottled water) at 0800, 1100, 1500, and 1900 hours and underwent 24-hour ABPM. The study periods were separated by a washout period (4-30 days). Mean 24-hour, daytime, and nighttime systolic (SBP), diastolic (DBP), and mean arterial (MAP) BP; BP load; and percent nocturnal dipping were compared between study periods. RESULTS: Nine subjects (5 females, mean [SD] age 27.7 [5.0] years) completed the study. Mean 24-hour SBP (123.2 vs 117.4 mm Hg, p = 0.04), DBP (73.6 vs 68.2 mm Hg, p = 0.02), and MAP (90.1 vs 84.8 mm Hg, p = 0.03) were significantly higher during energy drink supplementation versus caffeine supplementation. Daytime DBP (77.0 vs 72.0 mm Hg, p = 0.04) also was significantly higher with the energy drink versus caffeine supplementation. Trends in higher daytime SBP (127.0 vs 121.9 mm Hg, p = 0.05) and MAP (93.6 vs 88.6 mm Hg, p = 0.05) were recorded with energy drink supplementation versus caffeine supplementation. Nighttime SBP and DBP loads were significantly higher with the energy drink, but nocturnal dipping did not differ significantly between study periods. CONCLUSIONS: Single-day energy drink supplementation increased mean 24-hour and daytime BP compared to caffeine control in this pilot study. Additional research is warranted to better understand the hemodynamic effects of energy drink consumption

Freercks, R. J.; Swanepool, C. R.; Turest-Swartz, K. L.; Carrara, H. R.; El Moosa, S.; Lachman, A. S.; Rayner, B. L. (2014):

Vascular calcification is not associated with increased ambulatory central aortic systolic pressure in prevalent dialysis patients.

In: *Cardiovasc J Afr* 25 (1), S. 4–8. DOI: 10.5830/CVJA-2013-081.

Abstract:

INTRODUCTION: Central aortic systolic pressure (CASP) strongly predicts cardiovascular outcomes. We undertook to measure ambulatory CASP in 74 prevalent dialysis patients using the BPro (HealthStats, Singapore) device. We also determined whether coronary or abdominal aortic calcification was associated with changes in CASP and whether interdialytic CASP predicted ambulatory measurement. METHODS: All patients underwent computed tomography for coronary calcium score, lateral abdominal radiography for aortic calcium score, echocardiography for left ventricular mass index and ambulatory blood pressure measurement using BPro calibrated to brachial blood pressure. HealthStats was able to convert standard BPro SOFT((R)) data into ambulatory CASP. RESULTS: Ambulatory CASP was not different in those without and with coronary (137.6 vs 141.8 mmHg, respectively, p = 0.6) or aortic (136.6 vs 145.6 mmHg, respectively, p = 0.2) calcification. Furthermore, when expressed as a percentage of brachial systolic blood pressure to control for peripheral blood pressure, any difference in CASP was abolished: CASP: brachial systolic blood pressure ratio = 0.9 across all categories regardless of the presence of coronary or aortic calcification (p = 0.2 and 0.4, respectively). Supporting this finding, left ventricular mass index was also not different in those with or without vascular calcification (p = 0.7 and 0.8 for coronary and aortic calcification). Inter-dialytic office blood pressure and CASP correlated excellently with ambulatory measurements (r = 0.9 for both). CONCLUSION: Vascular calcification was not associated with changes in ambulatory central aortic systolic pressure in this cohort of prevalent dialysis patients. Inter-dialytic blood pressure and CASP correlated very well with ambulatory measurement.

The impact of school-time activity on total physical activity: the activitystat hypothesis (EarlyBird 46).

In: *International journal of obesity (2005)* 35 (10), S. 1277–1283. DOI: 10.1038/ijo.2011.52.

Abstract:

OBJECTIVES\r\nTo explore the activitystat hypothesis in primary school children by asking whether more physical activity (PA) in school time is compensated for by less PA at other times.\r\nSTUDY DESIGN\r\nObservational, repeated measures (four consecutive occasions over a 12-month period).\r\nSETTING\r\nSouth-west England.\r\nPARTICIPANTS\r\nA total of 206 children (115 boys, aged 8-10 years) from 3 primary schools (S1, S2 and S3), which recorded large differences in PA during school time.\r\nMEASUREMENTS\r\nTotal PA (TPA) and its moderate-and-vigorous component were recorded weekly by accelerometry, in school and out of school, and adjusted for local daily rainfall and daylight hours. Habitual PA was assessed by linear mixed-effects modelling on repeated measures.\r\nRESULTS\r\nS1 children recorded 64% more in-school PA, but S2 and S3 children compensated with correspondingly more out-of-school PA, so that TPA between the three schools was no different: 35.6 (34.3-36.9), 37.3 (36.0-38.6) and 36.2 (34.9-37.5) Units, respectively (P=0.38).\r\nCONCLUSIONS\r\nThe PA of children seems to compensate in such a way that more activity at one time is met with less activity at another. The failure of PA programmes to reduce childhood obesity could be attributable to this compensation.

Alexithymia in chronic fatigue syndrome: associations with momentary, recall, and retrospective measures of somatic complaints and emotions.

In: *Psychosomatic Medicine* 69 (1), S. 54–60.

Abstract:

OBJECTIVE:

The relationship between alexithymia and real-time momentary symptom assessments has not been reported. This cross-sectional study hypothesized that alexithymia would be a predictor of somatic symptoms using three different types of symptom measurement (momentary, recall, and retrospective) in the medically unexplained illness of chronic fatigue syndrome (CFS). In addition, it was hypothesized that negative affect would be a significant mediator of the relationship between alexithymia and somatic symptoms. Finally, the relation of alexithymia to physical illness attribution (a CFS illness predictor) was explored.

METHODS:

Participants were 111 adults with CFS. Alexithymia was assessed with the Toronto Alexithymia Scale. Momentary ratings of current symptoms and affect were recorded in electronic diaries carried for 3 weeks. Weekly recall of these momentary reports was also recorded. Retrospective measures included 6-month ratings of fatigue and pain, the Fatigue Severity Scale, the Brief Pain Inventory-Short Form, a CFS symptom measure, the Beck Depression Inventory-II, the Beck Anxiety Inventory, and an illness attribution rating.

RESULTS:

Partial correlations, controlling for age and sex, yielded no significant associations between general or specific forms of alexithymia and momentary ratings of fatigue or pain. On the other hand, a significant association, partially mediated by anxiety scores, was found between a specific form of alexithymia and a retrospective pain measure. Finally, physical illness attribution was not significantly associated with alexithymia.

CONCLUSION:

Based on assessments of real-time and retrospectively measured symptoms, these data provided only modest support for the alexithymia construct as a predictor of somatic symptoms in people with CFS.

Friedberg, Fred; Sohl, Stephanie J. (2009):

Longitudinal change in chronic fatigue syndrome: what home-based assessments reveal.

In: *Journal of Behavioral Medicine* 32 (2), S. 209–218. DOI: 10.1007/s10865-008-9189-9.

Abstract:

The purpose of this 2-year prospective study was to compare standard self-report and ecologically-based outcome measures in patients with chronic fatigue syndrome (CFS). Standard measures assessed physical function, fatigue impact, psychological variables, and global impression of change ratings. Ecological measures included actigraphy, a structured activity record, and an electronic fatigue/energy diary. Results for this high functioning sample (N = 75) revealed that self-report global improvement was significantly associated with lower momentary fatigue and fatigue impact, and a higher frequency of standing up (at home), but not with actigraphy or psychological variables. However, actigraphy change was significantly correlated with change in self-report physical function. At follow-up, only a small minority (<20%) scored in the healthy adult range for fatigue impact and physical function. The findings suggest that home-based measures of symptom severity and physical functioning may provide evidence of change (or lack of change) that is important for interpreting standard self-report outcomes in CFS.

Frings, Lars; Wagner, Kathrin; Maiwald, Thomas; Carius, Astrid; Schinkel, Anika; Lehmann, Christiane; Schulze-Bonhage, Andreas (2008):

Early detection of behavioral side effects of antiepileptic treatment using handheld computers.

In: *Epilepsy & Behavior* 13 (2), S. 402–406.

Abstract:

OBJECTIVE:

Treatment-emergent side effects are frequent events, particularly during the uptitration of antiepileptic drugs. So far, monitoring of such adverse events in outpatients has often been limited to intervals of weeks or months. We here report the application of a new device for temporally fine-grained assessment of objective well-being and cognitive performance using personal digital assistants (PDAs).

METHODS:

Twenty adult patients with epilepsy participated in this pilot study. Ten received add-on treatment with levetiracetam. Ten patients with constant medication served as a control group. Differences between groups with respect to self-rated cognitive condition, psychophysical condition, aggressiveness, and cognitive test performance in a concentration test assessed three times daily (morning, early afternoon, and evening), over the course of 6 days, were analyzed.

RESULTS:

Levetiracetam-treated patients manifested an early augmentation of self-rated aggressiveness, which increased in intensity over the course of days. Aggressiveness reached a maximum in the early afternoon across days. There were no major changes in cognitive performance, except for an increase in morning performance in the control group.

CONCLUSIONS:

This study demonstrates the feasibility of a new method of ambulatory assessment of behavioral and cognitive data during titration of antiepileptic drugs. Significant changes in aggressiveness under add-on treatment with levetiracetam were found to be dependent on the time of assessment during the day. These results suggest that PDA-based ambulatory monitoring of patients with epilepsy may be a promising tool for early detection of drug-related side effects and, thus, may constitute a significant improvement in patient care.

Frissen, Aleida; Lieverse, Ritsaert; Drukker, Marjan; Delespaul, Philippe; Lataster, Tineke; Myin-Germeys, Inez; van Os, Jim (2014):

Evidence that childhood urban environment is associated with blunted stress reactivity across groups of patients with psychosis, relatives of patients and controls.

In: *Social Psychiatry and Psychiatric Epidemiology* 49 (10), S. 1579–1587. DOI: 10.1037/t29468-000;

Abstract:

Purpose: Psychosis is associated with urban upbringing, and increased emotional reactivity is associated with psychosis. The aim of this study was to examine to what degree urban upbringing impacts emotional reactivity, and how this may be relevant for psychotic disorder and familial risk of psychotic disorder. Methods: Patients with a diagnosis of non-affective psychotic disorder (n = 57), 59 first degree relatives of patients and 75 healthy comparison subjects were studied with the experience sampling method (a random time sampling technique to assess affective experience in relation to fluctuating stressors in the flow of daily life), to measure a change in negative affect in relation to subjective stress. Urban exposure was defined at 5 levels, considering the population density and the number of moves between birth and the 15th birthday, using data from the Dutch Central Bureau of Statistics and the equivalent database in Belgium. Results: Multilevel random regression analyses showed that urban upbringing was consistently and strongly associated with a reduced increase in negative affect in relation to SS in adulthood in a dose–response fashion in all three groups. Regression coefficients in the patient group decreased from 0.148 (p < 0.001) in the lowest urbanicity level to 0.094 (p < 0.001) in the highest urbanicity level. Conclusion: The findings suggest that urban upbringing may occasion "habituation" rather than "sensitization" across groups, which may or may not be relevant for the onset of psychotic disorder. Froese, T.; Gould, C.; Seth, A. K. (2011):

Validating and calibrating first-and second-person methods in the science of consciousness.

In: *Journal of Consciousness Studies* 18 (2), S. 38.

Abstract:

Comments on the articles R.T. Hurlburt & S.A. Akhter (see record 2007-19512-002); Pierre Vermersch (see record 2009-23371-002); and Claire Petitmengin & Michel Bitbol (see record 2009-23371-015). In this paper we will concentrate on two of the most common second-person methods in the science of consciousness, namely the Descriptive Experience Sampling (DES) method and the Explicitation Interview (EI) method. After a survey of recent advances in the use of these methods in the science of consciousness, we identify a key problem that stands in the way of further progress: the DES and EI methods are driven by fundamentally different conceptions of consciousness, and these have important methodological ramifications. We suggest one possibility to obtain an objective measure that may help to resolve this methodological dispute. We may have developed sophisticated methods to study the neural and behavioral correlates of verbal reports, but how those reports are generated in the first place still remains mostly hidden inside the ‘black box’ of the experiencing subject. At the same time it is reasonable to suppose that first-person and/or second-person introspection alone will never be a sufficient guide to the mechanisms underlying lived experience. However, when taken in conjunction with other behavioral and neural properties and signatures, especially those that bear an explanatory, informing or constraining relation to phenomenal properties, introspective and especially second-person interview methods are likely to form an increasingly important part of the methodological toolkit in consciousness science.

Patients with renal dysfunction require a longer duration until blood pressure dips during the night.

In: *Hypertension* 52 (6), S. 1155–1160. DOI: 10.1161/HYPERTENSIONAHA.108.115329.

Abstract:

We have postulated that the diminished renal capacity to excrete sodium causes nocturnal blood pressure (BP) elevation, which enhances pressure natriuresis in compensation for impaired daytime natriuresis. If such a mechanism holds, high BP during sleep at night may continue until excess sodium is sufficiently excreted into urine. This study examined whether the duration, defined as \"dipping time,\" until nocturnal mean arterial pressure began to fall to <90% of daytime average became longer as renal function deteriorated. Ambulatory BP measurements and urinary sodium excretion rates were evaluated for daytime and nighttime to estimate their circadian rhythms in 65 subjects with chronic kidney disease. Dipping time showed an inverse relationship with creatinine clearance (C(cr); rho=-0.61; P<0.0001) and positive relationships with night/day ratios of mean arterial pressure (rho=0.84; P<0.0001) and natriuresis (rho=0.61; P<0.0001), both of which were also inversely correlated with C(cr) (mean arterial pressure: r=-0.58, P<0.0001; natriuresis: r=-0.69, P<0.0001). When divided into tertiles by C(cr) (mL/min), hazard ratios of nocturnal BP dip adjusted for age, gender, and body mass index were 0.37 (95% CI: 0.17 to 0.79; P=0.01) for the second tertile (C(cr): 50 to 90) and 0.20 (95% CI: 0.08 to 0.55; P=0.002) for the third tertile (C(cr): 5 to 41) compared with the first tertile (C(cr): 91 to 164). These findings demonstrate that patients with renal dysfunction require a longer duration until BP falls during the night. The prolonged duration until BP dip during sleep seems an essential component of the nondipper pattern of the circadian BP rhythm.

Development of a hand-held personal digital assistant-based food diary with food photographs for Japanese subjects.

In: *Journal of the American Dietetic Association* 109 (7), S. 1232–1236. DOI: 10.1016/j.jada.2009.04.013.

Abstract:

Hand-held personal digital assistant (PDA)-based food diaries have been developed for self-monitoring of dietary intake, but the accuracy of these diaries is unclear for patients with diabetes. The aim of the study was to assess the accuracy and feasibility of use of a new PDA-based food diary, including food photographs. The study included 44 Japanese participants without diabetes (mean age 23 years) and 16 Japanese patients with type 2 diabetes (mean age 53 years). The PDA-based food diary was used for 7 consecutive days. Information about all dietary intake on the 7th day of PDA self-monitoring was collected by a 24-hour recall interview on the 8th day. The PDA-based data for dietary intake on the 7th day were then compared to the 24-hour recall data for the same period. Feasibility was assessed based on the frequency and timeliness of self-monitoring. There was no significant difference in daily totals for energy, protein, carbohydrate, and fat between the two methods in each group. Pearson's correlation and intraclass correlation coefficients showed strong significant relationships for all variables between the two methods in both groups. Bland-Altman plots did not indicate any bias in estimated daily caloric intake. Participants recorded 98% of their meals in the PDA, with 75% of entries recorded within 6 hours after the meal starting time. The findings suggest that the PDA-based food diary is a potential clinical method to estimate dietary intake and may be a beneficial tool for self-monitoring of dietary intake.

New Insights Into Compliance With a Mobile Phone Diary and Pedometer Use in Sedentary Women.

In: *J Phys Act Health* 8 (3), S. 398–403.

Abstract:

Objectives: The purposes of this study were 1) to determine compliance with a pedometer and mobile phone-based physical activity diary, and 2) to assess concordance between self-reported daily steps recorded and transmitted by a mobile phone and pedometer-measured daily steps in sedentary women. Methods: In this 3-week pilot clinical study, 41 sedentary women who met all inclusion criteria were recruited from local communities. We asked the participants to wear a pedometer every day and to report their daily steps using a mobile phone diary each night before retiring. In the first week, women were asked to monitor their daily steps (baseline steps). In the second and third weeks, they were asked to increase their steps by 20% from the previous week. Although the pedometer can automatically store the most recent 41 days' performance, the participants were not

informed of this function of the pedometer. Results: Overall compliance was 93.8% with pedometer use and 88.3% with the mobile phone physical activity diary. Bland Altman plots showed that the agreement between self-reported daily steps by mobile phone diary and pedometer-recorded daily steps from week 1 to week 3 was high. Conclusion: The combination of a pedometer and a mobile phone diary may enhance the quality of self-reported data in clinical studies.

Fulcher, Krysten K.; Alosco, Michael L.; Miller, Lindsay; Spitznagel, Mary Beth; Cohen, Ronald; Raz, Naftali et al. (2014):

Greater physical activity is associated with better cognitive function in heart failure.

In: *Health Psychol* 33 (11), S. 1337–1343. DOI: 10.1037/t00742-000.

Abstract:

Objective: Nearly 6 million Americans have heart failure (HF), up to 80% of which exhibit cognitive deficits on testing. Physical inactivity is common in HF, yet little is known about the possible contribution of physical inactivity to cognitive dysfunction in this population. Method: Older adults with HF (N = 93; Mage = 68.5 years, 33.7% women) completed neuropsychological testing, as well as cardiac and physical activity assessment as part of a larger protocol. HF severity was measured via impedance cardiography. Physical activity was assessed via an Actigraph accelerometer and operationalized using daily step count and time engaged in moderate-vigorous activity (minutes/day). Results: Linear regression analyses controlling for sex, high blood pressure, diabetes, depressive symptomatology, and HF severity showed that greater physical activity (both step count and minutes spent in moderate-vigorous activity) was associated with better executive function/attention, processing speed, and scores on a screening measure of cognition. Conclusions: These findings indicate that physical activity is an independent predictor of cognitive function in persons with HF. Future work is needed to clarify the mechanisms by which physical activity benefits cognitive function in HF and determine whether interventions to promote physical activity can attenuate cognitive decline over time. Optimizing prediction of binge eating episodes: a comparison approach to test alternative conceptualizations of the affect regulation model.

In: *J Eat Disord* 2 (1), S. 28. DOI: 10.1186/s40337-014-0028-9.

Abstract:

BACKGROUND: Although a wealth of studies have tested the link between negative mood states and likelihood of a subsequent binge eating episode, the assumption that this relationship follows a typical linear dose-response pattern (i.e., that risk of a binge episode increases in proportion to level of negative mood) has not been challenged. The present study demonstrates the applicability of an alternative, non-linear conceptualization of this relationship, in which the strength of association between negative mood and probability of a binge episode increases above a threshold value for the mood variable relative to the slope below this threshold value (threshold dose response model). METHODS: A sample of 93 women aged 18 to 40 completed an online survey at random intervals seven times per day for a period of one week. Participants self-reported their current mood state and whether they had recently engaged in an eating episode symptomatic of a binge. RESULTS: As hypothesized, the threshold approach was a better predictor than the linear dose-response modeling of likelihood of a binge episode. The superiority of the threshold approach was found even at low levels of negative mood (3 out of 10, with higher scores reflecting more negative mood). Additionally, severity of negative mood beyond this threshold value appears to be useful for predicting time to onset of a binge episode. CONCLUSIONS: Present findings suggest that simple dose-response formulations for the association between negative mood and onset of binge episodes miss vital aspects of this relationship. Most notably, the impact of mood on binge eating appears to depend on whether a threshold value of negative mood has been breached, and elevation in mood beyond this point may be useful for clinicians and researchers to identify time to onset.

Does the burden of the experience sampling method undermine data quality in state body image research?

In: *Body Image*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-25718-001%26site%3dehost-live.

Abstract:

Despite growing popularity of experience sampling methodology (ESM) for evaluations of state-based components of body image, there have been concerns that the frequent repeated measurement might encourage problematic responding resulting in low data quantity and/or quality. Using a sample of 105 women (mean age=24.84), this study used multilevel modelling to investigate whether (a) there were changes in compliance or response variability across a 7-day period, and (b) whether such changes are explained by participant characteristics. Present findings suggest that demands of ESM protocol undermine quantity more so than quality of obtained data. Decline in procedural compliance across the testing period correlated with BMI and body shame, whereas reduced variability in state-based assessments did not adversely impact the strength of association between state body satisfaction ratings and other variables in the dataset. The authors make several recommendations for ensuring the quality of ESM-based data in future studies. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Gaborieau, Valérie; Delarche, Nicolas; Gosse, Philippe (2008):

Ambulatory blood pressure monitoring versus self-measurement of blood pressure at home: correlation with target organ damage.

In: *J Hypertens* 26 (10), S. 1919–1927. DOI: 10.1097/HJH.0b013e32830c4368.

Abstract:

OBJECTIVE\r\nAmbulatory blood pressure (BP) monitoring and home blood pressure measurements predicted the presence of target organ damage and the risk of cardiovascular events better than did office blood pressure.\r\nMETHODS\r\nTo compare these two methods in their correlation with organ damage, we consecutively included 325 treated (70%) or untreated hypertensives (125 women, mean age = 64.5 +/- 11.3) with office (three measurements at two consultations), home (three measurements morning and evening over 3 days) and 24-h ambulatory monitoring. Target organs were evaluated by ECG, echocardiography, carotid echography and detection of microalbuminuria. Data from 302 patients were analyzed.\r\nRESULTS\r\nMean BP levels were 142/82 mmHg for office, 135.5/77 mmHg for home and 128/76 mmHg for 24-h monitoring (day = 130/78 mmHg; night = 118.5/67 mmHg). With a 135 mmHg cut-off, home and daytime blood pressure diverged in 20% of patients. Ambulatory and Home blood pressure were correlated with organ damage more closely than was office BP with a trend to better correlations with home BP. Using regression analysis, a 140 mmHg home systolic blood pressure corresponded to a 135 mmHg daytime systolic blood pressure; a 133 mmHg daytime ambulatory blood pressure and a 140 mmHg home blood pressure corresponded to the same organ damage cut-offs (Left ventricular mass index = 50 g/m, Cornell.QRS = 2440 mm/ms, carotid intima media thickness = 0.9 mm). Home-ambulatory differences were significantly associated with age and antihypertensive treatment.\r\nCONCLUSION\r\nWe showed that home blood pressure was at least as well correlated with target organ damage, as was the ambulatory blood pressure. Home-ambulatory correlation and their correlation with organ damage argue in favor of different cut-offs, that are approximately 5 mmHg higher for systolic home blood pressure.

Gabriel, Kelley Pettee; McClain, James J.; Schmid, Kendra K.; Storti, Kristi L.; High, Robin R.; Underwood, Darcy A. et al. (2010):

Issues in accelerometer methodology: The role of epoch length on estimates of physical activity and relationships with health outcomes in overweight, post-menopausal women.

In: *Int J Behav Nutr Phys Act* 7. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32460-001%26site%3dehost-live;Kelley.P.Gabriel@uth.tmc.edu.

Abstract:

Current accelerometer technology allows for data collection using brief time sampling intervals (i.e., epochs). The study aims were to examine the role of epoch length on physical activity estimates and subsequent relationships with clinically-meaningful health outcomes in post-menopausal women. Methods: Data was obtained from the Woman On the Move through Activity and Nutrition Study (n = 102). Differences in activity estimates presented as 60s and 10s epochs were evaluated using paired t-tests. Relationships with health outcomes were examined using correlational and regression analyses to evaluate differences by epoch length. Results: Inactivity, moderate- and vigorous-intensity activity (MVPA) were significantly higher and light-intensity activity was significantly lower (all P < 0.001) when presented as 10s epochs. The correlation between inactivity and self-reported physical activity was stronger with 10s estimates (P < 0.03); however, the regression slopes were not significantly different. Conversely, relationships between MVPA and body weight, BMI, whole body and trunk lean and fat mass, and femoral neck bone mineral density was stronger with 60s estimates (all P < 0.05); however, regression slopes were similar. Conclusion: These findings suggest that although the use of a shorter time sampling interval may suggestively reduce misclassification error of physical activity estimates, associations with health outcomes did not yield strikingly different results. Additional studies are

needed to further our understanding of the ways in which epoch length contributes to the ascertainment of physical activity in research studies. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

GENETIC STUDY: Tryptophan hydroxylase 2 gene and alcohol use among college students.

In: *Addict Biol* 13 (3-4), S. 440–448.

Abstract:

Genes that regulate serotonin activity are regarded as promising predictors of heavy alcohol use. Tryptophan hydroxylase (TPH2) plays an important role in serotonergic neurotransmission by serving as the rate-limiting enzyme for serotonin biosynthesis in the midbrain and serotonergic neurons. Despite the link between TPH2 and serotonergic function, TPH2's role in the pathogenesis of alcohol-use disorders remains unclear. The goal of this study was to examine whether a variation in the TPH2 gene is associated with risky alcohol consumption. Specifically, this study examined whether the TPH2 G-703T polymorphism predicted alcohol consumption among college students. In two successive years, 351 undergraduates were asked to record their alcohol use each day for 30 days using an Internet-based electronic diary. Participants' DNA was collected and polymerase chain reaction genotyping was performed. Results show that alcohol consumption was not associated with the TPH2 G-703T polymorphism alone, or the interaction of TPH2 with two other candidate polymorphisms (TPH1 C218A and the SLC6A4 tri-allelic 5-HTTLPR), or negative life events. In conclusion, this study supports recent null findings relating TPH2 to drinking outcomes. It also extends these findings by showing null interactions with the TPH1 C218A polymorphism, the SLC6A4 tri-allelic 5-HTTLPR polymorphism and environmental stressors in predicting sub-clinical alcohol use among Caucasian American young adults.

Gadassi, Reuma; Snir, Avigal; Berenson, Kathy; Downey, Geraldine; Rafaeli, Eshkol (2014):

Out of the Frying Pan, Into the Fire: Mixed Affective Reactions to Social Proximity in Borderline and Avoidant Personality Disorders in Daily Life.

In: *Journal of Abnormal Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-24016-001%26site%3dehost-live.

Abstract:

Social proximity typically helps individuals meet their belongingness needs, but several forms of psychopathology, including borderline and avoidant personality disorders (BPD and APD, respectively) are characterized by social difficulties. This experience-sampling study is one of the first to directly investigate the affective reactions of individuals with BPD and APD (compared with healthy controls [HC]) to social proximity in daily life. We examined both person-level and day-level reactions. At the person level, the rate of social proximity across the diary period was associated with diminished feelings of rejection, isolation, shame, and dissociation in the HC group. In contrast, it was not associated with any affective reaction in the BPD group, and was associated with decreased rejection and isolation on the one hand, but also with increased anxiety in the APD group. At the day level, we used multilevel regression to examine affective reactions when in social proximity. The HC group showed a consistent benefit when in social proximity. In contrast, both PD groups exhibited mixed affective reactions to social proximity; specifically, benefits (increased positive affect, decreased rejection, isolation, and dissociation) were interspersed with costs (increased shame for both PD groups; increased anger for BPD; increased anxiety for APD). The mixed reactions found in both PDs may contribute to the disturbed relationships of individuals with these disorders. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Gage, William H.; Zabjek, Karl F.; Sibley, Kathryn M.; Tang, Ada; Brooks, Dina; McIlroy, William E. (2007):

Ambulatory monitoring of activity levels of individuals in the sub-acute stage following stroke: a case series.

In: *J Neuroeng Rehabil* 4, S. 41. DOI: 10.1186/1743-0003-4-41.

Abstract:

BACKGROUND\r\nThere is an important need to better understand the activities of individual patients with stroke outside of structured therapy since this activity is likely to have a profound influence on recovery. A case-study approach was used to examine the activity levels and associated physiological load of patients with stroke throughout a day.\r\nMETHODS\r\nActivities and physiologic measures were recorded during a continuous 8 hour period from 4 individuals in the sub-acute stage following stroke (ranging from 49 to 80 years old; 4 to 8 weeks post-stroke) in an in-patient rehabilitation hospital.\r\nRESULTS\r\nBoth heart rate ($p = 0.0207$) and ventilation rate ($p < 0.0001$) increased as intensity of activity increased. Results revealed individual differences in physiological response to daily activities, and large ranges in physiological response measures during 'moderately' and 'highly' therapeutic activities.\r\nCONCLUSION\r\nActivity levels of individuals with stroke during the day were generally low, though task-related changes in physiologic measures were observed. Large variability in the physiological response to even the activities deemed to be greatest intensity suggests that inclusion of such extended measurement of physiologic measures may improve understanding of physiological profile that could guide elements of the physical therapy prescription.

An experience sampling study of PTSD and alcohol-related problems.

In: *Psychology of Addictive Behaviors* 28 (4), S. 1013–1025. DOI: 10.1037/t04522-000.

Abstract:

Posttraumatic stress disorder (PTSD) represents a debilitating psychiatric condition that is affecting the lives of many returning veterans. PTSD and alcohol use and dependence are highly comorbid. The purpose of this study was to understand the functional mechanisms between PTSD and alcohol use and problems. Specifically, the role of negative urgency and emotional intelligence were investigated as vulnerability and resiliency factors, respectively. This study utilized experience sampling to test associations between PTSD symptoms and alcohol use and related problems in a sample of 90 OIF/OEF veterans. Participants completed 8 brief questionnaires daily for 2 weeks on palmtop computers. Elevations in PTSD symptoms during the day were associated with subsequent increases in alcohol use and associated problems that night. PTSD symptoms were associated with greater problems above and beyond the effect of drinking level at both the within- and between- person level. Emotional intelligence was associated with lower negative urgency, fewer PTSD symptoms, and less alcohol use and associated problems. The effects of emotional intelligence were primarily indirect via negative urgency and the effects of negative urgency on alcohol use and problems were indirect via its positive association with PTSD symptoms. Hypothesized cross-level effects of emotional intelligence and negative urgency were not supported. The findings suggest a functional association between PTSD symptoms and alcohol consumption. The association between PTSD symptoms and alcohol consumption is consistent with a self-medication model. However, the significant associations between PTSD symptoms and alcohol problems, after controlling for use level, suggest a broader role of dysregulation. Gajecki, Mikael; Berman, Anne H.; Sinadinovic, Kristina; Rosendahl, Ingvar; Andersson, Claes (2014):

Mobile phone brief intervention applications for risky alcohol use among university students: a randomized controlled study.

In: *Addict Sci Clin Pract* 9, S. 11. DOI: 10.1186/1940-0640-9-11.

Abstract:

BACKGROUND: Brief interventions via the internet have been shown to reduce university students' alcohol intake. This study tested two smartphone applications (apps) targeting drinking choices on party occasions, with the goal of reducing problematic alcohol intake among Swedish university students. METHODS: Students were recruited via e-mails sent to student union members at two universities. Those who gave informed consent, had a smartphone, and showed risky alcohol consumption according to the Alcohol Use Disorders Identification Test (AUDIT) were randomized into three groups. Group 1 had access to the Swedish government alcohol monopoly's app, Promillekoll, offering real-time estimated blood alcohol concentration (eBAC) calculation; Group 2 had access to a web-based app, PartyPlanner, developed by the research group, offering real-time eBAC calculation with planning and follow-up functions; and Group 3 participants were controls. Follow-up was conducted at 7 weeks. RESULTS: Among 28574 students offered participation, 4823 agreed to join; 415 were excluded due to incomplete data, and 1932 fulfilled eligibility criteria for randomization. Attrition was 22.7-39.3 percent, higher among heavier drinkers and highest in Group 2. Self-reported app use was higher in Group 1 (74%) compared to Group 2 (41%). Per-protocol analyses revealed only one significant time-by-group interaction, where Group 1 participants increased the frequency of their drinking occasions compared to controls ($p = 0.001$). Secondary analyses by gender showed a significant difference among men in Group 1 for frequency of drinking occasions per week ($p = 0.001$), but not among women. Among all participants, 29 percent showed high-

risk drinking, over the recommended weekly drinking levels of 9 (women) and 14 (men) standard glasses. CONCLUSIONS: Smartphone apps can make brief interventions available to large numbers of university students. The apps studied using eBAC calculation did not, however, seem to affect alcohol consumption among university students and one app may have led to a negative effect among men. Future research should: 1) explore ways to increase user retention, 2) include apps facilitating technical manipulation for evaluation of added components, 3) explore the effects of adapting app content to possible gender differences, and 4) offer additional interventions to high-risk users. TRIAL REGISTRATION: clinicaltrials.gov: NCT01958398.

Galan-Mercant, Alejandro; Cuesta-Vargas, Antonio I. (2014):

Differences in trunk accelerometry between frail and non-frail elderly persons in functional tasks.

In: *BMC Res Notes* 7, S. 100. DOI: 10.1186/1756-0500-7-100.

Abstract:

BACKGROUND: Physical conditions through gait and other functional task are parameters to consider for frailty detection. The aim of the present study is to measure and describe the variability of acceleration, angular velocity and trunk displacement in the ten meter Extended Timed Get-Up-and-Go test in two groups of frail and non-frail elderly people through instrumentation with the iPhone4(R) smartphone. Secondly, to analyze the differences and performance of the variance between the study groups (frail and non-frail).This is a cross-sectional study of 30 subjects aged over 65 years, 14 frail subjects and 16 non-frail subjects. RESULTS: The highest difference between groups in the Sit-to-Stand and Stand-to-Sit subphases was in the y axis (vertical vector). The minimum acceleration in the Stand-to-Sit phase was -2.69 (-4.17/-0.96) m/s2 frail elderly versus -8.49 (-12.1/-5.23) m/s2 non-frail elderly, $p < 0.001$. In the Gait Go and Gait Come subphases the biggest differences found between the groups were in the vertical axis: -2.45 (-2.77/-1.89) m/s2 frail elderly versus -5.93 (-6.87/-4.51) m/s2 non-frail elderly, $p < 0.001$. Finally, with regards to the turning subphase, the statistically significant differences found between the groups were greater in the data obtained from the gyroscope than from the accelerometer (the gyroscope data for the mean maximum peak value for Yaw movement angular velocity in the frail elderly was specifically 25.60 degrees /s, compared to 112.8 degrees /s for the non-frail elderly, $p < 0.05$). CONCLUSIONS: The inertial sensor fitted in the iPhone4(R) is capable of studying and analyzing the kinematics of the different subphases of the Extended Timed Up and Go test in frail and non-frail elderly people. For the Extended Timed Up and Go test, this device allows more sensitive differentiation between population groups than the traditionally used variable, namely time.

Galeana-Zapien, Hiram; Torres-Huitzil, Cesar; Rubio-Loyola, Javier (2014):

Mobile phone middleware architecture for energy and context awareness in location-based services.

In: *Sensors (Basel)* 14 (12), S. 23673–23696. DOI: 10.3390/s141223673.

Abstract:

The disruptive innovation of smartphone technology has enabled the development of mobile sensing applications leveraged on specialized sensors embedded in the device. These novel mobile phone applications rely on advanced sensor information processes, which mainly involve raw data acquisition, feature extraction, data interpretation and transmission. However, the continuous accessing of sensing resources to acquire sensor data in smartphones is still very expensive in terms of energy, particularly due to the periodic use of power-intensive sensors, such as the Global Positioning System (GPS) receiver. The key underlying idea to design energy-efficient schemes is to control the duty cycle of the GPS receiver. However, adapting the sensing rate based on dynamic context changes through a flexible middleware has received little attention in the literature. In this paper, we propose a novel modular middleware architecture and runtime environment to directly interface with application programming interfaces (APIs) and embedded sensors in order to manage the duty cycle process based on energy and context aspects. The proposed solution has been implemented in the Android software stack. It allows continuous location tracking in a timely manner and in a transparent way to the user. It also enables the deployment of sensing policies to appropriately control the sampling rate based on both energy and perceived context. We validate the proposed solution taking into account a reference location-based service (LBS) architecture. A cloud-based storage service along with online mobility analysis tools have been used to store and access sensed data. Experimental measurements demonstrate the feasibility and efficiency of our middleware, in terms of energy and location resolution.

Galliher, James M.; Stewart, Thomas V.; Pathak, Paramod K.; Werner, James J.; Dickinson, L. Miriam; Hickner, John M. (2008):

Data collection outcomes comparing paper forms with PDA forms in an office-based patient survey.

In: *Annals of family medicine* 6 (2), S. 154–160. DOI: 10.1370/afm.762.

Abstract:

PURPOSE\r\nWe compared the completeness of data collection using paper forms and using electronic forms loaded on handheld computers in an office-based patient interview survey conducted within the American Academy of Family Physicians National Research Network.\r\nMETHODS\r\nWe asked 19 medical assistants and nurses in family practices to administer a survey about pneumococcal immunizations to 60 older adults each, 30 using paper forms and 30 using electronic forms on handheld computers. By random assignment, the interviewers used either the paper or electronic form first. Using multilevel analyses adjusted for patient characteristics and clustering of forms by practice, we analyzed the completeness of the data.\r\nRESULTS\r\nA total of 1,003 of the expected 1,140 forms were returned to the data center. The overall return rate was better for paper forms (537 of 570, 94%) than for electronic forms (466 of 570, 82%) because of technical difficulties experienced with electronic data collection and stolen or lost handheld computers. Errors of omission on the returned forms, however, were more common using paper forms. Of the returned forms, only 3% of those gathered electronically had errors of omission, compared with 35% of those gathered on paper. Similarly, only 0.04% of total survey items were missing on the electronic forms, compared with 3.5% of the survey items using paper forms.\r\nCONCLUSIONS\r\nAlthough handheld computers produced more complete data than the paper method for the returned forms, they were not superior because of the large amount of missing data due to technical difficulties with the hand-held computers or loss or theft. Other hardware solutions, such as tablet computers or cell phones linked via a wireless network directly to a Web site, may be better electronic solutions for the future.

Galluzzi, Valerie; Herman, Ted; Shumaker, D. J.; MacInga, D. R.; Arbogast, J. W.; Segre, Elena M. et al. (2014):

Electronic recognition of hand hygiene technique and duration.

In: *Infect Control Hosp Epidemiol* 35 (10), S. 1298–1300. DOI: 10.1086/678059.

Abstract:

We captured 3-dimensional accelerometry data from the wrists of 116 healthcare professionals as they performed hand hygiene (HH). We then used these data to train a k-nearest-neighbors classifier to recognize specific aspects of HH technique (ie, fingertip scrub) and measure the duration of HH events.

Galvez, G.; Turbin, M. B.; Thielman, E. J.; Istvan, J. A.; Andrews, J. A.; Henry, J. A. (2012):

Feasibility of ecological momentary assessment of hearing difficulties encountered by hearing aid users.

In: *Ear Hear* 33 (4), S. 497–507. DOI: 10.1097/AUD.0b013e3182498c41.

Abstract:

OBJECTIVES: : Measurement of outcomes has become increasingly important to assess the benefit of audiologic rehabilitation, including hearing aids, in adults. Data from questionnaires, however, are based on retrospective recall of events and experiences, and often can be inaccurate. Questionnaires also do not capture the daily variation that typically occurs in relevant events and experiences. Clinical researchers in a variety of fields have turned to a methodology known as ecological momentary assessment (EMA) to assess quotidian experiences associated with health problems. The objective of this study was to determine the feasibility of using EMA to obtain real-time responses from hearing aid users describing their experiences with challenging hearing situations. DESIGN: : This study required three phases: (1) develop EMA methodology to assess hearing difficulties experienced by hearing aid users; (2) make use of focus groups to refine the methodology; and (3) test the methodology with 24 hearing aid users. Phase 3 participants carried a personal digital assistant 12 hr per day for 2 weeks. The personal digital assistant alerted participants to respond to questions four times a day. Each assessment started with a question to determine whether a hearing problem was experienced since the last alert. If "yes," then up to 23 questions (depending on contingent response branching) obtained details about the situation. If "no," then up to 11 questions obtained information that would help to explain why hearing was not a problem. Each participant completed the Hearing Handicap Inventory for the Elderly (HHIE) both before and after the 2-week EMA testing period to evaluate for "reactivity" (exacerbation of self-perceived hearing problems that could result from the repeated assessments). RESULTS: : Participants responded to the alerts with a 77% compliance rate, providing a total of 991 completed momentary assessments (mean = 43.1 per participant). A substantial amount of data were obtained with the methodology. It is important to note that participants reported a "hearing problem situation since the last alert" 37.6% of the time (372 responses). The most common problem situation involved "face-to-face

conversation" (53.8% of the time). The next most common problem situation was "telephone conversation" (17.2%) followed by "TV, radio, iPod, etc." (15.3%), "environmental sounds" (9.7%), and "movies, lecture, etc." (4.0%). Comparison of pre- and post-EMA mean HHIE scores revealed no significant difference (p > 0.05), indicating that reactivity did not occur for this group. It should be noted, however, that 37.5% of participants reported a greater sense of awareness regarding their hearing loss and use of hearing aids. CONCLUSIONS: : Results showed participants were compliant, gave positive feedback, and did not demonstrate reactivity based on pre- and post-HHIE scores. We conclude that EMA methodology is feasible with patients who use hearing aids and could potentially inform hearing healthcare (HHC) services. The next step is to develop and evaluate EMA protocols that provide detailed daily patient information to audiologists at each stage of HHC. The advantages of such an approach would be to obtain real-life outcome measures, and to determine within- and between-day variability in outcomes and associated factors. Such information at present is not available from patients who seek and use HHC services

Sleep, function and hiv: A multi-method assessment.

In: *AIDS and Behavior*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-00832-001%26site%3dehost-live;cgamald1@jhmi.edu.

Abstract:

Amongst HIV+ individuals, sleep complaints have been recognized as common and debilitating; but have rarely been formally assessed or compared to controls using validated sleep tools. In this study we conducted structured interview for sleep disorders, polysomnography, 2-week home (ambulatory) monitoring and validated sleep/functional questionnaires. 56 % (14/25) of HIV+ participants and 0 % (0/19) of controls fulfilled the diagnostic criteria for insomnia. Insomnia severity scores were correlated with fatigue and anxiety symptoms. Sleep latency on 2-week actigraphy was significantly longer (P = 0.027) for HIV+ participants and associated with lower MOS-HIV scores. Sleep quality was significantly reduced in HIV+ participants based on validated questionnaires of overall sleep quality (P = 0.0017) and insomnia related symptoms (P < 0.001) even after adjusting for education and affective symptoms. HIV+ individuals are suffering with under-diagnosed sleep disorders that are negatively impacting quality of life and functional capabilities. Further studies aimed at improving recognition of sleep disorders and implementation of efficacious medical and behavioral treatment could improve functioning and disease management.

Gao, L.; Bourke, A. K.; Nelson, J. (2012):

Activity recognition using dynamic multiple sensor fusion in body sensor networks.

In: *Conf.Proc.IEEE Eng Med.Biol.Soc.* 2012 (1557-170X (Linking)), S. 1077–1080. DOI: 10.1109/EMBC.2012.6346121.

Abstract:

Multiple sensor fusion is a main research direction for activity recognition. However, there are two challenges in those systems: the energy consumption due to the wireless transmission and the classifier design because of the dynamic feature vector. This paper proposes a multi-sensor fusion framework, which consists of the sensor selection module and the hierarchical classifier. The sensor selection module adopts the convex optimization to select the sensor subset in real time. The hierarchical classifier combines the Decision Tree classifier with the Naive Bayes classifier. The dataset collected from 8 subjects, who performed 8 scenario activities, was used to evaluate the proposed system. The results show that the proposed system can obviously reduce the energy consumption while guaranteeing the recognition accuracy

Garcia, Carolyn; Hardeman, Rachel R.; Kwon, Gyu; Lando-King, Elizabeth; Zhang, Lei; Genis, Therese et al. (2014):

Teenagers and texting: use of a youth ecological momentary assessment system in trajectory health research with latina adolescents.

In: *JMIR Mhealth Uhealth* 2 (1), S. e3. DOI: 10.2196/mhealth.2576.

Abstract:

BACKGROUND: Adolescent females send and receive more text messages than any others, with an average of 4050 texts a month. Despite this technological inroad among adolescents, few researchers are utilizing text messaging technology to collect real time, contextualized data. Temporal variables (ie, mood) collected regularly over a period of time could yield useful insights, particularly for evaluating health intervention outcomes. Use of text messaging technology has multiple benefits, including capacity of researchers to immediately act in response to texted information. OBJECTIVE: The objective of our study was to

custom build a short messaging service (SMS) or text messaging assessment delivery system for use with adolescents. The Youth Ecological Momentary Assessment System (YEMAS) was developed to collect automated texted reports of daily activities, behaviors, and attitudes among adolescents, and to examine the feasibility of YEMAS. This system was created to collect and transfer real time data about individual- and social-level factors that influence physical, mental, emotional, and social well-being. METHODS: YEMAS is a custom designed system that interfaces with a cloud-based communication system to automate scheduled delivery of survey questions via text messaging; we designed this university-based system to meet data security and management standards. This was a two-phase study that included development of YEMAS and a feasibility pilot with Latino adolescent females. Relative homogeneity of participants was desired for the feasibility pilot study; adolescent Latina youth were sought because they represent the largest and fastest growing ethnic minority group in the United States. Females were targeted because they demonstrate the highest rate of text messaging and were expected to be interested in participating. Phase I involved development of YEMAS and Phase II involved piloting of the system with Latina adolescents. Girls were eligible to participate if they were attending one of the participating high schools and self-identified as Latina. We contacted 96 adolescents; of these, 24 returned written parental consent forms, completed assent processes, and enrolled in the study. RESULTS: YEMAS was collaboratively developed and implemented. Feasibility was established with Latina adolescents (N=24), who responded to four surveys daily for two two-week periods (four weeks total). Each survey had between 12 and 17 questions, with responses including yes/no, Likert scale, and open-ended options. Retention and compliance rates were high, with nearly 18,000 texts provided by the girls over the course of the pilot period. CONCLUSIONS: Pilot results support the feasibility and value of YEMAS, an automated SMS-based text messaging data collection system positioned within a secure university environment. This approach capitalizes on immediate data transfer protocols and enables the documentation of participants' thoughts, feelings, and behaviors in real time. Data are collected using mobile devices that are familiar to participants and nearly ubiquitous in developed countries.

Garcia, Carolyn; Zhang, Lei; Holt, Katie; Hardeman, Rachel; Peterson, Barbara (2014):

Latina adolescent sleep and mood: an ecological momentary assessment pilot study.

In: *J Child Adolesc Psychiatr Nurs* 27 (3), S. 132–141. DOI: 10.1111/jcap.12082.

Abstract:

PROBLEM: Sleep and mood represent two important malleable opportunities for adolescent health. This study investigated the sleep-mood relationship in adolescent girls. METHODS: Short-term, longitudinal design. Latina adolescents (N = 19, mean age 15) completed ecological momentary assessments on sleep (perceived quality, self-report quantity) and mood (negative affect, positive affect, and positivity ratio). FINDINGS: Adolescents sent 1,598 texts on sleep and mood. Bidirectional sleep-mood relationships were in expected directions; negative affect and the positivity ratio affect predicted adolescents' sleep quality. CONCLUSIONS: Interventions should encourage sleep-mood relationship awareness, and further research should identify significant differences to inform tailored interventions with adolescents.

Garcia-Ortiz, L.; Recio-Rodriguez, J. I.; Puig-Ribera, A.; Lema-Bartolome, J.; Ibanez-Jalon, E.; Gonzalez-Viejo, N. et al. (2013):

Blood Pressure Circadian Pattern and Physical Exercise Assessment by Accelerometer and 7-Day Physical Activity Recall Scale.

In: *Am J Hypertens* (0895-7061 (Linking)). DOI: 10.1093/ajh/hpt159.

Abstract:

BACKGROUND: The relationship between regular physical activity, measured objectively and by self-report, and the circadian pattern of 24-hour ambulatory arterial blood pressure (BP) has not been clarified. METHODS: We performed a cross-sectional study in a cohort of healthy patients. We included 1,345 patients from the EVIDENT study (mean age 55+/-14 years; 59.3% women). Physical activity was assessed using the 7-day physical activity recall (PAR) questionnaire (metabolic equivalents (MET)/hour/week) and the Actigraph GT3X accelerometer (counts/minute) for 7 days; ambulatory arterial BP was measured with a radial tonometer (B-pro device). RESULTS: The dipper-pattern patients showed a higher level of activity than nondipper patients, as assessed by accelerometer and 7-day PAR. Physical activity measures correlated positively with the percent drop in systolic BP (SBP; rho = 0.19 to 0.11; P < 0.01) and negatively with the systolic and diastolic sleep to wake ratios (rho = -0.10 to -0.18; P < 0.01) and heart rate (rho = -0.13; P < 0.01). In logistic regression, considering the circadian pattern (1, dipper; 0, nondipper) as the dependent variable, the odds ratio of the third tertile of counts/minute was 1.79 (95% confidence interval [CI], 1.35-2.38; P < 0.01) and of MET/hour/week was 1.33 (95% CI, 1.01-1.75; P = 0.04) after adjustment for confounding variables. CONCLUSIONS: Physical activity, as evaluated by both the accelerometer and the 7-day PAR, was associated with a more marked nocturnal BP dip and, accordingly, a lower SBP and diastolic BP sleep to wake ratio. CLINICAL TRIAL REGISTRATION: Clinical Trials.gov Identifier: NCT01083082

Garcia-Ortiz, Luis; Recio-Rodriguez, Jose I.; Schmidt-Trucksass, Arno; Puigdomenech-Puig, Elisa; Martinez-Vizcaino, Vicente; Fernandez-Alonso, Carmen et al. (2014):

Relationship between objectively measured physical activity and cardiovascular aging in the general population - The EVIDENT trial.

In: *Atherosclerosis* 233 (2), S. 434–440. DOI: 10.1016/j.atherosclerosis.2014.01.021.

Abstract:

BACKGROUND: Aging has been associated with an increase in arterial stiffness. We analyzed the relationship between regular physical activity and cardiovascular aging evaluated by the radial augmentation index (rAIx), ambulatory arterial stiffness index (AASI), pulse pressure (PP) and heart age in subjects without atherosclerotic disease. METHODS: A cross-sectional study was performed including 1365 subjects from the EVIDENT trial (mean age 54.9 +/- 13.7 years; 60.3% women). As a measure of total volume of physical activity we used counts/minute recorded in an accelerometer (Actigraph GT3X) that participants wore for seven days, collecting data in 60-sec epochs, and respondents with >/=4 valid days were retained for the analysis. Arterial stiffness was evaluated using measures of rAIx, AASI, and central and peripheral PP on the B-pro device. rAIx was adjusted to 75 heart rate(rAIx75). Cardiovascular risk and heart age was estimated by the Framingham Risk Score. RESULTS: The median (IQR) of counts/min was 236.9 (176.3-307.8), rAIx75 90 (77-100), sleep PP 40 mmHg (33-47), central PP 39 mmHg (32-47) and heart age 57 years (45-73) and the mean +/- SD of the ASSI was 0.44 +/- 0.07. We found an inverse correlation between counts/minute and rAIx75 ($r = -0.086$; $p < 0.01$), AASI ($r = -0.146$; $p < 0.001$), heart age ($r = -0.163$; $p < 0.001$) and peripherals PP. These associations were remained after controlling for potential confounders, except for rAIx75. In the multiple regression analysis, after adjustment, an inverse association persisted between counts/minute and AASI, sleep PP and heart age, but not with rAIx75. Accordingly, for every 100 higher counts/minute of accelerometer measures, both AASI and sleep PP would be lower by one measurement unit (beta = -0.979 and -1.031 respectively, $p < 0.001$) and the estimated heart age by half year (beta = -0.525, $p = 0.023$). CONCLUSIONS: Regular physical activity was inversely associated with parameters related to advanced cardiovascular aging after adjustment for potentially influencing variables. Trial registration: Clinical Trials.gov Identifier: NCT01083082.

Ecological momentary assessment for chronic pain in fibromyalgia using a smartphone: a randomized crossover study.

In: *Eur J Pain* 18 (6), S. 862–872.

Abstract:

BACKGROUND: Daily diaries are a useful way of measuring fluctuations in pain-related symptoms. However, traditional diaries do not assure the gathering of data in real time, not solving the problem of retrospective assessment. Ecological momentary assessment (EMA) by means of electronic diaries helps to improve repeated assessment. However, it is important to test its feasibility in specific populations in order to reach a wider number of people who could benefit from these procedures. METHODS: The present study compares the compliance and acceptability of an electronic diary running on a smartphone using a crossover design for a sample with a specific pain condition, fibromyalgia and low familiarity with technology. Forty-seven participants were randomly assigned to one of two conditions: (1) paper diary - smartphone diary and (2) smartphone diary - paper diary, using each assessment method for 1 week. RESULTS: The findings of this study showed that the smartphone diary made it possible to gather more accurate and complete ratings. Besides, this method was well accepted by a sample of patients with fibromyalgia referred by a public hospital, with an important proportion of participants with low level of education and low familiarity with technology. CONCLUSIONS: The findings of this study support the use of smartphones for EMA even in specific populations with a specific pain condition, fibromyalgia and with low familiarity with technology. These methods could help clinicians and researchers to gather more accurate ratings of relevant pain-related variables even in populations with low familiarity with technology.

Gard, David E.; Sanchez, Amy H.; Cooper, Kathryn; Fisher, Melissa; Garrett, Coleman; Vinogradov, Sophia (2014):

Do people with schizophrenia have difficulty anticipating pleasure, engaging in effortful behavior, or both?

In: *Journal of Abnormal Psychology* 123 (4), S. 771–782. DOI: 10.1037/t05056-000.

Abstract:

Motivation deficits are common in schizophrenia, but little is known about underlying mechanisms, or the specific goals that people with schizophrenia set in daily life. Using neurobiological heuristics of pleasure anticipation and effort assessment, we

examined the quality of activities and goals of 47 people with and 41 people without schizophrenia, utilizing ecological momentary assessment. Participants were provided cell phones and called 4 times a day for 7 days, and were asked about their current activities and anticipation of upcoming goals. Activities and goals were later coded by independent raters on pleasure and effort. In line with recent laboratory findings on effort computation deficits in schizophrenia, relative to healthy participants, people with schizophrenia reported engaging in less effortful activities and setting less effortful goals, which were related to patient functioning. In addition, patients showed some inaccuracy in estimating how difficult an effortful goal would be, which in turn was associated with lower neurocognition. In contrast to previous research, people with schizophrenia engaged in activities and set goals that were more pleasure-based, and anticipated goals as being more pleasurable than controls. Thus, this study provided evidence for difficulty with effortful behavior and not anticipation of pleasure. These findings may have psychosocial treatment implications, focusing on effort assessment or effort expenditure. For example, to help people with schizophrenia engage in more meaningful goal pursuits, treatment providers may leverage low-effort pleasurable goals by helping patients to break down larger, more complex goals into smaller, lower-effort steps that are associated with specific pleasurable rewards. Gardner, Paula J.; Campagna, Phil D. (2011):

Pedometers as measurement tools and motivational devices: new insights for researchers and practitioners.

In: *Health promotion practice* 12 (1), S. 55–62. DOI: 10.1177/1524839909334623.

Abstract:

Pedometers are increasingly used in physical activity research and health promotion initiatives. This pilot study examines the efficacy of pedometers as motivational tools for increasing daily physical activity and exploring the practical issues related to pedometer use in research and intervention studies. A mixed-method design is used to collect data on the level of activity and in-depth information about participants' experiences wearing the pedometers. Participants are 10 midlife women between the ages of 45 and 64 (mean age = 52.9). Analysis indicates pedometers function as important motivational tools for increasing daily physical activity and improving the awareness of activity patterns for participants. Findings provide new insights into participants' experiences using the pedometers and understanding how these devices function as research tools. Several important methodological considerations for future research and intervention designs using pedometers are discussed.

Association between daily ambulatory activity patterns and exercise performance in patients with intermittent claudication.

In: *Journal of vascular surgery* 48 (5), S. 1238–1244. DOI: 10.1016/j.jvs.2008.06.062.

Abstract:

PURPOSE\r\nTo determine the association between daily ambulatory activity patterns and exercise performance in patients with intermittent claudication.\r\nMETHODS\r\nOne hundred thirty-three patients limited by intermittent claudication participated in this study. Patients were assessed on their ambulatory activity patterns for 1 week with a small, lightweight step activity monitor attached to the ankle using elastic velcro straps above the lateral malleolus of the right leg. The step activity monitor recorded the number of strides taken on a minute-to-minute basis and the time spent ambulating. Patients also were characterized on ankle-brachial index (ABI), ischemic window (IW) after a treadmill test, as well as initial claudication distance (ICD), and absolute claudication distance (ACD) during treadmill exercise.\r\nRESULTS\r\nThe patient characteristics (mean +/- SD) were as follows: ABI = 0.71 +/- 0.23, IW = 0.54 +/- 0.72 mm Hg.min.meter(-1), ICD = 236 +/- 198 meters, and ACD = 424 +/- 285 meters. The patients took 3366 +/- 1694 strides/day, and were active for 272 +/- 103 min/day. The cadence for the 30 highest, consecutive minutes of each day (15.1 +/- 7.2 strides/min) was correlated with ICD (r = 0.316, P < .001) and ACD (r = 0.471, P < 0.001), and the cadence for the 60 highest, consecutive minutes of each day (11.1 +/- 5.4 strides/min) was correlated with ICD (r = 0.290, P < .01) and ACD (r = 0.453, P < .001). Similarly, the cadences for the highest 1, 5, and 20 consecutive minutes, and the cadence for the 30 highest, nonconsecutive minutes all were correlated with ICD and ACD (P < .05). None of the ambulatory cadences were correlated with ABI (P > .05) or with ischemic window (P > .05).\r\nCONCLUSION\r\nDaily ambulatory cadences are associated with severity of intermittent claudication, as measured by ACD and ICD, but not with peripheral hemodynamic measures.

Gardner, Andrew W.; Parker, Donald E.; Montgomery, Polly S.; Khurana, Aman; Ritti-Dias, Raphael M.; Blevins, Steve M. (2010):

Gender differences in daily ambulatory activity patterns in patients with intermittent claudication.

In: *Journal of vascular surgery* 52 (5), S. 1204–1210.

Abstract:

OBJECTIVES:

To compare the pattern of daily ambulatory activity in men and women with intermittent claudication, and to determine whether calf muscle hemoglobin oxygen saturation (StO2) is associated with daily ambulatory activity.

METHODS:

Forty men and 41 women with peripheral arterial disease limited by intermittent claudication were assessed on their community-based ambulatory activity patterns for 1 week with an ankle-mounted step activity monitor and on calf muscle StO2 during a treadmill test.

RESULTS:

Women had lower adjusted daily maximal cadence (mean±SE) for 5 continuous minutes of ambulation (26.2±1.2 strides/min vs 31.0±1.2 strides/min; P=.009), for 1 minute of ambulation (43.1±0.9 strides/min vs 47.2±0.9 strides/min; P=.004), and for intermittent ambulation determined by the peak activity index (26.3±1.2 strides/min vs 31.0±1.2 strides/min; P=.009). Women also had lower adjusted time to minimum calf muscle StO2 during exercise (P=.048), which was positively associated with maximal cadence for 5 continuous minutes (r=0.51; P<.01), maximal cadence for 1 minute (r=0.42; P<.05), and peak activity index (r=0.44; P<.05). These associations were not significant in men.

CONCLUSION:

Women with intermittent claudication ambulate slower in the community setting than men, particularly for short continuous durations of up to 5 minutes and during intermittent ambulation at peak cadences. Furthermore, the daily ambulatory cadences of women are correlated with their calf muscle StO2 during exercise, as women who walk slower in the community setting reach their minimum calf muscle StO2 sooner than those who walk at faster paces. Women with intermittent claudication should be encouraged to not only walk more on a daily basis, but to do so at a pace that is faster than their preferred speed.

Intraindividual relations between the intensity and disclosure of daily emotional events: The moderating role of depressive symptoms.

In: *Journal of counseling psychology* 57 (2), S. 187–197. DOI: 10.1037/a0018386.

Abstract:

Individuals with high levels of depressive symptoms tend to engage in lower levels of emotional disclosure than individuals who are lower in depressive symptoms. However, little is known about how depressive symptoms relate to the intraindividual relation between daily disclosure and the intensity of the daily events. The authors addressed these relations using a daily diary methodology. College students (N = 239) completed a measure of depression symptoms. They then completed measures of the intensity of the day's most unpleasant event and their disclosure of that event each day for 7 days. Results indicated that depression moderated the intensity-disclosure relation such that depression symptoms were associated with diminished emotional disclosure for high-intensity events but not for low-intensity events. Individuals with relatively higher levels of depressive symptoms also experienced unpleasant daily events at a higher intensity level than did individuals with relatively fewer symptoms. Sex differences emerged such that men were less likely than women to disclose high-intensity negative events. These findings extend the use of the diary methodology to the study of emotional disclosure and also suggest possible interventions for counseling psychology practitioners.

Is “usual” blood pressure a proxy for 24-h ambulatory blood pressure in predicting cardiovascular outcomes?

In: *Am J Hypertens* 21 (9), S. 994–1000.

Abstract:

BACKGROUND:

The 24-h ambulatory blood pressure (ABP) is a stronger predictor of cardiovascular disease than conventional blood pressure (CBP), but it remains unclear how it compares with "usual" blood pressure (UBP), estimated after CBP has been corrected for regression dilution bias (RDB).

METHODS:

We compared the associations of cardiovascular mortality (n = 50), cardiovascular events (n = 101), and cardiac events (n = 71) with systolic CBP, UBP, and ABP over 13 years of follow-up (median) in 1,167 randomly selected Belgians. We estimated the correction factor to compute UBP from CBP at the midpoint of follow-up (6.5 years) in 723 untreated individuals without cardiovascular disease.

RESULTS:

Cardiovascular disease increased across quartiles of systolic CBP, UBP, and ABP (P for trend < or =0.02). For each 10 mm Hg increment in systolic ABP, the multivariate-adjusted hazard ratios for cardiovascular mortality and for cardiovascular and cardiac events were 1.38, 1.27, and 1.33, respectively (P < 0.001 for all). For CBP, the corresponding hazard ratios were 1.10 (P = 0.21), 1.09 (P = 0.12), and 1.14 (P = 0.06); and for UBP, they were 1.18 (P = 0.21), 1.16 (P = 0.12), and 1.23 (P = 0.06), respectively. The risk function for cardiovascular disease in relation to ABP was significantly steeper than that for CBP, but not UBP. In Cox models, including CBP or UBP in the presence of ABP, only ABP predicted cardiovascular outcomes.

CONCLUSIONS:

Correcting CBP for RDB resulted in a steeper slope of events on blood pressure than observed for CBP. The association with UBP was not statistically significant and did not enhance the prediction of outcome to the level of ABP.

Gassman-Pines, Anna (2011):

Associations of Low-Income Working Mothers' Daily Interactions With Supervisors and Mother-Child Interactions.

In: *J Marriage and Family* 73 (1), S. 67–76. DOI: 10.1111/j.1741-3737.2010.00789.x.

Abstract:

This study investigated associations of low-income working mothers' daily interactions with supervisors and their interactions with children. Sixty-one mothers of preschool-aged children were asked to report on their interactions with their supervisors at work and their interactions with children for 2 weeks (N = 520 workdays). Results show significant within-day spillover from the quality of mothers' perceived work interactions with supervisors to their reports of interactions with children. Supervisor criticism was positively correlated with harsh and withdrawn mother–child interactions on the same day. Supervisor recognition for good work was positively associated with warm mother–child interactions on the same day. Lagged analyses showed some significant associations between perceived supervisor interactions on a given day and mother–child interactions the next day.

Quantification of tackling demands in professional Australian football using integrated wearable athlete tracking technology.

In: *J Sci Med Sport* (1878-1861 (Electronic)). DOI: 10.1016/j.jsams.2013.01.007.

Abstract:

OBJECTIVES: To describe and quantify the frequency, velocity and acceleration at impact during tackling in Australian football using a combination of video and athlete tracking technology. DESIGN: Quasi-experimental. METHODS: Data was collected from twenty professional Australian Football League players during four in-season matches. All tackles made by the player and those against the player were video-coded and time stamped at the point of contact and then subjectively categorised into low, medium and high intensity impact groups. Peak GPS and acceleration data were identified at the point of contact. Two-way

analysis of variance was used to assess differences (p<0.05) between tackle type (made and against) and tackle intensity. RESULTS: A total of 173 tackles made and 179 tackles against were recorded. Significant differences were found between all tackle intensity groups. Peak velocity was significantly greater in high (19.5+/-6.1kmh(-1)) compared to medium (13.4+/-5.8kmh(-1)) and low intensity (11.3+/-5.0kmh(-1)) tackles. Peak Player Load, a modified vector magnitude of tri-axial acceleration, was significantly greater in high (7.5+/-1.7a.u.) compared to medium (4.9+/-1.5a.u.) and low intensity (4.0+/-1.3a.u.) tackles. CONCLUSIONS: High intensity tackles, although less frequent, are significantly greater in speed of movement immediately prior to contact and in the resultant impact acceleration compared to tackles of lower intensity. Differences in accelerometer data between tackles observed to be progressively greater in intensity suggest a level of ecological validity and provide preliminary support for the use of accelerometers to assess impact forces in contact invasion sports

Gastin, P. B.; Meyer, D.; Robinson, D. (2012):

Perceptions of wellness to monitor adaptive responses to training and competition in elite Australian football.

In: *J Strength.Cond.Res* (1064-8011 (Linking)). DOI: 10.1519/JSC.0b013e31827fd600.

Abstract:

ABSTRACT: Perceptions of wellness are often used by athletes and coaches to assess adaptive responses to training. The purpose of this research was to describe how players were coping with the demands of elite level Australian football over a competitive season using subjective ratings of physical and psychological wellness and to assess the ecological validity of such a monitoring approach. Twenty seven players completed ratings for nine items (fatigue, general muscle, hamstring, quadriceps, pain/stiffness, power, sleep quality, stress, wellbeing). Players subjectively rated each item as they arrived at the training or competition venue on a 1 - 5 visual analog scale, with 1 representing the positive end of the continuum. A total of 2,583 questionnaires were analysed from completions on 183 days throughout the season (92 +/- 24 per player, 103 +/- 20 per week; mean +/- SD). Descriptive statistics and multi-level modelling were used to understand how player ratings of wellness varied over the season and during the week leading into game day and whether selected player characteristics moderated these relationships. Results indicated that subjective ratings of physical and psychological wellness were sensitive to weekly training manipulations (i.e., improve steadily throughout the week to a game day low, $p < 0.001$), to periods of unloading during the season (i.e., a week of no competition, $p < 0.05$) and to individual player characteristics (e.g., muscle strain after a game was poorer in players with high maximum speed, $p < 0.01$). It is concluded that self-reported player ratings of wellness provide a useful tool for coaches and practitioners to monitor player responses to the rigorous demands of training, competition and life as a professional athlete

Personalised mobile health and fitness apps: lessons learned from myFitnessCompanion(R).

In: *Stud.Health Technol.Inform.* 177 (0926-9630 (Linking)), S. 248–253. Online verfügbar unter PM:22942063.

Abstract:

Smartphones and tablets are slowly but steadily changing the way we look after our health and fitness. Today, many high quality mobile apps are available for users and health professionals and cover the whole health care chain, i.e. information collection, prevention, diagnosis, treatment and monitoring. Our team has developed a mobile health and fitness app called myFitnessCompanion(R) which has been available via Android market since February 2011. The objective of this paper is to share our experience with rolling out a mobile health and fitness app. We discuss the acceptance of health apps by end-users and healthcare industry. We discuss how mobile health apps will be distributed in the near future, the use of Personal Health Record (PHR) systems such as Microsoft HealthVault and the impact of regulations (FDA) on the future of mobile health apps. The paper is based on seven years of experience by the authors as mobile health and fitness application developers and we discuss the challenges and opportunities for app developers in the health industry

Actigraphic measurement of motor deficits in acute ischemic stroke.

In: *Cerebrovascular diseases (Basel, Switzerland)* 26 (5), S. 533–540. DOI: 10.1159/000160210.

Abstract:

BACKGROUND\r\nThis study aimed to investigate the use of actigraphy (accelerometry) to measure disuse of the impaired arm in acute stroke patients. We correlated the National Institute of Health Stroke Scale (NIHSS) and the Fugl-Meyer Assessment arm section (FMA) findings with actigraphic data as a measure of validity.\r\nMETHODS\r\nThirty-nine acute ischemic stroke patients were included within 1 week after stroke onset. At inclusion, motor deficits were assessed by the NIHSS, FMA and 48-hour actigraphic recordings of both wrists were performed.\r\nRESULTS\r\nModerate but highly significant correlations (Spearman's rho) between actigraphic recordings and total NIHSS (ratio r = -0.59 and activity of impaired arm r = -0.75; p < 0.001) and FMA (ratio r = 0.54 and activity of impaired arm r = 0.69; p < 0.001) scores were found. Based on actigraphic motor activity scores, ROC curves were calculated following dichotomization of the population based on NIHSS = 7 and FMA = 45, showing good sensitivity and specificity, with negative predictive value of 100% and positive predictive value of 91% for the ratio variable.\r\nCONCLUSIONS\r\nModerate but highly significant correlations were found between actigraphy and the stroke scales NIHSS and FMA. Actigraphy was able to reliably discriminate less impaired from more impaired stroke patients with excellent sensitivity and specificity values. Actigraphy is a simple, valid, objective and reliable clinical research tool that can be used to determine motor impairment of the upper limb in stroke patients.

Gebruers, Nick; Truijen, Steven; Engelborghs, Sebastiaan; Deyn, Peter P. (2013):

Predictive value of upper-limb accelerometry in acute stroke with hemiparesis.

In: *J Rehabil Res Dev* 50 (8), S. 1099–1106. DOI: 10.1682/JRRD.2012.09.0166.

Abstract:

Few studies have investigated how well early activity measurements by accelerometers predict recovery after stroke. First, we assessed the predictive value of accelerometer-based measurements of upper-limb activity in patients with acute stroke with a hemiplegic arm. Second, we established the difference in arm activity between hospitalized stroke and nonstroke patients. In total, 129 patients with acute stroke and 19 controls participated. Activity of the upper limbs was monitored for 48 h, and these data were used to determine the predictive value of the activity variables compared with the modified Rankin Scale (mRS), which was assessed at 3 mo poststroke onset. The sensitivity and specificity in relation to the mRS were 0.80 and 0.77, respectively, for the activity of impaired arm (AIA) and 0.85 and 0.75, respectively, for the ratio variable calculated by dividing the AIA by the activity of the nonimpaired arm. The corresponding cutoff values were 597,546 counts for AIA and 0.33 for the ratio. The predictive value of AIA combined with age was 85% to the disability status defined as an mRS score of 2 or less.

Gehricke, Jean-G; Hong, Nuong; Whalen, Carol K.; Steinhoff, Kenneth; Wigal, Timothy L. (2009):

Effects of transdermal nicotine on symptoms, moods, and cardiovascular activity in the everyday lives of smokers and nonsmokers with attention-deficit/hyperactivity disorder.

In: *Psychology of Addictive Behaviors* 23 (4), S. 644–655. DOI: 10.1037/a0017441.

Abstract:

The aim of the study was to test the self-medication hypothesis by examining the effects of nicotine in the everyday lives of smokers and nonsmokers with attention-deficit/hyperactivity disorder (ADHD). Fifty-two adults with ADHD (25 abstinent smokers and 27 nonsmokers) participated in a double-blind placebo controlled study with one nicotine patch condition and one placebo patch condition in counterbalanced order. Each condition continued for two consecutive days in which patches were administered each morning. The effects of nicotine on ADHD symptoms, moods, and side effects were assessed with electronic diaries. Cardiovascular activity was recorded with ambulatory blood pressure monitors and physical activity was monitored with actigraphs. Nicotine reduced reports of ADHD symptoms by 8% and negative moods by 9%, independent of smoking status. In addition, nicotine increased cardiovascular activity during the first 3 to 6 hours after nicotine patch administration. The results support the self-medication hypothesis for nicotine in adults with ADHD and suggest that smoking cessation and prevention efforts for individuals with ADHD will need to address both the symptom reducing and mood enhancing effects of nicotine.

Gehricke, Jean-G; Hong, Nuong; Wigal, Timothy L.; Chan, Vivien; Doan, Ashley (2011):

ADHD medication reduces cotinine levels and withdrawal in smokers with ADHD.

In: *Pharmacology, biochemistry, and behavior* 98 (3), S. 485–491. DOI: 10.1016/j.pbb.2011.02.021.

Abstract:

Individuals with ADHD may self-medicate with nicotine, the main psychoactive ingredient in tobacco smoke, in order to reduce symptoms and negative moods associated with ADHD. ADHD medication (e.g., methylphenidate and atomoxetine) may mimic some of the effects of nicotine and may aid smoking cessation in smokers with ADHD. The present study examined if ADHD medication reduces smoking and withdrawal in non-treatment seeking smokers with ADHD. Fifteen adult smokers with ADHD participated in the study, which consisted of an experimental phase and field monitoring phase to examine the acute and extended effects, respectively, of ADHD medication. During the experimental phase, smokers were asked to complete a Continuous Performance Task (CPT) and the Shiffman-Jarvik smoking withdrawal questionnaire during the following four conditions: (1) ADHD medication+cigarette smoking, (2) ADHD medication+overnight abstinence, (3) placebo+cigarette smoking, and (4) placebo+overnight abstinence. During the field monitoring phase, participants were asked to provide salivary cotinine samples and complete electronic diaries about smoking, smoking urge, ADHD symptoms, and stress in everyday life for two days on ADHD medication and for two days on placebo. Results of the experimental phase showed that ADHD medication improved task performance on the CPT and reduced withdrawal during overnight abstinence. During the field monitoring phase, ADHD medication reduced salivary cotinine levels compared to placebo. In addition, the electronic diary revealed that ADHD medication improved difficulty concentrating during no smoking events and stress. The findings of the present study suggest that, along with other strategies, ADHD medication may be used to aid smoking withdrawal and cessation in smokers with ADHD.

Geiser, Christian; Bishop, Jacob; Lockhart, Ginger; Shiffman, Saul; Grenard, Jerry L. (2013):

Analyzing latent state-trait and multiple-indicator latent growth curve models as multilevel structural equation models.

In: *Front Psychol* 4, S. 975. DOI: 10.3389/fpsyg.2013.00975.

Abstract:

Latent state-trait (LST) and latent growth curve (LGC) models are frequently used in the analysis of longitudinal data. Although it is well-known that standard single-indicator LGC models can be analyzed within either the structural equation modeling (SEM) or multilevel (ML; hierarchical linear modeling) frameworks, few researchers realize that LST and multivariate LGC models, which use multiple indicators at each time point, can also be specified as ML models. In the present paper, we demonstrate that using the ML-SEM rather than the SL-SEM framework to estimate the parameters of these models can be practical when the study involves (1) a large number of time points, (2) individually-varying times of observation, (3) unequally spaced time intervals, and/or (4) incomplete data. Despite the practical advantages of the ML-SEM approach under these circumstances, there are also some limitations that researchers should consider. We present an application to an ecological momentary assessment study (N = 158 youths with an average of 23.49 observations of positive mood per person) using the software Mplus (Muthen and Muthen, 1998-2012) and discuss advantages and disadvantages of using the ML-SEM approach to estimate the parameters of LST and multiple-indicator LGC models.

Geisler, Fay C. M.; Kubiak, Thomas; Siewert, Kerstin; Weber, Hannelore (2013):

Cardiac vagal tone is associated with social engagement and self-regulation.

In: *Biol Psychol* 93 (2), S. 279–286. DOI: 10.1037/t13598-000;

Abstract:

The polyvagal theory (Porges, 2007) represents a biobehavioral model that relates autonomic functioning to self-regulation and social engagement. The aim of the two presented studies was to test the proposed association of cardiac vagal tone (CVT), assessed via resting high-frequency heart rate variability (respiratory sinus arrhythmia, RSA), with coping, emotion-regulation, and social engagement in young adults. In Study 1 (retrospective self-report), RSA was positively associated with engagement coping (situation control, response control, positive self-instructions, social-support seeking) and aspects of social wellbeing. In Study 2 (ecological momentary assessment), for 28 days following the initial assessment, RSA predicted less use of disengagement strategies (acceptance and avoidance) for regulating negative emotions and more use of socially adaptive emotion-regulation strategies (i.e., social-support seeking as a reaction to sadness and making a concession as a reaction to anger caused by others). Furthermore, RSA was higher in participants who reported no anger episodes compared to those who reported at least one anger episode and was positively associated with reported episodes of negative emotions. Results support the association proposed by the PVT between CVT and self-regulatory behavior, which promotes social bonds. Geschwind, Nicole; Nicolson, Nancy A.; Peeters, Frenk; van Os, Jim; Barge-Schaapveld, Daniela; Wichers, Marieke (2011):

Early improvement in positive rather than negative emotion predicts remission from depression after pharmacotherapy.

In: *Eur Neuropsychopharmacol* 21 (3), S. 241–247. DOI: 10.1016/j.euroneuro.2010.11.004.

Abstract:

Knowledge on mechanisms involved in early prediction of response to antidepressant medication may help optimize clinical decision making. Recent studies regarding response to pharmacotherapy implicate resilience-like mechanisms and involvement of positive, rather than negative emotions. The aim of the current study is to examine the contribution of early change in positive affect to the prediction of response to pharmacotherapy. Positive and negative emotions were measured at baseline and during the first week of pharmacotherapy, using experience sampling techniques. The association between early change in positive and negative emotions and severity of depressive symptoms at week six was examined in a sample of 49 depressed patients. The added benefits of measuring early change in positive emotions compared to early Hamilton Depression Rating Scale (HDRS) change alone were evaluated through model comparisons. Early improvement in positive affect during the first week of treatment predicted the continuous HDRS score (β=-0.64, p<0.001), response (50% reduction; OR=4.32, p<0.01), and remission (HDRS≤7; OR=9.29, p<0.001) at week six with moderate to large effect sizes. Effects of early change in negative emotions were only half as large and disappeared when evaluated simultaneously with early change in positive emotions. When early change in positive emotions was added to the models including early HDRS change only, all three models improved significantly. In conclusion, early change in positive rather than negative emotions best predicted response to treatment, supporting the notion that antidepressants activate resilience-like mechanisms. Moreover, monitoring of positive emotions in early stages of treatment may improve clinical decision making.

Geschwind, Nicole; Peeters, Frenk; Jacobs, Nele; Delespaul, Philippe; Derom, Catherine; Thiery, Evert et al. (2010):

Meeting risk with resilience: high daily life reward experience preserves mental health.

In: *Acta Psychiatrica Scandinavica* 122 (2), S. 129–138.

Abstract:

OBJECTIVE:

To examine prospectively whether high reward experience (the ability to generate positive affect boosts from pleasurable daily events) protects against affective symptoms and whether environmental or genetic risk factors moderate protective effects.

METHOD:

At baseline, 498 female twins participated in an experience sampling study measuring reward experience in daily life. They also completed questionnaires on childhood adversity and recent stressful life events (SLE). Affective symptoms were measured at baseline and at four follow-ups using SCL-90 anxiety and depression subscales. Co-twin affective symptoms were used as indicators of genetic risk.

RESULTS:

Baseline reward experience did not predict follow-up affective symptoms, regardless of level of genetic risk. However, high reward experience was associated with reduced future affective symptoms after previous exposure to childhood adversity or recent SLE.

CONCLUSION:

High daily life reward experience increases resilience after environmental adversity; modification of reward experience may constitute a novel area of therapeutic intervention.

Gevonden, M. J.; Myin-Germeys, I.; van Den Brink, W.; van Os, J.; Selten, J. P.; Booij, J. (2014):

Psychotic reactions to daily life stress and dopamine function in people with severe hearing impairment.

In: *Psychol Med*, S. 1–10. DOI: 10.1017/S0033291714002797.

Abstract:

Background. Minor stresses measured in daily life have repeatedly been associated with increased momentary psychotic experiences, both in individuals with psychotic disorders and in persons who are genetically at an increased risk for these

disorders. Severe hearing impairment (SHI) is an environmental risk factor for psychotic disorder, possibly due to the experience of social exclusion. The aim of the current study is to investigate whether people with SHI exhibit higher levels of psychotic reactivity to social stressors in daily life than normal-hearing controls and whether this reactivity is associated with decreased baseline dopamine (DA) D2/3 receptor availability and/or elevated DA release following a dexamphetamine challenge. Method. We conducted an experience sampling study in 15 young adults with SHI and 19 matched normal-hearing controls who had previously participated in a single photon emission computed tomography study measuring DA D2/3 receptor availability and DA release in response to dexamphetamine. Results. The association between social stress and momentary psychotic experiences in daily life was stronger among SHI participants than among normal-hearing controls. Interactions between social stress and baseline striatal DA D2/3 receptor availability or DA release were not significant in multilevel models of momentary psychotic experiences including age, sex and tobacco use. Conclusions. While both elevated striatal DA release and elevated psychotic stress reactivity have been found in the same population defined by an environmental risk factor, SHI, their inter-relationship cannot be established. Further research is warranted to clarify the association between biological and psychological endophenotypes and psychosis risk.

Gibson, Carolyn; Matthews, Karen; Thurston, Rebecca (2014):

Daily physical activity and hot flashes in the Study of Women's Health Across the Nation (SWAN) Flashes Study.

In: *Fertil Steril* 101 (4), S. 1110–1116. DOI: 10.1016/j.fertnstert.2013.12.029.

Abstract:

OBJECTIVE: To examine the role of physical activity in menopausal hot flashes. DESIGN: Physiologic hot flash monitor and activity monitor over two 48-hour periods, with self-report in an electronic diary. SETTING: Community. PATIENT(S): 51 midlife women. INTERVENTION(S): None. MAIN OUTCOME MEASURE(S): Physiologically detected hot flashes and reported hot flashes with and without physiologic corroboration. RESULT(S): Competing models conceptualize physical activity as a risk or protective factor for hot flashes, but few studies have examined this relationship prospectively using physiologic measures of hot flashes and physical activity. When physiologic hot flashes, reported hot flashes, and reported hot flashes without physiologic corroboration were related to activity changes using hierarchic generalized linear modeling, adjusting for potential confounders, hot flash reports without physiologic corroboration were more likely after activity increases, particularly among women with higher levels of depressive symptoms. No other types of hot flashes were related to physical activity. CONCLUSION(S): Acute increases in physical activity were associated with increased reporting of hot flashes that lacked physiologic corroboration, particularly among women with depressive symptoms. Clinicians should consider the role of symptom perception and reporting in relations between physical activity and hot flashes.

Gidlow, Christopher J.; Cochrane, Tom; Davey, Rachel; Smith, Hannah (2008):

In-school and out-of-school physical activity in primary and secondary school children.

In: *Journal of Sports Sciences* 26 (13), S. 1411–1419. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2011-26429-005%26site%3dehost-live;c.gidlow@staffs.ac.uk.

Abstract:

The aim of this study was to compare in-school and out-of-school physical activity within a representative sample. Socio-demographic, physical activity, and anthropometric data were collected from a random sample of children (250 boys, 253 girls) aged 3-16 years attending nine primary and two secondary schools. Actigraph GT1M accelerometers, worn for seven days, were used to estimate physical activity levels for in-school (typically 09.00-15.00 h), out-of-school (weekday), and weekend periods. Physical activity as accelerometer counts per minute were lower in school versus out of school overall (in school: 437.2 +/- 172.9; out of school: 575.5 +/- 202.8; P < 0.001), especially in secondary school pupils (secondary: 321.6 +/- 127.5; primary: 579.2 +/- 216.3; P < 0.001). Minutes of moderate-to-vigorous physical activity accumulated in school accounted for 29.4 +/- 9.8% of total weekly moderate-to-vigorous physical activity overall but varied by sector (preschool: 37.4 +/- 6.2%; primary: 33.6 +/- 8.1%; secondary: 23.0 +/- 9.3%; F = 114.3, P < 0.001). Approximately half of the children with the lowest in-school activity compensated out of school during the week (47.4%) and about one-third at the weekend (30.0%). Overall, physical activity during the school day appears to be lower than that out of school, especially in secondary school children, who accumulate a lower proportion of their total weekly moderate-to-vigorous physical activity at school than younger children. As low in-school activity was compensated for beyond the school setting by less than half of children, promoting physical activity within the school day is important, especially in secondary schools.

Giesbrecht, Gerald F.; Campbell, Tavis; Letourneau, Nicole; Kooistra, Libbe; Kaplan, Bonnie (2012):

Psychological distress and salivary cortisol covary within persons during pregnancy.

In: *Psychoneuroendocrinology* 37 (2), S. 270–279. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-29692-010&site=ehost-live;Gerald.Giesbrecht@albertahealthservices.ca.

Abstract:

The mechanisms whereby maternal stress during pregnancy exerts organizational effects on fetal development require elaboration. The aim of this study was to assess the plausibility of cortisol as a biological link between maternal psychological distress during pregnancy and fetal development. Previous research has resulted in equivocal findings for between-persons differences in stress and cortisol. Ecological momentary assessment was used to simultaneously assess mood and cortisol 5 times daily for 3 days in 83 women (gestational ages 6—37 weeks). Results from multilevel analysis indicated a robust within-person association between negative mood and cortisol. For each 1.0% increase in negative mood there was a corresponding 1.9% increase in cortisol. This association was unaffected by advancing gestational age. The results suggest that cortisol is a plausible biological mechanism for transducing the effects of maternal psychological distress during pregnancy to fetal development. Giesbrecht, G. F.; Campbell, T.; Letourneau, N.; Kaplan, B. J. (2013):

Advancing gestation does not attenuate biobehavioural coherence between psychological distress and cortisol.

In: *Biol.Psychol.* 93 (1), S. 45–51. DOI: 10.1016/j.biopsycho.2013.01.019.

Abstract:

BACKGROUND: Despite little evidence to suggest that HPA axis responses to psychological provocation are attenuated during pregnancy, it is widely held that dampening of the HPA axis response to psychological distress serves a protective function for the mother and fetus. The current study was designed to assess changes in biobehavioral coherence between psychological distress and cortisol over the course of pregnancy. METHODS: Ambulatory assessment of ecologically relevant psychological distress and salivary cortisol were repeated in all three trimesters for 82 pregnant women. Samples were collected 5 times per day over the course of 2days in each trimester. RESULTS: Psychological distress and cortisol were positively associated, beta=.024, p<.01, indicating that increases in psychological distress were associated with increases in cortisol. Gestational age did not moderate this association, beta=.0009, p=.13, suggesting that negative psychological experiences remain potent stimuli for the HPA axis during pregnancy. CONCLUSION: Biobehavioral coherence between ecologically relevant experiences of psychological distress and cortisol is not attenuated with advancing gestation

Salivary alpha-amylase during pregnancy: Diurnal course and associations with obstetric history, maternal demographics, and mood.

In: *Dev.Psychobiol.* (0012-1630 (Linking)). DOI: 10.1002/dev.21008.

Abstract:

Diurnal patterns of salivary alpha amylase (sAA) in pregnant women have not previously been described. The current study employed ecological momentary assessment to examine the association between the diurnal sAA, obstetric history, maternal demographics, and mood during pregnancy. Saliva was self-collected by 83 pregnant women (89% White, age 25.3-43.0 years; mean gestational age 21.9 weeks, range 6-37 weeks; gravida 1-6) at home over three days. Results indicated that current pregnancy (gestational age and fetal sex) and maternal demographics were not related to diurnal sAA. In contrast, a history of previous miscarriage (Parameter = -.17; SE = .05; p < .05) was associated with an atypical diurnal pattern. Even after accounting for obstetric history, trait anxiety (Parameter = .16; SE = .04; p < .001) was associated with increased sAA over the day while chronic levels of fatigue (Parameter = -.06; SE = .03; p < .05) were associated with decreased sAA. In a separate model, we also tested the time varying covariation of sAA and mood. The effects of momentary mood were in contrast to those for trait mood. Both momentary depression (Parameter = .22; SE = .09; p < .01) and vigour/positive mood (Parameter = .12; SE = .04; p < .001) were associated with momentary increases in sAA while momentary anxiety and fatigue were not related to sAA. The findings suggest that basal sAA during pregnancy is sensitive to emotional arousal. Evaluating diurnal patterns of sAA holds promise for advancing understanding of how emotional arousal during pregnancy may affect fetal development. (c) 2012 Wiley Periodicals, Inc. Dev Psychobiol

Giesbrecht, G. F.; Letourneau, N.; Campbell, T.; Kaplan, B. J. (2012):

Affective experience in ecologically relevant contexts is dynamic and not progressively attenuated during pregnancy.

In: *Arch.Womens Ment.Health* (1435-1102 (Electronic)). DOI: 10.1007/s00737-012-0300-4.

Abstract:

Pregnancy is thought to diminish a woman's appraisal of and affective response to stressors. To examine this assumption, we used an electronic diary and an ecological momentary assessment strategy to record women's (n = 85) experiences of positive and negative affect five times each day over 2 days within each trimester of pregnancy. The women also completed the Edinburgh Postnatal Depression Scale in each trimester. Multilevel modeling indicated nonlinear patterns for both positive and negative affect that differed by the level of depressive symptoms. The findings suggest that changes in the psychological experience over the course of pregnancy are dynamic and not progressively attenuated

A method to align the coordinate system of accelerometers to the axes of a human body: The depitch algorithm.

In: *Comput.Methods Programs Biomed.* (0169-2607 (Linking)). DOI: 10.1016/j.cmpb.2011.10.014.

Abstract:

One of the key problems in accelerometry based gait analyses is that it may not be possible to attach an accelerometer to the lower trunk so that its axes are perfectly aligned to the axes of the subject. In this paper we will present an algorithm that was designed to virtually align the axes of the accelerometer to the axes of the subject during walking sections. This algorithm is based on a physically reasonable approach and built for measurements in unsupervised settings, where the test persons are applying the sensors by themselves. For evaluation purposes we conducted a study with 6 healthy subjects and measured their gait with a manually aligned and a skewed accelerometer attached to the subject's lower trunk. After applying the algorithm the intra-axis correlation of both sensors was on average 0.89+/-0.1 with a mean absolute error of 0.05g. We concluded that the algorithm was able to adjust the skewed sensor node virtually to the coordinate system of the subject

Predicting habitual walking performance in multiple sclerosis: relevance of capacity and self-report measures.

In: *Multiple sclerosis (Houndmills, Basingstoke, England)* 16 (5), S. 618–626. DOI: 10.1177/1352458510361357.

Abstract:

The objective was to establish the extent to which physical functioning capacity and self-report measures are able to predict the habitual walking performance in ambulatory persons with multiple sclerosis. Fifty persons with multiple sclerosis (Expanded Disability Status Scale, EDSS, 1.5-6.5) were tested on leg muscle strength as well as walking and balance capacity, and completed self-report indices on perceived physical functioning. Habitual walking performance, that is, the real amount of steps that is performed in the customary living environment, was registered by means of an ambulant accelerometer-based monitor during seven consecutive days. Mild (EDSS 1.5-4.0, n = 29) and moderate (EDSS 4.5-6.5, n = 21) multiple sclerosis subgroups were additionally distinguished as predictor variables and values were hypothesized to differ depending on multiple sclerosis severity and concomitant ambulatory function. Multiple regression analyses yielded a single most significant predictor for each (sub)group with other variables making no independent contribution to the variation in habitual walking performance. For the total study sample, this was the 6-Minute Walking Test ($R(2) = 0.458$, $p < 0.01$). In the mild multiple sclerosis subgroup, the 6-Minute Walking Test was again most predictive, yet to a modest degree ($R(2) = 0.187$, $p = 0.02$). In the moderate multiple sclerosis subgroup, the 2-Minute Walking Test explained over half of the variance ($R(2) = 0.532$, $p < 0.01$). Habitual walking performance is best reflected by longer walking capacity tests. The extent to which it can be predicted based on clinical testing is larger in a multiple sclerosis patient sample with more severe walking disability. Ambulatory monitoring, however, includes aspects of community ambulation not captured in the clinic, and must be considered as an additional outcome for evaluating interventions in multiple sclerosis.

Superior consistency of ambulatory blood pressure monitoring in children: implications for clinical trials.

In: *J Hypertens* 27 (8), S. 1568–1574. DOI: 10.1097/HJH.0b013e32832cb2a8.

Abstract:

BACKGROUND\r\nCasual office blood pressure (CBP) measurements are still standard in antihypertensive drug trials. In pediatric hypertensive trials, ethical considerations, very low disease prevalence and the marked impact of white-coat hypertension create the need for very sensitive and reproducible techniques of BP assessment. We hypothesized that ambulatory BP monitoring (ABPM) may identify treatment effects more sensitively than CBP and thereby reduce sample sizes required in pediatric antihypertensive trials.\r\nMETHODS\r\nStandard deviations (SDs) were used to assess population variability of CBP and ABPM at baseline and after 6 months standardized antihypertensive treatment from a trial investigating the BP-lowering effect of ramipril in children with chronic kidney disease.\r\nRESULTS\r\nIn 157 hypertensive children, ramipril had a similar mean BP-lowering effect on clinic and ambulatory 24-h BP for systolic (-10 vs. -11 mmHg, P = NS) and diastolic values (-9 vs. -11 mmHg, P = NS). However, the SDs of the CBP responses were up to 39% larger than those of ABPM (SBP 15.5 vs. 9.4; DBP 13.8 vs. 8.8; both $P < 0.0001$). Using power analysis, we demonstrate that, depending on the magnitude of the expected antihypertensive

effect and trial design, the utilization of ABPM in antihypertensive drug efficacy studies allows reduction of sample sizes by 57-75%. This reduction of cohort size with ABPM is substantially greater than previously observed for adults.\r\nCONCLUSION\r\nThe primary use of ABPM can substantially reduce the number of children put at potential risk in blinded antihypertensive drug trials by up to three quarters.

The promise of intensive longitudinal data capture for behavioral health research.

In: *Nicotine Tob Res* 16 Suppl 2, S. S73-5. DOI: 10.1093/ntr/ntt273.

Abstract:

Advances in technology and the associated cultural norms, especially the advent of the smartphone, offer an unprecedented opportunity to collect data on relevant health behaviors and experiences unobtrusively at a greater frequency and in greater volumes than ever before. This special issue will acquaint the readership of Nicotine and Tobacco Research with the potential for intensive longitudinal data and will illustrate some innovative analytic techniques for addressing research questions associated with this type of complex data. This introductory article will provide a brief history of the analytic techniques for intensive longitudinal data and will point to some resources that support and enable the use of these techniques.

Examining perceptions of a smartphone-based intervention system for alcohol use disorders.

In: *Telemed J E Health* 20 (10), S. 923–929. DOI: 10.1089/tmj.2013.0222.

Abstract:

Abstract Background: This study presents results from qualitative interviews conducted with participants in a study on the effectiveness of the Location-Based Monitoring and Intervention System for Alcohol Use Disorders (LBMI-A), a smartphone-based, stand-alone intervention application (app) for adults with alcohol use disorders. MATERIALS AND METHODS: Participants were provided an LBMI-A-enabled smartphone to use during a 6-week pilot study. The LBMI-A was composed of psychoeducational modules, assessment and feedback of alcohol use patterns, geographic high-risk location monitoring and alerts, and in vivo assessment and intervention for alcohol cravings and help with managing psychological distress. Semistructured interviews were conducted with all participants following 6 weeks of interacting with the LBMI-A app (n=26). Interviews explored user perceptions of the ease and utility of LBMI-A features, module helpfulness, barriers to use, and recommendations for improvements to the program. Researchers applied a systematic qualitative coding process to transcripts that included both a priori themes identified as important by the research team and new themes that emerged during the coding process. RESULTS AND CONCLUSIONS: Narrative analysis found the emergence of five main themes identified by LBMI-A users as the most helpful functions of the phone: (1) Awareness, (2) Accountability, (3) Skill Transference, (4) Tracking Progress, and (5) Prompts. These themes are explored, and implications of these findings for future smartphone-based interventions are discussed.

Association Between Cardiotrophin 1 Levels and Central Blood Pressure in Untreated Patients With Essential Hypertension.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpt238.

Abstract:

BACKGROUND: Cardiotrophin 1 (CT-1) is an interleukin 6-related cytokine recently implicated in cardiac hypertrophy and vascular damage in essential hypertension (EH). We aimed first to determine CT-1 levels in naive, untreated patients with grade I EH (UH) as compared with normotensive (NT) individuals and, second, to investigate a possible association of CT-1 levels with indices of arterial stiffness. METHODS: We enrolled 45 consecutive untreated patients recently diagnosed with grade I EH by means of office and ambulatory blood pressure (BP) measurements and 25 age- and sex-matched NT subjects. CT-1 levels were measured with a commercially available enzyme-linked immunosorbent assay kit, and indices of arterial stiffness were determined by applanation tonometry. RESULTS: CT-1 levels were significantly elevated in UH patients compared with NT

subjects (P < 0.001). Furthermore, CT-1 levels correlated positively with office, ambulatory and central BP. A significant bivariable correlation was also found between CT-1 levels and pulse wave velocity (P = 0.02). In the multivariable analysis, central systolic and diastolic BP proved the only significant predictors of CT-1 levels after controlling for other related factors. CONCLUSIONS: To our knowledge, this is the first study that correlates CT-1 levels with ambulatory and central BP, as well as with pulse wave velocity in patients with essential hypertension. Thus, studying the effects of CT-1 in the cardiovascular system in patients with EH represents a promising area of investigation in the future.

Gladh, K.; Ang, B. O.; Lindholm, P.; Nilsson, J.; Westman, A. (2013):

Decelerations and muscle responses during parachute opening shock.

In: *Aviat.Space Environ.Med.* 84 (11), S. 1205–1210. Online verfügbar unter PM:24279237.

Abstract:

INTRODUCTION: Pain in the neck region among skydivers can be related to repeated parachute opening shocks (POS), but empirical data on ramair POS biomechanics is lacking in the literature. The aim of this study was to develop and evaluate a methodology for assessment of multidirectional accelerations and neck muscle activity during parachuting, and to describe preliminary data. METHODS: In an experimental design, four experienced skydivers made two consecutive skydives. Deceleration was recorded with two triaxial accelerometers, one placed on the skydiver's cervicothoracic junction (acc-neck) and the other on the harness (acc-rig). Surface electromyography (EMG) was sampled from four sites bilaterally: anterior-neck, posterior upper and lower neck, and upper shoulder muscles. EMG activity was normalized against a premeasured maximum voluntarily produced electrical signal (MVE). RESULTS: The measuring equipment did not interfere with the parachute jumps. High-quality signals were recorded. The median peak POS deceleration for the acc-neck vs. acc-rig indicated differences (4.0 G vs. 5.1 G), in addition to significant differences emerging for medians of average and maximum onset rates of deceleration (avg: 1.2 G x s(-1) vs. 19.5 G x s(-1); max: 23.0 G x s(-1) vs. 80.0 G x s(-1)). The median of overall muscleactivity was as high as 87% MVE, but no differences in peak activity were found between muscles. Temporal activations of the posterior upper neck occurred less than 50 ms after deceleration initiation, indicating feedforward control of the neck. CONCLUSION: All instruments recorded data of good quality without impeding the skydiving activity. Triaxial accelerometry on the neck vs. the harness yielded dissimilar results, underlining the importance of correct accelerometer placement. Muscle activity was high during POS and neck muscles showed anticipatory tendencies

Glaros, Alan G.; Hanson, Anne H.; Ryen, Chris C. (2014):

Headache and oral parafunctional behaviors.

In: *Appl Psychophysiol Biofeedback* 39 (1), S. 59–66. DOI: 10.1007/s10484-014-9242-0.

Abstract:

This study tested the hypotheses that individuals with headaches would show significantly more oral parafunctional behaviors than non-headache controls, be diagnosed with one or more temporomandibular disorders (TMD) significantly more frequently than controls, and would report significantly less pain and other symptoms of headache after participating in a habit reversal treatment to reduce oral parafunctional behaviors, compared to a wait list control. In Phase I, individuals with and without self-reported headaches were examined by a blinded examiner and participated in a week-long experience sampling protocol (ESM) to assess oral parafunctional behaviors, pain, and emotional states. In Phase II, those with headaches were randomly assigned to either a habit reversal treatment or to a wait list control group. In the last, sixth week of the program, participants again completed an ESM protocol. Results showed that headache patients were significantly more likely to report oral parafunctional behaviors than non-headache controls and to receive a Research Diagnostic Criteria/TMD diagnosis. Results from Phase II showed general improvement in both groups on pain and parafunctions. Individuals with headaches engage in significantly higher rates and intensities of oral parafunctional behaviors. Treatment of these behaviors using habit reversal techniques appears to have the same effect on pain as waiting.

Glaser, Jean-Paul; van Os, Jim; Portegijs, Piet J. M.; Myin-Germeys, Inez (2006):

Childhood trauma and emotional reactivity to daily life stress in adult frequent attenders of general practitioners.

In: *Journal of Psychosomatic Research* 61 (2), S. 229–236. DOI: 10.1016/j.jpsychores.2006.04.014.

Abstract:

OBJECTIVES\r\nChildhood trauma (CT) has consistently been associated with neuroticism--a personality trait reflecting vulnerability to stress. However, not much is known about the impact of a history of trauma on moment-to-moment emotions and experiences in the flow of daily life. The relationship between CT and emotional reactivity to daily life stress was investigated.\r\nMETHODS\r\nNinety frequent attenders of general practitioners, of which 29 fulfilled criteria for CT (sexual and/or physical trauma before the age of 19 years), were studied with the Experience Sampling Method (a structured diary technique assessing current context and mood in daily life) to assess: (a) appraised subjective stress related to daily events and activities, and (b) emotional reactivity conceptualized as changes in negative affect (NA).\r\nRESULTS\r\nMultilevel regression analysis revealed that subjects with a history of CT reported significantly increased emotional reactivity to daily life stress, as reflected in an increase in NA. This effect was significantly stronger for subjects who experienced trauma before the age of 10 years.\r\nCONCLUSION\r\nThese results confirm that CT may have long-lasting and enduring effects on adult psychological functioning, as exposed individuals continually react more strongly to small stressors occurring in the natural flow of everyday life. The finding that emotional stress reactivity is most pronounced for subjects who experienced trauma early in life confirms prior evidence suggesting that the effects of trauma are more detrimental when trauma occurs at a younger age.

Glaser, J-P; van Os, J.; Mengelers, R.; Myin-Germeys, I. (2008):

A momentary assessment study of the reputed emotional phenotype associated with borderline personality disorder.

In: *Psychological Medicine* 38 (09), S. 1231–1239.

Abstract:

BACKGROUND:

Stress is postulated to play an essential role in the expression of core borderline symptoms. However, the phenomenology of stress reactivity in borderline personality disorder remains unclear. The current study investigated the phenomenology of stress sensitivity in borderline personality disorder in the flow of daily life and compared this with stress sensitivity in patients suffering from psychotic disorders, a group so far known to report the largest reactivity to stress.

METHOD:

A total of 44 borderline patients, 42 patients with psychotic disorder and 49 healthy controls were studied with the Experience Sampling Method (a structured diary technique assessing current context and mood in daily life) to assess: (1) appraised subjective stress related to daily events and activities; and (2) emotional reactivity conceptualized as changes in positive and negative affect.

RESULTS:

Multilevel regression analysis revealed that subjects with borderline personality disorder experienced significantly more emotional reactivity to daily life stress compared with both patients with psychosis and healthy controls, as evidenced by a larger increase in negative affect and a larger decrease in positive affect following stress.

CONCLUSION:

These results are the first to ecologically validate the incorporation of stress reactive symptoms in the diagnosis of borderline personality disorder. Borderline patients continually react stronger than patients with psychosis and healthy controls to small disturbances that continually happen in the natural flow of everyday life. Altered emotional stress reactivity may define borderline personality disorder.

Glaser, J-P; van Os, J.; Thewissen, V.; Myin-Germeys, I. (2010):

Psychotic reactivity in borderline personality disorder.

In: *Acta Psychiatrica Scandinavica* 121 (2), S. 125–134. DOI: 10.1111/j.1600-0447.2009.01427.x.

Abstract:

OBJECTIVE\r\nTo investigate the stress relatedness and paranoia specificity of psychosis in borderline personality disorder (BPD).\r\nMETHOD\r\nFifty-six borderline patients, 38 patients with cluster C personality disorder, 81 patients with psychotic disorder and 49 healthy controls were studied with the experience sampling method (a structured diary technique) to assess: i) appraised subjective stress and ii) intensity of psychotic experiences.\r\nRESULTS\r\nAll patient groups experienced significantly more increases in psychotic experiences in relation to daily life stress than healthy controls, borderline patients displaying the strongest reactivity. Borderline patients, moreover, reported significantly more hallucinatory reactivity than healthy controls and subjects with cluster C personality disorder. Paranoid reactivity to daily life stress did not differ between the patient

groups.\r\nCONCLUSION\r\nThese results are the first to ecologically validate stress-related psychosis in BPD. However, psychotic reactivity was not limited to expression of paranoia but involved a broader range of psychotic experiences including hallucinations.

Using smartphones to collect time-activity data for long-term personal-level air pollution exposure assessment.

In: *J Expo Sci Environ Epidemiol. DOI:* 10.1038/jes.2014.78.

Abstract:

Because of the spatiotemporal variability of people and air pollutants within cities, it is important to account for a person's movements over time when estimating personal air pollution exposure. This study aimed to examine the feasibility of using smartphones to collect personal-level time-activity data. Using Skyhook Wireless's hybrid geolocation module, we developed "Apolux" (Air, Pollution, Exposure), an AndroidTM smartphone application designed to track participants' location in 5-min intervals for 3 months. From 42 participants, we compared Apolux data with contemporaneous data from two self-reported, 24-h time-activity diaries. About three-fourths of measurements were collected within 5 min of each other (mean=74.14%), and 79% of participants reporting constantly powered-on smartphones (n=38) had a daily average data collection frequency of <10 min. Apolux's degree of temporal resolution varied across manufacturers, mobile networks, and the time of day that data collection occurred. The discrepancy between diary points and corresponding Apolux data was 342.3 m (Euclidian distance) and varied across mobile networks. This study's high compliance and feasibility for data collection demonstrates the potential for integrating smartphone-based time-activity data into long-term and large-scale air pollution exposure studies.Journal of Exposure Science and Environmental Epidemiology advance online publication, 26 November 2014; doi:10.1038/jes.2014.78.

Correspondence of parent report and laboratory measures of inattention and hyperactivity in children with heavy prenatal alcohol exposure.

In: *Neurotoxicol Teratol* 42, S. 43–50. DOI: 10.1016/j.ntt.2014.01.007.

Abstract:

Clinical research and practice support a multi-method approach to validating behavioral problems in children. We examined whether parent-reported symptoms of hyperactivity and inattention (using the Disruptive Behavior Disorder Rating Scale) were substantiated by objective laboratory measures [hyperactivity measured by wrist-worn actigraphy (ACT) and inattention assessed using a 20-minute continuous performance task (CPT)] in three age- and demographically-matched groups of school-age children: children with prenatal alcohol exposure (AE), non-exposed children with idiopathic ADHD (ADHD), and controls (CON). Results indicated that the clinical groups (AE, ADHD) had significantly higher parent-reported levels for both domains compared to the CON group, and did not differ from each other. On the laboratory measures, the clinical groups were more inattentive than controls on the CPT, but did not differ from each other. In contrast, the ADHD group had higher objective activity on the ACT than AE and CON, which did not differ from each other. Thus, laboratory measures differentially validated parent reports in a group-dependent manner. Actigraphy substantiated parent-reported hyperactivity for children in the ADHD group but not for children in the AE group, while the CPT validated parent-reported inattention for both clinical groups. Although the majority of children in the AE group met the criteria for ADHD, objective activity levels were not different from controls, indicating that hyperactivity may be a less prominent feature in the AE group. Thus, while there is considerable overlap between the effects of prenatal alcohol exposure and ADHD, differences in behavioral profiles may be clinically useful in differential diagnosis. Further, these data indicate that objective measures should be used to validate parent reports.

Using digital and paper diaries for learning and assessment purposes in higher education: A comparative study of feasibility and reliability.

In: *Assessment & Evaluation in Higher Education* 32 (6), S. 631–643.

Abstract:

The incorporation of diaries and journals as learning and assessment vehicles into programmes of study within higher education has enabled the further growth of reflection, creative writing, critical thinking and meta-cognitive processes of students' learning. However, there is currently little research that aims to compare how different types of diary are used and for what specific learning and teaching purposes, so, with this in mind, a study was carried out to investigate digital diary use within a group of undergraduates, to some of whom the authors allocated Personal Digital Assistants (PDAs), which they used to contribute to a blog (digital diaries), and to some of whom hard-backed format (paper diaries) were given. This paper is the first of two from this study. The findings indicated that whilst students found both forms of diary acceptable and convenient, differences emerged in the way that the diaries were being used on a day-to-day basis, both in the frequency of entry and in the length of entries made. Throughout the study, the digital diaries were used more frequently, although the entries were often brief and incomplete. Conversely, students completing the paper diaries made significantly fewer entries in total, but those that were made were longer and more discursive in nature. Further, it was found that the paper diaries possessed positive qualities related to handling and attractiveness that promoted more prolonged use, whilst the negative qualities of the digital diaries were linked to technical limitations. The implications of this work are considered in relation to more general notions of using dynamic devices to encourage students to engage in reflexive criticism.

Glenn, Tasha; Monteith, Scott (2014):

New measures of mental state and behavior based on data collected from sensors, smartphones, and the Internet.

In: *Curr Psychiatry Rep* 16 (12), S. 523. DOI: 10.1007/s11920-014-0523-3.

Abstract:

With the rapid and ubiquitous acceptance of new technologies, algorithms will be used to estimate new measures of mental state and behavior based on digital data. The algorithms will analyze data collected from sensors in smartphones and wearable technology, and data collected from Internet and smartphone usage and activities. In the future, new medical measures that assist with the screening, diagnosis, and monitoring of psychiatric disorders will be available despite unresolved reliability, usability, and privacy issues. At the same time, similar non-medical commercial measures of mental state are being developed primarily for targeted advertising. There are societal and ethical implications related to the use of these measures of mental state and behavior for both medical and non-medical purposes.

Glomb, Theresa M.; Bhave, Devasheesh P.; Miner, Andrew G.; Wall, Melanie (2011):

DOING GOOD, FEELING GOOD: EXAMINING THE ROLE OF ORGANIZATIONAL CITIZENSHIP BEHAVIORS IN CHANGING MOOD.

In: *Personnel Psychology* 64 (1), S. 191–223. DOI: 10.1111/j.1744-6570.2010.01206.x.

Abstract:

This study investigates whether the altruism and courtesy dimensions of organizational citizenship behaviors (OCB) regulate mood at work. Social psychological theories of mood regulation suggest helping behaviors can improve individuals' moods because helping others provides gratification and directs attention away from one's negative mood. We capture mood states prior to and following the enactment of OCBs using experience sampling methodology in a sample of managerial and professional employees over a 3-week period. Results suggest altruism shows a pattern consistent with mood regulation; negative moods during the prior time period are associated with altruism and positive moods in the subsequent time period. The pattern of results for courtesy behaviors is only partially consistent with a mood regulation explanation. Consistent with theories of behavioral concordance, interaction results suggest individuals higher on Extroversion have more intense positive mood reactions after engaging in altruistic behaviors. Interactions with courtesy were not significant.

Accuracy of retrospective memory and covariation estimation in patients with obsessive–compulsive disorder.

In: *Behav Res Ther* 46 (5), S. 642–655.

Abstract:

Assessment methods relying on biased or inaccurate retrospective recall may distort knowledge about the nature of disorders and lead to faulty clinical inferences. Despite concerns about the accuracy of retrospective recall in general and in particular with obsessive-compulsive disorder (OCD) patients, the accuracy of retrospective recall for one's own symptoms assessed in vivo is unknown in this population. This study used a prospective ecological momentary assessment (EMA) methodology to create a criterion against which to assess recall accuracy in OCD patients. Although results indicated that patients' retrospective recall of OCD symptoms was fairly accurate, they consistently overestimated the magnitude of OCD symptom covariation with non-OCD facets (e.g., sleep duration, contemporaneous stress level, etc.). Findings suggest that even when recall of OCD symptoms is accurate, patients may be inaccurate in estimating symptom covariation. The findings have implications for the research, case conceptualization, and assessment of OCD, and may extend to other disorders.

Godard, C.; Roman, M.; Rodriguez, Mdel P.; Leyton, B.; Salazar, G. (2012):

Variability of physical activity in 4 to 10-year-old children: a study by accelerometry.

In: *Arch.Argent Pediatr.* 110 (5), S. 388–393. DOI: 10.1590/S0325-00752012000500005.

Abstract:

INTRODUCTION: When compared to popular questionnaires, accelerometry provides more reliable information regarding physical activity. Thus, the objective has been to document the variability of physical activity in Chilean children in relation to age, gender, nutritional status and days of the week, and to determine how many of them meet the recommendation for moderate to vigorous physical activity for more than an hour a day. POPULATION AND METHODS: One hundred and nine (109) school children aged 4-10 (67 boys, 42 girls) wore an accelerometer for 2, 3 or 4 consecutive days. Of them, 30 were obese (BMI>95th percentile by age and gender). In each subject, levels of physical activity were expressed in counts per minute (cpm) and means (SD) of cpm/hour. Moderate to vigorous physical activity was defined by the daily sum of cpm>900. RESULTS: Daytime physical activity had a mean of 21,697 (662) cpm/hour with considerable variation from one child to another, and from one time of the day to another in the same child. Individual cpm/hour was significantly associated to moderate to vigorous physical activity (R = 0.954). Differences were found between girls and boys ($p < 0.01$) and between obese and non-obese children ($p < 0.01$). There were no differences between children 9 years ($p = 0.12$). There was a slight difference between weekdays and weekends. Fifty-six (56) of 67 boys (83.6%) and 24 of 42 girls (57.1%) met the recommendation for moderate to vigorous physical activity for more than 60 minutes a day. CONCLUSION: There is a physical activity defcit in Chilean school children under 10 years, particularly in girls and obese kids

Godfrey, Acrmdog; Conway, R.; Meagher, D.; ólaighin, G. (2008):

Direct measurement of human movement by accelerometry.

In: *Med Eng Phys* 30 (10), S. 1364–1386.

Abstract:

Human movement has been the subject of investigation since the fifth century when early scientists and researchers attempted to model the human musculoskeletal system. The anatomical complexities of the human body have made it a constant source of research to this day with many anatomical, physiological, mechanical, environmental, sociological and psychological studies undertaken to define its key elements.

These studies have utilised modern day techniques to assess human movement in many illnesses. One such modern technique has been direct measurement by accelerometry, which was first suggested in the 1970s but has only been refined and perfected during the last 10–15 years.

Direct measurement by accelerometry has seen the introduction of the successful implementation of low power, low cost electronic sensors that have been employed in clinical and home environments for the constant monitoring of patients (and their controls). The qualitative and quantitative data provided by these sensors make it possible for engineers, clinicians and physicians to work together to be able to help their patients in overcoming their physical disability. This paper presents the underlying biomechanical elements necessary to understand and study human movement. It also reflects on the sociological elements of human movement and why it is important in patient life and well being. Finally the concept of direct measurement by accelerometry is presented with past studies and modern techniques used for data analysis.

Godfrey, A.; Conway, R.; Leonard, M.; Meagher, D.; Olaighin, G. (2009):

A classification system for delirium subtyping with the use of a commercial mobility monitor.

In: *Gait Posture* 30 (2), S. 245–252. DOI: 10.1016/j.gaitpost.2009.05.014.

Abstract:

The usefulness of motor subtypes of delirium is unclear due to inconsistency in subtyping methods and a lack of validation with objective measures of activity. The activity of 40 patients was measured over 24h with a commercial accelerometer-based activity monitor. Accelerometry data from patients with DSM-IV delirium that were readily divided into hyperactive, hypoactive and mixed motor subtypes, were used to create classification trees that were subsequently applied to the remaining cohort to define motoric subtypes. The classification trees used the periods of sitting/lying, standing, stepping and number of postural transitions as measured by the activity monitor as determining factors from which to classify the delirious cohort. The use of a classification system shows how delirium subtypes can be categorised in relation to overall activity and postural changes, which was one of the most discriminating measures examined. The classification system was also implemented to successfully define other patient motoric subtypes. Motor subtypes of delirium defined by observed ward behaviour differ in electronically measured activity levels.

Godfrey, Alan; Conway, Richard; Leonard, Maeve; Meagher, David; Olaighin, Gearóid M. (2009):

A continuous wavelet transform and classification method for delirium motoric subtyping.

In: *IEEE Trans Neural Syst Rehabil Eng* 17 (3), S. 298–307. DOI: 10.1109/TNSRE.2009.2023284.

Abstract:

The usefulness of motor subtypes of delirium is unclear due to inconsistency in subtyping methods and a lack of validation with objective measures of activity. The activity of 40 patients was measured over 24 h with a discrete accelerometer-based activity monitor. The continuous wavelet transform (CWT) with various mother wavelets were applied to accelerometry data from three randomly selected patients with DSM-IV delirium that were readily divided into hyperactive, hypoactive, and mixed motor subtypes. A classification tree used the periods of overall movement as measured by the discrete accelerometer-based monitor as determining factors for which to classify these delirious patients. This data used to create the classification tree were based upon the minimum, maximum, standard deviation, and number of coefficient values, generated over a range of scales by the CWT. The classification tree was subsequently used to define the remaining motoric subtypes. The use of a classification system shows how delirium subtypes can be categorized in relation to overall motoric behavior. The classification system was also implemented to successfully define other patient motoric subtypes. Motor subtypes of delirium defined by observed ward behavior differ in electronically measured activity levels.

Godfrey, Alan; Conway, Richard; Leonard, Maeve; Meagher, David; Olaighin, Gearóid M. (2010):

Motion analysis in delirium: a discrete approach in determining physical activity for the purpose of delirium motoric subtyping.

In: *Med Eng Phys* 32 (2), S. 101–110. DOI: 10.1016/j.medengphy.2009.10.012.

Abstract:

The purpose of this study was to determine the use and feasibility of accelerometry-based monitoring and to examine a discrete multi-resolution signal analysis technique to determine motoric subtypes in patients with DSM-IV delirium. Forty consecutive patients receiving palliative care (23 male, 17 female, mean age+/-standard deviation 68.4+/-11.9 years) were assessed using 24-h accelerometer-based monitoring. The total amount of time spent per activity of sitting/lying, standing and stepping were calculated. This was achieved through the multilevel decomposition and reconstruction of the accelerometer signals by means of the discrete wavelet transform. Both the reconstructed approximations and details of the discrete transform were used for motoric subtyping. This was compared to a validated activity monitor for validation purposes. Demographic and clinical data per patient were also collected. Of the 40 patients selected for accelerometry, complete 24-h readings were available for 34 patients and analyses were confined to this group. Of the 34 patients included, 25 met criteria for DSM-IV delirium while 9 were non-delirious comparison subjects with equivalent medical diagnoses receiving treatment in the same setting. It was concluded that accelerometry-based measurement of a delirious cohort within a palliative setting is both a reliable and feasible method of continuous monitoring. Of the activities performed by the patients, periods of standing proved to be the most discriminatory in determining between each subtype.

Godwin, Marshall; Birtwhistle, Richard; Delva, Dianne; Lam, Miu; Casson, Ian; MacDonald, Susan; Seguin, Rachelle (2011):

Manual and automated office measurements in relation to awake ambulatory blood pressure monitoring.

In: *Family practice* 28 (1), S. 110–117. DOI: 10.1093/fampra/cmq067.

Abstract:

BACKGROUND\r\nAutomated blood pressure (BP) devices are commonly used in doctor's offices. How BP measured on these devices relates to ambulatory BP monitoring is not clear.\r\nOBJECTIVE\r\nTo assess how well office-based manual and automated BP predicts ambulatory BP.\r\nMETHODS\r\nUsing data on 654 patients, we assessed how well sphygmomanometer measurements and measurements taken with an automated device (BpTRU) predicted results on ambulatory BP monitoring. We assess positive and negative predictive values and overall accuracy. We look at different cut-points for systolic (130, 135 and 140 mmHg) and diastolic (80, 85 and 90 mmHg) BP.\r\nRESULTS\r\nA single automated office BP (AOBP) assessment provides superior predictive values and overall accuracy compared to three manual office BP assessments. For systolic BP, the predictive values are ≤69% for any of the cut-points while the positive predictive values for the single automated measurement is between 80.0% and 86.9% and the overall accuracy gets as high as 74% for the 130 mmHg cut-point. For diastolic BP, the automated readings are also more predictive but in this case, it is the negative predictive values that are better, as well as the overall accuracy.\r\nCONCLUSIONS\r\nBased on the results, we suggest that 135/85 mmHg continue to be used as the cut-point defining high BP with the BpTRU device. However, future research might suggests that values in a grey zone between 130-139 mmHg systolic and 80-89 mmHg diastolic be confirmed using ambulatory BP monitoring. As well, three AOBP assessments might produce much greater accuracy than the single AOBP assessment used in the study.

Goetz, Thomas; Frenzel, Anne C.; Hall, Nathan C.; Nett, Ulrike E.; Pekrun, Reinhard; Lipnevich, Anastasiya A. (2014):

Types of boredom: An experience sampling approach.

In: *Motivation and Emotion* 38 (3), S. 401–419. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-40732-001%26site%3dehost-live.

Abstract:

The present study investigated different types of boredom as proposed in a four-categorical conceptual model by Goetz and Frenzel (2006; doi:10.1026/0049-8637.38.4. 149). In this model, four types of boredom are differentiated based on degrees of valence and arousal: indifferent, calibrating, searching, and reactant boredom. In two studies (Study 1: university students, N = 63, mean age 24.08 years, 66 % female; Study 2: high school students, grade 11, N = 80, mean age 17.05 years, 58 % female), real-time data were obtained via the experience-sampling method (personal digital assistants, randomized signals). Boredom experiences (N = 1,103/1,432 in Studies 1/2) were analyzed with respect to the dimensions of valence and arousal using multilevel latent profile analyses. Supporting the internal validity of the proposed boredom types, our results are in line with the assumed four types of boredom but suggest an additional, fifth type, referred to as "apathetic boredom." The present findings further support the external validity of the five boredom types in showing differential relations between the boredom types and other affective states as well as frequency of situational occurrence (achievement contexts vs. non-achievement contexts). Methodological implications as well as directions for future research are discussed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Goetz, Thomas; Haag, Ludwig; Lipnevich, Anastasiya A.; Keller, Melanie M.; Frenzel, Anne C.; Collier, Antonie P. M. (2014):

Between-domain relations of students' academic emotions and their judgments of school domain similarity.

In: *Front Psychol* 5, S. 1153. DOI: 10.3389/fpsyg.2014.01153.

Abstract:

With the aim to deepen our understanding of the between-domain relations of academic emotions, a series of three studies was conducted. We theorized that between-domain relations of trait (i.e., habitual) emotions reflected students' judgments of domain similarities, whereas between-domain relations of state (i.e., momentary) emotions did not. This supposition was based on the accessibility model of emotional self-report, according to which individuals' beliefs tend to strongly impact trait, but not state emotions. The aim of Study 1 (interviews; N = 40; 8th and 11th graders) was to gather salient characteristics of academic domains from students' perspective. In Study 2 (N = 1709; 8th and 11th graders) the 13 characteristics identified in Study 1 were assessed along with academic emotions in four different domains (mathematics, physics, German, and English) using a questionnaire-based trait assessment. With respect to the same domains, state emotions were assessed in Study 3 (N = 121; 8th

and 11th graders) by employing an experience sampling approach. In line with our initial assumptions, between-domain relations of trait but not state academic emotions reflected between-domain relations of domain characteristics. Implications for research and practice are discussed.

Goldbogen, Jeremy A.; Stimpert, Alison K.; Deruiter, Stacy L.; Calambokidis, John; Friedlaender, Ari S.; Schorr, Greg S. et al. (2014):

Using accelerometers to determine the calling behavior of tagged baleen whales.

In: *J Exp Biol. DOI:* 10.1242/jeb.103259.

Abstract:

Low-frequency acoustic signals generated by baleen whales can propagate over vast distances, making the assignment of calls to specific individuals problematic. Here we report the novel use of acoustic recording tags equipped with high-resolution accelerometers to detect vibrations on the surface of two tagged fin whales that directly match the timing of recorded acoustic signals. A tag deployed on a buoy in the vicinity of calling fin whales, and a recording from a tag that had just fallen off of a whale, were able to detect calls acoustically but did not record corresponding accelerometer signals that were measured on calling individuals. Across the hundreds of calls measured on two tagged fin whales, the accelerometer response was generally anisotropic across all three axes, appeared to depend on tag placement, and increased with the level of received sound. These data demonstrate that high-sample-rate accelerometry can provide important insights into the acoustic behavior of baleen whales that communicate at low frequencies. This method helps identify vocalizing whales, which in turn enables the quantification of call rates, a fundamental component of models used to estimate baleen whale abundance and distribution from passive acoustic monitoring.

Goldner, Jonathan (2009):

The relations among parental monitoring and warmth, and adolescent externalizing and internalizing distress: The effects of parent and adolescent perception of neighborhood danger.

Abstract:

Parental monitoring and warmth have traditionally been studied in the context of white, middle-class families. This paper adds to recent research that has begun to explore what levels of these parenting behaviors are optimal for the prevention of adolescent psychopathology in impoverished, urban high crime areas. It also takes into account parent and child perceptions of neighborhood danger. This study employs a longitudinal design, with data collected at two times points one year apart, among a sample of 240 African American young adolescents and their parents in urban, high crime neighborhoods. It aims to study parental monitoring, parental warmth, parent perception of neighborhood danger, child perception of neighborhood danger, child internalizing distress, and child externalizing distress. Further, child internalizing and externalizing distress are measured both through retrospective questionnaire reports of psychopathology as well as in vivo accounts of daily distress through the use of the Experience Sampling Method (ESM), a time sampling technique.

Parents' perception of neighborhood danger predicted an increase in adolescents' externalizing behavior, but not internalizing distress. Contrary to expectation, parents' awareness of danger did not relate to the degree to which they monitored their children. Parental monitoring was associated with children's externalizing behavior, although a hypothesized quadratic relation between parents' monitoring and externalizing did not exist. Both linear and quadratic relations were discovered between parental monitoring and children's internalizing distress. One of the most consistent predictors of adolescents' distress, surprisingly, was their perception of neighborhood danger, which was associated with higher levels of both adolescent internalizing and externalizing symptoms. Adolescents' perception of neighborhood danger emerged as an equally strong predictor of internalizing and externalizing symptoms as parental monitoring and parental warmth. The rate of parent-child agreement regarding the presence of extreme levels of danger was lower than expected. Finally, differential relations existed between parental monitoring and parental warmth as they pertained to internalizing and externalizing. In general, parental monitoring more strongly predicted adolescent externalizing than parental warmth; however, parental warmth was a stronger predictor of adolescent internalizing than parental monitoring. Significant interactions are also discussed, as well as the implications of these findings and how they can serve as a guide to future research.

Goldner, Jonathan; Peters, Tracy L.; Richards, Maryse H.; Pearce, Steven (2011):

Exposure to community violence and protective and risky contexts among low income urban African American adolescents: a prospective study.

In: *Journal of Youth and Adolescence* 40 (2), S. 174–186. DOI: 10.1007/s10964-010-9527-4.

Abstract:

This study examined protective and risky companionship and locations for exposure to community violence among African American young adolescents living in high crime, urban areas. The Experience Sampling Method (ESM), an in vivo data collection method, was employed to gather information from 233 students (62% female) over 3 years, beginning in the 6th grade. Questionnaire variables of exposure to community violence were regressed onto ESM companionship and location variables, cross-sectionally and longitudinally, separately for boys and girls. At different points, time spent with parents, in school, and outside in private space was associated with less exposure to violence for boys and girls, while time spent with girls was protective for boys. In addition, time spent outside in public and with older peers was associated with increased risk for boys and girls. These findings are discussed in relation to previous and potential future research, and to strategies to prevent exposure to community violence.

Goldschmidt, A. B.; Crosby, R. D.; Engel, S. G.; Crow, S. J.; Cao, L.; Peterson, C. B.; Durkin, N. (2013):

Affect and eating behavior in obese adults with and without elevated depression symptoms.

In: *Int.J Eat.Disord.* (0276-3478 (Linking)). DOI: 10.1002/eat.22188.

Abstract:

OBJECTIVE: Although there is a modest relation between obesity and depression, mechanisms that contribute to this co-occurrence are unclear. This study examined mood and eating behavior among obese adults with and without elevated depression symptoms. METHOD: Obese adults (N = 50) were subtyped according to a Beck Depression Inventory (BDI) cutoff of 14, indicating "probable depression." Participants with (BDI >/= 14; n = 15) and without (BDI < 14; n = 35) elevated depression symptoms were compared on affect- and eating-related variables measured via questionnaire and ecological momentary assessment (EMA) using ANCOVA and mixed model regression. RESULTS: After adjusting for group differences in body mass index (BMI; p = .03), participants with elevated depression symptoms reported greater emotional eating via self-report questionnaire [F(1,50) = 4.3; p = .04], as well as more frequent binge eating (Wald chi2 = 13.8; p < .001) and higher daily negative affect (Wald chi2 = 7.7; p = .005) on EMA recordings. Emotional eating mediated the relationship between depression status and BMI (indirect effect estimate = 3.79; 95% CI = 1.02-7.46). DISCUSSION: Emotional eating and binge eating were more commonly reported by obese adults with elevated depression symptoms compared to those without and may occur against a general backdrop of overall low mood. Intervention and prevention programs for obesity and/or depression should address disordered eating to prevent or minimize adverse health consequences. (c) 2013 Wiley Periodicals, Inc. (Int J Eat Disord 2013)

Goldschmidt, A. B.; Peterson, C. B.; Wonderlich, S. A.; Crosby, R. D.; Engel, S. G.; Mitchell, J. E. et al. (2012):

Trait-level and momentary correlates of bulimia nervosa with a history of anorexia nervosa.

In: *Int.J Eat.Disord.* (0276-3478 (Linking)). DOI: 10.1002/eat.22054.

Abstract:

OBJECTIVE: Some investigators have suggested subtyping bulimia nervosa (BN) by anorexia nervosa (AN) history. We examined trait-level and momentary eating-related and psychosocial factors in BN with and without an AN history. METHOD: Interview, questionnaire, and ecological momentary assessment data of eating-related and psychological symptoms were collected from 122 women with BN, including 43 with (BN+) and 79 without an AN history (BN-). RESULTS: Body mass index (kg/m(2)) was lower in BN+ than BN- (p = 0.001). Groups did not differ on trait-level anxiety, shape/weight concerns, psychiatric comorbidity, or dietary restraint; or on momentary anxiety, dietary restriction, binge eating, purging, or exercise frequency, or affective patterns surrounding binge/purge behaviors. Negative affect increased prior to exercise and decreased thereafter in BN+ but not BN-, although groups did not statistically differ. DISCUSSION: Results do not support formally subtyping BN by AN history. Exercise in BN+ may modulate negative affect, which could have important treatment implications. (c) 2012 by Wiley Periodicals, Inc. (Int J Eat Disord 2012)

Goldschmidt, Andrea B.; Wonderlich, Stephen A.; Crosby, Ross D.; Engel, Scott G.; Lavender, Jason M.; Peterson, Carol B. et al. (2013):

Ecological Momentary Assessment of Stressful Events and Negative Affect in Bulimia Nervosa.

In: *Journal of Consulting and Clinical Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-39411-001%26site%3dehost-live.

Abstract:

Objective: Negative affect precedes binge eating and purging in bulimia nervosa (BN), but little is known about factors that precipitate negative affect in relation to these behaviors. We aimed to assess the temporal relation among stressful events, negative affect, and bulimic events in the natural environment using ecological momentary assessment. Method: A total of 133 women with current BN recorded their mood, eating behavior, and the occurrence of stressful events every day for 2 weeks. Multilevel structural equation mediation models evaluated the relations among Time 1 stress measures (i.e., interpersonal stressors, work/environment stressors, general daily hassles, and stress appraisal), Time 2 negative affect, and Time 2 binge eating and purging, controlling for Time 1 negative affect. Results: Increases in negative affect from Time 1 to Time 2 significantly mediated the relations between Time 1 interpersonal stressors, work/environment stressors, general daily hassles, and stress appraisal and Time 2 binge eating and purging. When modeled simultaneously, confidence intervals for interpersonal stressors, general daily hassles, and stress appraisal did not overlap, suggesting that each had a distinct impact on negative affect in relation to binge eating and purging. Conclusions: Our findings indicate that stress precedes the occurrence of bulimic behaviors and that increases in negative affect following stressful events mediate this relation. Results suggest that stress and subsequent negative affect may function as maintenance factors for bulimic behaviors and should be targeted in treatment. Goldschmidt, Andrea B.; Wonderlich, Stephen A.; Crosby, Ross D.; Cao, Li; Engel, Scott G.; Lavender, Jason M. et al. (2014):

Latent profile analysis of eating episodes in anorexia nervosa.

In: *Journal of Psychiatric Research* 53, S. 193–199. DOI: 10.1037/t04751-000;

Abstract:

Background: Despite being characterized primarily by disturbances in eating behavior, relatively little is known about specific eating behaviors in anorexia nervosa (AN) and how they relate to different emotional, behavioral, and environmental features. Methods: Women with AN (n = 118) completed a 2-week ecological momentary assessment (EMA) protocol during which they reported on daily eating- and mood-related patterns. Latent profile analysis was used to identify classes of eating episodes based on the presence or absence of the following indicators: loss of control; overeating; eating by oneself; food avoidance; and dietary restraint. Results: The best-fitting model supported a 5-class solution: avoidant eating; solitary eating; binge eating; restrictive eating; and loss of control eating. The loss of control and binge eating classes were characterized by high levels of concurrent negative affect and a greater likelihood of engaging in compensatory behaviors. The restrictive eating class was associated with the greatest number of concurrently-reported stressful events, while the avoidant and solitary eating episode classes were characterized by relatively few accompanying stressful events. Body checking was least likely to occur in conjunction with restrictive eating behaviors. Conclusions: Results support the presence of discrete types of eating episodes in AN that are associated with varying degrees of negative affect, stress, and behavioral features of eating disorders. Loss of control and dietary restriction may serve distinct functional purposes in AN, as highlighted by their differing associations with negative affect and stress. Clinical interventions for AN may benefit from targeting functional aspects of eating behavior among those with the disorder. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Goldstein, Abby L.; Stewart, Sherry H.; Hoaken, Peter N. S.; Flett, Gordon L. (2013):

Mood, Motives, and Gambling in Young Adults: An Examination of Within- and Between-Person Variations Using Experience Sampling.

In: *Psychology of Addictive Behaviors*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-20770-001%26site%3dehost-live.

Abstract:

It is well established that young adults are a population at risk for problem gambling and that young adults gamble for various reasons, including positive mood enhancement and negative mood reduction. Although these motives have been identified as

important proximal predictors of gambling, the research to date has focused on between-subjects relationships. What is missing is a process-level understanding of the specific within-subjects relations between mood-regulation motives for gambling, mood states, and gambling behaviors. The current study used experience sampling to assess the specific link between gambling motives, mood states, and gambling behavior. Participants were 108 young adults (ages 19–24 years), who completed baseline measures of gambling motives and gambling problems and then reported on their mood states and gambling behavior three times a day for 30 days. Multilevel modeling analyses revealed a significant positive moderating effect for enhancement motives on the relationship between positive mood and amount of time spent gambling and number of drinks consumed while gambling. In addition, problem gambling status was associated with consuming fewer drinks while gambling at higher levels of positive mood, and spending more money than intended at higher levels of negative mood. Unexpectedly, there was only one moderating effect for coping motives on the mood-gambling relationship; low coping motivated gamblers consumed more alcohol while gambling at higher levels of positive mood, whereas high coping motivated gamblers did not change their drinking in response to positive mood. The current findings highlight enhancement motives as risky motives for young adult gambling, particularly in the context of positive mood, and suggest that gambling interventions should include strategies to address positive mood management. Goldstein, David H.; Wilson, Rosemary; Vandenkerkhof, Elizabeth G. (2007):

Electronic monitoring in an acute pain management service.

In: *Pain Medicine* 8 (s3), S. S94-S100.

Abstract:

Objectives. This article will address the process involved in the development and implementation of a clinician-driven portable electronic chart on an Acute Pain Management Service (APMS). We describe the latest version of the program and provide 1 year of clinical data.

Setting. Tertiary care center in Kingston, Ontario, Canada.

Patients. All patients admitted to the APMS between August 1, 2005, and July 31, 2006.

Results. A total of 8,726 APMS visits were made to 2,528 patients. Mean length of stay on the Service was 2.3 days. Sixty-one percent of patients reported an active pain score >3/10. Pain scores were highest with hip or knee surgery. Thirty-five percent of patients reported nausea.

Conclusions. Executive sponsorship, alignment with institutional priorities, and user input are essential to the development, implementation, adoption, and sustainability of an electronic patient record. Ready access to data at the bedside can improve quality of care, while ongoing, comprehensive data can contribute to Phase IV drug trials. Incorporating both clinical and research outcomes in the database improves data quality and usability, but must be balanced with the impact of clinical time constraints on documentation. Wireless technology and Tablet computers provide portability and adequate screen size for documentation and reviewing of patient data on an acute pain service. It is necessary to provide solutions to process issues, such as printing electronic records during the transition from paper to electronic records.

Can Pulse Transit Time Be Useful for Detecting Hypertension in Patients in a Sleep Unit?

In: *Arch Bronconeumol. DOI:* 10.1016/j.arbres.2013.12.001.

Abstract:

INTRODUCTION: Pulse transit time (PTT) is the time that a pulse wave takes to travel between two different arterial points, and may be useful in estimating blood pressure. This noninvasive technique, which does not add any cost to the procedure, offers the advantage of avoiding 'arousals' during sleep measurement as occurs with ambulatory blood pressure monitoring (ABPM). We aim to confirm the usefulness of PTT for the detection of hypertension, and to study the correlation between both measurements. METHODS: Prospective observational study in a multidisciplinary sleep unit. We recruited 30consecutive patients attending a sleep clinic and ran a baseline polysomnography followed by an ABPM the following day. Average systolic and diastolic blood pressure (SBP, DBP) by PTT were calculated and compared with ABMP results. In accordance with international guidelines, patients with mean nocturnal ABMP >/= 120/70 mmHg were diagnosed as having arterial hypertension. RESULTS: Mean age of 60years; 66% male, 80% suffered from sleep apnoea (OSAS). Taking the ABPM as the reference technique, we found that the diagnostic sensitivity of PTT is 85% with a specificity of 88% in the case of SBP, with a positive predictive value of 85% and negative predictive value of 88%. By studying the relationship between mean SBP measured by ABPM and PTT, we found a linear correlation coefficient (R) of 0.88, showing a distribution of all subjects with a difference of between +/-15mmHg between tests. There is also a positive correlation between mean DBP measured for the two tests, with a weaker linear

correlation. CONCLUSIONS: Pulse transit time shows a strong correlation with blood pressure (measured by ABPM). PTT provides continuous, non-invasive, cuffless blood pressure monitoring free of additional cost and could be an alternative for screening hypertension.

Architecture, cost-model and customization of real-time monitoring systems based on mobile biological sensor data-streams.

In: *Computer methods and programs in biomedicine* 96 (2), S. 141–157. DOI: 10.1016/j.cmpb.2009.04.010.

Abstract:

Innovation in the fields of wireless data communications, mobile devices and biosensor technology enables the development of new types of monitoring systems that provide people with assistance anywhere and at any time. In this paper we present an architecture useful to build those kind of systems that monitor data streams generated by biological sensors attached to mobile users. We pay special attention to three aspects related to the system efficiency: selection of the optimal granularity, that is, the selection of the size of the input data stream package that has to be acquired in order to start a new processing cycle; the possible use of compression techniques to store and send the acquired input data stream and; finally, the performance of a local analysis versus a remote one. Moreover, we introduce two particular real systems to illustrate the suitability and applicability of our proposal: an anywhere and at any time monitoring system of heart arrhythmias and an apnea monitoring system.

Ambulatory estimation of mean step length during unconstrained walking by means of COG accelerometry.

In: *Computer methods in biomechanics and biomedical engineering* 12 (6), S. 721–726. DOI: 10.1080/10255840902896000.

Abstract:

It has been reported that spatio-temporal gait parameters can be estimated using an accelerometer to calculate the vertical displacement of the body's centre of gravity. This method has the potential to produce realistic ambulatory estimations of those parameters during unconstrained walking. In this work, we want to evaluate the crude estimations of mean step length so obtained, for their possible application in the construction of an ambulatory walking distance measurement device. Two methods have been tested with a set of volunteers in 20 m excursions. Experimental results show that estimations of walking distance can be obtained with sufficient accuracy and precision for most practical applications (errors of 3.66 +/- 6.24 and 0.96 +/- 5.55%), the main difficulty being inter-individual variability (biggest deviations of 19.70 and 15.09% for each estimator). Also, the results indicate that an inverted pendulum model for the displacement during the single stance phase, and a constant displacement per step during double stance, constitute a valid model for the travelled distance with no need of further adjustments. It allows us to explain the main part of the erroneous distance estimations in different subjects as caused by fundamental limitations of the simple inverted pendulum approach.

Goodman, Anna; Page, Angie S.; Cooper, Ashley R. (2014):

Daylight saving time as a potential public health intervention: an observational study of evening daylight and objectively-measured physical activity among 23,000 children from 9 countries.

In: *Int J Behav Nutr Phys Act* 11, S. 84. DOI: 10.1186/1479-5868-11-84.

Abstract:

BACKGROUND: It has been proposed that introducing daylight saving measures could increase children's physical activity, but there exists little research on this issue. This study therefore examined associations between time of sunset and activity levels, including using the bi-annual 'changing of the clocks' as a natural experiment. METHODS: 23,188 children aged 5-16 years from 15 studies in nine countries were brought together in the International Children's Accelerometry Database. 439 of these children were of particular interest for our analyses as they contributed data both immediately before and after the clocks changed. All children provided objectively-measured physical activity data from Actigraph accelerometers, and we used their average physical activity level (accelerometer counts per minute) as our primary outcome. Date of accelerometer data collection was matched to

time of sunset, and to weather characteristics including daily precipitation, humidity, wind speed and temperature. RESULTS: Adjusting for child and weather covariates, we found that longer evening daylight was independently associated with a small increase in daily physical activity. Consistent with a causal interpretation, the magnitude of these associations was largest in the late afternoon and early evening and these associations were also evident when comparing the same child just before and just after the clocks changed. These associations were, however, only consistently observed in the five mainland European, four English and two Australian samples (adjusted, pooled effect sizes 0.03-0.07 standard deviations per hour of additional evening daylight). In some settings there was some evidence of larger associations between daylength and physical activity in boys. There was no evidence of interactions with weight status or maternal education, and inconsistent findings for interactions with age. CONCLUSIONS: In Europe and Australia, evening daylight seems to play a causal role in increasing children's activity in a relatively equitable manner. Although the average increase in activity is small in absolute terms, these increases apply across all children in a population. Moreover, these small effect sizes actually compare relatively favourably with the typical effect of intensive, individual-level interventions. We therefore conclude that, by shifting the physical activity mean of the entire population, the introduction of additional daylight saving measures could yield worthwhile public health benefits.

Goodrich, Suanne; Orr, William C. (2009):

An investigation of the validity of the Lifeshirt in comparison to standard polysomnography in the detection of obstructive sleep apnea.

In: *Sleep Medicine* 10 (1), S. 118–122.

Abstract:

BACKGROUND:

Due to the cost and waiting times for traditional sleep studies, there is great interest in finding alternatives for the diagnosis of sleep apnea. Several alternatives exist, including ambulatory devices. Our laboratory utilized one such device, a form-fitting vest called the Lifeshirt, and compared its accuracy to that of polysomnography (PSG).

METHODS:

PSG was performed with simultaneous utilization of the Lifeshirt on 50 individuals who met screening criteria for obstructive sleep apnea. Participants came to the sleep laboratory approximately 2 h before their normal bedtime. A sleep technician prepared each participant for PSG and Lifeshirt monitoring. "Lights Out" occurred when the participant was ready for bed, and time in bed was standardized to approximately 7 h. PSGs were scored by experienced personnel in our laboratory, while Lifeshirt data were sent electronically to the Lifeshirt manufacturer for analysis. The major variable that was compared between PSG and Lifeshirt was the apnea hypopnea index (AHI), or the number of apneas and hypopneas per hour. Due to incomplete data on two participants, analyses were completed on 48 individuals.

RESULTS:

Sensitivity of the Lifeshirt ranged from .85 (AHI of > or =5) to 1.00 (AHI of > or =25). Specificity ranged from .67 to 1.00. Using the Bland-Altman technique of determining agreement, the mean difference between the AHI of the Lifeshirt and PSG was 1.02 (+/-16.36). When these values are plotted, every case falls within the limits of agreement, with one exception.

CONCLUSIONS:

The Lifeshirt compared favorably with PSG and could be used with considerable confidence for the screening of patients with suspected obstructive sleep apnea.

Gorczynski, Paul; Faulkner, Guy; Cohn, Tony; Remington, Gary (2014):

Examining Strategies to Improve Accelerometer Compliance for Individuals Living With Schizophrenia.

In: *Psychiatr Rehabil J. DOI:* 10.1037/prj0000093.

Abstract:

Objective: This study examined the feasibility and effect of 2 investigator-based and 2 participant-based strategies on accelerometer wear time in individuals living with schizophrenia in order to improve accelerometry compliance. Method: Four adults with schizophrenia were asked to wear an accelerometer for 1 week during the baseline, intervention, and follow-up phases of a study that evaluated exercise counseling. To encourage participants to wear their accelerometers, investigators modeled proper accelerometer use, provided verbal and written instructions, and placed reminder phone calls. Participants were also given wear time logs and reminder magnets. Results: All participants wore their accelerometers for the required amount of time during the study. Conclusions and Implications for Practice: Researchers should use multiple techniques to help ensure

compliance. Research is needed to identify the most effective combination of strategies for this population. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Gorelick, Mark L.; Bizzini, Mario; Maffiuletti, Nicola A.; Munzinger, Jeannette Petrich; Munzinger, Urs (2009):

Test-retest reliability of the IDEEA system in the quantification of step parameters during walking and stair climbing.

In: *Clinical physiology and functional imaging* 29 (4), S. 271–276. DOI: 10.1111/j.1475-097X.2009.00864.x.

Abstract:

The aim of this investigation was to evaluate the inter- and intra-session reliability of spatio-temporal gait variables collected during walking and stair climbing with the Intelligent Device for Energy Expenditure and physical Activity (IDEEA) accelerometer-based system. Eighteen healthy subjects (10 men, 8 women) completed a standardized indoor circuit comprised of walking and stair climbing. Intra-and inter-session reliability was investigated for several pertinent spatio-temporal gait variables using intraclass correlations [ICC (3,1)]. Intra-session reliability during walking showed a high reliability of the IDEEA with ICCs ranging between 0.84 (number of steps) and 0.97 (single limb support/double limb support). The ICCs for stair climbing were slightly lower than those during walking with values ranging between 0.74 (step duration) and 0.92 (number of steps). Inter-session reliability during walking showed a high reliability of the IDEEA between all trials, with values ranging between 0.87 (speed) to 0.98 (step duration). The ICCs of stair climbing were again lower than those during walking with values ranging from 0.64 (swing duration) to 0.79 (number of steps). The IDEEA accelerometer-based system provided a highly reliable measurement of spatio-temporal variables, in healthy subjects, during walking with moderately reduced correlations during stair climbing.

Gorely, Trish; Atkin, Andrew J.; Biddle, Stuart Jh; Marshall, Simon J. (2009):

Family circumstance, sedentary behaviour and physical activity in adolescents living in England: Project STIL.

In: *Int J Behav Nutr Phys Act* 6, S. 33. DOI: 10.1186/1479-5868-6-33.

Abstract:

BACKGROUND\r\nIdentification of non-modifiable correlates of physical activity and sedentary behaviour in youth contributes to the development of effective targeted intervention strategies. The purpose of this research was to examine the relationships between family circumstances (e.g. socio-economic status, single vs. dual parent household, presence/absence of siblings) and leisure-time physical activity and sedentary behaviours in adolescents.\r\nMETHODS\r\nA total of 1171 adolescents (40% male; mean age 14.8 years) completed ecological momentary assessment diaries every 15 minutes for 3 weekdays outside of school hours and 1 weekend day. Analysed behaviours were sports/exercise, active travel, TV viewing, computer use, sedentary socialising (hanging-out, using the telephone, sitting and talking) and total sedentary behaviour. Linear regression was employed to estimate levels of association between individual family circumstance variables and each behaviour.\r\nRESULTS\r\nCompared to girls from higher socioeconomic status (SES) groups, girls from low SES groups reported higher weekend TV viewing and higher weekday total sedentary behaviour. For boys, single parent status was associated with greater total sedentary behaviour compared to those from dual parent households. Boys and girls from low socio-economic neighbourhoods reported lower participation in sports/exercise compared to those living in higher socio-economic neighbourhoods.\r\nCONCLUSION\r\nAssociations were not consistent across behaviours or between genders. Overall, findings indicate that boys from single parent households and girls from low socio-economic families may be at increased risk of high sedentary behaviour. Those living in low socioeconomic neighbourhoods may be at increased risk of reduced participation in sports and exercise.

Gorely, Trish; Biddle, Stuart J. H.; Marshall, Simon J.; Cameron, Noel (2009):

The prevalence of leisure time sedentary behaviour and physical activity in adolescent boys: an ecological momentary assessment approach.

In: *International journal of pediatric obesity : IJPO : an official journal of the International Association for the Study of Obesity* 4 (4), S. 289–298. DOI: 10.3109/17477160902811181.

Abstract:

STUDY OBJECTIVE\r\nTo use ecological momentary assessment to describe how adolescent boys in the United Kingdom spend their leisure time. Design. Cross-sectional, stratified, random sample from secondary schools in 15 regions within the United Kingdom. The data are from a larger study of adolescent lifestyles (Project STIL).\r\nPARTICIPANTS\r\nA total of 561 boys with a mean age of 14.6 years (range 12.7-16.7 years). The majority were white-European (86.5%).\r\nMAIN RESULTS\r\nTelevision viewing occupied the most leisure time on both weekdays (131 minutes) and weekend (202.5 minutes) days. On weekdays the five most time consuming sedentary activities (television viewing, homework, motorised travel, playing computer/video games and shopping/hanging out) occupied on average 272.2 minutes. On weekend days, the five most time consuming sedentary activities (television viewing, shopping/hanging out, motorised travel, sitting and talking and playing computer/video games) occupied 405.5 minutes. In total, 54 minutes were occupied by active transport or sports and exercise per weekday and 81 minutes per weekend day. Only a minority watched more than 4 hours of TV per day (8.9% on weekdays and 33.8% on weekend days). Differences were noted in the means and prevalence between weekend and weekdays, reflecting the greater discretionary time available at the weekend.\r\nCONCLUSIONS\r\nAdolescent boys engage in a variety of sedentary and active free time behaviours. It appears prudent to encourage adolescents to adopt overall healthy lifestyles by considering the combination of both active and sedentary pursuits an individual engages in and by moving beyond a focus on any one single behaviour.

Gorely, Trish; Marshall, Simon J.; Biddle, Stuart J. H.; Cameron, Noel (2007):

Patterns of sedentary behaviour and physical activity among adolescents in the United Kingdom: Project STIL.

In: *Journal of Behavioral Medicine* 30 (6), S. 521–531.

Abstract:

The purpose of this study was to use ecological momentary assessment to investigate the patterning of physical activity and sedentary behaviours in UK adolescents and to examine if different lifestyle groups differ on key explanatory variables. A total of 1,371 (38% boys, mean age 14.7 years) adolescents completed diaries every 15 min for 3 weekdays outside of school hours and 1 weekend day. Cluster analysis yielded five-cluster solutions for both boys and girls to explain the grouping of sedentary behaviours and physical activity. The clusters demonstrated that adolescents engage in many leisure time behaviours but have one activity that predominates. Active adolescents spend more time outside and more time with their friends. Few demographic and environmental variables distinguished between clusters. The findings suggest a potential need for different behavioural targets in interventions to reduce sedentary behaviour in sub groups of the adolescent population. Further research is required to examine the modifiable determinants of different sedentary lifestyles among young people.

Gorely, Trish; Marshall, Simon J.; Biddle, Stuart J. H.; Cameron, Noel (2007):

The prevalence of leisure time sedentary behaviour and physical activity in adolescent girls: An ecological momentary assessment approach.

In: *International Journal of Pediatric Obesity* 2 (4), S. 227–234.

Abstract:

STUDY OBJECTIVE:

To use ecological momentary assessment to describe how adolescent girls in the United Kingdom spend their leisure time.

DESIGN:

Cross-sectional, stratified, random sample from secondary schools in 15 regions within the United Kingdom. The data are from a larger study of adolescent lifestyles (Project STIL).

PARTICIPANTS:

A total of 923 girls with a mean age of 14.7 years (range 12.5-17.6 years). The majority were white-European (88.7%).

MAIN RESULTS:

Across all behaviours, television viewing occupied the most leisure time on both weekdays and weekend days. The five most time consuming sedentary weekday activities occupied on average 262.9 minutes per weekday and 400 minutes per weekend day. In contrast, only 44.2 minutes was occupied by active transport or sports and exercise per weekday, and 53 minutes per weekend day. Only a minority watched more than 4 hours of TV per day (3.3% on weekdays and 20.7% on weekend days). Computer use is low in this group. Some differences were noted in the means and prevalences between weekend and weekdays, most likely reflecting the greater discretionary time available at the weekend. Few age differences were noted.

CONCLUSIONS:

Adolescent girls engage in a variety of behaviours that contribute to an overall lifestyle that may be active or sedentary. Effective physical activity promotion strategies must focus on facilitating shifts towards healthy overall patterns of behaviour rather than shifts in any one single behaviour.

Gorman, E.; Hanson, H. M.; Yang, P. H.; Khan, K. M.; Liu-Ambrose, T.; Ashe, M. C. (2014):

Accelerometry analysis of physical activity and sedentary behavior in older adults: a systematic review and data analysis.

In: *Eur Rev Aging Phys Act* 11, S. 35–49. DOI: 10.1007/s11556-013-0132-x.

Abstract:

Accelerometers objectively monitor physical activity and sedentary patterns and are increasingly used in the research setting. It is important to maintain consistency in data analysis and reporting, therefore, we: (1) systematically identified studies using accelerometry (ActiGraph, Pensacola, FL, USA) to measure moderate-to-vigorous physical activity (MVPA) and sedentary time in older adults, and (2) based on the review findings, we used different cut-points obtained to analyze accelerometry data from a sample of community-dwelling older women. We identified 59 articles with cut-points ranging between 574 and 3,250 counts/min for MVPA and 50 and 500 counts/min for sedentary time. Using these cut-points and data from women (mean age, 70 years), the median MVPA minutes per day ranged between 4 and 80 min while percentage of sedentary time per day ranged between 62 % and 86 %. These data highlight (1) the importance of reporting detailed information on the analysis assumptions and (2) that results can differ greatly depending on analysis parameters.

Gorostidi, Manuel; Vinyoles, Ernest; Banegas, Jose R.; La Sierra, Alejandro (2015):

Prevalence of white-coat and masked hypertension in national and international registries.

In: *Hypertens Res* 38 (1), S. 1–7. DOI: 10.1038/hr.2014.149.

Abstract:

In the past two decades, techniques for the measurement of blood pressure outside the medical setting have unmasked highly prevalent situations. A significant proportion of patients with office blood pressure levels above the thresholds for diagnosing hypertension or above the limits where those being treated are considered to be adequately controlled actually show normal ambulatory blood pressure levels. These patients have white-coat hypertension if untreated or false resistance to antihypertensive therapy because of the white-coat effect if treated. However, some individuals with normal office blood pressure measurements show elevated ambulatory blood pressure levels, and thus have masked hypertension if untreated or masked uncontrolled hypertension if treated. When looking for white-coat hypertension in patients with elevated office blood pressure levels or when looking for masked hypertension in office-controlled patients, up to one in three patients in each scenario would have white-coat or masked hypertension. Although related clinical factors, such as age, gender and global cardiovascular risk, are associated with both conditions, their abilities to predict such a misclassification are very low. Thus, assessing individual blood pressure levels by means of an ambulatory technique, particularly ambulatory blood pressure monitoring, is now considered a priority in diagnosing hypertension and in evaluating hypertension control.

Gorzelniak, L.; Dias, A.; Schultz, K.; Wittmann, M.; Karrasch, S.; Jorres, R. A.; Horsch, A. (2012):

Comparison of Recording Positions of Physical Activity in Patients with Severe COPD Undergoing LTOT.

In: *COPD* 9 (5), S. 528–537. DOI: 10.3109/15412555.2012.708066.

Abstract:

Abstract Background: Accelerometry is increasingly used to assess physical activity (PA) in patients with chronic obstructive pulmonary disease (COPD). It is not known how the relationship of PA to clinical results depends on the position of the PA sensor. Methods: We assessed the effect of monitor position by measuring lower extremity (ankle), upper extremity (wrist) and total body movement (hip) in 52 patients with severe COPD (mean [+/- SD] age, 62 +/- 10 years; FEV(1), 38 +/- 12% predicted) undergoing long-term oxygen therapy with and without walkers during a pulmonary rehabilitation (PR) program. Sensors were

worn 8.5 +/- 3.1 days and data was compared to the BODE score and the 6-minute walk distance (6MWD) assessed at the beginning and end of the PR. Results: Mean ankle PA was moderately related to the 6MWD, irrespective of patients being equipped with a walker or not ($p < 0.05$). Mean PA values were considerably lower in COPD patients with walker compared to patients without for all sensor positions. No significant association was observed between mean hip PA data and 6MWD; however, hip and ankle PA data were moderately related in walker-free and strongly related in walker patients ($p < 0.01$). In a multivariate regression model only ankle activity was significantly associated with the BODE score ($p < 0.01$). Conclusion: The sensor position had a significant impact on the association between PA recordings and the 6MWD in very severe COPD. In our setting, ankle measurement seemed to best reflect the clinical state of patients

Gosse, Philippe; Papaioanou, Georgios; Coulon, Paul; Reuter, Sylvain; Lemetayer, Philippe; Safar, Michel (2007):

Can ambulatory blood-pressure monitoring provide reliable indices of arterial stiffness?

In: *Am J Hypertens* 20 (8), S. 831–838.

Abstract:

BACKGROUND:

The use of ambulatory recordings of blood pressure (BP) was proposed to estimate arterial stiffness (AS). We compared the relative value of the ambulatory AS index (AASI), and of the slope of pulse pressure (PP) according to mean BP (MBP) obtained from 24-h ambulatory BP monitoring, to the monitoring of the arrival time of Korotkoff sounds (QKD interval) in the prediction of cardiovascular (CV) events.

METHODS:

Twenty-four-hour ambulatory BP and QKD monitoring were recorded at baseline, before antihypertensive treatment of hypertensive patients in our Bordeaux cohort. From these recordings, the AASI, the PP/MBP slope, and the theoretical value of the QKD for a systolic pressure of 100 mm Hg and a heart rate of 60 beats/min (QKD100-60) were calculated. The patients were then given antihypertensive treatment and followed by their family physicians, who were unaware of the QKD, AASI, and PP/MBP slope results. Regular updates on patients were obtained. The reproducibility of measurements was studied in 38 normal subjects evaluated on two occasions.

RESULTS:

The reproducibility of the AASI and the PP/MBP slope was less than that of BP over 24 h and of QKD100-60. The cohort comprised 469 patients. With an average follow-up of 70+/-39 months, 62 CV complications, including 13 deaths, were recorded. In the monovariate analysis, age, PP over 24 h, QKD100-60, AASI, and the PP/MBP slope were significantly related to the occurrence of complications. In the multivariate analysis, when age and PP over 24 were included in the model, only QKD100-60 remained significantly linked to CV events.

CONCLUSIONS:

Our data support the value of the AASI as an indirect estimate of AS and as an element in the evaluation of CV risk in hypertensive patients. However, the reproducibility of this index is less, and its predictive value for complications is poorer, than that of QKD100-60, a parameter that we believe is more closely linked to AS.

Goto, M.; Takedani, H.; Haga, N.; Kubota, M.; Ishiyama, M.; Ito, S.; Nitta, O. (2014):

Self-monitoring has potential for home exercise programmes in patients with haemophilia.

In: *Haemophilia* 20 (2), S. e121-7. DOI: 10.1111/hae.12355.

Abstract:

Haemophiliacs who have had to keep a physically inactive lifestyle due to bleeding during childhood are likely to have little motivation for exercise. The purpose of this study is to clarify the effectiveness of the self-monitoring of home exercise for haemophiliacs. A randomized controlled trial was conducted with intervention over 8 weeks at four hospitals in Japan. Subjects included 32 male outpatients aged 26-64 years without an inhibitor who were randomly allocated to a self-monitoring group and a control group. Individual exercise guidance with physical activity for improvement of their knee functions was given to both groups. The self-monitoring materials included an activity monitor and a feedback system so that the self-monitoring group could send feedback via the Internet and cellular phone. The self-monitoring was performed by checking exercise adherence and physical activity levels, bleeding history and injection of a coagulation factor. Both groups showed significant improvements in exercise adherence ($P < 0.001$) and physical function such as the strength of knee extension ($P < 0.001$), range of knee extension ($P < 0.001$), range of ankle dorsiflexion ($P < 0.01$), a modified Functional Reach ($P < 0.05$) and 10 metre gait

time (P < 0.01). In particular, improvements in exercise adherence (P < 0.05), self-efficacy (P < 0.05), and strength of knee extension (P < 0.05) were significant in the self-monitoring group compared with those in the control group. No increase in bleeding frequency and pain scale was noted. The self-monitoring of home exercise for haemophilic patients is useful for the improvement of exercise adherence, self-efficacy and knee extension strength.

Gould, Laura Feagans; Hussong, Andrea M.; Hersh, Matthew A. (2012):

Emotional distress may increase risk for self-medication and lower risk for mood-related drinking consequences in adolescents.

In: *The International Journal of Emotional Education* 4 (1), S. 6–24. DOI: 10.1037/t15197-000;

Abstract:

The current study examines indicators of emotional distress and coping that may define sub-populations of adolescents at risk for two potential affect-related mechanisms underlying substance misuse: self-medication and mood-related drinking consequences. Although theory and empirical evidence point to the salience of affect-related drinking to current and future psychopathology, we have little knowledge of whether or for whom such mood-related processes exist in adolescents because few studies have used methods that optimally match the phenomenon to the level of analysis. Consequently, the current study uses multi-level modeling in which daily reports of negative mood and alcohol use are nested within individuals to examine whether adolescents with more emotional distress and poorer coping skills are more likely to evidence self-medication and mood-related drinking consequences. Seventy-five adolescents participated in a multi-method, multi-reporter study in which they completed a 21-day experience sampling protocol assessing thrice daily measures of mood and daily measures of alcohol use. Results indicate that adolescents reporting greater anger are more likely to evidence self-medication. Conversely, adolescents displaying lower emotional distress and more active coping are more likely to evidence mood-related drinking consequences. Implications for identifying vulnerable sub-populations of adolescents at risk for these mechanisms of problematic alcohol use are discussed. Goulet, Geneviève; Mongrain, Valérie; Desrosiers, Catherine; Paquet, Jean; Dumont, Marie (2007):

Daily light exposure in morning-type and evening-type individuals.

In: *Journal of biological rhythms* 22 (2), S. 151–158.

Abstract:

Morning-type individuals (M-types) have earlier sleep schedules than do evening types (E-types) and therefore differ in their exposure to the external light-dark cycle. M-types and E-types usually differ in their endogenous circadian phase as well, but whether this is the cause or the consequence of the difference in light exposure remains controversial. In this study, ambulatory monitoring was used to measure 24-h light exposure in M-type and E-type subjects for 7 consecutive days. The circadian phase of each subject was then estimated in the laboratory using the dim-light melatonin onset in saliva (DLMO) and the core body temperature minimum (Tmin). On average, M-types had earlier sleep schedules and earlier circadian phases than E-types. They also showed more minutes of daily bright light exposure (> 1000 lux) than E-types. As expected, the 24-h patterns of light exposure analyzed in relation to clock time indicated that M-types were exposed to more light in the morning than E-types and that the reverse was true in the late evening. However, there was no significant difference when the light profiles were analyzed in relation to circadian phase, suggesting that, on average, the circadian pacemaker of both M-types and E-types was similarly entrained to the light-dark cycle they usually experience. Some M-types and E-types had different sleep schedules but similar circadian phases. These subjects also had identical light profiles in relation to their circadian phase. By contrast, M-types and E-types with very early or very late circadian phases showed large differences in their profiles of light exposure in relation to their circadian phase. This observation suggests that in these individuals, early or late circadian phases are related to relatively short and long circadian periods and that a phase-delaying profile of light exposure in M-types and a phase-advancing profile in E-types are necessary to ensure a stable entrainment to the 24-h day.

Goyder, Elizabeth; Hind, Daniel; Breckon, Jeff; Dimairo, Munyaradzi; Minton, Jonathan; Everson-Hock, Emma et al. (2014):

A randomised controlled trial and cost-effectiveness evaluation of 'booster' interventions to sustain increases in physical activity in middle-aged adults in deprived urban neighbourhoods.

In: *Health Technol Assess* 18 (13), S. 1–210. DOI: 10.3310/hta18130.

Abstract:

BACKGROUND: More evidence is needed on the potential role of 'booster' interventions in the maintenance of increases in physical activity levels after a brief intervention in relatively sedentary populations. OBJECTIVES: To determine whether objectively measured physical activity, 6 months after a brief intervention, is increased in those receiving physical activity 'booster' consultations delivered in a motivational interviewing (MI) style, either face to face or by telephone. DESIGN: Three-arm, parallel-group, pragmatic, superiority randomised controlled trial with nested qualitative research fidelity and geographical information systems and health economic substudies. Treatment allocation was carried out using a web-based simple randomisation procedure with equal allocation probabilities. Principal investigators and study statisticians were blinded to treatment allocation until after the final analysis only. SETTING: Deprived areas of Sheffield, UK. PARTICIPANTS: Previously sedentary people, aged 40-64 years, living in deprived areas of Sheffield, UK, who had increased their physical activity levels after receiving a brief intervention. INTERVENTIONS: Participants were randomised to the control group (no further intervention) or to two sessions of MI, either face to face ('full booster') or by telephone ('mini booster'). Sessions were delivered 1 and 2 months post-randomisation. MAIN OUTCOME MEASURES: The primary outcome was total energy expenditure (TEE) per day in kcal from 7-day accelerometry, measured using an Actiheart device (CamNtech Ltd, Cambridge, UK). Independent evaluation of practitioner competence was carried out using the Motivational Interviewing Treatment Integrity assessment. An estimate of the per-participant intervention costs, resource use data collected by questionnaire and health-related quality of life data were analysed to produce a range of economic models from a short-term NHS perspective. An additional series of models were developed that used TEE values to estimate the long-term cost-effectiveness. RESULTS: In total, 282 people were randomised (control = 96; mini booster = 92, full booster = 94) of whom 160 had a minimum of 4 out of 7 days' accelerometry data at 3 months (control = 61, mini booster = 47, full booster = 52). The mean difference in TEE per day between baseline and 3 months favoured the control arm over the combined booster arm but this was not statistically significant (-39 kcal, 95% confidence interval -173 to 95, p = 0.57). The autonomy-enabled MI communication style was generally acceptable, although some participants wanted a more paternalistic approach and most expressed enthusiasm for monitoring and feedback components of the intervention and research. Full boosters were more popular than mini boosters. Practitioners achieved and maintained a consistent level of MI competence. Walking distance to the nearest municipal green space or leisure facilities was not associated with physical activity levels. Two alternative modelling approaches both suggested that neither intervention was likely to be cost-effective. CONCLUSIONS: Although some individuals do find a community-based, brief MI 'booster' intervention supportive, the low levels of recruitment and retention and the lack of impact on objectively measured physical activity levels in those with adequate outcome data suggest that it is unlikely to represent a clinically effective or cost-effective intervention for the maintenance of recently acquired physical activity increases in deprived middle-aged urban populations. Future research with middle-aged and relatively deprived populations should explore interventions to promote physical activity that require less proactive engagement from individuals, including environmental interventions. STUDY REGISTRATION: Current Controlled Trials ISRCTN56495859, ClinicalTrials.gov NCT00836459. FUNDING: This project was funded by the NIHR Health Technology Assessment programme and will be published in full in Health Technology Assessment; Vol. 18, No. 13. See the NIHR Journals Library website for further project information.

Fetal electrocardiography: feasibility of long-term fetal heart rate recordings.

In: *BJOG : an international journal of obstetrics and gynaecology* 116 (2), S. 334-7; discussion 337-8. DOI: 10.1111/j.1471-0528.2008.01951.x.

Abstract:

The feasibility and accuracy of long-term transabdominal fetal electrocardiogram (fECG) recordings throughout pregnancy were studied using a portable fECG monitor. Fifteen-hour recordings of fetal heart rate (FHR) were performed in 150 pregnant women at 20-40 weeks of gestation and 1-hour recordings were performed in 22 women in labour and compared with simultaneous scalp electrode recordings. When >or=60% of fECG signals was present, the recording was defined as good. Eighty-two percent (123/150) of antenatal recordings were of good quality. This percentage increased to 90.7 (136/150 recordings) when only the night part (11 p.m.-7 a.m.) was considered. Transabdominal measurement of FHR and its variability correlated well with scalp electrode recordings (r=0.99, P<0.01; r=0.79, P<0.01, respectively). We demonstrated the feasibility and accuracy of long-term transabdominal fECG monitoring.

Grandhi, Sukeshini; Jones, Quentin (2010):

Technology-mediated interruption management.

In: *International Journal of Human-Computer Studies* 68 (5), S. 288–306.

Abstract:

INTRODUCTION:

Nurses' work in hospital departments is highly collaborative and includes communication with a variety of actors. To further support nurses' communications, wireless phones, on which nurses receive both nurse calls and ordinary phone calls, have been introduced. However, while they ensure high availability among the mobile nurses, these phones also contribute to an increased number of interruptions.

PURPOSE:

This paper aims to discover whether all interruptions caused by the wireless phones are unwanted. Further, it investigates how nurses handle these interruptions in a hospital setting in order to construct a foundation for guidelines to use in designing these types of systems.

METHODS:

Qualitative and ethnographically inspired fieldwork, including workshops with both ordinary and student nurses from a Norwegian hospital, was undertaken. Patients from two hospital departments were interviewed.

RESULTS:

Nurses struggle to handle interruptions caused by the wireless nurse call system. Deciding whether to abort an activity or not to respond to an interruption is regarded as stressful. The decision is further complicated by the complex nature of the interruptions. At the same time, patients anticipate that nurses are able to make these judgements with limited information. Nurses' work is highly collaborative, and nurses depend on one another to carry out their work and manage interruptions.

CONCLUSION:

The dual nature of the interruptions is complex, and whether an interruption is wanted or unwanted depends on many factors. Nurses manage interruptions mainly by making their own activities visible and monitoring colleagues' work. Therefore, nurses' awareness of colleagues' activities is a key factor in how they handle interruptions in the form of nurse calls.

Mobile Assessment and Treatment for Schizophrenia (MATS): A Pilot Trial of An Interactive Text-Messaging Intervention for Medication Adherence, Socialization, and Auditory Hallucinations.

In: *Schizophr.Bull.* (0586-7614 (Linking)). DOI: 10.1093/schbul/sbr155.

Abstract:

Mobile Assessment and Treatment for Schizophrenia (MATS) employs ambulatory monitoring methods and cognitive behavioral therapy interventions to assess and improve outcomes in consumers with schizophrenia through mobile phone text messaging. Three MATS interventions were developed to target medication adherence, socialization, and auditory hallucinations. Participants received up to 840 text messages over a 12-week intervention period. Fifty-five consumers with schizophrenia or schizoaffective disorder were enrolled, but 13 consumers with more severe negative symptoms, lower functioning, and lower premorbid IQ did not complete the intervention, despite repeated prompting and training. For completers, the average valid response rate for 216 outcome assessment questions over the 12-week period was 86%, and 86% of phones were returned undamaged. Medication adherence improved significantly, but only for individuals who were living independently. Number of social interactions increased significantly and a significant reduction in severity of hallucinations was found. In addition, the probability of endorsing attitudes that could interfere with improvement in these outcomes was also significantly reduced in MATS. Lab-based assessments of more general symptoms and functioning did not change significantly. This pilot study demonstrated that low-intensity text-messaging interventions like MATS are feasible and effective interventions to improve several important outcomes, especially for higher functioning consumers with schizophrenia

Graves, John W.; Grossardt, Brandon R.; Gullerud, Rachel E.; Bailey, Kent R.; Feldstein, Jeffrey (2006):

The trained observer better predicts daytime ABPM diastolic blood pressure in hypertensive patients than does an automated (Omron) device.

In: *Blood Press Monit* 11 (2), S. 53–58. DOI: 10.1097/01.mbp.0000200480.26669.72.

Abstract:

OBJECTIVES\r\nAccurate blood pressure measurement is critical to successful clinical trials. Concerns about observer errors have led to the use of automated oscillometric devices without evidence that their performance is similar to that of trained observers. This study compares blood pressures obtained by trained observers and with an oscillometric device (Omron 705CP) to 24-h ambulatory blood pressure monitoring.\r\nMETHODS\r\nWe performed a post-hoc analysis of 313 untreated hypertensive

patients at the end of the washout phase of a Novartis hypertension trial. Patients had three seated trained observer mercury auscultatory blood pressure measurements followed by 24-h ambulatory blood pressure monitoring. The next day, the ambulatory blood pressure monitoring was removed and three seated readings were obtained with an Omron 705CP. Correlations for systolic blood pressure and diastolic blood pressure were obtained between daytime ambulatory blood pressure monitoring (0900 and 2100) and the two office methods. In addition, we investigated the degree of difference of trained observer and Omron measurements from ambulatory blood pressure monitoring.\r\nRESULTS\r\nFor systolic blood pressure, the correlation with ambulatory blood pressure monitoring of the trained observer was significantly better than with that of the Omron 705CP (0.641 vs. 0.555, P=0.01). For diastolic blood pressure values, even greater disparity between the two office method correlations with ambulatory blood pressure monitoring was observed (trained observer=0.593 vs. Omron=0.319, P<0.0001). Both trained observer and Omron readings were consistently higher than ambulatory blood pressure monitoring for systolic blood pressure (P<0.0001) and diastolic blood pressure (P<0.0001). Omron measurements, however, deviated from ambulatory blood pressure monitoring more than those of the trained observer (P<0.0001 for systolic blood pressure and diastolic blood pressure).\r\nCONCLUSIONS\r\nFor clinical trials using diastolic blood pressure targets, the Omron 705CP cannot replace the auscultatory blood pressure measurements of a trained observer. For systolic blood pressure, the Omron device and the trained observer had similar correlations with ambulatory blood pressure monitoring; however, both methods gave consistently higher systolic blood pressure values. Further study of oscillometric devices should be conducted before universally replacing auscultatory blood pressure determinations by trained observers in clinical trials.

Graves, Lee E. F.; Ridgers, Nicola D.; Stratton, Gareth (2008):

The contribution of upper limb and total body movement to adolescents' energy expenditure whilst playing Nintendo Wii.

In: *European journal of applied physiology* 104 (4), S. 617–623.

Abstract:

Little research documents the contribution of upper limb and total body movement to energy expenditure (EE) during active video gaming. To address this, EE, heart rate (HR), and, upper limb and total body movement were assessed in 11- to 17-year-old adolescents whilst playing three active (Nintendo Wii) and one sedentary (XBOX 360) video games. Non-dominant upper limb activity, EE and HR were significantly greater during Wii Sports boxing [mean 267.2 (SD 115.8) J kg(-1) min(-1); 136.7 (24.5) beats min(-1)] than tennis or bowling (P < or = 0.044). For all active games hip activity best predicted EE (R (2) > or = 0.53), with two-measure models of HR and single-site activity data, and multi-site activity data, similarly explaining the variance in EE (R (2) > or = 0.64). The physiological cost of upper-body orientated active video games increased when movement of both upper limbs was encouraged. Improvements in EE explanatory power provide support for multi-site activity monitoring during unique, non-ambulatory activities.

Gregori, Mario; Tocci, Giuliano; Giammarioli, Benedetta; Befani, Alberto; Ciavarella, Giuseppino Massimo; Ferrucci, Andrea; Paneni, Francesco (2014):

Abnormal regulation of renin angiotensin aldosterone system is associated with right ventricular dysfunction in hypertension.

In: *Can J Cardiol* 30 (2), S. 188–194. DOI: 10.1016/j.cjca.2013.11.009.

Abstract:

BACKGROUND: Right ventricular dysfunction (RVD) is a major predictor of cardiovascular mortality. Inadequate suppression of the renin-angiotensin-aldosterone system (RAAS) after postural manoeuvres favours alterations of left ventricular (LV) function. The effects of RAAS dysregulation on RV performance remain elusive. The present study investigated RV function in hypertensive patients with or without altered RAAS activation. METHODS: Plasma renin activity (PRA) and plasma aldosterone concentration (PAC) were measured in 104 newly diagnosed hypertensive patients after both supine and upright positioning to assess dynamic changes of RAAS induced by antigravitational stress. Twenty-four-hour ambulatory blood pressure monitoring and echocardiographic evaluation of the right ventricle including tissue Doppler imaging (TDI) were performed. Patients were divided as follows: (1) normal PRA and PAC (N group [n = 58]), (2) suppressible RAAS after supine positioning (SR group [n = 24]), and (3), nonsuppressible RAAS (NSR group [n = 22]). RVD was identified by the TDI-derived myocardial performance index (MPI) calculated with a multisegmental approach. RESULTS: Patients in the NSR group had reduced indices of RV function compared with patients in the N and SR groups. MPI of the right ventricle as well as prevalence of RVD were also significantly higher in the NSR group. Regression models showed that inadequate RAAS suppression was independently associated with RVD, regardless of blood pressure values and LV dysfunction (LVD). CONCLUSIONS: Patients without supine normalization of RAAS display a significant impairment of RV function. Our findings suggest that a dynamic RAAS evaluation may help to identify hypertensive patients at higher risk of RVD.

Breathing awareness meditation and LifeSkills Training programs influence upon ambulatory blood pressure and sodium excretion among African American adolescents.

In: *The Journal of adolescent health : official publication of the Society for Adolescent Medicine* 48 (1), S. 59–64. DOI: 10.1016/j.jadohealth.2010.05.019.

Abstract:

PURPOSE\r\nTo evaluate the effect of breathing awareness meditation (BAM), Botvin LifeSkills Training (LST), and health education control (HEC) on ambulatory blood pressure and sodium excretion in African American adolescents.\r\nMETHODS\r\nFollowing 3 consecutive days of systolic blood pressure (SBP) screenings, 166 eligible participants (i.e., SBP >50th-95th percentile) were randomized by school to either BAM (n = 53), LST (n = 69), or HEC (n = 44). In-school intervention sessions were administered for 3 months by health education teachers. Before and after the intervention, overnight urine samples and 24-hour ambulatory SBP, diastolic blood pressure, and heart rate were obtained.\r\nRESULTS\r\nSignificant group differences were found for changes in overnight SBP and SBP, diastolic blood pressure, and heart rate over the 24-hour period and during school hours. The BAM treatment exhibited the greatest overall decreases on these measures (Bonferroni adjusted, ps < .05). For example, for school-time SBP, BAM showed a change of -3.7 mmHg compared with no change for LST and a change of -.1 mmHg for HEC. There was a nonsignificant trend for overnight urinary sodium excretion (p = .07), with the BAM group displaying a reduction of -.92 ± 1.1 mEq/hr compared with increases of .89 ± 1.2 mEq/hr for LST and .58 ± .9 mEq/hr for HEC group.\r\nCONCLUSION\r\nBAM appears to improve hemodynamic function and may affect sodium handling among African American adolescents who are at increased risk for development of cardiovascular disease.

Tension Tamer: Delivering Meditation With Objective Heart Rate Acquisition for Adherence Monitoring Using a Smart Phone Platform.

In: *J Altern.Complement Med.* (1075-5535 (Linking)). DOI: 10.1089/acm.2011.0772.

Abstract:

Abstract Objectives: This brief report demonstrates the proof of concept of the Tension Tamer (TT) smartphone application, which integrates photoplethysmograph capabilities with breathing awareness meditation (BAM), to reduce stress and measure heart rate and adherence. Design: Methods for objectively measuring heart rate and adherence to BAM were developed as part of a future randomized controlled trial. Setting/Location: The study was conducted at Jerry Zucker Middle School of Science and the Medical University of South Carolina, Charleston. Subjects: The subjects were three prehypertensive male teachers. Intervention: The method used was smartphone delivered BAM. Outcome measures: Objective measures included heart rate, adherence, and ambulatory blood pressure (BP). Results: Adherence data was successfully collected by the TT application. Increased adherence to TT coincided with increased improvements in ambulatory BP over a 3-month period. Conclusions: TT shows promise as a simple inexpensive program for administering BAM and capturing adherence data in future clinical trials

Time-Based Indicators of Emotional Complexity: Interrelations and Correlates.

In: *Emotion*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-30610-001%26site%3dehost-live.

Abstract:

Emotional complexity has been regarded as one correlate of adaptive emotion regulation in adulthood. One novel and potentially valuable approach to operationalizing emotional complexity is to use reports of emotions obtained repeatedly in real time, which can generate a number of potential time-based indicators of emotional complexity. It is not known, however, how these indicators relate to each other, to other measures of affective complexity, such as those derived from a cognitive-developmental view of emotional complexity, or to measures of adaptive functioning, such as well-being. A sample of 109 adults, aged 23 to 90 years, participated in an experience-sampling study and reported their negative and positive affect five times a day for one week. Based on these reports, we calculated nine different time-based indicators potentially reflecting emotional complexity. Analyses showed three major findings: First, the indicators showed a diverse pattern of interrelations suggestive of four distinct components of emotional complexity. Second, age was generally not related to time-based indicators of emotional complexity; however, older adults showed overall low variability in negative affect. Third, time-based indicators of emotional complexity were either unrelated or inversely related to measures of adaptive functioning; that is, these measures

tended to predict a less adaptive profile, such as lower subjective and psychological well-being. In sum, time-based indicators of emotional complexity displayed a more complex and less beneficial picture than originally thought. In particular, variability in negative affect seems to indicate suboptimal adjustments. Future research would benefit from collecting empirical data for the interrelations and correlates of time-based indicators of emotional complexity in different contexts. Griffith, Sandra D.; Shiffman, Saul; Heitjan, Daniel F. (2009):

A method comparison study of timeline followback and ecological momentary assessment of daily cigarette consumption.

In: *Nicotine Tob Res* 11 (11), S. 1368–1373. DOI: 10.1093/ntr/ntp150.

Abstract:

INTRODUCTION\r\nUncertainty exists about how best to measure daily cigarette consumption. Two common measures are timeline followback (TLFB), which involves structured, prompted recall, and ecological momentary assessment (EMA), which involves recording consumption, as it occurs, on a handheld electronic device.\r\nMETHODS\r\nWe evaluated the agreement between TLFB and EMA measures collected for 14 days prior to the target quit date from 236 smokers in a smoking cessation program. We performed a Bland-Altman analysis to assess agreement of TLFB and EMA using a regression-based model that allows for a nonuniform difference between methods and limits of agreement that can vary with the number of cigarettes smoked.\r\nRESULTS\r\nFor pairs of measurements taken on the same smoker, TLFB counts were on average 3.2 cigarettes higher than EMA counts; this difference increased for larger numbers of cigarettes. Using a model that allows for variable limits of agreement, the width of the 95% interval ranged from 8.7 to 61.8 cigarettes, with an average of 26.4 cigarettes. Variation between the methods increased substantially for larger cigarette counts, leading to wider limits and poorer agreement for heavy smokers.\r\nDISCUSSION\r\nThroughout the measurement range, the estimated limits of agreement were far wider than the limits of clinical significance, defined a priori to be 20% of the number of cigarettes smoked. We conclude that TLFB and EMA cannot be considered equivalent for the assessment of daily cigarette consumption, especially for heavy smokers.

Grondin, Olivier; Johnson, Elizabeth I.; Husky, Mathilde; Swendsen, Joel (2011):

Sociotropy and autonomy vulnerabilities to depressed mood: A daily life comparison of Reunion Island and metropolitan France.

In: *Journal of Cross-Cultural Psychology* 42 (6), S. 928–943. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-15298-003&site=ehost-live;Joel.Swendsen@u-bordeaux2.fr.

Abstract:

The current study examines whether sociotropy and autonomy traits prospectively predict depressed mood following daily events in young adults and considers whether relationships between personality, daily events, and mood differ by cultural context. Samples in Metropolitan France (n = 99) and Reunion Island (n = 70) participated in identical ambulatory monitoring procedures over a 1-week period and were assessed relative to cultural variables and additional psychological vulnerabilities known to influence depression or stress reactivity. Sociotropy heightened depressed mood responses to negative interpersonal events in Metropolitan France but not in Reunion Island. This finding was replicated when a continuous measure of cultural investment replaced geographic location. Contrary to Beck's theory, there was no evidence that autonomy moderated the relationship between subjective achievement events and depressed mood at either site. The results are discussed in terms of the cultural specificity of cognitive vulnerability-stress theories of depression, as well as their usefulness for explaining normal mood variance in daily life. Groot, J. F.; Jong, A. S.; Visser, T.; Takken, T. (2013):

Validation of the Actical and Actiheart monitor in ambulatory children with Spina Bifida.

In: *J Pediatr.Rehabil.Med* 6 (2), S. 103–111. DOI: 10.3233/PRM-130244.

Abstract:

BACKGROUND: Ambulatory children with Spina Bifida (SB) often show a decline in physical activity leading to deconditioning and functional decline. Therefore, assessment and promotion of physical activity is important. Because energy expenditure

during activities is higher in these children, the use of existing pediatric equations to predict physical activity energy expenditure (PAEE) may not be valid. AIMS: (1) To evaluate criterion validity of existing predictions converting accelerocounts into PAEE in ambulatory children with SB and (2) to establish new disease-specific equations for PAEE. METHODS: Simultaneous measurements using the Actical, the Actiheart, and indirect calorimetry took place to determine PAEE in 26 ambulatory children with SB. DATA ANALYSIS: Paired T-tests, Intra-class correlations limits of agreement (LoA), and explained variance (R<formula>^2</formula>) were used to analyze validity of the prediction equations using true PAEE as criterion. New equations were derived using regression techniques. RESULTS: While T-tests showed no significant differences for some models, the predictions developed in healthy children showed moderate ICC's and large LoA with true PAEE. The best regression models to predict PAEE were: PAEE=174.049+3.861 x H

Grossman, Ehud; Laudon, Moshe; Yalcin, Ridvan; Zengil, Hakan; Peleg, Edna; Sharabi, Yehonatan et al. (2006):

Melatonin reduces night blood pressure in patients with nocturnal hypertension.

In: *The American journal of medicine* 119 (10), S. 898–902. DOI: 10.1016/j.amjmed.2006.02.002.

Abstract:

PURPOSE\r\nNocturnal hypertension is associated with a high risk of morbidity and mortality. A blunted nocturnal surge in melatonin excretion has been described in nondipping hypertensive patients. We therefore studied the potency of melatonin to reduce nighttime blood pressure (BP) in treated hypertensive patients with nocturnal hypertension.\r\nPATIENTS AND METHODS\r\nThirty-eight treated hypertensive patients (22 males, mean age 64+/-11 years) with confirmed nocturnal hypertension (mean nighttime systolic BP >125 mm Hg), according to repeated 24-hour ambulatory blood pressure monitoring (ABPM), were randomized in a double-blind fashion to receive either controlled release (CR)-melatonin 2 mg or placebo 2 hours before bedtime for 4 weeks. A 24-hour ABPM was then performed.\r\nRESULTS\r\nMelatonin treatment reduced nocturnal systolic BP significantly from 136+/-9 to 130+/-10 mm Hg (P=.011), and diastolic BP from 72+/-11 to 69+/-9 mm Hg (P=.002), whereas placebo had no effect on nocturnal BP. The reduction in nocturnal systolic BP was significantly greater with melatonin than with placebo (P=.01), and was most prominent between 2:00 AM and 5:00 AM (P=.002).\r\nCONCLUSIONS\r\nEvening CR-melatonin 2 mg treatment for 4 weeks significantly reduced nocturnal systolic BP in patients with nocturnal hypertension. Thus, an addition of melatonin 2 mg at night to stable antihypertensive treatment may improve nocturnal BP control in treated patients with nocturnal hypertension.

Grossman, Paul; Wilhelm, Frank H.; Brutsche, Martin (2010):

Accuracy of ventilatory measurement employing ambulatory inductive plethysmography during tasks of everyday life.

In: *Biol Psychol* 84 (1), S. 121–128. DOI: 10.1016/j.biopsycho.2010.02.008.

Abstract:

Ambulatory inductive plethysmography (AIP) has recently been introduced to permit monitoring of ventilation outside the clinic and laboratory. It provides a method for nonintrusive assessment of both timing (e.g. respiration rate; RR) and volumetric parameters (e.g. tidal volume and minute ventilation volume; V(T) and V'(E), respectively). Although inductive plethysmography has been validated in laboratory investigations, quantitative validation during ambulatory, naturalistic conditions has not yet been assessed. Should AIP yield accurate estimation of ventilatory parameters, real-life monitoring of breathing pattern may provide new insights into respiratory functioning in health and disease. We examined the accuracy of AIP for assessing RR, V(T) and V'(E) during a 90-min protocol simulating activities of everyday life. A mobile backpack metabolic cart with integrated flowmeter was employed as the reference standard. Within- and between-participant minute-by-minute comparisons were made for each ventilatory measure among 9 healthy adults. Average within-participant minute-by-minute correlations between reference method and AIP were 0.96, 0.91 and 0.92 for V'(E), V(T) and RR, respectively. Average correlations across participants yielded r's of 0.98, 0.98 and 1.0. Analysis of mean task levels across participants revealed, in all cases, very close correspondences between both methods of measurement, with only a significant but minor deviance during a period of supine posture. Additionally, results indicated that within-individual variations in oxygen consumption were highly correlated with AIP-estimated V'(E), suggesting that ambulatory assessment of V'(E) may provide a reliable index of metabolic activity during everyday life.

Grover, Sukhdev S.; Pittman, Stephen D. (2008):

Automated detection of sleep disordered breathing using a nasal pressure monitoring device.

In: *Sleep Breath* 12 (4), S. 339–345.

Abstract:

To assess the accuracy of a single channel portable monitoring device (RUSleepingtrade mark RTS, Respironics, Murrysville, PA) that measures nasal pressure (a surrogate for airflow) to detect sleep disordered breathing (SDB). Twenty-five adult patients referred to a community sleep laboratory with suspected obstructive sleep apnea (OSA) participated in this investigation. The portable monitoring device was used in the sleep laboratory to acquire data concurrently with a standard multi-channel polysomnogram (PSG) to assess SDB. Respiratory events were scored manually on the PSG using standard criteria for clinical research to quantify an apnea-hypopnea index (AHI) based on events during sleep. The portable monitoring device automatically calculated an unedited respiratory event index (REI) based on recording time. These data were then compared using the Pearson product-moment correlation coefficient, Bland-Altman analysis, receiver operating characteristic (ROC) curves, and likelihood ratios. All 25 subjects completed the study. Mean age of subjects was 42.4 +/- 12.9 years and mean body mass index was 31.0 +/- 7.4 kg m(-2). There was good agreement between the REI and the AHI (R = 0.77, p < 0.001, mean difference 2.6 events per hour [2 SD: 39.8] using a Bland-Altman plot). The area under the ROC curve for detecting SDB (PSG AHI greater than or equal to five events per hour) with the REI was 0.94 (95% CI 0.84-1.0). For an REI >11.9 events per hour, the sensitivity was 0.89 (95% CI 0.65-0.99) and the specificity was 0.86 (95% CI 0.42-1.0) with a likelihood ratio of 6.2 for a positive test (LR+) and 0.13 for a negative test (LR-). Similar results were observed for detecting moderate-severe SDB (PSG AHI > or = 15 events h(-1)) using REI >15.2 events h(-1). In a population of subjects with suspected OSA, this portable monitoring device can automatically quantify an REI that compares well to the AHI scored manually on a concurrent PSG. Such a device may prove useful to assess SDB in high risk populations with self-administered testing in ambulatory settings such as the home.

Gruber, R.; Fontil, L.; Bergmame, L.; Wiebe, S. T.; Amsel, R.; Frenette, S.; Carrier, J. (2012):

Contributions of circadian tendencies and behavioral problems to sleep onset problems of children with ADHD.

In: *BMC Psychiatry* 12 (1471-244X (Linking)), S. 212. DOI: 10.1186/1471-244X-12-212.

Abstract:

ABSTRACT: BACKGROUND: Children with attention-deficit/hyperactivity disorder (ADHD) are two to three times more likely to experience sleep problems. The purpose of this study is to determine the relative contributions of circadian preferences and behavioral problems to sleep onset problems experienced by children with ADHD and to test for a moderation effect of ADHD diagnosis on the impact of circadian preferences and externalizing problems on sleep onset problems. METHODS: After initial screening, parents of children meeting inclusion criteria documented child bedtime over 4 nights, using a sleep log, and completed questionnaires regarding sleep, ADHD and demographics to assess bedtime routine prior to PSG. On the fifth night of the study, sleep was recorded via ambulatory assessment of sleep architecture in the child's natural sleep environment employing portable polysomnography equipment. Seventy-five children (26 with ADHD and 49 controls) aged 7-11 years (mean age 8.61 years, SD 1.27 years) participated in the present study. RESULTS: In both groups of children, externalizing problems yielded significant independent contributions to the explained variance in parental reports of bedtime resistance, whereas an evening circadian tendency contributed both to parental reports of sleep onset delay and to PSG-measured sleep-onset latency. No significant interaction effect of behavioral/circadian tendency with ADHD status was evident. CONCLUSIONS: Sleep onset problems in ADHD are related to different etiologies that might require different interventional strategies and can be distinguished using the parental reports on the CSHQ

Gruber, June; Kogan, Aleksandr; Mennin, Douglas; Murray, Greg (2013):

Real-world emotion? An experience-sampling approach to emotion experience and regulation in bipolar I disorder.

In: *Journal of Abnormal Psychology* 122 (4), S. 971–983. DOI: 10.1037/t20936-000;

Abstract:

Laboratory studies suggest that bipolar disorder is characterized by emotion dysregulation, yet emotion disturbance has not been systematically described using more ecologically valid methods. Using an experience-sampling approach, we therefore sought to investigate positive and negative emotionality, emotion regulation strategies, and functioning among remitted

individuals with bipolar I disorder (BD; n = 31) compared with both healthy controls (CTL; n = 32) and remitted individuals with major depressive disorder (MDD; n = 21). Hierarchical linear modeling analyses of self-report data spanning a 6-day consecutive period revealed that the BD group aligned with the CTL group in reporting greater positive emotionality than the MDD group, but aligned with the MDD group in reporting greater negative emotionality than the CTL group. Furthermore, the BD and MDD groups reported greater general use of emotion regulation strategies than the CTL group. These findings suggest that BD is characterized by amplified emotionality as well as increased efforts to regulate emotions in everyday life. Discussion focuses on implications for BD, as well as identification of unique (disorder-specific) and shared (transdiagnostic) features of emotion disturbance. Grubler, Martin R.; Kienreich, Katharina; Gaksch, Martin; Verheyen, Nicolas; Fahrleitner-Pammer, Astrid; Schmid, Johannes et al. (2014):

Aldosterone to Active Renin Ratio Is Associated With Nocturnal Blood Pressure in Obese and Treated Hypertensive Patients: The Styrian Hypertension Study.

In: *J Clin Hypertens (Greenwich). DOI:* 10.1111/jch.12274.

Abstract:

High aldosterone levels are considered to play a key role in arterial hypertension. Data on the relationship between the aldosterone to active renin ratio (AARR), a quantity of aldosterone excess, and ambulatory blood pressure (BP) monitoring (ABPM) during the night are, however, sparse. Hypertensive patients were recruited from local outpatient clinics who underwent 24-hour urine collection and in parallel ABPM. Plasma aldosterone and renin concentrations were measured by radioimmunoassay. A total of 211 patients (age, 60.2+/-10.2 years; 51.9% female) with a mean systolic/diastolic ABPM value of 128.7+/-12.8/77.1+/-9.2 mm Hg were evaluated. In backwards linear regression analyses adjusted for age, sex, body mass index, smoking, glomerular filtration rate, hemoglobin A1c , N-terminal prohormone of brain natriuretic peptide, urinary sodium/potassium ratio, and ongoing antihypertensive medication, AARR was significantly associated with nocturnal systolic (ss-coefficient: 0.177; P=.017) and diastolic BP (ss-coefficient: 0.162; P=.027). In patients with arterial hypertension, a significant association between AARR and nighttime BP even after adjustment for a broad panel of confounders was found.

Smart-Phone Based Recognition of States and State Changes in Bipolar Disorder Patients.

In: *IEEE J Biomed Health Inform. DOI:* 10.1109/JBHI.2014.2343154.

Abstract:

Today's health care is difficult to imagine without the possibility to objectively measure various physiological parameters related to patients symptoms (from temperature through blood pressure to complex tomographic procedures). Psychiatric care remains a notable exception that heavily relies on patient interviews and self assessment. This is due to the fact that mental illnesses manifest themselves mainly in the way patients behave throughout their daily life and, until recently there were no "behavior measurement devices". This is now changing with the progress in wearable activity recognition and sensor enabled smartphones. In this article we introduce a system, which, based on smartphone-sensing is able to recognize depressive and manic states and detect state changes of patients suffering from bipolar disorder. Drawing upon a real-life dataset of 10 patients, recorded over a time-period of 12 weeks (in total over 800 days of data tracing 17 state changes) by 4 different sensing modalities we could extract features corresponding to all disease-relevant aspects in behavior. Using these features we gain recognition accuracies of 76% by fusing all sensor modalities and state change detection precision and recall of over 97%. This article furthermore outlines the applicability of this system in the physician-patient relations in order to facilitate the life and treatment of bipolar patients.

Measurement and assessment of electromagnetic fields near radiophones in line with provisions of European Directive 2013/35/EU and Polish labour law.

In: *Med Pr* 64 (5), S. 671–680.

Abstract:

BACKGROUND: The activities of rescue and uniformed services require the use of wireless communication devices, such as portable radiophones. Assessment of workers' exposure to electromagnetic fields emitted by radiophones is important in view of occupational safety and health (OSH), legislation requirements and reports on possible adverse health effects in users of devices emitting radiofrequency electromagnetic field. MATERIALS AND METHODS: In this study 50 portable radiophones of conventional and trunked communication systems were investigated. The assessment of electromagnetic hazards to users involved unperturbed electromagnetic field measurements near radiophones' antennas. RESULTS: The electric field strength corresponding to the occupational exposure level (fields of so-called safety zones established by OSH legislation in Poland) was measured at a distance of 45-65 cm from the portable radiophones antennas of conventional system and 75-95 cm from antennas of trunked system radiophones, depending on their type and mode of work. The assessment was based on the averaged results of series of measurements. The electric field strength exceeding action levels defined by Directive 2013/35/EU was found up to 15 cm from radiophone antennas of conventional system and up to 10 cm from the antennas of trunked system radiophones. CONCLUSIONS: Taking into account the range of safety zones and the use of portable radiophones near the body, their users should be classified into the group of workers occupationally exposed to electromagnetic fields. Electromagnetic field measurement results and typical conditions of using portable radiophones justify the need for additional assessment of electromagnetic hazards--the analysis of compliance with relevant exposure limit values provided by Directive 2013/35/EU.

A smartphone-driven methodology for estimating physical activities and energy expenditure in free living conditions.

In: *J Biomed Inform. DOI:* 10.1016/j.jbi.2014.07.009.

Abstract:

This paper introduces a function dedicated to the estimation of total energy expenditure (TEE) of daily activities based on data from accelerometers integrated into smartphones. The use of mass-market sensors such as accelerometers offers a promising solution for the general public due to the growing smartphone market over the last decade. The TEE estimation function quality was evaluated using data from intensive numerical experiments based, first, on 12 volunteers equipped with a smartphone and two research sensors (Armband and Actiheart) in controlled conditions (CC) and, then, on 30 other volunteers in free-living conditions (FLC). The TEE given by these two sensors in both conditions and estimated from the metabolic equivalent tasks (MET) in CC served as references during the creation and evaluation of the function. The TEE mean gap in absolute value between the function and the three references was 7.0%, 16.4% and 2.7% in CC, and 17.0% and 23.7% according to Armband and Actiheart, respectively, in FLC. This is the first step in the definition of a new feedback mechanism that promotes self-management and daily-efficiency evaluation of physical activity as part of an information system dedicated to the prevention of chronic diseases.

Guimaraes, Guilherme Veiga; de Barros Cruz, Lais Galvani; Fernandes-Silva, Miguel Morita; Dorea, Egidio Lima; Bocchi, Edimar Alcides (2014):

Heated water-based exercise training reduces 24-hour ambulatory blood pressure levels in resistant hypertensive patients: A randomized controlled trial (HEx trial).

In: *Int J Cardiol* 172 (2), S. 434–441. DOI: 10.1016/j.ijcard.2014.01.100.

Abstract:

BACKGROUND: Regular exercise is an effective intervention to decrease blood pressure (BP) in hypertension, but no data are available concerning the effects of heated water-based exercise (HEx). This study examines the effects of HEx on BP in resistant hypertensive patients. METHODS: This is a parallel, randomized controlled trial. 125 nonconsecutive sedentary patients with resistant hypertension from a hypertension outpatient clinic in a university hospital were screened; 32 patients fulfilled the study requirements. The training was performed for 60-minute sessions in a heated pool (32 degrees C), three times a week for 12weeks. The HEx protocol consisted of callisthenic exercises and walking inside the pool. The control group was asked to maintain habitual activities. The main outcome measure was change in mean 24-hour ambulatory BP (ABPM). RESULTS: 32 patients (HEx n=16; control n=16) were randomized; none were lost to follow-up. Office BPs decreased significantly after heated water exercise (36/12mmHg). HEx decreased 24-hour systolic (from 137+/-23 to 120+/-12mmHg, p=0.001) and diastolic BPs (from 81+/-13 to 72+/-10mmHg, p=0.009); daytime systolic (from 141+/-24 to 120+/-13mmHg, p<0.0001) and diastolic BPs (from 84+/-14 to 73+/-11mmHg, p=0.003); and nighttime systolic (from 129+/-22 to 114+/-12mmHg, p=0.006) and diastolic BPs (from 74+/-11 to 66+/-10mmHg, p<0.0001). The control group after 12weeks significantly increased in 24-hour systolic and diastolic BPs, and daytime and nighttime diastolic BPs. CONCLUSION: HEx reduced office BPs and 24-hour ABPM levels in resistant hypertensive patients. These effects suggest that HEx may be a potential new therapeutic approach in these patients.

Guiry, John J.; van de Ven, Pepijn; Nelson, John; Warmerdam, Lisanne; Riper, Heleen (2014):

Activity recognition with smartphone support.

In: *Med Eng Phys. DOI:* 10.1016/j.medengphy.2014.02.009.

Abstract:

In this paper, the authors describe a method of accurately detecting human activity using a smartphone accelerometer paired with a dedicated chest sensor. The design, implementation, testing and validation of a custom mobility classifier are also presented. Offline analysis was carried out to compare this custom classifier to de-facto machine learning algorithms, including C4.5, CART, SVM, Multi-Layer Perceptrons, and Naive Bayes. A series of trials were carried out in Ireland, initially involving N=6 individuals to test the feasibility of the system, before a final trial with N=24 subjects took place in the Netherlands. The protocol used and analysis of 1165min of recorded activities from these trials are described in detail in this paper. Analysis of collected data indicate that accelerometers placed in these locations, are capable of recognizing activities including sitting, standing, lying, walking, running and cycling with accuracies as high as 98%.

Post-transplant hypertension in pediatric kidney transplant recipients.

In: *Pediatr Nephrol. DOI:* 10.1007/s00467-013-2721-3.

Abstract:

BACKGROUND: The aim of the study was to investigate the prevalence of post-transplant hypertension (HT) and to assess the blood pressure (BP) of transplanted children with possible risk factors. METHODS: Office and ambulatory blood pressure measurements were performed for each patient. RESULTS: Twenty-nine patients were included in the study, including 13 patients with newly diagnosed untreated HT according to the results of ambulatory blood pressure monitoring (ABPM). Fourteen patients were on antihypertensive medication, but only in five of these patients was the HT under control; nine patients receiving antihypertensive drugs had uncontrolled HT. Of the 29 patients, two had normotension without any antihypertensive drug(s). Standard deviation scores (SDS) of the nocturnal diastolic BP of the ABPM were positively correlated with the prednisolone dosage per kilogram ($p = 0.013$, $r = 0.45$) and negatively correlated with the time period after transplantation ($p = 0.024$, $r = -0.41$). Similarly, the SDS of the 24-h diastolic BP was positively correlated with the prednisolone dosage per kilogram ($p = 0.006$, $r = 0.50$) and negatively correlated with the time period after transplantation ($p = 0.016$, $r = -0.44$). Patients with alternate-day steroid treatment had lower nocturnal systolic ($p = 0.016$), nocturnal diastolic ($p = 0.001$) and 24-h diastolic ($p = 0.008$) SDS when compared to those receiving daily steroid medication. CONCLUSION: The prevalence of HT among children after renal transplantation was high among our patient cohort, and steroids had direct impact on nocturnal and diastolic BP.

Gulur, Padma; Rodi, Scott W.; Washington, Tabitha A.; Cravero, Joseph P.; Fanciullo, Gilbert J.; McHugo, Gregory J.; Baird, John C. (2009):

Computer Face Scale for measuring pediatric pain and mood.

In: *J Pain* 10 (2), S. 173–179. DOI: 10.1016/j.jpain.2008.08.005.

Abstract:

UNLABELLED\r\nThis investigation determined the psychometric properties and acceptability of an animated face scale presented on a hand-held computer as a means to measure pediatric pain and mood. In study 1, 79 hospitalized, pediatric patients indicated their levels of pain by adjusting the expression of an animated cartoon face. The first objective was to determine feasibility, concurrent validity, and acceptability of the method. All patients were tested both with the Computer Face Scale and the poster format of the Wong-Baker Faces Scale. A second objective was to evaluate test-retest reliability of the method. In study 2, 50 hospitalized, pediatric patients were tested on 2 occasions, but in this case the patients used the Computer Face Scale to indicate both their pain (how much they hurt) and their mood (how they felt). Children in study 1 were able to use the Computer Face Scale to express relative amounts of pain/hurt; the method showed concurrent validity with the Wong-Baker Face Scale; and most children expressed a preference for the Computer Face Scale. The method also showed adequate test-retest reliability. In study 2, adequate test-retest reliability was demonstrated for ratings of both pain and mood.\r\nPERSPECTIVE\r\nThe Computer Face Scale allows the health provider to obtain reliable and valid measures of pediatric pain and mood. The method can be understood and used by children as young as 3 years and is appropriate for use with adults.

Gunay, Fatih; Alpay, Harika; Gokce, Ibrahim; Bilgen, Hulya (2013):

Is late-preterm birth a risk factor for hypertension in childhood?

In: *Eur J Pediatr. DOI:* 10.1007/s00431-013-2242-x.

Abstract:

Late-preterm birth is associated with higher rates of neonatal morbidity and mortality and higher health care utilization, but its impact on later life is not well known. In this study, we aimed to evaluate whether late-preterm birth affects blood pressure, renal function, and urinary protein excretion in children later in life. Sixty-five children aged 4 to 13 years born as late-preterm and 65 age- and sex-matched children born full term were evaluated with 24-h ambulatory blood pressure monitoring (ABPM), urinary microalbumin excretion (UAE), and glomerular filtration rate (GFR). All subjects underwent ABPM prospectively. For each gender, daytime, nighttime, and 24-h systolic and diastolic and mean blood pressures (SBP, DBP, and MAP) were transformed to standard deviation scores (SDS). Blood pressure profiles (SBP DBP, and MAP) were considered abnormal when the corresponding SDS values exceeded 1.63. Urinary microalbumin excretion was expressed as milligrams per day, and the value between 30 and 300 mg/day was defined as microalbuminuria (MA). There was no significant difference in the mean GFR and MA levels between late-preterm and term children. 24-h systolic BP SDS, daytime systolic BP SDS, nighttime systolic BP SDS, 24-h diastolic BP SDS, nighttime diastolic BP SDS, 24-h MAP BP SDS, daytime MAP BP SDS, and nighttime MAP BP SDS were found to be significantly higher in late-preterm children compared to term children. Conclusion: We conclude that late-preterm children have higher BP levels, so those children should be followed up carefully by the pediatrician regarding probable hypertension in their future life.

Gunnarsdóttir, Anna; Stenström, Pernilla; Arnbjörnsson, Einar (2008):

Wireless esophageal pH monitoring in children.

In: *Journal of Laparoendoscopic & Advanced Surgical Techniques* 18 (3), S. 443–447.

Abstract:

INTRODUCTION:

A wireless BRAVO (Medtronic, Shoreview, MN) capsule for pH measurement in the diagnosis of gastroesophageal reflux disease (GERD) is intended to be less uncomfortable, and facilitates activity during the measuring period, compared to the usual method with a naso-esophageal catheter. The aim of this study was to report on our experience with the wireless system in children. A secondary aim was to see if there was any cut-off level for esophageal acid exposure causing esophagitis as verified by pathologic examination.

MATERIALS AND METHODS:

A total of 62 wireless 24-hour pH measurements with the BRAVO capsule were carried out over a period of 2 years in 58 children with symptoms of GERD. The median age of the children was 8 +/- 4 years (range, 1-15). They underwent upper endoscopies and the placement of the capsule under general anesthesia. Correlations between endoscope findings and pathologic diagnosis were done.

RESULTS:

In 10 children, the endoscopies showed esophagitis. The median percent time of pH <4 was 7.0 +/- 9.6% (range, 0-61). The DeMeester score was abnormally high in 33 children. Three children described dysphagia during the measuring time. In 3 patients, we experienced technical problems with the wireless system. Biopsies were taken in 49 children, of which 18 showed esophagitis, with no correlation to the 24-hour pH-measurement findings.

CONCLUSIONS:

Ambulatory pH monitoring, using the wireless pH system, is feasible and was well tolerated by the children. No cut-off level for the acid exposure in correlation to pathologic diagnosis of esophagitis could be found. We recommend the use of the wireless pH-measurement system in children.

Gunter, Jedidiah D. (2012):

Examining experience in depressed and nondepressed individuals.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (1-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99140-162&site=ehost-live.

Abstract:

The inner experience of nine depressed and nine nondepressed individuals was explored using Descriptive Experience Sampling. Each participant completed four days of descriptive experience sampling, exploring about six moments of their inner experience on each sampling day. Although the Depressed participants self-reported substantially higher levels of depressive symptomatology on the Center for Epidemiological Studies Depression scale (CES-D) on each day of sampling, the differences in the frequency of depressive symptomatology in the inner experiences of these two groups were not statistically significant. Despite the group differences not reaching statistical significance, the Depressed group experienced somewhat more frequent moments of depression, anxiety, fatigue, body discomfort, negative feelings, negative content, and fewer instances of positive feelings and content than the Nondepressed group. The two groups experienced the five most frequent phenomena of inner experience identified in prior DES studies (inner seeing, inner speaking, unsymbolized thinking, feelings, and sensory awareness) at similar rates. Moments reflecting constructs related to depression, such as Beck's Negative Cognitive Triad, were either very infrequent or absent. Overall, differences in the inner experience of the depressed and nondepressed participants observed via descriptive experience sampling were much less pronounced than the differences in their global self-reports of depressive symptomatology via the CES-D. The implications and possible reasons for this are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Gupta-Malhotra, Monesha; Devereux, Richard B.; Dave, Archana; Bell, Cynthia; Portman, Ronald; Milewicz, Diana (2014):

Aortic dilatation in children with systemic hypertension.

In: *J Am Soc Hypertens. DOI:* 10.1016/j.jash.2014.01.002.

Abstract:

The aim of the study was to determine the presence of aortic dilatation in hypertensive children, the prevalence of which is 4% to 10% in hypertensive adults. Prospectively enrolled multiethnic children, untreated for their hypertension, underwent an echocardiogram to exclude congenital heart disease and evaluate for end-organ damage and aortic size. The aorta was measured in the parasternal long-axis view at three levels: the sinus of Valsalva, supra-tubular junction, and the ascending aorta. Aortic dilatation was determined by z-score >2 at any one of the levels measured. Hypertension was defined as blood pressure above the 95th percentile based on the Fourth Working Group criteria confirmed by 24-hour ambulatory blood pressure monitoring. Among 142 consecutive hypertensive children (median age, 14 years; 45% females) aortic dilatation was detected in 2.8% (95% confidence interval, 1%-7%; median age, 16 years; 100% females). Children with aortic dilatation, when compared with those without, had significantly more aortic valve insufficiency (P = .005) and left ventricular hypertrophy (P = .018). Prevalence of aortic dilatation was 2.8% and was associated with significantly more aortic insufficiency and left ventricular hypertrophy in comparison to those without aortic dilatation.

Gurrin, C.; Qiu, Z.; Hughes, M.; Caprani, N.; Doherty, A. R.; Hodges, S. E.; Smeaton, A. F. (2013):

The smartphone as a platform for wearable cameras in health research.

In: *Am J Prev.Med* 44 (3), S. 308–313. DOI: 10.1016/j.amepre.2012.11.010.

Abstract:

BACKGROUND: The Microsoft SenseCam, a small camera that is worn on the chest via a lanyard, increasingly is being deployed in health research. However, the SenseCam and other wearable cameras are not yet in widespread use because of a variety of factors. It is proposed that the ubiquitous smartphones can provide a more accessible alternative to SenseCam and similar devices. PURPOSE: To perform an initial evaluation of the potential of smartphones to become an alternative to a wearable camera such as the SenseCam. METHODS: In 2012, adults were supplied with a smartphone, which they wore on a lanyard, that ran life-logging software. Participants wore the smartphone for up to 1 day and the resulting life-log data were both manually annotated and automatically analyzed for the presence of visual concepts. The results were compared to prior work using the SenseCam. RESULTS: In total, 166,000 smartphone photos were gathered from 47 individuals, along with associated sensor readings. The average time spent wearing the device across all users was 5 hours 39 minutes (SD=4 hours 11 minutes). A subset of 36,698 photos was selected for manual annotation by five researchers. Software analysis of these photos supports the automatic identification of activities to a similar level of accuracy as for SenseCam images in a previous study. CONCLUSIONS: Many aspects of the functionality of a SenseCam largely can be replicated, and in some cases enhanced, by the ubiquitous smartphone platform. This makes smartphones good candidates for a new generation of wearable sensing devices in health research, because of their widespread use across many populations. It is envisioned that smartphones will provide a compelling alternative to the dedicated SenseCam hardware for a number of users and application areas. This will be achieved by integrating new types of sensor data, leveraging the smartphone's real-time connectivity and rich user interface, and providing support for a range of relatively sophisticated applications

Gustafson, David H.; McTavish, Fiona M.; Chih, Ming-Yuan; Atwood, Amy K.; Johnson, Roberta A.; Boyle, Michael G. et al. (2014):

A Smartphone Application to Support Recovery From Alcoholism: A Randomized Clinical Trial.

In: *JAMA Psychiatry. DOI:* 10.1001/jamapsychiatry.2013.4642.

Abstract:

IMPORTANCE Patients leaving residential treatment for alcohol use disorders are not typically offered evidence-based continuing care, although research suggests that continuing care is associated with better outcomes. A smartphone-based application could provide effective continuing care. OBJECTIVE To determine whether patients leaving residential treatment for alcohol use disorders with a smartphone application to support recovery have fewer risky drinking days than control patients. DESIGN, SETTING, AND PARTICIPANTS An unmasked randomized clinical trial involving 3 residential programs operated by 1 nonprofit treatment organization in the Midwestern United States and 2 residential programs operated by 1 nonprofit organization in the Northeastern United States. In total, 349 patients who met the criteria for DSM-IV alcohol dependence when they entered residential treatment were randomized to treatment as usual (n = 179) or treatment as usual plus a smartphone (n = 170) with the Addiction-Comprehensive Health Enhancement Support System (A-CHESS), an application designed to improve continuing care for alcohol use disorders. INTERVENTIONS Treatment as usual varied across programs; none offered patients coordinated continuing care after discharge. A-CHESS provides monitoring, information, communication, and support services to patients, including ways for patients and counselors to stay in contact. The intervention and follow-up period lasted 8 and 4 months, respectively. MAIN OUTCOMES AND MEASURES Risky drinking days-the number of days during which a patient's drinking in a 2-hour period exceeded 4 standard drinks for men and 3 standard drinks for women, with standard drink defined as one that contains roughly 14 g of pure alcohol (12 oz of regular beer, 5 oz of wine, or 1.5 oz of distilled spirits). Patients were asked to report their risky drinking days in the previous 30 days on surveys taken 4, 8, and 12 months after discharge from residential treatment. RESULTS For the 8 months of the intervention and 4 months of follow-up, patients in the A-CHESS group reported significantly fewer risky drinking days than did patients in the control group, with a mean of 1.39 vs 2.75 days (mean difference, 1.37; 95% CI, 0.46-2.27; P = .003). CONCLUSIONS AND RELEVANCE The findings suggest that a multifeatured smartphone application may have significant benefit to patients in continuing care for alcohol use disorders. TRIAL REGISTRATION clinicaltrials.gov Identifier: NCT01003119.

Haakstad, Lene A. H.; Gundersen, Ingvild; Bø, Kari (2010):

Self-reporting compared to motion monitor in the measurement of physical activity during pregnancy.

In: *Acta obstetricia et gynecologica Scandinavica* 89 (6), S. 749–756. DOI: 10.3109/00016349.2010.484482.

Abstract:

UNLABELLED\r\nMost pregnancy-studies have relied on retrospective, cross-sectional surveys to measure physical activity level. Questionnaires are cost-effective, but validity of the data may be questionable.\r\nOBJECTIVE\r\nThe aim of the present study was to validate a physical activity and pregnancy questionnaire (PAPQ) with a portable activity monitor (ActiReg).\r\nDESIGN\r\nProspective comparison study.\r\nSETTING\r\nHealthy pregnant women recruited in a capital area.\r\nPOPULATION\r\nSeventy-seven pregnant women wore the ActiReg sensors during waking hours for seven consecutive days and answered the PAPQ.\r\nMAIN OUTCOME MEASURES\r\nAgreement between the two methods was analyzed by Bland-Altman plots and Spearman correlation coefficients.\r\nRESULTS\r\nThe results indicated only small differences between the PAPQ and the ActiReg((R)) in cross-tabulation of total physical activity level and proportion of participants meeting the current exercise guidelines. The correlation between the methods was good (r = 0.59) for time spent in activities with high intensity (METS > 6), moderate for time spent standing/moving (r = 0.36) and fair for sitting/lying (r = 0.29). The Bland-Altman plot of the activity patterns, showed a mean difference near zero with no apparent trends and wide scatter of individual observations.\r\nCONCLUSIONS\r\nThe PAPQ may be considered an acceptable method for assessing habitual physical activity and exercise among pregnant women at group level. However, as questionnaires and portable activity monitors have their strengths in measuring different aspects of physical activity, there may be advantages in combining these two types of instruments for registrations of physical activity level during pregnancy.

Haar, Sherry; Fees, Bronwyn; Trost, Stewart; Crowe, Linda K.; Murray, Ann (2013):

Design of a garment for data collection of toddler language and physical activity.

In: *Clothing & Textiles Research Journal* 31 (2), S. 125–140. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-10758-005%26site%3dehost-live;haar@ksu.edu.

Abstract:

Design process phases of development, evaluation and implementation were used to create a garment to simultaneously collect reliable data of speech production and intensity of movement of toddlers (18-36 months). A series of prototypes were developed and evaluated that housed accelerometer-based motion sensors and a digital transmitter with microphone. The approved test garment was a top constructed from loop-faced fabric with interior pockets to house devices. Extended side panels allowed for sizing. In total, 56 toddlers (28 male; 28 female; 16-36 months of age) participated in the study providing pilot and baseline data. The test garment was effective in collecting data as evaluated for accuracy and reliability using ANOVA for accelerometer data, transcription of video for type of movement, and number and length of utterances for speech production. The data collection garment has been implemented in various studies across disciplines. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Haaren, Birte; Loeffler, Simone Nadine; Haertel, Sascha; Anastasopoulou, Panagiota; Stumpp, Juergen; Hey, Stefan; Boes, Klaus (2013):

Characteristics of the activity-affect association in inactive people: An ambulatory assessment study in daily life.

In: *Front Psychol* 4. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-16227-001%26site%3dehost-live;birte.haaren@kit.edu.

Abstract:

Acute and regular exercise as well as physical activity (PA) is related to well-being and positive affect. Recent studies have shown that even daily, unstructured physical activities increase positive affect. However, the attempt to achieve adherence to PA or exercise in inactive people through public health interventions has often been unsuccessful. Most studies analyzing the activity-affect association in daily life, did not report participants' habitual activity behavior. Thus, samples included active and inactive people, but they did not necessarily exhibit the same affective reactions to PA in daily life. Therefore the present study investigated whether the association between PA and subsequent affective state in daily life can also be observed in inactive individuals. We conducted a pilot study with 29 inactive university students (mean age 21.3 -&#65533; 1.7 years) using the method of ambulatory assessment. Affect was assessed via electronic diary and PA was measured with accelerometers. Participants had to rate affect every 2 h on a six item bipolar scale reflecting the three basic mood dimensions energetic arousal, valence, and calmness. We calculated activity intensity level [mean Metabolic Equivalent (MET) value] and the amount of time spent in light activity over the last 15 min before every diary prompt and conducted within-subject correlations. We did not find significant associations between activity intensity and the three mood dimensions. Due to the high variability in within-subject correlations we conclude that not all inactive people show the same affective reactions to PA in daily life. Analyzing the PA-affect association of inactive people was difficult due to little variance and distribution of the assessed variables. Interactive assessment and randomized controlled trials might help solving these problems. Future studies should examine characteristics of affective responses of inactive people to PA in daily life. General assumptions considering the relation between affect and PA might not be suitable for this target group. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Habets, P.; Collip, D.; Myin-Germeys, I.; Gronenschild, E.; Van, Bronswijk S.; Hofman, P. et al. (2011):

Pituitary volume, stress reactivity and genetic risk for psychotic disorder.

In: *Psychol Med* (0033-2917 (Linking)), S. 1–11. DOI: 10.1017/S0033291711002728.

Abstract:

BACKGROUND: Hypothalamic-pituitary-adrenal (HPA) axis hyperactivity, associated with increased pituitary volume, may mediate observed alterations in stress reactivity in patients with psychotic disorder. We examined the association between pituitary volume, real-life stress reactivity and genetic liability for psychotic disorder.MethodPituitary volumes were derived from magnetic resonance imaging (MRI) scans of 20 patients with psychotic disorder, 37 non-psychotic siblings of these patients, and 32 controls. The Experience Sampling Method (ESM) was used to measure emotional stress reactivity [changes in negative affect (NA) associated with daily life stress] in the three groups, and biological stress reactivity (changes in cortisol associated with daily life stress) in siblings and controls. Interactions between group, stress and pituitary volume in models of NA and cortisol were examined. RESULTS: Groups did not differ in pituitary volume. Patients showed significantly higher emotional stress reactivity than siblings and controls. In addition, emotional stress reactivity increased with increasing pituitary volume to a greater degree in patients than in controls and siblings. Siblings had higher cortisol levels than controls but did not show increased cortisol reactivity to stress. There was no interaction between pituitary volume, stress and group in the model of cortisol. CONCLUSIONS: Higher pituitary volume was associated with increased emotional stress reactivity in patients with psychotic disorder, siblings

and controls. The association was significantly stronger in the patient group, suggesting a process of progressive sensitization mediating clinical outcome

Development of a personal digital assistant (PDA) system to collect symptom information from home hospice patients.

In: *Journal of palliative medicine* 13 (6), S. 647–651. DOI: 10.1089/jpm.2009.0350.

Abstract:

PURPOSE\r\nPrevious studies have found that inappropriate assessment of cancer pain can lead to inadequate pain management. To improve assessment, it may be helpful to collect real-time data in a natural environment using computerized ecological momentary assessment (cEMA). Therefore, the aim of the study was to develop a personal digital assistant (PDA) system to collect information on symptoms such as pain and mood states in patients with cancer using cEMA.\r\nMETHODS\r\nFollowing a pilot study in inpatients with cancer, the second phase of the study involved patients with terminal cancer receiving home hospice care. These patients were asked to record their symptoms in a PDA (a palm-sized portable device) several times per day for a week when they took rescue medications and when an alarm sounded. At the end of the week, an interview on the usability of the device was conducted and overall response rates were calculated.\r\nRESULTS\r\nFifteen patients completed the second phase of the study. Their median age was 64 years and the median survival time after the study period was 22 days. The overall response rates were 90.3% to the sound of the alarm and 80.2% after taking rescue medications. The user-friendliness of the device was rated as 8.8 on a scale of 0 (worst) to 10 (best).\r\nCONCLUSIONS\r\nThe cEMA technique using a PDA might be applicable to patients with cancer in palliative care to evaluate symptoms in a natural setting. This system may also be useful for managing symptoms such as pain and mood states in patients with cancer.

Haedt-Matt, A. A.; Keel, P. K. (2011):

Hunger and binge eating: a meta-analysis of studies using ecological momentary assessment.

In: *Int J Eat.Disord.* 44 (7), S. 573–578. DOI: 10.1002/eat.20868.

Abstract:

OBJECTIVE: Binge eating has been associated with increased hunger, suggesting a role for impaired appetite regulation. Ecological momentary assessment (EMA) is ideally suited to examine whether hunger is a precipitant of binge eating but results from such studies have not been systematically reviewed. This study provides a meta-analysis of EMA studies that have examined hunger as an antecedent of binge eating. METHOD: Electronic database and manual searches produced seven EMA studies with N = 180 participants. Meta-analyses were conducted to compare: (1) pre-binge eating hunger to average ratings of hunger, and (2) pre-binge eating hunger to hunger before regular eating. RESULTS: Across studies, hunger was significantly greater before binge eating compared with average hunger ratings, but was significantly lower before binge eating compared with before other eating episodes. DISCUSSION: Excessive hunger does not appear to be a precipitant of binge eating because higher levels of hunger are observed before regular eating episodes. However, lower hunger before food consumption may contribute to the experience of a particular eating episode as a binge

Haffey, F.; Brady, R. R.; Maxwell, S. (2013):

A comparison of the reliability of smartphone apps for opioid conversion.

In: *Drug Saf* 36 (2), S. 111–117. DOI: 10.1007/s40264-013-0015-0.

Abstract:

BACKGROUND: Many medical professionals use smartphone applications (apps) on a daily basis to support clinical decision making. Opioid switching (conversion of one opioid to another at equianalgesic dose) is common in clinical practice and often challenging for doctors. Apps providing an opioid conversion tool can therefore be a useful resource. Despite rapid growth in the use of medical apps, the lack of robust regulation and peer review to ensure the accuracy and reliability of app content is currently an area of concern. METHOD: We searched major online app stores for apps providing an opioid dose conversion tool.

We assessed output variability between apps in the dose calculation of seven opioid switches, as well as assessing the level of professional medical involvement in the authorship, creation and design of the apps. RESULTS: Of 23 different apps identified, more than half (n = 12; 52 %) had no stated medical professional involvement and only 11 (48 %) apps provided direct references to primary sources for their opioid conversion ratios. Conversion of 1 mg of oral morphine to oral codeine demonstrated the largest conversion output range (median 6.67 mg, range 3.333-12 mg). Conversion of 1 mg of oral morphine to methadone ranged from 0.05-0.67 mg, with only 44 % of methadone-converting apps (n = 4) commenting that the conversion ratio changes with magnitude of methadone dose. Overall, 35 % of apps (n = 8) did not warn the user about the standard practice of dose reduction when opioid switching. There was a statistically significant difference in the mean conversion output for hydromorphone (oral) between apps with and without medical professional involvement (0.2256 vs 0.2536; p = 0.0377). CONCLUSIONS: There are significant concerns with regard to the reliability of information provided by apps offering opioid dose conversion, with lack of information regarding evidence-based content and peer review in many cases. It is crucial that better regulation of medical apps is instigated in order to ensure that patient safety is maintained

Haffey, F.; Brady, R. R.; Maxwell, S. (2013):

Smartphone apps to support hospital prescribing and pharmacology education: a review of current provision.

In: *Br.J Clin.Pharmacol.* (0306-5251 (Linking)). DOI: 10.1111/bcp.12112.

Abstract:

AIMS: Junior doctors write the majority of hospital prescriptions but many indicate they feel underprepared to assume this responsibility and around 10% of prescriptions contain errors. Medical smartphone apps are now widely used in clinical practice and present an opportunity to provide support to inexperienced prescribers. This study assesses the contemporary range of smartphone apps with prescribing or related content. METHODS: Six smartphone app stores were searched for apps aimed at the healthcare professional with drug, pharmacology or prescribing content. RESULTS: 306 apps were identified. 34% appeared to be for use within the clinical environment in order to aid prescribing, 14% out with the clinical setting, and 51% of apps were deemed appropriate for both clinical and non-clinical use. Apps with drug reference material, such as textbooks, manuals or medical apps with drug information were the commonest app found (51%), followed by apps offering drug or infusion rate dose calculation (26%). 68% of apps charged for download, with a mean price of pound14.25 per app and a range of pound0.62 - 101.90. CONCLUSIONS: A diverse range of pharmacology-themed apps are available and there is further potential for the development of contemporary apps to improve prescribing performance. Personalised app stores may help universities/healthcare organisations offer high-quality apps to students to aid in pharmacology education. Users of prescribing apps must be aware of the lack of information regarding the medical expertise of app developers; this will enable them to make informed choices about the use of such apps in their clinical practice

Hagins, Marshall; Rundle, Andrew; Consedine, Nathan S.; Khalsa, Sat Bir S. (2014):

A randomized controlled trial comparing the effects of yoga with an active control on ambulatory blood pressure in individuals with prehypertension and stage 1 hypertension.

In: *J Clin Hypertens (Greenwich)* 16 (1), S. 54–62. DOI: 10.1111/jch.12244.

Abstract:

The purpose of this study was to compare the effects of yoga with an active control (nonaerobic exercise) in individuals with prehypertension and stage 1 hypertension. A randomized clinical trial was performed using two arms: (1) yoga and (2) active control. Primary outcomes were 24-hour day and night ambulatory systolic and diastolic blood pressures. Within-group and between-group analyses were performed using paired t tests and repeated-measures analysis of variance (time x group), respectively. Eighty-four participants enrolled, with 68 participants completing the trial. Within-group analyses found 24-hour diastolic, night diastolic, and mean arterial pressure all significantly reduced in the yoga group (-3.93, -4.7, -4.23 mm Hg, respectively) but no significant within-group changes in the active control group. Direct comparisons of the yoga intervention with the control group found a single blood pressure variable (diastolic night) to be significantly different (P=.038). This study has demonstrated that a yoga intervention can lower blood pressure in patients with mild hypertension. Although this study was not adequately powered to show between-group differences, the size of the yoga-induced blood pressure reduction appears to justify performing a definitive trial of this intervention to test whether it can provide meaningful therapeutic value for the management of hypertension.

Hagstromer, Maria; Ainsworth, Barbara E.; Oja, Pekka; Sjostrom, Michael (2010):

Comparison of a subjective and an objective measure of physical activity in a population sample.

In: *J Phys Act Health* 7 (4), S. 541.

Abstract:

BACKGROUND:

The aim of this study was to compare physical activity components in the long, self-administrated version of IPAQ with an accelerometer in a population sample.

METHODS:

In total 980 subjects (18-65 years) wore an accelerometer (Actigraph) for 7 consecutive days and thereafter filled in the IPAQ. Measures of total physical activity, time spent in moderate and in vigorous activity as well as time spent sitting as assessed by the IPAQ and the Actigraph were compared.

RESULTS:

The results showed significant low to moderate correlations (Rs = 0.07-0.36) between the 2 instruments and significantly (P < .001) higher values for sitting and vigorous intensity physical activity from the IPAQ compared with the Actigraph. The higher the values reported by the IPAQ the bigger differences were seen between the instruments. Comparison between the tertiles of total physical activity by the 2 instruments showed significant overall association with consistent agreement in the low and the high tertiles.

CONCLUSION:

The long form of IPAQ is a valid measure of physical activity in population research. However, the IPAQ likely overestimates actual physical activity as shown by its limited ability to classify adults into low and high categories of physical activity based on accelerometer data.

Hagströmer, M.; Bergman, P.; Bourdeaudhuij, I.; Ortega, F. B.; Ruiz, J. R.; Manios, Y. et al. (2008):

Concurrent validity of a modified version of the International Physical Activity Questionnaire (IPAQ-A) in European adolescents: The HELENA Study.

In: *International journal of obesity (2005)* 32 Suppl 5, S. S42-8. DOI: 10.1038/ijo.2008.182.

Abstract:

INTRODUCTION\r\nThe International Physical Activity Questionnaire (IPAQ) was developed to measure health-enhancing physical activity in adult populations. This study explores the concurrent validity of a modified version of the long IPAQ (the IPAQ-A) for the assessment of physical activity among adolescents.\r\nPARTICIPANTS AND METHODS\r\nIn total, 248 healthy adolescents, divided into one older and one younger age group (aged 15-17 years (N=188) and 12-14 years (N=60), respectively) from nine Healthy Lifestyle by Nutrition in Adolescence (HELENA) Study centres across Europe, voluntarily participated in the study. Data on total physical activity, as well as activities in different intensities derived from the IPAQ-A, were compared using Spearman's correlation coefficient and Bland-Altman analysis, with data from an accelerometer. Tertiles of total physical activity for the IPAQ-A and the accelerometer were compared using Kendall's tau-b.\r\nRESULTS\r\nFor the older age group, significant correlations between the instruments were found for time spent walking, for moderate and vigorous activities as well as for total physical activity (Rs=0.17-0.30, P<0.05). No significant correlations were found for any of the variables studied in the younger age group. Kendall's tau-b showed low but significant correlations for tertiles of total physical activity (P<0.001).\r\nCONCLUSIONS\r\nThe IPAQ-A has reasonable validity properties for assessing activities in different intensities and for total physical activity in healthy European adolescents aged 15-17 years. For adolescents aged 14 years and younger, the correlations were unsatisfactorily low and objective methodology, such as accelerometry, may be the appropriate alternative.

Hagströmer, Maria; Oja, Pekka; Sjöström, Michael (2007):

Physical activity and inactivity in an adult population assessed by accelerometry.

In: *Med Sci Sports Exerc* 39 (9), S. 1502–1508.

Abstract:

INTRODUCTION:

Strong evidence suggests a link between physical inactivity and chronic disease prevalence in the adult population. To target the right groups for interventions in a population, accurate assessment of physical activity is important. The objective of this study was to assess the levels and pattern of physical activity and inactivity in an adult population sample using an objective method.

METHODS:

In total, 1114 adults (56% women, 45+/-15 yr), randomly recruited from the Swedish population across a year, used an accelerometer (Actigraph MTI) for seven consecutive days. Inactivity was defined as <100 counts per minute, and cutoff values for moderate and vigorous activity were 1952-5724 and >5724 counts per minute, respectively. Average intensity was measured as counts per minute.

RESULTS:

The adults were active in at least moderate-intensity activity for a median (intraquartile range) of 31 (18-47) min.d(-1). Fifty-two percent accumulated 30 min.d(-1) of at least moderate-intensity physical activity. Only 1% achieved those 30 min from three or more bouts of at least 10 min. Average intensity, moderate and vigorous physical activity was lower with higher age or body mass index (BMI). Men spent more time than women in moderate and vigorous physical activity, but there was no gender difference in average intensity. The variation in inactivity could not be explained by gender, age, or BMI.

CONCLUSION:

Objectively obtained estimates of physical activity yielded lower values and a different activity pattern compared with those obtained by commonly used self-reports. This highlights the need to better understand the nature and measurement issues of health-enhancing physical activity of adults.

Håkanson, Bengt S.; Berggren, Per; Granqvist, Staffan; Ljungqvist, Olle; Thorell, Anders (2009):

Comparison of wireless 48-h (Bravo) versus traditional ambulatory 24-h esophageal pH monitoring.

In: *Scandinavian journal of gastroenterology* 44 (3), S. 276–283. DOI: 10.1080/00365520802588109.

Abstract:

OBJECTIVE\r\nTo compare wireless with catheter-based esophageal pH recordings.\r\nMATERIAL AND METHODS\r\nForty-five patients with symptoms suggestive of gastroesophageal reflux disease and 47 healthy volunteers were investigated in a university-affiliated hospital; 48-h wireless esophageal pH recording was performed. During the first 24 h, simultaneous traditional pH recording by catheter was undertaken. Nine of the volunteers underwent repeated measurements with both techniques. Outcome measures were feasibility, agreement, concordance of diagnostic yield, reproducibility, and subjective symptoms.\r\nRESULTS\r\nSubjective parameters were less affected when using the wireless technique alone ($p<0.05$). On using the wireless technique, esophageal acid exposure was underestimated approximately by half compared with traditional recording ($p<0.05$). Although pH data obtained with the two techniques were correlated ($r(2)=0.66$, $p<0.001$), the range between limits of agreement was wide (-3.7 to 10.0 percentage units of total time pH <4). Coefficients of variation for repeated measurements were 60.1+/-26.3% for catheter recordings, and 66.0+/-47.3 for wireless recordings on day 1 (NS). Concordance of diagnostic yield was 81.5% with all subjects included.\r\nCONCLUSIONS\r\nForty-eight-hour wireless Bravo pH monitoring is feasible but consistently underestimates esophageal acid exposure compared to the conventional technique. Although there is a significant correlation between the two techniques for pH recordings, the wide range in limits of agreement and the large coefficient of variation with both techniques suggest that the two methods are not immediately interchangeable for use in clinical practice.

Halen, Nisha (2011):

A randomized controlled study of the acute and sustained effects of perceived racism on negative affect.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (1-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-99140-094&site=ehost-live.

Abstract:

Racism is a stressor that has significant effects on the psychological and physical wellbeing of individuals belonging to various ethnic and minority groups. Racism may affect health by increasing the intensity and frequency of negative affect. The aim of this study was to investigate how racism acts as a unique stressor, eliciting acute affect reactivity that extends from the laboratory into the field to produce sustained distress, as measured by daily affect. In a hybrid experimental design, 65 Black college students were randomly assigned to perform either a race-related stress task (RACE) or a social evaluation stress task

(TV). Participants rated 9 emotion states at baseline, pre-task, post-task and after recovery. Ecological momentary assessment (EMA) was used to collect diary ratings in the field for the remainder of the day. Participants completed measures of hope and rumination to test the mediating mechanisms through which racial stress produces sustained negative affect. Measures of lifetime perceived racism and trait anger were completed to test the moderating effects of experiential and personality variables. Analyses revealed a significant main effect of stress exposure on acute affect, whereby individuals in the RACE condition reported greater pre- to post-task increases in anger and hurt, and greater decreases in happiness. This association was moderated by lifetime perceived racism. Individuals exposed to racial stress who report greater lifetime perceived racism exhibited greater increases in negative affect immediately following stress exposure. The interaction of condition and acute helpless reactivity was a significant predictor of daily helplessness, such that participants who reported increases in helplessness in response to the RACE task later reported feeling less daily helplessness. In contrast, participants who reported more anger and helplessness in response to the TV task experienced significantly more anger and helplessness during the day in comparison to those who had less of an emotional reaction to the stress task. These findings suggest that race-related stress elicits acute emotional reactivity that may continue to influence mood beyond exposure to the original stressor. (PsycINFO Database Record (c) 2011 APA, all rights reserved)

Hall, Amanda K.; Dodd, Virginia; Harris, Amy; McArthur, Kara; Dacso, Clifford; Colton, Lara M. (2014):

Heart failure patients' perceptions and use of technology to manage disease symptoms.

In: *Telemed J E Health* 20 (4), S. 324–331. DOI: 10.1089/tmj.2013.0146.

Abstract:

Abstract Background: Technology use for symptom management is beneficial for both patients and physicians. Widespread acceptance of technology use in healthcare fuels continued development of technology with ever-increasing sophistication. Although acceptance of technology use in healthcare by medical professionals is evident, less is known about the perceptions, preferences, and use of technology by heart failure (HF) patients. This study explores patients' perceptions and current use of technology for managing HF symptoms (MHFS). Materials and Methods: A qualitative analysis of in-depth individual interviews using a constant comparative approach for emerging themes was conducted. Fifteen participants (mean age, 64.43 years) with HF were recruited from hospitals, cardiology clinics, and community groups. Results: All study participants reported use of a home monitoring device, such as an ambulatory blood pressure device or bathroom scale. The majority of participants reported not accessing online resources for additional MHFS information. However, several participants stated their belief that technology would be useful for MHFS. Participants reported increased access to care, earlier indication of a worsening condition, increased knowledge, and greater convenience as potential benefits of technology use while managing HF symptoms. For most participants financial cost, access issues, satisfaction with current self-care routine, mistrust of technology, and reliance on routine management by their current healthcare provider precluded their use of technology for MHFS. Conclusions: Knowledge about HF patients' perceptions of technology use for self-care and better understanding of issues associated with technology access can aid in the development of effective health behavior interventions for individuals who are MHFS and may result in increased compliance, better outcomes, and lower healthcare costs.

Hall, Scott S.; Hammond, Jennifer L.; Hustyi, Kristin M. (2013):

Examining the relationship between heart rate and problem behavior: a case study of severe skin picking in Prader-Willi syndrome.

In: *Am J Intellect Dev Disabil* 118 (6), S. 460–474. DOI: 10.1352/1944.7558-118.6.460.

Abstract:

Few studies have examined the relationship between heart rate and self-injurious behavior (SIB) shown by individuals with IDD (intellectual and developmental disabilities). In this single-case study, we simultaneously monitored heart rate and activity levels during a functional analysis of severe skin picking behavior exhibited by a young man with Prader-Willi syndrome (PWS). Results of the functional analysis indicated that the participant's skin picking was maintained by automatic reinforcement. A within-session analysis of the data indicated that skin picking bouts resulted in an increase in heart rate, suggesting a positive-automatic reinforcement function. These data indicate that inclusion of heart rate and activity-level monitoring during a functional analysis may provide important additional information concerning the determinants of SIB.

Hall, Charles B.; Lipton, Richard B.; Tennen, Howard; Haut, Sheryl R. (2009):

Early follow-up data from seizure diaries can be used to predict subsequent seizures in same cohort by borrowing strength across participants.

In: *Epilepsy Behav* 14 (3), S. 472–475. DOI: 10.1016/j.yebeh.2008.12.011.

Abstract:

Accurate prediction of seizures in persons with epilepsy offers opportunities for both precautionary measures and preemptive treatment. Previously identified predictors of seizures include patient-reported seizure anticipation, as well as stress, anxiety, and decreased sleep. In this study, we developed three models using 30 days of nightly seizure diary data in a cohort of 71 individuals with a history of uncontrolled seizures to predict subsequent seizures in the same cohort over a 30-day follow-up period. The best model combined the individual's seizure history with that of the remainder of the cohort, resulting in 72% sensitivity for 80% specificity, and 0.83 area under the receiver operating characteristic curve. The possibility of clinically relevant prediction should be examined through electronic data capture and more specific and more frequent sampling, and with patient training to improve prediction.

Hall, Martica H.; Matthews, Karen A.; Kravitz, Howard M.; Gold, Ellen B.; Buysse, Daniel J.; Bromberger, Joyce T. et al. (2008):

Race and Financial Strain are Independent Correlates of Sleep in Midlife Women: The SWAN Sleep Study.

In: *Sleep* 32 (1), S. 73–82. Online verfügbar unter http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2625326/.

Abstract:

STUDY OBJECTIVES:: To examine racial differences in sleep in a large cohort of midlife women and to evaluate whether indices of socioeconomic status (SES) are associated with racial differences in sleep. DESIGN:: Cross-sectional study. SETTING:: Participants' homes. PARTICIPANTS:: Caucasian (n = 171), African American (n = 138) and Chinese women (n = 59). INTERVENTIONS:: None. MEASUREMENTS:: Sleep quality was assessed with the Pittsburgh Sleep Quality Index. Polysomnographically assessed sleep duration, continuity, architecture, and NREM electroencephalograhic (EEG) power were calculated over multiple nights. Sleep disordered breathing and periodic leg movements were measured on a separate night. Linear regression analysis was used to model the independent and synergistic effects of race and SES on sleep after adjusting for other factors that impact sleep in midlife women. Indices of SES were self-reported educational attainment and financial strain. RESULTS:: Sleep was worse in African American women than Caucasian participants as measured by self-report, visual sleep stage scoring, and NREM EEG power. Slow wave sleep differences were also observed between Chinese and Caucasian participants. Racial differences persisted after adjustment for indices of SES. Although educational attainment was unrelated to sleep, financial strain was associated with decreased sleep quality and lower sleep efficiency. Financial strain-by-race interactions were not statistically significant, suggesting that financial strain has additive effects on sleep, independent of race. CONCLUSIONS:: Independent relationships between race and financial strain with sleep were observed despite statistical adjustment for other factors that might account for these relationships. Results do not suggest that assessed indices of SES moderate the race-sleep relationship, perhaps due to too few women of low SES in the study. CITATION:: Hall MH; Matthews KA; Kravitz HM; Gold EB; Buysse DJ; Bromberger JT; Owens JF; Sowers M. Race and financial strain are independent correlates of sleep in midlife women: the SWAN sleep study. SLEEP 2009;32(1):73-82.

Hall, Katherine S.; McAuley, Edward (2010):

Individual, social environmental and physical environmental barriers to achieving 10 000 steps per day among older women.

In: *Health education research* 25 (3), S. 478–488. DOI: 10.1093/her/cyq019.

Abstract:

UNLABELLED\r\nThis study examined the determinants of attaining/not attaining 10 000 steps per day among older women.\r\nMETHODS\r\nDaily step counts over 7 days were measured using accelerometry. Self-reported environmental characteristics, self-efficacy, social support and functional limitations were assessed in 128 older women. The presence of areas for activity within 1 km of each participant's residence was assessed using Geographic Information Systems. Multivariate analysis of variances were used to examine the degree to which these groups differed on measured constructs, and discriminant analysis was used to determine the profiles that discriminate among those who did not attain 10 000 steps per day and those who did.\r\nRESULTS\r\nParticipants who did not attain 10 000 steps per day reported lower self-efficacy ($P < 0.05$), greater functional limitations ($P < 0.05$), had significantly fewer walking paths ($P < 0.05$) within 1 km of their home and reported

significantly less street connectivity (P < 0.05) and safety from traffic (P < 0.05) than those who achieved 10 000 steps per day.\r\nCONCLUSION\r\nLack of perceived and actual environmental supports for walking, more functional limitations and lower self-efficacy are barriers to achieving 10 000 steps per day. The absence of these individual and environmental characteristics inhibits walking behavior in older women and should be considered in campaigns to promote a physically active lifestyle.

Hallal, Pedro C.; Simoes, Eduardo; Reichert, Felipe F.; Azevedo, Mario R.; Ramos, Luiz R.; Pratt, Michael; Brownson, Ross C. (2010):

Validity and reliability of the telephone-administered International Physical Activity Questionnaire in Brazil.

In: *J Phys Act Health* 7 (3), S. 402.

Abstract:

PURPOSE:

To evaluate the validity and reliability of the telephone-administered long IPAQ version.

METHODS:

The questionnaire was administered by telephone to adults on days 1 and 6. On day 1, the same questionnaire was administered by face-to-face interview, and accelerometers were delivered to subjects. Reliability was measured by comparing data collected using the telephone questionnaire on days 1 and 6. Validity was measured by comparing the telephone questionnaire data with (a) face-to-face questionnaire and (b) accelerometry.

RESULTS:

Data from all instruments were available for 156 individuals. The Spearman correlation coefficient for telephone interview reliability was 0.92 for the leisure-time section of IPAQ, and 0.87 for the transport-related section of IPAQ. The telephone interview reliability kappa was 0.78. The Spearman correlation between the telephone-administered and the face-to-face questionnaire was 0.94 for the leisure-time and 0.82 for the transport-related section. The kappa was 0.69. There was a positive association between quartiles of accelerometer data and total telephone-administered IPAQ score (P < .001). The Spearman correlation was 0.22.

CONCLUSIONS:

The telephone-administered IPAQ presented almost perfect reliability and very high agreement with the face-to-face version. The agreement with accelerometer data were fair for the continuous score, but moderate for the categorical physical activity variables.

Hallman, D. M.; Ekman, A. H.; Lyskov, E. (2013):

Changes in physical activity and heart rate variability in chronic neck-shoulder pain: monitoring during work and leisure time.

In: *Int.Arch.Occup.Environ.Health* (0340-0131 (Linking)). DOI: 10.1007/s00420-013-0917-2.

Abstract:

OBJECTIVES: Neck-shoulder pain (NSP) is a common work-related musculoskeletal disorder with unclear mechanisms. Changes in physical activity and autonomic nervous system regulation may be involved in the pathogenesis of chronic NSP. The aim of the current study was to investigate autonomic regulation in relation to physical activity and perceived symptoms during work and leisure time among workers with chronic NSP (n = 29) as compared to a healthy control group (CON, n = 27). METHODS: Physical activity was objectively monitored for 7 days using accelerometry. Beat-to-beat heart rate was collected continuously for 72 h, with simultaneous momentary ratings of pain, stress, and fatigue. Duration of sitting/lying, standing and walking, number of steps, and energy expenditure were used as measures of physical activity. Heart rate variability (HRV) indices were extracted in time and frequency domains as reflecting autonomic regulation. Data were divided into work hours, leisure time, and sleep. RESULTS: The NSP group rated higher levels of stress and fatigue at work and leisure, and reduced sleep quality as compared to CON. Elevated heart rate and reduced HRV were found in NSP compared with CON, especially during sleep. The NSP group demonstrated a different pattern of physical activity than CON, with a lower activity level in leisure time. Higher physical activity was associated with increased HRV in both groups. CONCLUSION: Changes in HRV reflected an autonomic imbalance in workers with chronic musculoskeletal pain. This can be explained by reduced physical activity in leisure time. Intervention studies aimed at increasing physical activity may shed further light on the association between autonomic regulation and physical activity in work-related NSP

Autonomic regulation, physical activity and perceived stress in subjects with musculoskeletal pain: 24-hour ambulatory monitoring.

In: *Int.J Psychophysiol.* 86 (3), S. 276–282. DOI: 10.1016/j.ijpsycho.2012.09.017.

Abstract:

The aim of the study was to investigate autonomic nervous system regulation, physical activity (PA) and perceived stress and energy during daily activities in subjects with chronic muscle pain in the neck-shoulders (trapezius myalgia) (n=23) and symptom-free controls (n=22). Subjects underwent 24-hour objective ambulatory monitoring of heart rate variability (HRV) and PA, and reported their perceived stress and energy in a diary. Standard HRV measures were extracted in time and frequency domains. The volume and pattern of different types of activities were quantified in terms of intensity and duration of walking, and time spent sitting, standing and lying during the 24-hour measurement. Results showed shortened inter-beat-intervals (higher heart rate) and reduced HRV in the pain group, most pronounced during sleep ($p<0.05$). For overall PA, the pain group showed increased lying time, compared to controls ($p<0.05$). A different activity pattern was found in the pain group, with reduced leisure time PA and increased PA during morning hours, in comparison with controls ($p<0.05$). Both groups demonstrated low levels of perceived stress, whereas reduced energy was observed in the pain group ($p<0.05$). In conclusion, monitoring of 24-hour HRV demonstrated diminished HRV among persons with chronic neck-shoulder pain. This reflected aberration in autonomic regulation, suggesting reduced parasympathetic activation and increased sympathetic tone as an element in maintenance of chronic muscle pain

Assessing the development and application of the accelerometry technique for estimating energy expenditure.

In: *Comparative Biochemistry and Physiology Part A: Molecular & Integrative Physiology* 158 (3), S. 305–314.

Abstract:

A theoretically valid proxy of energy expenditure is the acceleration of an animal's mass due to the movement of its body parts. Acceleration can be measured by an accelerometer and recorded onto a data logging device. Relevant studies have usually derived a measure of acceleration from the raw data that represents acceleration purely due to movement of the animal. This is termed 'overall dynamic body acceleration' (ODBA) and to date has proved a robust derivation of acceleration for use as an energy expenditure proxy. Acceleration data loggers are generally easy to deploy and the measures recorded appear robust to slight variation in location and orientation. This review discusses important issues concerning the accelerometry technique for estimating energy expenditure and ODBA; deriving ODBA, calibrating ODBA, acceleration logger recording frequencies, scenarios where ODBA is less likely to be valid, and the power in recording acceleration and heart rate together. While present evidence suggests that ODBA may not quantify energy expenditure during diving by birds and mammals, several recent studies have assessed changes in mechanical work in such species qualitatively through variation in ODBA during periods of submergence. The use of ODBA in field metabolic studies is likely to continue growing, supported by its relative ease of use and range of applications.

Pedometer-based gait training in children with spastic hemiparetic cerebral palsy: a randomized controlled study.

In: *Clinical Rehabilitation* 25 (2), S. 157–165.

Abstract:

OBJECTIVE:

To study the effect of pedometer-based gait training on changing gait parameters in children with spastic hemiparetic cerebral palsy.

DESIGN:

Two group randomized controlled trial with pre-treatment and post-treatment measures.

SETTING:

Rehabilitation clinics.

SUBJECTS:

Thirty spastic hemiparetic children with cerebral palsy of both sexes (13 females and 17 males) ranging in age from six to eight years old with mean age 7.05 ± 0.78 years.

INTERVENTIONS:

Children were randomized equally to receive pedometer-based gait training or a traditional gait training programme three times per week for three successive months.

MAIN MEASURES:

Assessment was done before and after three months of treatment application using 3D motion analysis system with six pro-reflex cameras to evaluate spatiotemporal gait parameters. The primary outcome measure was the walking velocity while the secondary outcome measures were stride length, cadence and cycle duration.

RESULTS:

There was a high statistically significant improvement in favour of the study group more than the control group concerning all the measured gait parameters. T-test results showed that velocity was 0.68 ± 0.09 m/sec (0.26 ± 0.07 change score) for study group and 0.42 ± 0.11 m/sec (0.06 ± 0.05 change score) for control group (t = 6.2) (P < 0.0001) while cadence was much less significant 124.3 ± 4.3 step/min (-5.8 ± 2.1 change score) for study group and 128.7 ± 4.1 step/min (-0.86 ± 0.05 change score) for control group (t = 2.8) (P < 0.008).

CONCLUSION:

Pedometer-based gait training is a useful tool that can be used in improving gait parameters in children with spastic hemiparetic cerebral palsy.

Hamer, Mark; Kivimaki, Mika; Steptoe, Andrew (2012):

Longitudinal patterns in physical activity and sedentary behaviour from mid-life to early old age: A substudy of the Whitehall II cohort.

In: *Journal of Epidemiology and Community Health* 66 (12), S. 1110–1115. DOI: 10.1037/t06708-000;

Abstract:

BACKGROUND:

There are few longitudinal data on physical activity patterns from mid-life into older age. The authors examined associations of self-reported physical activity, adiposity and socio-demographic factors in mid-life with objectively assessed measures of activity in older age.

METHODS:

Participants were 394 healthy men and women drawn from the Whitehall II population-based cohort study. At the baseline assessment in 1997 (mean age 54 years), physical activity was assessed through self-report and quantified as metabolic equivalent of task hours/week. At the follow-up in 2010 (mean age 66 years), physical activity was objectively measured using accelerometers worn during waking hours for seven consecutive days (average daily wear time 891 ± 68 min/day).

RESULTS:

Self-reported physical activity at baseline was associated with objectively assessed activity at follow-up in various activity categories, including light-, moderate- and vigorous-intensity activity (all ps<0.04). Participants in the highest compared with lowest quartile of self-reported activity level at baseline recorded on average 64.1 (95% CI 26.2 to 102.1) counts per minute more accelerometer-assessed activity at follow-up and 9.0 (2.0-16.0) min/day more moderate-to-vigorous daily activity, after adjusting for baseline covariates. Lower education, obesity and self-perceived health status were also related to physical activity at follow-up. Only age and education were associated with objectively measured sedentary time at follow-up.

CONCLUSION:

Physical activity behaviour in middle age was associated with objectively measured physical activity in later life after 13 years of follow-up, suggesting that the habits in adulthood are partly tracked into older age.

Fibromyalgia: The role of sleep in affect and in negative event reactivity and recovery.

In: *Health Psychol* 27 (4), S. 490.

Abstract:

OBJECTIVE:

Fibromyalgia (FM) syndrome is a chronic pain condition characterized by diffuse muscle pain, increased negative mood, and sleep disturbance. Until recently, sleep disturbance in persons with FM has been modeled as the result of the disease process or its associated pain. The current study examined sleep disturbance (i.e., sleep duration and sleep quality) as a predictor of daily affect, stress reactivity, and stress recovery.

DESIGN AND MEASURES:

A hybrid of daily diary and ecological momentary assessment methodology was used to evaluate the psychosocial functioning of 89 women with FM. Participants recorded numeric ratings of pain, fatigue, and positive and negative affect 3 times throughout the day for 30 consecutive days. At the end of each day, participants completed daily diary records of positive and negative life events. In addition, participants reported on their sleep duration and sleep quality each morning.

RESULTS:

After accounting for the effects of positive events, negative events, and pain on daily affect scores, it was found that sleep duration and quality were prospectively related to affect and fatigue. Furthermore, the effects of inadequate sleep on negative affect were cumulative. In addition, an inadequate amount of sleep prevented affective recovery from days with a high number of negative events.

CONCLUSIONS:

These results lend support to the hypothesis that sleep is a component of allostatic load and has an upstream role in daily functioning.

Adherence to Antidepressant Medications: A Randomized Controlled Trial of Medication Reminding in College Students.

In: *J Am Coll Health*, S. 0. DOI: 10.1080/07448481.2014.975716.

Abstract:

Abstract. Objectives: To determine if medication reminding via smartphone app increases adherence to antidepressant medications in college students. Participants: College students (N = 57) enrolled at a state-funded institution who had a current prescription for an antidepressant and regularly used a smartphone device. Methods: Participants were randomized to either a reminder group or a control group. Both groups were asked to complete a survey and undergo a manual pill count at the beginning of the study and 30-days later. Results: There was a strong trend suggesting that the use of a medication reminder app was beneficial for adherence to antidepressant medication regimens. Factors influencing medication adherence in college students included health beliefs, use of illicit drugs, and type of professional care received. Conclusions: Use of a medication reminder may increase adherence to antidepressant medications in college students.

Medical students' online learning technology needs.

In: *Clin Teach* 11 (1), S. 15–19. DOI: 10.1111/tct.12092.

Abstract:

PURPOSE: This study investigated medical students' online learning technology needs at a medical school. The study aimed to provide evidence-based guidance for technology selection and online learning design in medical education. METHODS: The authors developed a 120-item survey in collaboration with the New Technology in Medical Education (NTIME) committee at the Southern Illinois University School of Medicine (SIUSOM). Overall, 123 of 290 medical students (42%) at the medical school participated in the survey. The survey focused on five major areas: students' hardware and software use; perception of educational technology (ET) in general; online behaviours; perception of ET use at the school; and demographic information. RESULTS: Students perceived multimedia tools, scheduling tools, communication tools, collaborative authoring tools, learning

management systems and electronic health records useful educational technologies for their learning. They did not consider social networking tools useful for their learning, despite their frequent use. Third-year students were less satisfied with current technology integration in the curriculum, information sharing and collaborative learning than other years. Students in clerkships perceived mobile devices as useful for their learning. Students using a mobile device (i.e. a smartphone) go online, text message, visit social networking sites and are online during classes more frequently than non-users. CONCLUSIONS: Medical students' ET needs differ between preclinical and clinical years. Technology supporting ubiquitous mobile learning and health information technology (HIT) systems at hospitals and out-patient clinics can be integrated into clerkship curricula.

Comprehensive context recognizer based on multimodal sensors in a smartphone.

In: *Sensors.(Basel)* 12 (9), S. 12588–12605. DOI: 10.3390/s120912588.

Abstract:

Recent developments in smartphones have increased the processing capabilities and equipped these devices with a number of built-in multimodal sensors, including accelerometers, gyroscopes, GPS interfaces, Wi-Fi access, and proximity sensors. Despite the fact that numerous studies have investigated the development of user-context aware applications using smartphones, these applications are currently only able to recognize simple contexts using a single type of sensor. Therefore, in this work, we introduce a comprehensive approach for context aware applications that utilizes the multimodal sensors in smartphones. The proposed system is not only able to recognize different kinds of contexts with high accuracy, but it is also able to optimize the power consumption since power-hungry sensors can be activated or deactivated at appropriate times. Additionally, the system is able to recognize activities wherever the smartphone is on a human's body, even when the user is using the phone to make a phone call, manipulate applications, play games, or listen to music. Furthermore, we also present a novel feature selection algorithm for the accelerometer classification module. The proposed feature selection algorithm helps select good features and eliminates bad features, thereby improving the overall accuracy of the accelerometer classifier. Experimental results show that the proposed system can classify eight activities with an accuracy of 92.43%

Analysis and Prediction of the Freezing of Gait using EEG Brain Dynamics.

In: *IEEE Trans Neural Syst Rehabil Eng. DOI:* 10.1109/TNSRE.2014.2381254.

Abstract:

Freezing of Gait (FOG) is a common symptom in the advanced stages of Parkinson's disease (PD), which significantly affects patients' quality of life. Treatment options offer limited benefit and there are currently no mechanisms able to effectively detect FOG before it occurs, allowing time for a sufferer to avert a freezing episode. Electroencephalography (EEG) offers a novel technique that may be able to address this problem. In this paper, we investigated the univariate and multivariate EEG features determined by both Fourier and wavelet analysis in the confirmation and prediction of FOG. The EEG power measures and network properties from 16 patients with PD and FOG were extracted and analyzed. It was found that both power spectral density and wavelet energy could potentially act as biomarkers during FOG. Information in the frequency domain of the EEG was found to provide better discrimination of EEG signals during transition to freezing than information coded in the time domain. The performance of the FOG prediction systems improved when the information from both domains was used. This combination resulted in a sensitivity of 86.0%, specificity of 74.4%, and accuracy of 80.2% when predicting episodes of freezing, outperforming current accelerometry-based tools for the prediction of FOG.

Hanlon, Michael; Anderson, Ross (2009):

Real-time gait event detection using wearable sensors.

In: *Gait Posture* 30 (4), S. 523–527. DOI: 10.1016/j.gaitpost.2009.07.128.

Abstract:

Real-time gait event detection is a requirement for functional electrical stimulation and gait biofeedback. This gait event detection should ideally be achieved using an ambulatory system of durable, lightweight, low-cost sensors. Previous research has reported issues with durability in footswitch systems. Therefore, this study describes the development and assessment of novel detection algorithms using footswitch and accelerometer sensors on 12 healthy individuals. Subjects were equipped with

one force sensitive resistor on the heel, one accelerometer at the foot, and one accelerometer at the knee. Subjects performed 10, 8-m walking trials in each of three conditions: normal, slow, and altered (reduced knee ROM) walking. Data from a subset of four subjects were used to develop prediction algorithms for initial contact (IC). Subsequently, these algorithms were tested on the remaining eight subjects against standard forceplate IC data (threshold of 5 N on a rising edge). The footswitch force threshold algorithm was most accurate for IC detection (mean absolute error of 2.4+/-2.1 ms) and was significantly more accurate ($p<0.001$) than the optimal accelerometer algorithm (mean absolute error of 9.5+/-9.0 ms). The optimal accelerometer algorithm used data from both accelerometers, with IC determined from the second derivative of foot fore-aft acceleration. The error results for footswitch and accelerometer algorithms are lower (approximately 60%) than in previous research on ambulatory real-time gait event detection systems. Currently, footswitch systems must be recommended over accelerometer systems for accurate detection of IC, however, further research into accelerometer algorithms is merited due to its advantages as a durable, low-cost sensor.

Hanlon, Erin; Bir, Cynthia (2010):

Validation of a wireless head acceleration measurement system for use in soccer play.

In: *J Appl Biomech* 26 (4), S. 424–431.

Abstract:

Soccer heading has been studied previously with conflicting results. One major issue is the lack of knowledge regarding what actually occurs biomechanically during soccer heading impacts. The purpose of the current study is to validate a wireless head acceleration measurement system, head impact telemetry system (HITS) that can be used to collect head accelerations during soccer play. The HIT system was fitted to a Hybrid III (HIII) head form that was instrumented with a 3-2-2-2 accelerometer setup. Fifteen impact conditions were tested to simulate impacts commonly experienced during soccer play. Linear and angular acceleration were calculated for both systems and compared. Root mean square (RMS) error and cross correlations were also calculated and compared for both systems. Cross correlation values were very strong with $r = .95 \pm 0.02$ for ball to head forehead impacts and $r = .96 \pm 0.02$ for head to head forehead impacts. The systems showed a strong relationship when comparing RMS error, linear head acceleration, angular head acceleration, and the cross correlation values.

Anthropometric and demographic correlates of dual-axis swallowing accelerometry signal characteristics: a canonical correlation analysis.

In: *Dysphagia* 25 (2), S. 94–103. DOI: 10.1007/s00455-009-9229-9.

Abstract:

Swallowing accelerometry has been proposed as a potential minimally invasive tool for collecting assessment information about swallowing. The first step toward using sounds and signals for dysphagia detection involves characterizing the healthy swallow. The purpose of this article is to explore systematic variations in swallowing accelerometry signals that can be attributed to demographic factors (such as participant gender and age) and anthropometric factors (such as weight and height). Data from 50 healthy participants (25 women and 25 men), ranging in age from 18 to 80 years and with approximately equal distribution across four age groups (18-35, 36-50, 51-65, 66 and older) were analyzed. Anthropometric and demographic variables of interest included participant age, gender, weight, height, body fat percent, neck circumference, and mandibular length. Dual-axis (superior-inferior and anterior-posterior) swallowing accelerometry signals were obtained for five saliva and five water swallows per participant. Several swallowing signal characteristics were derived for each swallowing task, including variance, amplitude distribution skewness, amplitude distribution kurtosis, signal memory, total signal energy, peak energy scale, and peak amplitude. Canonical correlation analysis was performed between the anthropometric/demographic variables and swallowing signal characteristics. No significant linear relationships were identified for saliva swallows or for superior-inferior axis accelerometry signals on water swallows. In the anterior-posterior axis, signal amplitude distribution kurtosis and signal memory were significantly correlated with age ($r = 0.52$, $P = 0.047$). These findings suggest that swallowing accelerometry signals may have task-specific associations with demographic (but not anthropometric) factors. Given the limited sample size, our results should be interpreted with caution and replication studies with larger sample sizes are warranted.

Hannon, James C.; Brown, Barbara B. (2008):

Increasing preschoolers' physical activity intensities: an activity-friendly preschool playground intervention.

In: *Prev Med* 46 (6), S. 532–536.

Abstract:

OBJECTIVE:

The purpose of this study was to see if portable play equipment added to a preschool playground resulted in higher intensities of physical activity among 3-5-year-old children.

METHODS:

Activity-friendly equipment was added to an outdoor preschool playground. Accelerometry-measured intensities of 15-s epochs of physical activity were tracked for 5 pre-intervention and 5 post-intervention days during outdoor play. Data were collected during fall 2005 in Salt Lake City for 64 preschoolers aged 3, 4, and 5 years.

RESULTS:

After the intervention, both male and female 3- to 5-year-olds significantly decreased sedentary behavior and significantly increased light, moderate, and vigorous physical activity as measured by accelerometry.

CONCLUSIONS:

Results suggest simple interventions, requiring little teacher training, can yield increases in healthy physical activity.

Hansen, A. L.; Carstensen, B.; Helge, J. W.; Johansen, N. B.; Gram, B.; Christiansen, J. S. et al. (2013):

Combined Heart Rate- and Accelerometer-Assessed Physical Activity Energy Expenditure and Associations With Glucose Homeostasis Markers in a Population at High Risk of Developing Diabetes: The ADDITION-PRO Study.

In: *Diabetes Care* (0149-5992 (Linking)). DOI: 10.2337/dc12-2671.

Abstract:

OBJECTIVERegular physical activity (PA) reduces the risk of developing type 2 diabetes, and different subtypes of dysglycemia have shown different associations with PA. To better understand the associations of PA and glucose homeostasis, we examined the association of objectively measured PA energy expenditure (PAEE) with detailed measures of glucose homeostasis.RESEARCH DESIGN AND METHODSIn 1,531 men and women, with low to high risk of developing type 2 diabetes, we measured 7 days of PAEE using a combined accelerometry and heart rate monitor (ActiHeart). Measures and indices of glucose homeostasis were derived from a 3-point oral glucose tolerance test in addition to measures of long-term glycemia (glycated hemoglobin A1c and advanced glycation end products). Associations of PAEE with glucose homeostasis markers were examined using linear regression models.RESULTSMedian age (IQR) was 66.6 years (62.1-71.6) (54% men) with a median ActiHeart wear time of 6.9 days (6.0-7.1) and PAEE level of 33.0 kJ/kg/day (23.5-46.1). In fully adjusted models, we found higher levels of PAEE to be positively associated with insulin sensitivity and negatively with insulin 2 h after glucose load ($P < 0.05$).CONCLUSIONSEven in an elderly population with low levels of PA, we found higher objectively measured PAEE levels to be associated with a more beneficial glucose metabolic profile. Although our findings are cross-sectional, they indicate that even without high-intensity exercise, increasing the overall level of PAEE slightly in an entire population at risk for developing type 2 diabetes may be a realistic and worthwhile goal to reach in order to achieve beneficial effect in terms of glucose metabolism

Hansen, Tine W.; Li, Yan; Boggia, José; Thijs, Lutgarde; Richart, Tom; Staessen, Jan A. (2011):

Predictive role of the nighttime blood pressure.

In: *Hypertension* 57 (1), S. 3–10. DOI: 10.1161/HYPERTENSIONAHA.109.133900.

Abstract:

Numerous studies addressed the predictive value of the nighttime blood pressure (BP) as captured by ambulatory monitoring. However, arbitrary cutoff limits in dichotomized analyses of continuous variables, data dredging across selected subgroups, extrapolation of cross-sectional studies to prospective outcomes, and lack of comprehensive adjustments for confounders make interpretation of the literature difficult. We reviewed prospective studies with total mortality or a composite cardiovascular end point as an outcome in relation to the level and the circadian profile of systolic BP. We analyzed studies in hypertensive patients

(n = 23 856) separately from those in individuals randomly recruited from populations (n = 9641). We pooled summary statistics and individual subject data, respectively. In both patients and populations, in analyses in which nighttime BP was additionally adjusted for daytime BP and vice versa, nighttime BP was a stronger predictor than daytime BP. With adjustment for the 24-hour BP, both the night-to-day BP ratio and dipping status remained significant predictors of outcome but added little prognostic value over and beyond the 24-hour BP level. In the absence of conclusive evidence proving that nondipping is a reversible risk factor, the option whether or not to restore the diurnal blood pressure profile to a normal pattern should be left to the clinical judgment of doctors and should be individualized for each patient. Current guidelines on the interpretation of ambulatory BP recording need to be updated.

Hansen, Tine W.; Thijs, Lutgarde; Boggia, José; Li, Yan; Kikuya, Masahiro; Björklund-Bodegård, Kristina et al. (2008):

Prognostic value of ambulatory heart rate revisited in 6928 subjects from 6 populations.

In: *Hypertension* 52 (2), S. 229–235.

Abstract:

The evidence relating mortality and morbidity to heart rate remains inconsistent. We performed 24-hour ambulatory blood pressure monitoring in 6928 subjects (not on beta-blockers; mean age: 56.2 years; 46.5% women) enrolled in prospective population studies in Denmark, Belgium, Japan, Sweden, Uruguay, and China. We computed standardized hazard ratios for heart rate, while stratifying for cohort, and adjusting for blood pressure and other cardiovascular risk factors. Over 9.6 years (median), 850, 325, and 493 deaths accrued for total, cardiovascular, and noncardiovascular mortality, respectively. The incidence of fatal combined with nonfatal end points was 805, 363, 439, and 324 for cardiovascular, stroke, cardiac, and coronary events, respectively. Twenty-four-hour heart rate predicted total (hazard ratio: 1.15) and noncardiovascular (hazard ratio: 1.18) mortality but not cardiovascular mortality (hazard ratio: 1.11) or any of the fatal combined with nonfatal events (hazard ratio: < or =1.02). Daytime heart rate did not predict mortality (hazard ratio: < or =1.11) or any fatal combined with nonfatal event (hazard ratio: < or =0.96). Nighttime heart rate predicted all of the mortality outcomes (hazard ratio: > or =1.15) but none of the fatal combined with nonfatal events (hazard ratio: < or =1.11). The night:day heart rate ratio predicted total (hazard ratio: 1.14) and noncardiovascular mortality (hazard ratio: 1.12) and all of the fatal combined with nonfatal events (hazard ratio: > or =1.15) with the exception of stroke (hazard ratio: 1.06). Sensitivity analyses, in which we stratified by risk factors or from which we excluded 1 cohort at a time or the events occurring within 2 years of enrollment, showed consistent results. In the general population, heart rate predicts total and noncardiovascular mortality. With the exception of the night:day heart rate ratio, heart rate did not add to the risk stratification for fatal combined with nonfatal cardiovascular events. Thus, heart rate adds little to the prediction of cardiovascular risk.

Hansen, T. W.; Thijs, L.; Li, Y.; Boggia, J.; Liu, Y.; Asayama, K. et al. (2014):

Ambulatory blood pressure monitoring for risk stratification in obese and non-obese subjects from 10 populations.

In: *J Hum Hypertens. DOI:* 10.1038/jhh.2013.145.

Abstract:

Overweight clusters with high blood pressure (BP), but the independent contribution of both risk factors remains insufficiently documented. In a prospective population study involving 8467 participants (mean age 54.6 years; 47.0% women) randomly recruited from 10 populations, we studied the contribution of body mass index (BMI) to risk over and beyond BP, taking advantage of the superiority of ambulatory over conventional BP. Over 10.6 years (median), 1271 participants (15.0%) died and 1092 (12.9%), 637 (7.5%) and 443 (5.2%) experienced a fatal or nonfatal cardiovascular, cardiac or cerebrovascular event. Adjusted for sex and age, low BMI (<20.7 kg m-2) predicted death (hazard ratio (HR) vs average risk, 1.52; P<0.0001) and high BMI (>/=30.9 kg m-2) predicted the cardiovascular end point (HR, 1.27; P=0.006). With adjustments including 24-h systolic BP, these HRs were 1.50 (P<0.001) and 0.98 (P=0.91), respectively. Across quartiles of the BMI distribution, 24-h and nighttime systolic BP predicted every end point (1.13</=standardized HR </=1.67; 0.046 </=P<0.0001). The interaction between systolic BP and BMI was nonsignificant (P>/=0.22). Excluding smokers removed the contribution of BMI categories to the prediction of mortality. In conclusion, BMI only adds to BP in risk stratification for mortality but not for cardiovascular outcomes. Smoking probably explains the association between increased mortality and low BMI.Journal of Human Hypertension advance online publication, 16 January 2014; doi:10.1038/jhh.2013.145.

Hanson, Margaret D.; Chen, Edith (2010):

Daily stress, cortisol, and sleep: the moderating role of childhood psychosocial environments.

In: *Health Psychol* 29 (4), S. 394–402. DOI: 10.1037/a0019879.

Abstract:

OBJECTIVE\r\nThe purpose of this study was to explore whether childhood family environments moderated the relation between daily stress and daily biological outcomes (sleep, cortisol output) in healthy young adults.\r\nDESIGN\r\nThere were 87 participants, ages 19 to 25 who provided information on characteristics of their childhood family environment (conflict, parental warmth).\r\nMAIN OUTCOME MEASURES\r\nFor 1 week they completed a daily stress checklist via electronic diary, provided salivary cortisol samples 4 times a day, and wore an Actiwatch to measure sleep (minutes, efficiency). Data was analyzed using hierarchical linear modeling.\r\nRESULTS\r\nFamily risk significantly moderated the relation between daily number of stressors and sleep minutes (b = -12.10, p = .02), such that the more difficult one's childhood environment, the less sleep individuals got on days in which they experienced a greater number of stressors. Parental warmth moderated the relation between stress severity and cortisol output (b = -0.19, p = .04), such that the less parental warmth individuals received during childhood, the more cortisol they secreted on days that they experienced more severe stress.\r\nCONCLUSIONS\r\nThe childhood psychosocial environment may have long-term effects on biological responses to daily stress, creating vulnerability to disease in individuals from difficult childhoods.

Hanss, R.; Block, D.; Bauer, M.; Ilies, C.; Magheli, A.; Schildberg-Schroth, H. et al. (2008):

Use of heart rate variability analysis to determine the risk of cardiac ischaemia in high-risk patients undergoing general anaesthesia.

In: *Anaesthesia* 63 (11), S. 1167–1173. DOI: 10.1111/j.1365-2044.2008.05602.x.

Abstract:

The aim of this study was to investigate the use of pre-operative heart rate variability analysis to predict postoperative cardiac events (identified by 24 h Holter-ECG recording and an increase of creatine kinase MB) in high-risk cardiac patients. Length of hospital stay, the incidence of postoperative cardiac ischaemia and cardiac events after discharge were recorded. Fifty patients were assigned by the presence of cardiac events and the heart rate variability in 17 patients with an event was compared with 33 patients without. Total power was identified as a predictive parameter. The usefulness of this test was assessed in a second group of 50 patients. The incidence of cardiac events detected by Holter-ECG recording or an increased creatine kinase MB was greater and the duration of hospital stay longer in the 26 patients with total power < 400 ms(2).Hz(-1) compared with those with total power > 400 ms(2).Hz(-1) (eight and four patients and 10 (7) days (mean (SD)), vs 1 ($p < 0.05$) and 0 ($p < 0.05$) patients and 6 (2) days ($p < 0.05$), respectively). The total power of high-risk cardiac patients predicted postoperative cardiac events and extended length of hospital stay.

Acute effects of night-time noise exposure on blood pressure in populations living near airports.

In: *Eur Heart J* 29 (5), S. 658–664.

Abstract:

AIMS:

Within the framework of the HYENA (hypertension and exposure to noise near airports) project we investigated the effect of short-term changes of transportation or indoor noise levels on blood pressure (BP) and heart rate (HR) during night-time sleep in 140 subjects living near four major European airports.

METHODS AND RESULTS:

Non-invasive ambulatory BP measurements at 15 min intervals were performed. Noise was measured during the night sleeping period and recorded digitally for the identification of the source of a noise event. Exposure variables included equivalent noise level over 1 and 15 min and presence/absence of event (with LAmax > 35 dB) before each BP measurement. Random effects models for repeated measurements were applied. An increase in BP (6.2 mmHg (0.63-12) for systolic and 7.4 mmHg (3.1, 12) for diastolic) was observed over 15 min intervals in which an aircraft event occurred. A non-significant increase in HR was also

observed (by 5.4 b.p.m.). Less consistent effects were observed on HR. When the actual maximum noise level of an event was assessed there were no systematic differences in the effects according to the noise source.

CONCLUSION:

Effects of noise exposure on elevated subsequent BP measurements were clearly shown. The effect size of the noise level appears to be independent of the noise source.

Dimensions of family connectedness among adolescents with Mexican, Chinese, and European backgrounds.

In: *Developmental Psychology* 42 (6), S. 1246–1258. DOI: 10.1037/0012-1649.42.6.1246.

Abstract:

Multiple dimensions of adolescents' connectedness with their families were investigated among 489 9th-grade students (M = 14.86 years) from families with Mexican, Chinese, and European backgrounds. Participants reported on various aspects of their family relationships and completed diary checklists of daily behaviors for a 2-week period. Adolescents from European backgrounds reported levels of family identification and dyadic closeness with parents similar to or greater than those reported by their peers. For adolescents from Mexican and Chinese backgrounds, particularly those from immigrant families, family connectedness included a stronger emphasis on family obligation and assistance. The extent to which family demographic variables, including parental level of education and residence in a single-parent family, accounted for group differences was examined.

The use of handheld technology in nursing research and practice.

In: *Orthopaedic Nursing* 26 (4), S. 251–255.

Abstract:

Use of handheld devices with electronic patient diaries (EPDs) can improve the quality of patient-reported information collected in clinical and research settings. EPDs have advantages compared with traditional paper-based instruments that include decreased data entry error and decreased time spent on data management. Orthopaedic pain management, which is often dependent on patient-reported pain levels, can benefit from the use of EPDs. A pilot survey was conducted to compare two self-report pain diary methods in shoulder surgery patients: (a) EPD or (b) paper entry. Compliance was lower in the EPD group, which was attributed to insufficient ease of use. Handheld technology can be used by nurses to improve and streamline patient care by capturing clinical data, by organizing and reporting home health services, and by providing references for evidence-based practice. Handheld technology can facilitate the transformation of clinical documentation of assessments, interventions, and outcomes into evidence-based decision making in orthopaedic nursing.

Hardy, Sam A.; Zhang, Zhiyong; Skalski, Jonathan E.; Melling, Brent S.; Brinton, Chauncy T. (2014):

Daily religious involvement, spirituality, and moral emotions.

In: *Psychology of Religion and Spirituality* 6 (4), S. 338–348. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-33990-001%26site%3dehost-live.

Abstract:

This study examined relations among intraindividual variability in daily religious activities, daily spiritual experiences, and daily moral emotions (empathy, gratitude, and forgiveness). We hypothesized that spiritual experiences would mediate relations between religious activities and moral emotions, the quality of religious activities would moderate links to spiritual experiences, and the quality of spiritual experiences would moderate links to moral emotions. The sample included 139 individuals ages 18–69 who completed daily online surveys for up to 50 days. Participants completed multiple daily items reporting their religious activities, spiritual experiences, and moral emotions. Multilevel regression analyses found that daily religious activities were linked to daily moral emotions by way of daily spiritual experiences. Furthermore, the quality of the daily religious activities and spiritual experiences moderated links in the mediation model. Thus, we found evidence of mediating and moderating processes

in associations between religious activities, spiritual experiences, and moral emotions on a daily basis. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Anxiety in Asperger's syndrome: Assessment in real time.

In: *Autism. DOI:* 10.1177/1362361314531340.

Abstract:

Anxiety is a major problem for many people with Asperger's syndrome who may have qualitatively different fears from a non-Asperger's syndrome population. Research has relied on measures developed for non-Asperger's syndrome populations that require reporting past experiences of anxiety, which may confound assessment in people with Asperger's syndrome due to problems with autobiographical memory as are often reported in this group.Experience sampling methodology was used to record real-time everyday experiences in 20 adults with Asperger's syndrome and 20 neurotypical adults. Within-subject analysis was used to explore the phenomenology of thoughts occurring in people with Asperger's syndrome when they were anxious. Comparisons were made with the group that did not have Asperger's syndrome. The Asperger's syndrome group were significantly more anxious than the comparison group. Factors associated with feelings of anxiety in the Asperger's syndrome group were high levels of self-focus, worries about everyday events and periods of rumination lasting over 10 min. People in the Asperger's syndrome group also had a tendency to think in the image form, but this was not associated with feelings of anxiety. The results are discussed with reference to psychological models of Asperger's syndrome, cognitive models of anxiety and implications for psychological therapy for this group.

Estimating posture-recognition performance in sensing garments using geometric wrinkle modeling.

In: *Information Technology in Biomedicine, IEEE Transactions on* 14 (6), S. 1436–1445.

Abstract:

A fundamental challenge limiting information quality obtained from smart sensing garments is the influence of textile movement relative to limbs. We present and validate a comprehensive modeling and simulation framework to predict recognition performance in casual loose-fitting garments. A statistical posture and wrinkle-modeling approach is introduced to simulate sensor orientation errors pertained to local garment wrinkles. A metric was derived to assess fitting, the body-garment mobility. We validated our approach by analyzing simulations of shoulder and elbow rehabilitation postures with respect to experimental data using actual casual garments. Results confirmed congruent performance trends with estimation errors below 4% for all study participants. Our approach allows to estimate the impact of fitting before implementing a garment and performing evaluation studies with it. These simulations revealed critical design parameters for garment prototyping, related to performed body posture, utilized sensing modalities, and garment fitting. We concluded that our modeling approach can substantially expedite design and development of smart garments through early-stage performance analysis.

What factors are associated with physical activity in older people, assessed objectively by accelerometry?

In: *British Journal of Sports Medicine* 43 (6), S. 442–450.

Abstract:

OBJECTIVS:

To assess physical activity (PA) levels measured objectively using accelerometers in community-dwelling older people and to examine the associations with health, disability, anthropometric measures and psychosocial factors.

DESIGN:

Cross-sectional survey.

SETTING:

Single general practice (primary care centre), United Kingdom.

PARTICIPANTS:

Random selection of 560 community-dwelling older people at least 65 years old, registered with the practice. 43% (238/560) participated.

ASSESSMENT OF RISK FACTORS:

Participants completed a questionnaire assessing health, disability, psychosocial factors and PA levels; underwent anthropometric assessment; and wore an accelerometer (Actigraph) for 7 days.

MAIN OUTCOME MEASURES:

Average daily accelerometer step-counts and time spent in different PA levels. Associations between step-counts and other factors were examined using linear regression.

RESULTS:

Average daily step-count was 6443 (95% CI 6032 to 6853). Men achieved 754 (84 to 1424) more steps daily than women. Step-count declined steadily with age. Independent predictors of average daily step-count were: age; general health; disability; diabetes; body mass index; exercise self-efficacy; and perceived exercise control. Activities associated independently with higher step-counts included number of long walks and dog-walking. Only 2.5% (6/238) of participants achieved the recommended 150 minutes weekly of at least moderate-intensity activity in > or = 10 minute bouts; 62% (147/238) achieved none.

CONCLUSIONS:

This is the first population-based sample of older people with objective PA and anthropometric measures. PA levels in older people are well below recommended levels, emphasising the need to increase PA in this age group, particularly in those who are overweight/obese or have diabetes. The independent effects of exercise self-efficacy and exercise control on PA levels highlight their role as potential mediators for intervention studies.

Measuring physical activity during pregnancy.

In: *Int J Behav Nutr Phys Act* 8. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31144-001%26site%3dehost-live;Catherine.Lombard@monash.edu.

Abstract:

BACKGROUND:

Currently, little is known about physical activity patterns in pregnancy with prior estimates predominantly based on subjective assessment measures that are prone to error. Given the increasing obesity rates and the importance of physical activity in pregnancy, we evaluated the relationship and agreement between subjective and objective physical activity assessment tools to inform researchers and clinicians on optimal assessment of physical activity in pregnancy.

METHODS:

48 pregnant women between 26-28 weeks gestation were recruited. The Yamax pedometer and Actigraph accelerometer were worn for 5-7 days under free living conditions and thereafter the International Physical Activity Questionnaire (IPAQ) was completed. IPAQ and pedometer estimates of activity were compared to the more robust and accurate accelerometer data.

RESULTS:

Of 48 women recruited, 30 women completed the study (mean age: 33.6 ± 4.7 years; mean BMI: 31.2 ± 5.1 kg/m(2)) and 18 were excluded (failure to wear [n = 8] and incomplete data [n = 10]). The accelerometer and pedometer correlated significantly on estimation of daily steps (ρ = 0.69, p < 0.01) and had good absolute agreement with low systematic error (mean difference: 505 ± 1498 steps/day). Accelerometer and IPAQ estimates of total, light and moderate Metabolic Equivalent minutes/day (MET min(-1) day(-1)) were not significantly correlated and there was poor absolute agreement. Relative to the accelerometer, the IPAQ

under predicted daily total METs (105.76 ± 259.13 min(-1) day(-1)) and light METs (255.55 ± 128.41 min(-1) day(-1)) and over predicted moderate METs (-112.25 ± 166.41 min(-1) day(-1)).

CONCLUSION:

Compared with the accelerometer, the pedometer appears to provide a reliable estimate of physical activity in pregnancy, whereas the subjective IPAQ measure performed less accurately in this setting. Future research measuring activity in pregnancy should optimally encompass objective measures of physical activity.

Hart, Teresa L.; Swartz, Ann M.; Cashin, Susan E.; Strath, Scott J. (2011):

How many days of monitoring predict physical activity and sedentary behaviour in older adults?

In: *Int J Behav Nutr Phys Act* 8. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31394-001%26site%3dehost-live;sstrath@uwm.edu.

Abstract:

BACKGROUND:

The number of days of pedometer or accelerometer data needed to reliably assess physical activity (PA) is important for research that examines the relationship with health. While this important research has been completed in young to middle-aged adults, data is lacking in older adults. Further, data determining the number of days of self-reports PA data is also void. The purpose of this study was to examine the number of days needed to predict habitual PA and sedentary behaviour across pedometer, accelerometer, and physical activity log (PA log) data in older adults.

METHODS:

Participants (52 older men and women; age = 69.3 ± 7.4 years, range= 55-86 years) wore a Yamax Digiwalker SW-200 pedometer and an ActiGraph 7164 accelerometer while completing a PA log for 21 consecutive days. Mean differences each instrument and intensity between days of the week were examined using separate repeated measures analysis of variance for with pairwise comparisons. Spearman-Brown Prophecy Formulae based on Intraclass Correlations of .80, .85, .90 and .95 were used to predict the number of days of accelerometer or pedometer wear or PA log daily records needed to represent total PA, light PA, moderate-to-vigorous PA, and sedentary behaviour.

RESULTS:

Results of this study showed that three days of accelerometer data, four days of pedometer data, or four days of completing PA logs are needed to accurately predict PA levels in older adults. When examining time spent in specific intensities of PA, fewer days of data are needed for accurate prediction of time spent in that activity for ActiGraph but more for the PA log. To accurately predict average daily time spent in sedentary behaviour, five days of ActiGraph data are needed.

CONCLUSIONS:

The number days of objective (pedometer and ActiGraph) and subjective (PA log) data needed to accurately estimate daily PA in older adults was relatively consistent. Despite no statistical differences between days for total PA by the pedometer and ActiGraph, the magnitude of differences between days suggests that day of the week cannot be completely ignored in the design and analysis of PA studies that involve < 7-day monitoring protocols for these instruments. More days of accelerometer data were needed to determine typical sedentary behaviour than PA level in this population of older adults.

Hartley, S.; Haddock, G.; Vasconcelos E Sa; Emsley, R.; Barrowclough, C. (2013):

An experience sampling study of worry and rumination in psychosis.

In: *Psychol.Med* (0033-2917 (Linking)), S. 1–10. DOI: 10.1017/S0033291713002080.

Abstract:

BACKGROUND: Increasing research effort is being dedicated to investigating the links between emotional processes and psychosis, despite the traditional demarcation between the two. Particular focus has alighted upon two specific anxious and depressive processes, worry and rumination, given the potential for links with aspects of delusions and auditory hallucinations. This study rigorously explored the nature of these links in the context of the daily life of people currently experiencing psychosis. METHOD: Experience sampling methodology (ESM) was used to assess the momentary links between worry and rumination on the one hand, and persecutory delusional ideation and auditory hallucinations on the other. Twenty-seven participants completed the 6-day experience sampling period, which required repeated self-reports on thought processes and experiences.

Multilevel modelling was used to examine the links within the clustered data. RESULTS: We found that antecedent worry and rumination predicted delusional and hallucinatory experience, and the distress they elicited. Using interaction terms, we have shown that the links with momentary symptom severity were moderated by participants' trait beliefs about worry/rumination, such that they were reduced when negative beliefs about worry/rumination (meta-cognitions) were high. CONCLUSIONS: The current findings offer an ecologically valid insight into the influence of worry and rumination on the experience of psychotic symptoms, and highlight possible avenues for future intervention strategies

Hartley, Samantha; Haddock, Gillian; Vasconcelos E Sa, Debora; Emsley, Richard; Barrowclough, Christine (2014):

The influence of thought control on the experience of persecutory delusions and auditory hallucinations in daily life.

In: *Behav Res Ther* 65C, S. 1–4. DOI: 10.1016/j.brat.2014.12.002.

Abstract:

Attempts to control or suppress thoughts are often unsuccessful and may even lead to an increase in the unwanted content. Intrusive thoughts and thought control are influential in the experience of psychosis, although recent findings have arisen from non-clinical samples and data tend to be retrospective in nature. The current study utilised repeated momentary assessments (experience sampling methodology) delivered as part of participants' daily routine to examine the associations between thought control and the experience of persecutory delusions and auditory hallucinations. The findings revealed that thought control was related to the subsequent severity and distress in relation to psychotic symptoms. Moreover, most of these effects persisted over two subsequent monitoring timepoints, although their size was diminished. These findings add weight to models of psychosis that include a role for thought control, and also highlight opportunities for targeted momentary interventions. Future work might seek to elucidate which specific aspects of thought control are important, alongside the use of more multifaceted measures of psychotic experiences.

Hartmann, Jessica A.; Wichers, Marieke; van Bemmel, Alex L.; Derom, Catherine; Thiery, Evert; Jacobs, Nele et al. (2014):

The serotonin transporter 5-HTTLPR polymorphism in the association between sleep quality and affect.

In: *Eur Neuropsychopharmacol. DOI:* 10.1016/j.euroneuro.2014.01.015.

Abstract:

A link between sleep and affect is well-known. Serotonin (5-HT) is associated with the regulation of affective as well as sleep-related processes. A functional polymorphism in the serotonin transporter gene (5-HTTLPR) has been associated with serotonergic functioning. The present study investigated whether allelic variation of this gene moderates the association between nighttime subjective sleep quality and affect the following day. A population-based sample of 361 ethnically homogenous adult female twins underwent a five day protocol based on the experience sampling method (ESM), assessing momentary negative affect, positive affect, and subjective sleep quality repeatedly and prospectively. There was a significant interaction between sleep quality and genotype in predicting positive affect the next day: carriers of one (n=167) or two S-alleles (n=78) had a significantly steeper slope compared to LL carriers (n=116) (chi2=4.16, p=.042 and chi2=3.90, p=.048 respectively). The association between subjective sleep quality and positive affect the next day varied as a function of 5-HTTLPR: it was stronger in carriers of at least one copy of the S-allele compared to homozygous L-carriers, supporting a link between sleep and affect regulation, in which serotonin may play a role. However, these results are preliminary and require replication.

Hasin, Deborah S.; Aharonovich, Efrat; Greenstein, Eliana (2014):

HealthCall for the smartphone: technology enhancement of brief intervention in HIV alcohol dependent patients.

In: *Addict Sci Clin Pract* 9 (1), S. 5. DOI: 10.1186/1940-0640-9-5.

Abstract:

BACKGROUND: Heavy drinking jeopardizes the health of patients in HIV primary care. In alcohol dependent patients in HIV primary care, a technological enhancement of brief intervention, HealthCall administered via interactive voice response (HealthCall-IVR) was effective at reducing heavy drinking. The smartphone offered a technology platform to improve HealthCall. METHODS: Working with input from patients, technology experts, and HIV clinic personnel, we further developed HealthCall,

harnessing smartphone technological capacities (HealthCall-S). In a pilot study, we compared rates of HealthCall-S daily use and drinking outcomes in 41 alcohol dependent HIV-infected patients with the 43 alcohol dependent HIV-infected patients who used HealthCall-IVR in our previous efficacy study. Procedures, clinic, personnel, and measures were largely the same in the two studies, and the two groups of patients were demographically similar (~90% minority). RESULTS: Pilot patients used HealthCall-S a median of 85.0% of the 60 days of treatment, significantly greater than the corresponding rate (63.8%) among comparison patients using HealthCall-IVR ($p < .001$). Mean end-of-treatment drinks per drinking day was similar in the two groups. Patients were highly satisfied with HealthCall-S (i.e., 92% reported that they liked using HealthCall-S). CONCLUSIONS: Among alcohol dependent patients in HIV primary care, HealthCall delivered via smartphone is feasible, obtains better patient engagement than HealthCall-IVR, and is associated with decreased drinking. In HIV primary care settings, HealthCall-S may offer a way to improve drinking outcomes after brief intervention by extending patient engagement with little additional demands on staff time.

Hausenblas, Heather A.; Gauvin, Lise; Downs, Danielle Symons; Duley, Aaron R. (2008):

Effects of abstinence from habitual involvement in regular exercise on feeling states: an ecological momentary assessment study.

In: *British Journal of Health Psychology* 13 (2), S. 237–255.

Abstract:

Regular exercise was experimentally reduced to determine its effects on positive feeling states. Using ecological momentary assessments, 40 participants maintained their regular exercise routine on 3 days and were deprived of their scheduled exercise on 3 other days. They recorded their feeling states, using the Exercise-Induced Feeling Inventory, four times daily as well as prior to and following exercise. Multi-level modelling analyses controlling for diurnal variations in feeling states revealed that positive feeling states were elevated on days when exercise deprivation occurred compared with non-exercise days and when no deprivation manipulation occurred. People with lower exercise dependence symptoms felt better on days when they were deprived from exercise compared with non-exercise days, whereas people with higher exercise dependence symptoms felt about the same when they were deprived from exercise compared with non-exercise days. These findings demonstrate that positive feeling states occur following an acute bout of exercise and that exercise deprivation had a positive impact on feeling states, with the level of exercise dependence symptoms moderating this effect.

Haut, S. R.; Hall, C. B.; Borkowski, T.; Tennen, H.; Lipton, R. B. (2013):

Modeling seizure self-prediction: an e-diary study.

In: *Epilepsia* 54 (11), S. 1960–1967. DOI: 10.1111/epi.12355.

Abstract:

PURPOSE: A subset of patients with epilepsy successfully self-predicted seizures in a paper diary study. We conducted an e-diary study to ensure that prediction precedes seizures, and to characterize the prodromal features and time windows that underlie self-prediction. METHODS: Subjects 18 or older with localization-related epilepsy (LRE) and >/=3 seizures per month maintained an e-diary, reporting a.m./p.m. data daily, including mood, premonitory symptoms, and all seizures. Self-prediction was rated by, "How likely are you to experience a seizure (time frame)?" Five choices ranged from almost certain (>95% chance) to very unlikely. Relative odds of seizure (odds ratio, OR) within time frames was examined using Poisson models with log normal random effects to adjust for multiple observations. KEY FINDINGS: Nineteen subjects reported 244 eligible seizures. OR for prediction choices within 6 h was as high as 9.31 (CI 1.92-45.23) for "almost certain." Prediction was most robust within 6 h of diary entry, and remained significant up to 12 h. For nine best predictors, average sensitivity was 50%. Older age contributed to successful self-prediction, and self-prediction appeared to be driven by mood and premonitory symptoms. In multivariate modeling of seizure occurrence, self-prediction (2.84; CI 1.68-4.81), favorable change in mood (0.82; CI 0.67-0.99), and number of premonitory symptoms (1.11; CI 1.00-1.24) were significant. SIGNIFICANCE: Some persons with epilepsy can self-predict seizures. In these individuals, the odds of a seizure following a positive prediction are high. Predictions were robust, not attributable to recall bias, and were related to self-awareness of mood and premonitory features. The 6-h prediction window is suitable for the development of preemptive therapy

Hautala, Arto J.; Karjalainen, Jaana; Kiviniemi, Antti M.; Kinnunen, Hannu; Mäkikallio, Timo H.; Huikuri, Heikki V.; Tulppo, Mikko P. (2010):

Physical activity and heart rate variability measured simultaneously during waking hours.

In: *American journal of physiology. Heart and circulatory physiology* 298 (3), S. H874-80. DOI: 10.1152/ajpheart.00856.2009.

Abstract:

Heart rate (HR) variability (HRV) during ambulatory recordings may be affected by individual differences in daily physical activity (PA). However, the influence of various levels of PA on different measures of HRV is not exactly known. We examined the association between simultaneously measured HRV and objective PA data obtained with an accelerometer during waking hours among 45 healthy adults. Bouts of PA were identified from minute-by-minute accelerometer data as metabolic equivalent (METs) values and calculated as mean METs for 30 min. HRV was analyzed concurrently. Within-individual correlation analyses and sign tests were performed to study the relationships between various HRV indexes and PA. The mean PA time was 15:44 +/- 1:01 h, and the mean MET was 1.91 +/- 0.14. HR and sample entropy, but not the other measures of HRV, had a significant relationship with PA, as shown by both correlation analyses ($r = 0.64$, $P = 0.021$, and $r = -0.55$, $P = 0.022$, respectively) and sign tests ($P < 0.0001$ for both). Beat-to-beat R-R interval fluctuation expressed as SD1 also demonstrated a significant relation to PA according to the sign test ($P = 0.037$) and a trend of association according to the correlation analysis ($r = -0.40$, $P = 0.129$). The complexity measure of HRV, in addition to average HR and the short-term index of HRV (SD1), is significantly influenced by the level of PA during ambulatory conditions. Long-term HRV indexes remained relatively stable at various activity levels, making them the most robust indexes for the assessment of cardiac autonomic function during free-running ambulatory conditions.

Havermans, Rob; Nicolson, Nancy A. (2007):

Daily hassles, uplifts, and time use in individuals with bipolar disorder in remission.

In: *The Journal of nervous and mental disease* 195 (9), S. 745–751.

Abstract:

Although life stress has been shown to trigger relapse in bipolar disorder, little is known about how bipolar patients perceive daily hassles or their positive counterparts, uplifts. We used the experience sampling method to investigate the daily experience of hassles and uplifts in 38 patients with remitted bipolar disorder and 38 healthy controls. Largely because of current unemployment, patients were more often alone and at home and spent less time working and more time in passive leisure activities. Contrary to expectations, the groups did not differ in total frequencies or appraisals of events. Within the patient group, however, those patients with current depressive symptoms and more previous depressive episodes experienced negative events as more stressful. These findings are consistent with hypothesized processes linking depressive symptoms to the generation of stressful conditions or to the reactivation of negative cognitive schemas.

Havermans, Rob; Nicolson, Nancy A.; Devries, Marten W. (2007):

Daily hassles, uplifts, and time use in individuals with bipolar disorder in remission.

In: *The Journal of nervous and mental disease* 195 (9), S. 745–751. DOI: 10.1097/NMD.0b013e318142cbf0.

Abstract:

Although life stress has been shown to trigger relapse in bipolar disorder, little is known about how bipolar patients perceive daily hassles or their positive counterparts, uplifts. We used the experience sampling method to investigate the daily experience of hassles and uplifts in 38 patients with remitted bipolar disorder and 38 healthy controls. Havermans, Rob; Nicolson, Nancy A.; Berkhof, Johannes; Devries, Marten W. (2010):

Mood reactivity to daily events in patients with remitted bipolar disorder.

In: *Psychiatry Res* 179 (1), S. 47–52. DOI: 10.1016/j.psychres.2009.10.020.

Abstract:

Information about mood reactions to naturally occurring stress in remitted bipolar patients may help elucidate the mechanism by which stressors influence the propensity to manic or depressive relapse in these patients. Using the experience sampling method (ESM), we therefore investigated negative and positive mood states and their reactivity to daily hassles and uplifts in 38 outpatients with remitted bipolar disorder and 38 healthy volunteers. Multilevel regression analyses confirmed that mean levels of negative affect (NA) were higher and positive affect (PA) lower in bipolar patients. Reactivity of NA and PA to hassles and

uplifts in bipolar patients was similar to controls and was unrelated to the number of previous episodes. Bipolar patients with subsyndromal depressive symptoms, however, showed particularly large NA responses to daily hassles, which they also rated as more stressful. Subsyndromal depressive symptoms in patients with remitted bipolar disorder thus appear to increase sensitivity to everyday stressors.

Hawkins, Ashley A.; Furr, R. Michael; Arnold, Elizabeth Mayfield; Law, Mary Kate; Mneimne, Malek; Fleeson, William (2014):

The structure of borderline personality disorder symptoms: A multi-method, multi-sample examination.

In: *Personality Disorders: Theory, Research, and Treatment* 5 (4), S. 380–389. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-42878-001%26site%3dehost-live.

Abstract:

We examined the factor structure of borderline personality disorder (BPD) symptoms by using a multimethod, multisample approach. The factorial structure of BPD has previously been examined through the lens of broad retrospective reports of symptoms without directly contrasting results from different samples of participants, with studies producing inconsistent patterns of results. We go beyond previous work by examining symptoms from multiple timeframes and by examining results across and within 2 diagnostic groups—individuals with and without BPD. Participants (n = 281) completed a structured clinical interview for personality disorders, 2 weekly reports of BPD symptoms, and 2 weeks of in-the-moment "immediate" symptom reports, assessed 5 times daily. Across all participants, results revealed a robust 1-factor structure that replicated across all assessment methods. Moreover, these results replicated within each diagnostic group, with the lone exception of an unclear structure in interview assessment among participants who had a BPD diagnosis. Results have implications regarding the nature, assessment, and treatment of BPD. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Hawkins, Leah K.; Rossi, Brooke V.; Correia, Katharine F.; Lipskind, Shane T.; Hornstein, Mark D.; Missmer, Stacey A. (2014):

Perceptions among infertile couples of lifestyle behaviors and in vitro fertilization (IVF) success.

In: *J Assist Reprod Genet* 31 (3), S. 255–260. DOI: 10.1007/s10815-014-0176-5.

Abstract:

PURPOSE: To assess how patients perceive various lifestyle behaviors impact IVF success. METHODS: Cross-sectional study of heterosexual, English-speaking couples (n = 138) who completed web-based surveys during IVF treatment cycle. Perceived impact of lifestyle choices assessed by multivariable logistic regression and p-value tests for linear trend (Pt). RESULT(S): During the IVF cycle, most patients consider it helpful for women to exercise (76 %), avoid stress (87 %) and limit activity after embryo transfer (92 %). The majority of patients (62 %) consider rigorous exercise (4+ h/week) helpful and nearly one-third (32 %) perceive benefit to complete bed rest after transfer. Overall, couples with a sex-specific infertility diagnosis are more likely to consider partner's lifestyle choices impactful: male-factor couples are more likely to consider it helpful for men to limit cellular phone use (OR:2.73,CI:1.06-7.04) and diminished ovarian reserve couples are more likely to consider it helpful for women to limit exposure to plastics (OR:2.38,CI:1.03-5.51). Patients at higher levels of education (Pt < 0.01) and income (Pt < 0.01) are less likely to consider lifestyle impactful. CONCLUSION(S): Patient perceptions of the impact of lifestyle factors on IVF success vary by sex, infertility diagnosis and socioeconomic factors. Despite counseling to the contrary, many patients perceive benefit to rigorous exercise during the IVF cycle and complete bedrest following transfer. Results provide insight into patient beliefs and highlight opportunities to improve patient education, alleviate patient anxieties and potentially improve IVF outcomes.

Improved estimation of energy expenditure by artificial neural network modeling.

In: *Applied Physiology, Nutrition, and Metabolism* 33 (6), S. 1213–1222. DOI: 10.1139/h08-117.

Abstract:

Estimation of energy expenditure in daily living conditions can be a tool for clinical assessment of health status, as well as a self-measure of lifestyle and general activity levels. Criterion measures are either prohibitively expensive or restricted to laboratory settings. Portable devices (heart rate monitors, pedometers) have gained recent popularity, but accuracy of the prediction

equations remains questionable. This study applied an artificial neural network modeling approach to the problem of estimating energy expenditure with different dynamic inputs (accelerometry, heart rate above resting (HRar), and electromyography (EMG)). Nine feed-forward back-propagation models were trained, with the goal of minimizing the mean squared error (MSE) of the training datasets. Model 1 (accelerometry only) and model 2 (HRar only) performed poorly and had significantly greater MSE than all other models ($p < 0.001$). Model 3 (combined accelerometry and HRar) had overall performance similar to EMG models. Validation of all models was performed by simulating untrained datasets. MSE of all models increased when tested with validation data. While models 1 and 2 again performed poorly, model 3 MSE was lower than all but 2 EMG models. Squared correlation coefficients of measured and predicted energy expenditure for models 3 to 9 ranged from 0.745 to 0.817. Analysis of mean error within specific movement categories indicates that EMG models may be better at predicting higher-intensity energy expenditure, but combined accelerometry and HRar provides an economical solution, with sufficient accuracy.

Hayakawa, M.; Uchimura, Y.; Omae, K.; Waki, K.; Fujita, H.; Ohe, K. (2013):

A Smartphone-based Medication Self-management System with Realtime Medication Monitoring.

In: *Appl.Clin.Inform.* 4 (1), S. 37–52. DOI: 10.4338/ACI-2012-10-RA-0045.

Abstract:

BACKGROUND: Most patients cannot remember their entire medication regimen and occasionally forget to take their medication. OBJECTIVES: The objective of the study was to design, develop, and demonstrate the feasibility of a new type of medication self-management system using smartphones with real-time medication monitoring. METHODS: We designed and developed a smartphone-based medication self-management system (SMSS) based on interviews of 116 patients. The system offered patients two main functions by means of smartphones: (1) storage and provision of an accurate, portable medication history and medication-taking records of patients; and (2) provision of a reminder to take medication only when the patient has forgotten to take his/her medication. These functions were realized by two data input methods: (a) reading of prescription data represented in two-dimensional barcodes using the smartphone camera and getting the photographic images of the pills; and (b) real-time medication monitoring by novel user-friendly wireless pillboxes. RESULTS: Interviews suggested that a pocket-sized pillbox was demanded to support patient's medication-taking outside the home and pillboxes for home use should be adaptable to the different means of pillbox storage. In accordance with the result, we designed and developed SMSS. Ten patients participated in the feasibility study. In 17 out of 47 cases (36.2%), patients took their medication upon being presented with reminders by the system. Correct medication-taking occurrence was improved using this system. CONCLUSIONS: The SMSS is acceptable to patients and has the advantage of supporting ubiquitous medication self-management using a smartphone. We believe that the proposed system is feasible and provides an innovative solution to encourage medication self-management

Hayes, Gillian R.; Truong, Khai N. (2013):

Paratyping: A contextualized method of inquiry for understanding perceptions of mobile and ubiquitous computing technologies.

In: *Human-Computer Interaction* 28 (3), S. 265–286. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-09426-003%26site%3dehost-live;khai@cs.toronto.edu;gillianrh@ics.uci.edu.

Abstract:

In this article, we describe the origins, use, and efficacy of a contextualized method for evaluating mobile and ubiquitous computing systems. This technique, which we called paratyping, is based on experience prototyping and event-contingent experience sampling and allows researchers to survey people in real-life situations without the need for costly and sometimes untenable deployment evaluations. We used this tool to probe the perceptions of the conversation partners of users of the Personal Audio Loop, a memory aid with the potential for substantial privacy implications. Based on that experience, we refined and adapted the approach to evaluate SenseCam, a wearable, automatic picture-taking device, across multiple geographic locations. We describe the benefits, challenges, and methodological considerations that emerged during our use of the paratyping method across these two studies. We describe how this method blends some of the benefits of survey-based research with more contextualized methods, focusing on trustworthiness of the method in terms of generating scientific knowledge. In particular, this method is a good fit for studying certain classes of mobile and ubiquitous computing applications but can be applied to many types of applications. Haze, K. A.; Lynaugh, J. (2013):

Building Patient Relationships: A Smartphone Application Supporting Communication Between Teenagers With Asthma and the RN Care Coordinator.

In: *Comput.Inform.Nurs.* 31 (6), S. 272–273. DOI: 10.1097/NXN.0b013e3182a01eaa.

Abstract:

Smartphone applications used in healthcare are emerging as an adjunct therapy to assist patients in self-management. Often, smartphone technology is not integrated into healthcare delivery and does not build the nurse-patient relationship, an essential mechanism to guide the patient toward health. In a pilot study using smartphones with teenagers with asthma, the application provided a method not only to share health information at the point-of-living, including health assessments, personalized health plans, and disease information, but also to allow text messaging communication between the teenager and his/her RN care coordinator. Twenty-five teenagers piloted the smartphone application and provided feedback about its use. Eighty-five percent of the teenagers responding to the end-of-pilot, semistructured interview indicated a positive change in the nurse-patient relationship. Teenagers perceived that they could ask more questions along with having improved access and quicker response times. The RN care coordinators perceived improved ability to contact teenagers and improved accuracy of assessment data. Although the pilot had several limitations, it demonstrates that smartphone technology and text messaging can further the nurse-patient relationship. For this to occur, nurses need to become involved in the development and integration of technology to focus applications on innovative ways to enhance communication in patient care.

Head, Geoffrey A.; Andrianopoulos, Nick; McGrath, Barry P.; Martin, Catherine A.; Carrington, Melinda J.; Lukoshkova, Elena V. et al. (2014):

Predictors of mean arterial pressure morning rate of rise and power function in subjects undergoing ambulatory blood pressure recording.

In: *PLoS One* 9 (3), S. e93186. DOI: 10.1371/journal.pone.0093186.

Abstract:

BACKGROUND: We determined clinical predictors of the rate of rise (RoR) in blood pressure in the morning as well as a novel measure of the power of the BP surge (BPpower) derived from ambulatory blood pressure recordings. METHODS: BPpower and RoR were calculated from 409 ambulatory blood pressure (ABP) recordings from subjects attending a cardiovascular risk clinic. Anthropometric data, blood biochemistry, and history were recorded. The 409 subjects were 20-82 years old (average 57, SD = 13), 46% male, 9% with hypertension but not on medication and 34% on antihypertensive medication. RESULTS: Average RoR was 11.1 mmHg/hour (SD = 8) and BPpower was 273 mmHg2/hour (SD = 235). Only cholesterol, low density lipoprotein and body mass index (BMI) were associated with higher BPpower and RoR ($P<0.05$) from 25 variables assessed. BPpower was lower in those taking beta-blockers or diuretics. Multivariate analysis identified that only BMI was associated with RoR (4.2% increase/unit BMI, $P = 0.020$) while cholesterol was the only remaining associated variable with BPpower (17.5% increase/mmol/L cholesterol, $P = 0.047$). A follow up of 213 subjects with repeated ABP after an average 1.8 years identified that baseline cholesterol was the only predictor for an increasing RoR and BPpower ($P<0.05$). 37 patients who commenced statin subsequently had lower BPpower whereas 90 age and weight matched controls had similar BPpower on follow-up. CONCLUSIONS: Cholesterol is an independent predictor of a greater and more rapid rise in morning BP as well as of further increases over several years. Reduction of cholesterol with statin therapy is very effective in reducing the morning blood pressure surge.

Head, Geoffrey A.; Lukoshkova, Elena V. (2008):

Understanding the morning rise in blood pressure.

In: *Clinical and Experimental Pharmacology and Physiology* 35 (4), S. 516–521.

Abstract:

1. The morning period has been recognized as the highest risk period of the day for cardiovascular events, particularly stroke and is also associated with a rapid surge in blood pressure. 2. Evidence now exists to show that the morning surge in blood pressure is an independent risk factor in some elderly hypertensive subjects. 3. However, methods to assess the contribution of the morning blood pressure surge from ambulatory recordings or home recordings, using clock times or times of waking, do not take into consideration the individual patterns of blood pressure change which can range from a rapid rise prior to or following waking to a slow increase over several hours. 4. In the present review we describe a novel method for determining the individual changes using a double logistic equation fitted to the individual pattern of blood pressure change. 5. Methods are presented to determine the rate of rise function over the morning period as well as predicting the change over a fixed time window which may be useful in refining the contribution of the blood pressure surge to cardiovascular risk. 6. Hypertensive people have an

exaggerated rise in morning blood pressure as well as a greater rate of rise. 7. Antihypertensive drugs and dosing regimes are being developed which may be useful adjuncts to standard therapy for preventing morning hypertension and hopefully also reducing cardiovascular damage or events.

Head, Geoffrey A.; Reid, Christopher M.; Shiel, Louise M.; Jennings, Garry L.; Lukoshkova, Elena V. (2006):

Rate of morning increase in blood pressure is elevated in hypertensives.

In: *Am J Hypertens* 19 (10), S. 1010–1017. DOI: 10.1016/j.amjhyper.2006.03.014.

Abstract:

BACKGROUND\r\nWe applied a new logistic curve fitting procedure to ambulatory blood pressure (ABP) recordings to determine whether the rate of increase in systolic (SBP), mean (MBP) and diastolic blood pressure (DBP) and heart rate (HR) in the morning is related to the level of BP in subjects.\r\nMETHODS\r\nThe rate of transition in the morning and evening period was determined using a six-parameter double-logistic equation applied to 528 ABP recordings from a cardiovascular risk assessment clinic. Based on daytime BP (MBP, SBP, or DBP), the upper quartile (UQ, n = 132) and lower quartile (LQ) were compared.\r\nRESULTS\r\nSubjects in the UQ of daytime MBP were hypertensive and showed greater day-night differences compared to normotensive subjects in the LQ (29 +/- 1 mm Hg for MBP compared to 20 +/- 1 mm Hg). The rate of morning increase in SBP and DBP was 42% and 30% greater in UQ subjects compared to the LQ subjects (P < .05). The rates of evening decrease in all BPs were 69% to 84% greater in the subjects in the UQ. Similar results were obtained if subjects were divided according to daytime SBP or DBP. The rate of morning increase in MBP was correlated with daytime BP, but not night-time or 24 h MBP.\r\nCONCLUSIONS\r\nThe rate of morning increase in BP is greater in those subjects with the highest daytime BP. The exaggerated rate of morning increase in BP in this group, which were all hypertensive, may also be important for greater cardiovascular risk.

Using interactive voice response to measure pain and quality of life.

In: *Pain Medicine* 8 (s3), S. S145-S154.

Abstract:

Objectives. To describe the feasibility of using Interactive Voice Response (IVR) technology to collect daily, prospective data about pain and quality of life in a randomized clinical trial of transdermal fentanyl (TDF).

Design. This article focuses on the use of IVR technology within a larger study that compared the relative efficacy of TDF to short-acting opioids for treating chronic noncancer pain. IVR allows individuals to call into a telephone system to answer questions using the telephone keypad.

Participants. Forty-six participants consented to be in the study and made at least one IVR phone call. Thirty-one participants completed the study. All participants were veterans from the VA Connecticut Healthcare System, and all reported chronic pain that had previously been treated with short-acting oral opioids.

Outcome Measures. Participant adherence with calling into the IVR system was assessed via frequency counts of the number of calls placed vs the number of expected calls. Participants provided data about average pain, pain interference, medication adherence and side effects, satisfaction with pain control, and sleep quality.

Results. Participants who completed the study made 84.6% of the 1302 expected calls into the IVR system, and an additional 4% of missed calls were obtained through follow-up. Proportion of completed calls declined slightly across the three call-in intervals, but remained high (from 87.5% to 81.3%).

Conclusions. These data suggest that IVR is an effective way to collect prospective treatment data. Detailed discussion of additional benefits and potential drawbacks to the use of IVR technology is provided.

Heavey, Christopher L.; Hurlburt, Russell T.; Lefforge, Noelle L. (2010):

Descriptive experience sampling: A method for exploring momentary inner experience.

In: *Qualitative Research in Psychology* 7 (4), S. 345–368.

Abstract:

Descriptive Experience Sampling (DES) is a method developed to provide high fidelity accounts of pristine inner experience. A DES investigator gives a subject a random beeper to take into her natural environments. When the beep sounds, the subject jots down notes about her ongoing experience. The subject repeats this process, typically collecting about six moments of experience in a sampling day. Within 24 hours the investigator interviews the subject. During this expositional interview subject and investigator collaborate to develop high fidelity accounts of each sampled moment of experience. This process is repeated over a number of days until an idiographic description of the subject's inner experience has been developed. DES is open-ended, qualitative, and minimally retrospective. Because of the close examination of brief moments of experience, DES is capable of providing highly detailed accounts of inner experience. We summarize some important DES results and contrast DES with the methods of van Manen and Moustakas.

Hebden, L.; Balestracci, K.; McGeechan, K.; Denney-Wilson, E.; Harris, M.; Bauman, A.; Allman-Farinelli, M. (2013):

'TXT2BFiT' a mobile phone-based healthy lifestyle program for preventing unhealthy weight gain in young adults: study protocol for a randomized controlled trial.

In: *Trials* 14 (1745-6215 (Linking)), S. 75. DOI: 10.1186/1745-6215-14-75.

Abstract:

BACKGROUND: Despite international efforts to arrest increasing rates of overweight and obesity, many population strategies have neglected young adults as a target group. Young adults are at high risk for unhealthy weight gain which tends to persist throughout adulthood with associated chronic disease health risks. METHODS/DESIGN: TXT2BFiT is a nine month two-arm parallel-group randomized controlled trial aimed at improving weight management and weight-related dietary and physical activity behaviors among young adults. Participants are recruited via general practice (primary medical care) clinics in Sydney, New South Wales, Australia. All participants receive a mailed resource outlining national physical activity and dietary guidelines and access to the study website. Additional resources accessible to the intervention arm via the study website include Smartphone mobile applications, printable handouts, an interactive healthy weight tracker chart, and a community blog. The study consists of two phases: (1) Intensive phase (weeks 1 to 12): the control arm receives four short message service (SMS) text messages; the intervention arm receives eight SMS messages/week tailored to their baseline stage-of-change, one Email/week, and personalized coaching calls during weeks 0, 2, 5, 8, and 11; and (2) Maintenance phase (weeks 14 to 36): the intervention arm receives one SMS message/month, one Email/month and booster coaching calls during months 5 and 8. A sample of N = 354 (177 per arm) is required to detect differences in primary outcomes: body weight (kg) and body mass index (kg/m2), and secondary outcomes: physical activity, sitting time, intake of specific foods, beverages and nutrients, stage-of-change, self-efficacy and participant well-being, at three and nine months. Program reach, costs, implementation and participant engagement will also be assessed. DISCUSSION: This mobile phone based program addresses an important gap in obesity prevention efforts to date. The method of intervention delivery is via platforms that are highly accessible and appropriate for this population group. If effective, further translational research will be required to assess how this program might operate in the broader community. TRIAL REGISTRATION: Australian New Zealand Clinical Trials Registry ACTRN12612000924853

Hebden, L.; Cook, A.; van der Ploeg, H. P.; King, L.; Bauman, A.; Allman-Farinelli, M. (2013):

A mobile health intervention for weight management among young adults: a pilot randomised controlled trial.

In: *J Hum.Nutr.Diet.* (0952-3871 (Linking)). DOI: 10.1111/jhn.12155.

Abstract:

BACKGROUND: Today's generation of young adults are gaining weight faster than their parents; however, there remains insufficient evidence to inform interventions to prevent this weight gain. Mobile phones are a popular means of communication that may provide a convenient, inexpensive means to deliver health intervention programmes. This pilot study aimed to measure the effect of a 12-week mobile health (mHealth) intervention on body weight, body mass index and specific lifestyle behaviours addressed by the programme. METHODS: University students and staff aged 18-35 years (n = 51) were randomised (ratio 1 : 1, intervention : control). Both groups received a printed diet booklet with instructions prepared by a dietitian. The intervention group also received Short Message Service (SMS) text messages (four per week), e-mails (four per week), and had access to smartphone applications and Internet forums. RESULTS: Pre- to post-intervention, participants in the intervention group

decreased their body weight [mean (SD)] [-1.6 (2.6) kg], increased their light intensity activity [34 (35) min day-1] and reported an increased vegetable (1.0 median serving day-1) and decreased sugar-sweetened beverage intake [-355 (836) mL week-1]. Despite this, post-intervention changes in outcomes were not significantly different from controls. CONCLUSIONS: The piloted mHealth programme provided some short-term positive changes in weight, nutrition and physical activity using a low cost, convenient delivery method for this population. However, changes were no different from those observed among controls. This might partly be explained by intervention participants' low engagement with the programme, which is likely to require further modification to provide more regular, personalised, monitored support

Hedeker, Donald; Mermelstein, Robin J. (2012):

Mood changes associated with smoking in adolescents: An application of a mixed-effects location scale model for longitudinal ecological momentary assessment data. In: Jeffrey R. Harring und Gregory R. Hancock (Hg.): Advances in longitudinal methods in the social and behavioral sciences.

Charlotte, NC US: IAP Information Age Publishing (CILVR series on latent variable methodology), S. 59–79. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31006-003%26site%3dehost-live.

Abstract:

(from the chapter) In this chapter, the authors extend the mixed-effects location scale model to focus on the variation of mood change that is associated with smoking across measurement waves, and the degree to which subject and wave characteristics influence the variation in mood changes. Also, while Hedeker et al. (2008) only considered random subject intercepts for the one wave of ecological momentary assessment (EMA) data, here the authors allow random subject time trends for the multiple waves of EMA data. The authors further consider a three-level model that treats observations nested within waves within subjects. To aid in making this class of models accessible, sample computer syntax is provided in the Appendix. The data are drawn from a natural history study of adolescent smoking. The number of subjects at each measurement wave equaled 116 (baseline), 91 (6 months), 92 (15 months), and 88 (24 months). The study utilized a multimethod approach to assess adolescents including self-report questionnaires, a week-long time/event sampling method via hand-held computers (EMA), and detailed surveys. Overall, following smoking, adolescents reported higher positive affect and lower negative affect than before their smoking report. Additionally, the analyses indicated an increased consistency of subjective mood responses as a person's smoking experience increased over time and a diminishing of the mood change associated with smoking. The authors' data thus provide one of the few ecologically valid examinations of the development of tolerance. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (chapter)

Hedeker, Donald; Mermelstein, Robin J.; Demirtas, Hakan (2008):

An application of a mixed-effects location scale model for analysis of ecological momentary assessment (EMA) data.

In: *Biometrics* 64 (2), S. 627–634.

Abstract:

For longitudinal data, mixed models include random subject effects to indicate how subjects influence their responses over repeated assessments. The error variance and the variance of the random effects are usually considered to be homogeneous. These variance terms characterize the within-subjects (i.e., error variance) and between-subjects (i.e., random-effects variance) variation in the data. In studies using ecological momentary assessment (EMA), up to 30 or 40 observations are often obtained for each subject, and interest frequently centers around changes in the variances, both within and between subjects. In this article, we focus on an adolescent smoking study using EMA where interest is on characterizing changes in mood variation. We describe how covariates can influence the mood variances, and also extend the standard mixed model by adding a subject-level random effect to the within-subject variance specification. This permits subjects to have influence on the mean, or location, and variability, or (square of the) scale, of their mood responses. Additionally, we allow the location and scale random effects to be correlated. These mixed-effects location scale models have useful applications in many research areas where interest centers on the joint modeling of the mean and variance structure.

Hedeker, Donald; Mermelstein, Robin J.; Berbaum, Michael L.; Campbell, Richard T. (2009):

Modeling mood variation associated with smoking: an application of a heterogeneous mixed-effects model for analysis of ecological momentary assessment (EMA) data.

In: *Addiction* 104 (2), S. 297–307. DOI: 10.1111/j.1360-0443.2008.02435.x.

Abstract:

AIMS\r\nMixed models are used increasingly for analysis of ecological momentary assessment (EMA) data. The variance parameters of the random effects, which indicate the degree of heterogeneity in the population of subjects, are considered usually to be homogeneous across subjects. Modeling these variances can shed light on interesting hypotheses in substance abuse research.\r\nDESIGN\r\nWe describe how these variances can be modeled in terms of covariates to examine the covariate effects on between-subjects variation, focusing on positive and negative mood and the degree to which these moods change as a function of smoking.\r\nSETTING\r\nThe data are drawn from an EMA study of adolescent smoking.\r\nPARTICIPANTS\r\nParticipants were 234 adolescents, either in 9th or 10th grades, who provided EMA mood reports from both random prompts and following smoking events.\r\nMEASUREMENTS\r\nWe focused on two mood outcomes: measures of the subject's negative and positive affect and several covariates: gender, grade, negative mood regulation and smoking level.\r\nFINDINGS AND CONCLUSIONS\r\nFollowing smoking, adolescents experienced higher positive affect and lower negative affect than they did at random, non-smoking times. Our analyses also indicated an increased consistency of subjective mood responses as smoking experience increased and a diminishing of mood change.

Hedeker, D.; Mermelstein, R. J.; Demirtas, H. (2012):

Modeling between-subject and within-subject variances in ecological momentary assessment data using mixed-effects location scale models.

In: *Stat.Med.* (0277-6715 (Linking)). DOI: 10.1002/sim.5338.

Abstract:

Ecological momentary assessment and/or experience sampling methods are increasingly used in health studies to study subjective experiences within changing environmental contexts. In these studies, up to 30 or 40 observations are often obtained for each subject. Because there are so many measurements per subject, one can characterize a subject's mean and variance and can specify models for both. In this article, we focus on an adolescent smoking study using ecological momentary assessment where interest is on characterizing changes in mood variation. We describe how covariates can influence the mood variances and also extend the statistical model by adding a subject-level random effect to the within-subject variance specification. This permits subjects to have influence on the mean, or location, and variability, or (square of the) scale, of their mood responses. These mixed-effects location scale models have useful applications in many research areas where interest centers on the joint modeling of the mean and variance structure. Obese children without comorbidities have impaired microvascular endothelial function.

In: *Acta Paediatr* 103 (4), S. 411–417. DOI: 10.1111/apa.12549.

Abstract:

AIM: The aim was to test acetylcholine-induced endothelium-dependent vasodilatation in obese children without comorbidities, compared with normal weight controls, and to analyse associations between vasodilatation and other potential risk factors. METHODS: Endothelium-dependent vasodilatation was induced by transdermal iontophoresis of acetylcholine in 54 obese children (8.3-18.2 years old, 41% girls) and 44 normal weight controls (7.5-20.2 years old, 82% girls), and the subsequent change in perfusion was measured with laser Doppler flowmetry. In a subgroup of the obese children, associations between acetylcholine-induced vasodilatation and blood lipids, glucose/insulin metabolism, inflammation, 24-h ambulatory blood pressure (ABP), cardiovascular fitness and duration of obesity were evaluated. RESULTS: We found a lower endothelium-dependent vasodilatory response to acetylcholine in the obese children than the controls ($p < 0.001$). The peak perfusion response was 33% lower in obese children ($p = 0.001$). There was a trend towards lower vasodilatation in obese children with higher levels of triglycerides ($p = 0.07$). Children with the shortest duration of obesity exhibited the lowest vasodilatation ($p = 0.03$). No associations were found between 24-h ABP, cardiovascular fitness, inflammation and glucose/insulin metabolism. CONCLUSION: Obese children without comorbidities have significantly impaired microvascular endothelial function. The children who had been obese for a longer time seemed less affected.

Heebner, Nicholas R.; Akins, Jonathan S.; Lephart, Scott M.; Sell, Timothy C. (2014):

Reliability and validity of an accelerometry based measure of static and dynamic postural stability in healthy and active individuals.

In: *Gait Posture*. *DOI:* 10.1016/j.gaitpost.2014.12.009.

Abstract:

Postural stability is an important measure in both research and clinical practice. A portable, easy to use device that can provide higher resolution than current clinical tests may allow for better identification of patients or athletes with postural stability deficits. The purpose of this study was to evaluate the ability of a tri-axial accelerometer to quantify postural stability in a healthy athletic population. Ten subjects were recruited to determine the reliability of the accelerometer to measure dynamic postural stability and thirteen were recruited to compare the accelerometer measures across tasks of varying difficulty. Subjects were asked to complete four static postural stability tasks with eyes open and eyes closed and two dynamic postural stability tasks for a total of ten tasks. During each task postural stability was measured using a tri-axial accelerometer and force platform. Differences between postural stability scores between tasks and the correlation between the two measures were assessed. The accelerometer demonstrated moderate to good test-retest reliability (ICC=0.732 to 0.899). Only the medial-lateral axis of the accelerometer showed significant differences between static tasks but all directions were able to show significant differences between static and dynamic tasks. Additionally, Spearman's ranked correlations showed little to no correlation between the accelerometer and force platform scores. Accelerometers are a reliability tool for postural stability that measure low difficulty tasks best in the medial-lateral direction. Low correlation between the accelerometer and force platform suggest that these two methods are not measuring the same components of postural stability.

Feature-level analysis of a novel smartphone application for smoking cessation.

In: *Am J Drug Alcohol Abuse* 41 (1), S. 68–73. DOI: 10.3109/00952990.2014.977486.

Abstract:

Abstract Background: Currently, there are over 400 smoking cessation smartphone apps available, downloaded an estimated 780,000 times per month. No prior studies have examined how individuals engage with specific features of cessation apps and whether use of these features is associated with quitting. OBJECTIVES: Using data from a pilot trial of a novel smoking cessation app, we examined: (i) the 10 most-used app features, and (ii) prospective associations between feature usage and quitting. METHODS: Participants (n = 76) were from the experimental arm of a randomized, controlled pilot trial of an app for smoking cessation called "SmartQuit," which includes elements of both Acceptance and Commitment Therapy (ACT) and traditional cognitive behavioral therapy (CBT). Utilization data were automatically tracked during the 8-week treatment phase. Thirty-day point prevalence smoking abstinence was assessed at 60-day follow-up. RESULTS: The most-used features - quit plan, tracking, progress, and sharing - were mostly CBT. Only two of the 10 most-used features were prospectively associated with quitting: viewing the quit plan (p = 0.03) and tracking practice of letting urges pass (p = 0.03). Tracking ACT skill practice was used by fewer participants (n = 43) but was associated with cessation (p = 0.01). CONCLUSIONS: In this exploratory analysis without control for multiple comparisons, viewing a quit plan (CBT) as well as tracking practice of letting urges pass (ACT) were both appealing to app users and associated with successful quitting. Aside from these features, there was little overlap between a feature's popularity and its prospective association with quitting. Tests of causal associations between feature usage and smoking cessation are now needed.

Accuracy of the LifeShirt®(Vivometrics) in the detection of cardiac rhythms.

In: *Biol Psychol* 75 (3), S. 300–305.

Abstract:

The use of heart rate measures in research requires accurate detection and timing of beat-to-beat values. Numerous technologies are available to researchers; however, benchmarking of a specific apparatus is seldom conducted. Since heart rate variability provides a portal to the neural regulation of the heart, accurate detection and timing of beat-to-beat values is essential to both basic physiological research and the clinical application of heart rate variability measures. The current study evaluated the accuracy of an ambulatory system, the LifeShirt® (Vivometrics), relative to a standard laboratory-based heart rate monitoring equipment (Biopac), during baseline and exercise conditions. LifeShirt® performed equivalently to the Biopac during both conditions, experienced few errors of detection, generated similar times between sequential heart periods, and produced similar summary indices of heart rate and heart rate variability.

Back to basics: A naturalistic assessment of the experience and regulation of emotion.

In: *Emotion* 14 (5), S. 878–891. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-27224-001%26site%3dehost-live.

Abstract:

Emotion regulation research links regulatory responding to important outcomes in psychological well-being, physical health, and interpersonal relations, but several fundamental questions remain. As much of the previous research has addressed generalized regulatory habits, far less is known about the ways in which individuals respond to emotions in daily life. The literature is particularly sparse in explorations of positive emotion regulation. In the current study, we provide an assessment of naturalistic experiences and regulation of emotion, both positive and negative in valence. Using an electronic experience sampling methodology, participants reported on their use of 40 regulatory strategies in response to 14 emotions for 10 consecutive days. On average, participants used 15 different regulatory strategies in response to negative emotions over this time, most frequently relying on acceptance, behavioral activation, and rumination. Participants used a similarly large repertoire of strategies, approximately 16 total, in response to positive emotions, particularly savoring, future focus, and behavioral activation. Participants' mood ratings following strategy use, however, indicated that the most frequently used strategies were often not the most effective strategies. The results of this study provide estimates of the frequency and effectiveness of a large number of emotion regulation strategies in response to both negative and positive emotions. Such findings characterize naturalistic emotion regulation, and estimates of normative emotion regulation processes are imperative to determining the ways in which deviations (e.g., small emotion regulation repertoires, insufficient attention to regulation of positive emotions) impact emotional functioning. Hektner, Joel M. (2012):

Developmental psychology. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 585–600. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-033%26site%3dehost-live.

Abstract:

(from the chapter) The development of persons is not often perceptible from one moment to the next, or even from one day to the next. Thus, the pillars of developmental science are longitudinal studies spanning years. Nevertheless, micro-longitudinal studies of daily life that produce intensive longitudinal data have been invaluable to the study of development across most of the lifespan. Beginning with Csikszentmihalyi and Larson's (1984) landmark study of the daily life of adolescents, developmental psychologists have used the experience sampling method (ESM) and its variants to capture the contexts of development, and the relations between those contexts and the behavior and inner psychological life of people. Developmental researchers have always taken context seriously, but they have also striven for methodological rigor, a frequent casualty when moving out of the laboratory. There is also a growing recognition of and interest in variations within people across time and situations. People do not all develop at the same rate or in the same direction, and some may have episodes of regressions followed by spurts of growth. Only research methods designed for studying daily life combine the "real-world," "real-time," and "within-person" perspectives in a methodologically rigorous way to satisfy many of the needs of the field of developmental science. The growing importance of such studies to the field is evident from their ever-increasing number and wider range (for a recent review, see Hoppmann & Riediger, 2009). These studies of daily life have been conducted with people ranging from childhood to old age. In the sections that follow, periods of the lifespan provide an organizational structure to a targeted review of the relevant literature. This is done, not to imply that the developmental questions and issues are different in each period—indeed, several themes recur throughout the lifespan—but because nearly all of this research is confined to a single developmental period, and most developmental psychologists still specialize in just one part of the lifespan. Tailored behavioral medicine intervention for enhanced physical activity and healthy eating in patients with obstructive sleep apnea syndrome and overweight.

In: *Sleep Breath. DOI:* 10.1007/s11325-013-0929-x.

Abstract:

PURPOSE: This study aims to evaluate the effects on physical activity (PA) and eating behavior (EB) of a tailored behavioral medicine intervention and first-time continuous positive airway pressure (CPAP) treatment compared with first-time CPAP treatment and advice in patients with obstructive sleep apnea syndrome (OSAS) and overweight. METHODS: Seventy-three patients (mean +/- SD, 55 +/- 12 years) with overweight (body mass index (BMI), 34.5 +/- 4.8) and moderate or severe OSAS (Apnea-Hypopnea Index, 41.7 +/- 20.9) scheduled for CPAP prescription were randomized to a control group (CPAP and advice on the association between weight and OSAS) or an experimental group (CPAP and a 6-month behavioral medicine intervention targeting PA and EB). At baseline and after 6 months, eating behavior (food frequency screening and Dutch Eating Behavior Questionnaire), weight, BMI, and waist circumference were assessed at one point, while PA and sedentary time were measured with accelerometry during 4 days. RESULTS: The experimental group reduced 2.1 kg (+/-4.6) in weight and 3 cm (+/-4.9) in waist circumference, significantly more than the control group. At 6 months, the experimental group ate more fruit and fish/shellfish than the control group. Low and moderate to vigorous PA did not change over time either within or between groups. Regarding BMI, steps, and sedentary time, there were within-group differences but no differences between groups. CONCLUSIONS: The behavioral medicine intervention did not change physical activity but facilitated changes in EB in patients with OSAS and overweight. The amount of weight loss and reduction in waist circumference favored the participants receiving this treatment. Since the strategies for achieving behavioral changes were tailored according to the individual's goals and personal functional behavioral analyses and progressed slowly in a graded manner, it might require higher PA quotas or a period longer than 6 months to reveal a behavioral change of larger proportions.

Peer relationships and diabetes: retrospective and ecological momentary assessment approaches.

In: *Health Psychol* 28 (3), S. 273–282. DOI: 10.1037/a0013784.

Abstract:

OBJECTIVE\r\nTo examine the association of positive and negative aspects of friendship to psychological well-being, self-care behavior, and blood glucose control and to determine whether these relations were moderated by gender.\r\nDESIGN\r\nAdolescents with Type 1 diabetes (n = 76) completed baseline measures of friendship quality, depressive symptoms, and self-care. A measure of metabolic control was obtained from medical records. Adolescents also tested blood glucose periodically over the course of 4 days and completed ecological momentary assessments of interpersonal interactions and mood using PDAs.\r\nMAIN OUTCOME MEASURES\r\nFor between-groups analyses, primary outcomes were depressive symptoms, self-care behavior, and metabolic control. For within-groups analyses, primary outcomes were mood and blood glucose.\r\nRESULTS\r\nResults showed baseline reports of peer conflict but not support were associated with outcomes, particularly among girls. Conflict was more strongly related to poor metabolic control for girls than boys. Momentary interaction enjoyment and interaction upset were associated with mood, but were unrelated to blood glucose. Aggregate indices of enjoyable interactions were associated with fewer depressive symptoms and better self-care-especially among girls.\r\nCONCLUSIONS\r\nThese results suggest that the positive and negative aspects of peer relationships are related to the psychological well-being and physical health of adolescents with diabetes.

Aerophagia: excessive air swallowing demonstrated by esophageal impedance monitoring.

In: *Clinical gastroenterology and hepatology : the official clinical practice journal of the American Gastroenterological Association* 7 (10), S. 1127–1129. DOI: 10.1016/j.cgh.2009.06.029.

Abstract:

BACKGROUND & AIMS\r\nPatients with aerophagia suffer from the presence of an excessive volume of intestinal gas, which is thought to result from excessive air ingestion. However, this has not been shown thus far. The aim of this study was therefore to assess swallowing and air swallowing frequencies in patients with suspected aerophagia.\r\nMETHODS\r\nAmbulatory 24-hour pH-impedance monitoring was performed in patients in whom excessive amounts of intestinal gas were visualized on plain abdominal radiograms. All patients had symptoms of bloating, abdominal distention, flatulence, or excessive belching. Reflux parameters and the number of swallows and air swallows were assessed.\r\nRESULTS\r\nThe most common symptoms were bloating, abdominal distention, and constipation. Only 3 patients reported excessive belching and 1 patient reported flatulence as their predominant symptom. During the 24-hour measurement, patients showed high incidences of air swallows (521 +/- 63) and gastric belches (126 +/- 37). Patients had normal swallowing frequency (741 +/- 71).\r\nCONCLUSIONS\r\nThis study

presents objective parameters that confirm the existence of excessive air swallowing or aerophagia using esophageal impedance monitoring.

Can accelerometry be used to discriminate levels of activity?

In: *Ergonomics* 52 (8), S. 1019–1025. DOI: 10.1080/00140130902846464.

Abstract:

The aims of this study were to investigate the associations between an activity logbook and the RT3 accelerometer and to assess whether the RT3 can discriminate activity levels in healthy adults. Ten participants completed two trials wearing an RT3 accelerometer over a 4-6 h period and completed a detailed activity log. Results showed a poor correlation between the RT3 in moderate activities (r = 0.22) in comparison to low (r = 0.52) and hard (r = 0.70) from the logbook. A significant difference was found in average RT3 vector magnitude (VM) counts/min in each activity level ($p < 0.0001$). Discriminant analysis demonstrated that an RT3VM counts/min value of approximately 500 was found to have high sensitivity (88%), and specificity (88%) for discriminating between low and moderate activity levels from the logbook. This study found that accelerometry has the potential to discriminate activity levels in free living. This study is the first to investigate whether tri-axial accelerometry can discriminate different levels of free-living activity recorded in an activity logbook. The RT3 accelerometer can discriminate between low and moderate physical activities and offers a methodology that may be applicable to future research in occupational settings.

Why are locals happier than internal migrants? The role of daily life.

In: *Social Indicators Research*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-57850-001%26site%3dehost-live.

Abstract:

Several survey studies have found that internal migrants report lower levels of happiness than locals, even after accounting for socio-economic factors. Traditional global self-ratings reveal that the migrant–local happiness-gap is also present in the data we present. The reasons for the migrant–local happiness-gap are as yet unclear. This paper aims to open this 'black box' by exploring the role of daily activities among a population that has generally been overlooked despite their high migration frequency: young adults. An innovative smartphone application is used that combines two techniques for multiple moment assessment: the experience sampling method and the day reconstruction method. Based on the application data, we examine whether internal migrants spend their time differently than locals and in which situations they feel noticeably less happy than locals. The data reveal that internal migrants distribute less time to happiness-producing activities such as active leisure, social drinking/parties, and activities outside home/work/transit. Internal migrants feel less happy than locals when spending time with friends and while eating. Possible explanations focusing on the role of social capital are discussed. Further analyses reveal that daily life experiences greatly enhance the explanation of the migrant–local happiness-gap. This paper demonstrates the potential value of real-time data and phone applications in solving happiness puzzles. (PsycINFO Database Record (c) 2015 APA, all rights reserved). (journal abstract)

Hendrix, Yvonne; Reelick, Miriam F.; van Mierlo, Patricia; Rikkert, Marcel Olde (2012):

Activity in older people with and without a major depressive disorder.

In: *International Journal of Geriatric Psychiatry* 27 (4). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-06543-013&site=ehost-live.

Abstract:

Psychomotor disturbances are an essential feature of major depressive disorders. Many studies have been carried out to investigate these psychomotor disturbances, except in the geriatric population. This may be caused by their frailty and intrinsic problems in including depressive geriatric subjects in studies that ask compliance to protocols that require physical activity, for which depressive subjects are often not motivated. In the present pilot study, we compared the physical activity in patients with a major depressive disorder (DSM-IV), before and after treatment with a Selective Serotonin Reuptake Inhibitor, with older subjects without an affective disorder as controls. Similar to younger patients, there is less activity in patients with a major

depressive disorder, compared with controls. Although depressive symptoms improve after treatment with a Selective Serotonin Reuptake Inhibitor, there was no improvement in activity. The use of an accelerometer in the geriatric depressed population is complicated: it encountered low acceptance. A proper validation study in a larger subject sample is warranted for confirmation. Next, older depressed patients probably need specific mobility training and activation during antidepressive drug treatment to sufficiently regain their former activity level and prevent sarcopenia and malnutrition. Cross-species assessments of motor and exploratory behavior related to bipolar disorder.

In: *Neuroscience and Biobehavioral Reviews* 34 (8), S. 1296–1306.

Abstract:

Alterations in exploratory behavior are a fundamental feature of bipolar mania, typically characterized as motor hyperactivity and increased goal-directed behavior in response to environmental cues. In contrast, abnormal exploration associated with schizophrenia and depression can manifest as prominent withdrawal, limited motor activity, and inattention to the environment. While motor abnormalities are cited frequently as clinical manifestations of these disorders, relatively few empirical studies have quantified human exploratory behavior. This article reviews the literature characterizing motor and exploratory behavior associated with bipolar disorder and genetic and pharmacological animal models of the illness. Despite sophisticated assessment of exploratory behavior in rodents, objective quantification of human motor activity has been limited primarily to actigraphy studies with poor cross-species translational value. Furthermore, symptoms that reflect the cardinal features of bipolar disorder have proven difficult to establish in putative animal models of this illness. Recently, however, novel tools such as the Human Behavioral Pattern Monitor provide multivariate translational measures of motor and exploratory activity, enabling improved understanding of the neurobiology underlying psychiatric disorders.

Hensel, D. J.; Harezlak, J.; Craig, D.; Fortenberry, J. D. (2012):

The feasibility of cell phone based electronic diaries for STI/HIV research.

In: *BMC.Med.Res Methodol.* 12 (1), S. 75. DOI: 10.1186/1471-2288-12-75.

Abstract:

ABSTRACT: BACKGROUND: Self-reports of sensitive, socially stigmatized or illegal behavior are common in STI/HIV research, but can raise challenges in terms of data reliability and validity. The use of electronic data collection tools, including ecological momentary assessment (EMA), can increase the accuracy of this information by allowing a participant to self-administer a survey or diary entry, in their own environment, as close to the occurrence of the behavior as possible. In this paper, we evaluate the feasibility of using cell phone-based EMA as a tool for understanding sexual risk and STI among adult men and women. METHODS: As part of a larger prospective clinical study on sexual risk behavior and incident STI in clinically recruited adult men and women, using study-provided cell phones, participants (N= 243) completed thrice daily EMA diaries monitoring individual and partner-specific emotional attributes, non-sexual activities, non-coital or coital sexual behaviors, and contraceptive behaviors. Using these data, we assess feasibility in terms of participant compliance, behavior reactivity, general method acceptability and method efficacy for capturing behaviors. RESULTS: Participants were highly compliant with diary entry protocol and schedule: over the entire 12 study weeks, participants submitted 89.7% (54,914/61,236) of the expected diary entries, with an average of 18.86 of the 21 expected diaries (85.7%) each week. Submission did not differ substantially across gender, race/ethnicity and baseline sexually transmitted infection status. A sufficient volume and range of sexual behaviors were captured, with reporting trends in different legal and illegal behaviors showing small variation over time. Participants found the

methodology to be acceptable, enjoyed and felt comfortable participating in the study. CONCLUSION: Achieving the correct medium of data collection can drastically improve, or degrade, the timeliness and quality of an individual's self-reported sexual risk behavior, which in turn, is a key factor in the success of intervention or education programs relying on this information. Our findings demonstrate that completion of electronic diaries via cellular phone is feasible way to describe STI/HIV risk among clinically recruited adult men and women

Heo, Jaesung; Chun, Mison; Lee, Ki Young; Oh, Young-Taek; Noh, O. Kyu; Park, Rae Woong (2013):

Effects of a smartphone application on breast self-examination: a feasibility study.

In: *Healthc Inform Res* 19 (4), S. 250–260. DOI: 10.4258/hir.2013.19.4.250.

Abstract:

OBJECTIVES: The aims of this study were to develop a smartphone application to encourage breast self-examination (BSE), and to evaluate the effects of this application in terms of modifying BSE behavior. METHODS: A smartphone application, based on the Android OS, was developed with functions including a BSE date alarm, a reminder to encourage mother and daughter to practice BSE together, record keeping, and educational content with video clips. Females aged 19 and over were enrolled to evaluate the effectiveness of the application. Two series of questionnaires were carried out (before and after use of the application) by e-mail, telephone, and face-to-face interviews between July and September 2012. RESULTS: Forty-five subjects were enrolled in the study (age 29.5-5.9 years). Of the participants, only 28 (62.2%) had ever practiced BSE and only one of these (2.2%) was carried out at the appropriate time, based on the results of the baseline survey. After using the application, the number of participants practicing BSE increased from 28 to 32 (62.2% to 71.1%, p = 0.503). In subgroup analysis (age < 30 years), the number of participants using BSE increased from 8 to 18 (36.4% to 81.8%, p = 0.002), and the number of those using it at the appropriate time rose from 1 to 15 (2.2% to 33.3%, p < 0.001). CONCLUSIONS: The use of the developed smartphone application increased BSE in females younger than 30 years. To confirm the long-term benefits of the mobile application, additional studies must be carried out.

Heo, Jinmoo; Kim, Junhyoung; Kim, Byung-Gook; Heo, Seongmoo (2014):

Weekend Experiences and Subjective Well-being of Retired Older Adults.

In: *Am J Health Behav* 38 (4), S. 598–604. DOI: 10.5993/AJHB.38.4.13.

Abstract:

OBJECTIVES: To examine how involvement in activities is related to subjective well-being (SWB) among older adults in particular during weekends. To explore the situational and behavioral factors such as day of week, type of activities, and social context and their impact on subjective well being of older adults. METHODS: The experience sampling method (ESM) was used with retired older adults. RESULTS: Participants reported lower levels of SWB on the weekend. They experienced higher levels of SWB when they were engaged in active leisure on the weekend. Social contexts were significant predictors of older adults' SWB on the weekend. CONCLUSION: These findings extend the body of knowledge that involvement in active leisure and socializing with friends improve SWB of older adults.

Heo, Jinmoo; Lee, Youngkhill; Pedersen, Paul M.; McCormick, Bryan P. (2010):

Flow experience in the daily lives of older adults: an analysis of the interaction between flow, individual differences, serious leisure, location, and social context.

In: *Canadian journal on aging = La revue canadienne du vieillissement* 29 (3), S. 411–423. DOI: 10.1017/S0714980810000395.

Abstract:

This study examined how serious leisure, individual differences, social context, and location contribute to older adults' experiences of flow - an intense psychological state - in their daily lives. The Experience Sampling Method was used with 19 older adults in a Midwestern city in the United States. Experience of flow was the outcome measure, and the data were analyzed using hierarchical linear modeling. Results indicated that location and employment status influenced the subjects' flow experience. Furthermore, the findings revealed that retirement was negatively related to experiencing flow, and there was a significant association between home and the flow experience. The results of this study enhance the understanding of flow experiences in the everyday lives of older adults.

Hermida, Ramón C.; Ayala, Diana E.; Smolensky, Michael H.; Portaluppi, Francesco (2007):

Chronotherapy in hypertensive patients: administration-time dependent effects of treatment on blood pressure regulation.

Abstract:

Ambulatory blood pressure measurements (ABPM) correlate more closely with target organ damage and cardiovascular events than clinical cuff measurements. ABPM reveals the significant circadian variation in BP, which in most individuals presents a morning increase, small post-prandial decline, and more extensive lowering during nocturnal rest. However, under certain pathophysiological conditions, the nocturnal BP decline may be reduced (nondipper pattern) or even reversed (riser pattern). This is clinically relevant since the nondipper and riser circadian BP patterns constitute a risk factor for left ventricular hypertrophy, microalbuminuria, cerebrovascular disease, congestive heart failure, vascular dementia and myocardial infarction. Hence, there is growing interest in how to best tailor and individualize the treatment of hypertension according to the circadian BP pattern of each patient. Significant administration-time differences in the kinetics and in the beneficial and adverse effects of antihypertensive medications are well known. Thus, bedtime dosing with nifedipine gastrointestinal therapeutic system (GITS) is more effective than morning dosing, while also significantly reducing adverse effects. The therapeutic coverage and efficacy of doxazosin GITS are dependent on the circadian time of drug administration. Moreover, valsartan administration at bedtime, as opposed to upon wakening, results in an improved diurnal/nocturnal BP ratio, increased percentage of controlled patients, and significant reduction in urinary albumin excretion in hypertensive patients. Chronotherapy provides a means of individualizing the treatment of hypertension according to the circadian BP profile of each patient, and constitutes a new option to optimize BP control and reduce the risk of cardiovascular disease.

Hermida, Ramón C.; Ayala, Diana E.; Fernández, José R.; Mojón, Artemio; Calvo, Carlos (2007):

Influence of measurement duration and frequency on ambulatory blood pressure monitoring.

In: *Revista Española de Cardiología (English Edition)* 60 (2), S. 131–138.

Abstract:

INTRODUCTION AND OBJECTIVES:

Most studies of ambulatory blood pressure monitoring have involved taking measurements every 15-30 minutes over a 24-hour period. We investigated the effect of measurement duration and frequency on the diagnostic blood pressure values obtained by ambulatory monitoring.

METHODS:

The study involved 1450 hypertensive patients and a control group of 378 normotensive volunteers. Blood pressure was measured at 20-minute intervals from 07:00 to 23:00 and at 30-minute intervals at night for 48 consecutive hours. Data were subdivided in such a way as to generate different series of data that were collected at 1-, 2-, 3-, or 4-hour intervals over the 48-hour period. In addition, two data series at the original measurement frequency were derived for the first and second 24-hour periods. The correspondence between the mean blood pressure values derived from the original data series and those from the different subdivided data series was assessed.

RESULTS:

Variability in the estimated mean blood pressure increased progressively as the measurement frequency decreased: the error range grew from 11 mmHg for hourly data to 28 mmHg for 4-hourly data. The error range was even greater (i.e., 36 mmHg) for data divided into 24-hour series at the original sampling rate.

CONCLUSIONS:

This study demonstrates that the reproducibility of mean blood pressure values depends more on measurement duration than measurement frequency. The findings indicate that monitoring blood pressure for only 24 hours may be insufficient for diagnosing hypertension, identifying a dipper circadian pattern, or assessing treatment efficacy.

Hermida, Ramón C.; Ayala, Diana E.; Fernández, José R.; Calvo, Carlos (2008):

Chronotherapy improves blood pressure control and reverts the nondipper pattern in patients with resistant hypertension.

In: *Hypertension* 51 (1), S. 69–76.

Abstract:

Therapeutic strategies in resistant hypertension include adding another drug or changing drugs in search for a better synergic combination. Most patients, however, receive all of their drugs in a single morning dose. We have evaluated the impact on the circadian pattern of blood pressure on modifying the time of treatment without increasing the number of prescribed drugs. We studied 250 hypertensive patients who were receiving 3 antihypertensive drugs in a single morning dose. Patients were randomly assigned to 1 of 2 groups according to the modification in their treatment strategy: changing 1 of the drugs but keeping all 3 in the morning or the same approach but administering the new drug at bedtime. Blood pressure was measured for 48 hours before and after 12 weeks of treatment. There was no effect on ambulatory blood pressure when all of the drugs were taken on awakening. The baseline prevalence of nondipping (79%) was slightly increased after treatment (86%; P=0.131). The ambulatory blood pressure reduction was statistically significant (9.4/6.0 mm Hg for systolic/diastolic blood pressure; P<0.001) with 1 drug at bedtime. This reduction was larger in the nocturnal than in the diurnal mean of blood pressure. Thus, whereas only 16% of the patients in this group were dippers at baseline, 57% were dippers after therapy (P<0.001). Results indicate that, in resistant hypertension, time of treatment may be more important for blood pressure control and for the proper modeling of the circadian blood pressure pattern than just changing the drug combination.

Hermida, Ramón C.; Ayala, Diana E.; Mojón, Artemio; Fernández, José R. (2010):

Effects of time of antihypertensive treatment on ambulatory blood pressure and clinical characteristics of subjects with resistant hypertension.

In: *Am J Hypertens* 23 (4), S. 432–439. DOI: 10.1038/ajh.2009.260.

Abstract:

BACKGROUND\r\nSubjects with resistant hypertension present high prevalence of a nondipper blood pressure (BP) pattern, associated with increased risk of cardiovascular events. Nondipping is partly related to the absence of 24-h therapeutic coverage in hypertensives treated with single morning doses.\r\nMETHODS\r\nWe studied the impact of treatment time on ambulatory BP and clinical characteristics of 1,794 subjects with resistant hypertension, categorized according to the time of treatment (either ingesting all antihypertensive medications upon awakening, or > or =1 drug at bedtime). BP was measured for 48 consecutive hours, and physical activity was simultaneously monitored every minute by wrist actigraphy.\r\nRESULTS\r\nThe percentage of controlled subjects was higher among those taking medication at bedtime (P < 0.001). Among the 1,306 participants with true resistant hypertension, those ingesting > or =1 drug at bedtime showed significantly lower 24-h mean of systolic BP (SBP)/diastolic BP (DBP) (by 4.1/1.5 mm Hg, respectively; P < 0.015). The difference between groups was more prominent in asleep BP (9.7/4.4 mm Hg, P < 0.001). The awake/asleep BP ratio was significantly higher by 5.8% (P < 0.001) and the prevalence of nondipping lower from 83 to 40% (P < 0.001) in subjects receiving bedtime treatment. This latter group also showed significant lower mean values of glucose, total cholesterol, low-density lipoprotein-cholesterol, fibrinogen, and urinary albumin excretion.\r\nCONCLUSIONS\r\nIn resistant hypertension, pharmacological therapy should take into account when to treat with respect to the rest-activity cycle of each subject. Bedtime treatment was associated with greater clinic and ambulatory BP control, lower prevalence of a high-risk nondipper pattern, and lower values of relevant clinical markers of cardiovascular risk.

Hermida, R. C.; Ayala, D. E.; Fontao, M. J.; Mojon, A.; Fernandez, J. R. (2012):

Ambulatory Blood Pressure Monitoring: Importance of Sampling Rate and Duration-48 Versus 24 Hours-on the Accurate Assessment of Cardiovascular Risk.

In: *Chronobiol.Int.* (0742-0528 (Linking)). DOI: 10.3109/07420528.2012.701457.

Abstract:

Independent prospective studies have found that ambulatory blood pressure (BP) monitoring (ABPM) is more closely correlated with target organ damage and cardiovascular disease (CVD) risk than clinic BP measurement. This is based on studies in which BP was sampled every 15-30 min for </=24 h, without taking into account that reproducibility of any estimated parameter from a time series to be potentially used for CVD risk assessment might depend more on monitoring duration than on sampling rate. Herein, we evaluated the influence of duration (48 vs. 24 h) and sampling rate of BP measurements (form every 20-30 min up to every 2 h) on the prognostic value of ABPM-derived parameters. We prospectively studied 3344 subjects (1718 men/1626 women), 52.6 +/- 14.5 yrs of age, during a median follow-up of 5.6 yrs. Those with hypertension at baseline were randomized to ingest all their prescribed hypertension medications upon awakening or >/=1 of them at bedtime. At baseline, BP was measured at 20-min intervals from 07:00 to 23:00 h and at 30-min intervals at night for 48 h, and physical activity was simultaneously monitored every min by wrist actigraphy to accurately derive the awake and asleep BP means. Identical assessment was scheduled annually and more frequently (quarterly) if treatment adjustment was required. ABPM profiles were modified to generate time series of identical 48-h duration but with data sampled at 1- or 2-h intervals, or shorter, i.e., first 24 h, time series with data sampled at the original rate (daytime 20-min intervals/nighttime 30-min intervals). Bland-Altman plots indicated that

the range of individual differences in the estimated awake and asleep systolic (SBP) and diastolic BP (DBP) means between the original and modified ABPM profiles was up to 3-fold smaller for data sampled every 1 h for 48 h than for data sampled every 20-30 min for the first 24 h. Reduction of ABPM duration to just 24 h resulted in error of the estimated asleep SBP mean, the most significant prognostic marker of CVD events, in the range of -21.4 to +23.9 mm Hg. Cox proportional-hazard analyses adjusted for sex, age, diabetes, anemia, and chronic kidney disease revealed comparable hazard ratios (HRs) for mean BP values and sleep-time relative BP decline derived from the original complete 48-h ABPM profiles and those modified to simulate a sampling rate of one BP measurement every 1 or 2 h. The HRs, however, were markedly overestimated for SBP and underestimated for DBP when the duration of ABPM was reduced from 48 to only 24 h. This study on subjects evaluated prospectively by 48-h ABPM documents that reproducibility in the estimates of prognostic ABPM-derived parameters depends markedly on duration of monitoring, and only to a lesser extent on sampling rate. The HR of CVD events associated with increased ambulatory BP is poorly estimated by relying on 24-h ABPM, indicating ABPM for only 24 h may be insufficient for proper diagnosis of hypertension, identification of dipping status, evaluation of treatment efficacy, and, most important, CVD risk stratification. Hermida, R. C.; Ayala, E.; Mojón, A.; Fernández (2013):

Blunted sleep-time relative blood pressure decline increases cardiovascular risk independent of blood pressure level—The 'normotensive non-dipper' paradox.

In: *Chronobiology International* 30 (1-2), S. 87–98. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-06540-008%26site%3dehost-live;rhermida@uvigo.es.

Abstract:

Numerous studies have consistently shown an association between blunted sleep-time relative blood pressure (BP) decline (non-dipping) and increased cardiovascular disease (CVD) risk in hypertension. Normotensive persons with a non-dipper BP profile also have increased target organ damage, namely, increased left ventricular mass and relative wall thickness, reduced myocardial diastolic function, increased urinary albumin excretion, increased prevalence of diabetic retinopathy, and impaired glucose tolerance. It remains a point of contention, however, whether the non-dipper BP pattern or just elevated BP, alone, is the most important predictor of advanced target organ damage and future CVD events. Accordingly, we investigated the role of dipping status and ambulatory BP level as contributing factors for CVD morbidity and mortality in the MAPEC (Monitorización Ambulatoria para Predicción de Eventos Cardiovasculares, i.e., Ambulatory Blood Pressure Monitoring for Prediction of Cardiovascular Events) study. We prospectively studied 3344 individuals (1718 men/1626 women), 52.6 ± 14.5 (mean ± SD) yrs of age, during a median follow-up of 5.6 yrs. BP was measured by ambulatory monitoring (ABPM) for 48 h at baseline, and again annually or more frequently (quarterly) if treatment adjustment was required in treated hypertensive patients. At baseline, those with ABPM-substantiated hypertension were randomized to one of two treatment-time regimen groups: (i) ingestion of all prescribed hypertension medications upon awakening or (ii) ingestion of the entire dose of ≥1 of them at bedtime. Those found to be normotensive at baseline were untreated but followed and evaluated by repeated ABPM like the hypertensive patients. Participants were divided into four investigated categories on the basis of dipping status and ambulatory BP: (i) dipper vs. non-dipper, and (ii) normal ambulatory BP if the awake systolic (SBP)/diastolic (DBP) BP means were <135/85 mm Hg and the asleep SBP/DBP means were <120/70 mm Hg, and elevated ambulatory BP otherwise. Cox survival analyses, adjusted for significant confounding variables, documented that non-dippers had significantly higher CVD risk than dippers, whether they had normal ($p = .017$) or elevated ambulatory BP ($p < .001$). Non-dippers with normal awake and asleep SBP and DBP means, who accounted for 21% of the studied population, had similar hazard ratio (HR) of CVD events (1.61 [95% confidence interval, CI: 1.09-2.37]) as dippers with elevated ambulatory BP (HR: 1.54 [95% CI: 1.01-2.36]; $p = .912$ between groups). These results remained mainly unchanged for treated and untreated patients analyzed separately. Our findings document that the risk of CVD events is influenced not only by ambulatory BP elevation, but also by blunted nighttime BP decline, even within the normotensive range, thus supporting ABPM as a requirement for proper CVD risk assessment in the general population. The elevated CVD risk in "normotensive" individuals with a non-dipper BP profile represents a clear paradox, as those persons do not have "normal BP" or low CVD risk. Our findings also indicate the need to redefine the concepts of normotension/hypertension, so far established on the unique basis of BP level, mainly if not exclusively measured at the clinic, independently of circadian BP pattern.

Sleep-time ambulatory blood pressure as a novel therapeutic target for cardiovascular risk reduction.

In: *J Hum Hypertens. DOI:* 10.1038/jhh.2014.1.

Abstract:

Diagnosis of hypertension and clinical decisions regarding its treatment are typically based upon daytime clinic blood pressure (BP) measurements, occasionally supplemented by wake-time patient self-assessment. Yet, correlation between BP level and target organ damage, cardiovascular disease (CVD) risk, and long-term prognosis is higher for ambulatory BP monitoring (ABPM) measurements. Numerous studies consistently reveal CVD events are better predicted by the asleep than awake or 24 h BP means. In addition, when the asleep BP mean is adjusted by the awake mean, only the former is a significant independent predictor of outcome. Endogenous circadian rhythms explain statistically and clinically significant ingestion time differences in efficacy, duration of action, safety and/or effects on the daily BP pattern of most hypertension medications and their combinations. Bedtime versus morning-time ingestion of angiotensin-converting enzyme inhibitors or angiotensin receptor blockers, independent of drug terminal half-life, both better reduces asleep BP and normalizes the daily BP profile into a more normal dipper pattern. The recently completed prospective outcome MAPEC Study verifies therapeutic restoration of the normal sleep-time BP decline, a novel therapeutic goal most effectively achieved by ingestion of the entire daily dose of >/=1 conventional hypertension medications at bedtime, best decreases CVD morbidity and mortality. Our findings indicate around-the-clock ABPM is a clinical necessity to accurately detect abnormal sleep-time BP and assess CVD risk, and that hypertension ought to be managed by a bedtime therapeutic strategy, preferably one including medication that antagonizes the activities and actions of the renin-angiotensin-aldosterone system.Journal of Human Hypertension advance online publication, 6 February 2014; doi:10.1038/jhh.2014.1.

Hernández-Del Rey, Raquel; Martin-Baranera, Montserrat; Sobrino, Javier; Gorostidi, Manuel; Vinyoles, Ernest; Sierra, Cristina et al. (2007):

Reproducibility of the circadian blood pressure pattern in 24-h versus 48-h recordings: the Spanish Ambulatory Blood Pressure Monitoring Registry.

In: *J Hypertens* 25 (12), S. 2406–2412. DOI: 10.1097/HJH.0b013e3282effed1.

Abstract:

OBJECTIVES\r\nTo assess the reproducibility of the circadian blood pressure (BP) pattern over a 48-h period by comparing the first 24 h of ambulatory blood pressure monitoring (ABPM) with the following 24 h and with the mean over 48 h.\r\nPATIENTS AND METHODS\r\nPatients undergoing 48-h ABPM within the National ABPM Registry of the Spanish Society of Hypertension, based on 800 Spacelabs 90207 monitors distributed throughout Spain in hypertension units and primary healthcare centres, were included. Between June 2004 and September 2005, 611 valid 48-h ABPM recordings were obtained, 235 corresponded to patients without antihypertensive treatment.\r\nRESULTS\r\nThe percentages of patients classified as non-dipper for the first 24 h, the second 24 h and the 48-h average were 47, 50 and 48%, respectively. When the first and second 24-h periods were compared, 147 (24%) subjects switched from dipper (D) to non-dipper (ND) or vice-versa. When the first 24-h period was compared to the 48-h average, 66 (11%) subjects switched patterns. The proportions were similar separately for systolic blood pressure (SBP) and diastolic blood pressure (DBP) and between treated and untreated patients. In subjects with poor ABPM reproducibility, night-to-day ratios were of an intermediate value between those of subjects always classified as D or ND.\r\nCONCLUSION\r\nCategorization of D or ND based on a single 24-h ABPM is moderately reproducible, since one out of every five patients change profile over the following 24 h. Nevertheless, the use of 48-h ABPM in clinical practice should be assessed according to cost-effectiveness criteria. Night-to-day ratios may be helpful in identifying patients with a stable profile.

Heron, Kristin E. (2012):

Ecological momentary intervention {emi}: Incorporating mobile technology into a disordered eating treatment program for college women.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (10-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99080-236&site=ehost-live.

Abstract:

Psychosocial and health behavior treatments can be extended beyond research and clinical settings by using mobile technology to provide Ecological Momentary Interventions [EMI] to individuals as they go about their daily lives. This study integrates the assessment (i.e., Ecological Momentary Assessment; EMA) and intervention (i.e., EMI) capacities of palmtop computers to provide individually tailored EMI to participants in real time. The feasibility and efficacy of using EMI to augment a disordered eating treatment intervention for college women was evaluated. Participants were randomized to view psychoeducational videos on a computer (attention control), complete an interactive CD-ROM-based intervention aimed at reducing body dissatisfaction and disordered eating behaviors (CD), or receive the CD-ROM supplemented with EMI (CD+EMI). The content and timing of EMI was individually tailored in real time and provided on palmtop computers for one week following the CD intervention. Very high compliance rates with the EMA/EMI protocol were demonstrated and women were generally satisfied with the intervention,

suggesting it is feasible to implement tailored EMI. An evaluation of treatment efficacy revealed the computerized CD-ROM intervention did not reliably produce significant improvements in body-related constructs and there was no unique or added benefit of EMI. This study was innovative in that it used palmtop computers to combine ambulatory assessment and intervention strategies to provide tailored and contextually sensitive EMI. As such, it adds to the relatively young, but growing EMI literature by identifying challenges and opportunities for ambulatory assessment and intervention methods in psychosocial and health behavior treatments. Eating behaviors and negative affect in college women's everyday lives.

In: *Int J Eat Disord. DOI:* 10.1002/eat.22292.

Abstract:

OBJECTIVE: A growing body of research seeks to understand the relationship between mood and eating behaviors. Ecological Momentary Assessment (EMA) methods provide a method for assessing these processes in natural settings. We used EMA to examine the relationship between mood and eating behaviors in everyday life among women with subclinical disordered eating behaviors. METHOD: Participants (N = 127, age M = 19.6 years, BMI M = 25.5) completed five daily EMA reports on palmtop computers for 1 week. Assessments included measures of negative affect (NA) and eating-related behavior during eating (eating large amounts of food, loss of control over eating, and restricting food intake) and noneating episodes (skip eating to control weight/shape). Time-lagged multilevel models tested mood-eating behavior relationships. RESULTS: Higher NA did not precede any unhealthy eating and weight control behaviors. However, NA was higher when women reported eating large quantities of food, losing control over eating, and restricting food intake during their most recent eating episode, but not after skipping eating to control weight/shape. DISCUSSION: These findings elucidate the processes in daily life that may influence the development and maintenance of unhealthy eating and weight control behaviors that, in turn, can inform interventions. Heron, Kristin E.; Smyth, Joshua M. (2010):

Ecological momentary interventions: incorporating mobile technology into psychosocial and health behaviour treatments.

In: *British Journal of Health Psychology* 15 (Pt 1), S. 1–39. DOI: 10.1348/135910709X466063.

Abstract:

PURPOSE\r\nPsychosocial and health behaviour treatments and therapies can be extended beyond traditional research or clinical settings by using mobile technology to deliver interventions to individuals as they go about their daily lives. These ecological momentary interventions (EMIs) are treatments that are provided to people during their everyday lives (i.e. in real time) and in natural settings (i.e. real world). The goal of the present review is to synthesize and critique mobile technology-based EMI aimed at improving health behaviours and psychological and physical symptoms.\r\nMETHODS\r\nTwenty-seven interventions using palmtop computers or mobile phones to deliver ambulatory treatment for smoking cessation, weight loss, anxiety, diabetes management, eating disorders, alcohol use, and healthy eating and physical activity were identified.\r\nRESULTS\r\nThere is evidence that EMI can be successfully delivered, are accepted by patients, and are efficacious for treating a variety of health behaviours and physical and psychological symptoms. Limitations of the existing literature were identified and recommendations and considerations for research design, sample characteristics, measurement, statistical analyses, and clinical implementation are discussed.\r\nCONCLUSIONS\r\nMobile technology-based EMI can be effectively implemented as interventions for a variety of health behaviours and psychological and physical symptoms. Future research should integrate the assessment and intervention capabilities of mobile technology to create dynamically and individually tailored EMI that are ecologically sensitive.

Heron, Kristin E.; Smyth, Joshua M. (2013):

Is intensive measurement of body image reactive? A two-study evaluation using Ecological Momentary Assessment suggests not.

In: *Body Image* 10 (1), S. 35–44. DOI: 10.1037/t13685-000;

Abstract:

Intensive assessment methods (e.g., Ecological Momentary Assessment [EMA]) are increasingly used to capture body image experiences in daily life. One concern with EMA is multiple assessments may increase reactivity to internal or external cues, potentially biasing measurement. Reactivity to EMA was evaluated in two studies (Study 1: N = 63 female undergraduates, Study 2: N = 131 women with high body dissatisfaction/disordered eating). Participants completed five daily surveys on handheld computers for 1–2 weeks and body image-related questionnaires at the start and end of each study. Results showed no systematic changes in pre- and post-EMA measures or momentary EMA reports, suggesting women were not reactive to the EMA protocols. Completing 1–2 weeks of EMA does not appear to affect body dissatisfaction, mood, or attitudes in non-clinical or at-risk samples of women. These studies provide evidence that EMA methods can be used to assess real-world body image experiences without undue concern about measurement reactivity. Herrera, Socrates; Vallejo, Andres F.; Quintero, Juan P.; Arevalo-Herrera, Myriam; Cancino, Marcela; Ferro, Santiago (2014):

Field evaluation of an automated RDT reader and data management device for Plasmodium falciparum/Plasmodium vivax malaria in endemic areas of Colombia.

In: *Malar J* 13 (1), S. 87. DOI: 10.1186/1475-2875-13-87.

Abstract:

BACKGROUND: Massive implementation of malaria diagnostics in low-resource countries is regarded as a pivotal strategy in control and elimination efforts. Although malaria rapid diagnostic tests (RDTs) are considered a viable alternative, there are still obstacles to the widespread implementation of this strategy, such as reporting constraints and lack of proper quality assurance of RDT-based programmes at point-of-care (POC). METHODS: A prospective cohort of patients, seeking routine care for febrile episodes at health centres in malaria-endemic areas of Colombia, was used to assess the diagnostic performance of a device based on smartphone technology (Deki ReaderTM, former codename "GenZero"), that assists users at POC to process RDTs. After informed consent, patients were enrolled into the study and blood samples were collected for thick blood smear (TBS) and RDT. The RDT results were interpreted by both visual inspection and Deki Reader device and concordance between visual and device interpretation was measured. Microscopy corrected by real-time polymerase chain reaction (PCR) and microscopy were "gold standard" tests to assess the diagnostic performance. RESULTS: In total, 1,807 patients were enrolled at seven health centres in malaria-endemic areas of Colombia. Thirty-three Plasmodium falciparum and 100 Plasmodium vivax cases were positive by corrected microscopy. Both sensitivity and specificity were 93.9% (95% CI 69.7-95.2) and 98.7% (95% CI 98.5-99.4) for P. falciparum, and 98.0% (95% CI 90.3-98.9) and 97.9% (95% CI 97.1-98.5) for P. vivax. Percentage concordance between visual and device interpretation of RDT was 98.5% and 99.0% for P. vivax and P. falciparum, respectively.The RDT, when compared to TBS, showed high sensitivity and specificity for P. falciparum in both visual and device interpretation, and good overall diagnostic performance for P. vivax. Comparison between PCR as gold standard and visual and device interpretation showed acceptable overall performance for both species. CONCLUSIONS: The diagnostic performance of the Deki Reader was comparable to visual interpretation of RDTs (without significant differences) for both malaria species. Providing standardized automated interpretation of RDTs at POC in remote areas, in addition to almost real-time reporting of cases and enabling quality control would greatly benefit large-scale implementation of RDT-based malaria diagnostic programmes.

Hesketh, Kathryn R.; Goodfellow, Laura; Ekelund, Ulf; McMinn, Alison M.; Godfrey, Keith M.; Inskip, Hazel M. et al. (2014):

Activity levels in mothers and their preschool children.

In: *Pediatrics* 133 (4), S. e973-80. DOI: 10.1542/peds.2013-3153.

Abstract:

OBJECTIVES: To investigate the association between objectively measured maternal and preschool-aged children's physical activity, determine how this association differs by demographic and temporal factors, and identify factors associated with maternal activity levels. METHODS: In the UK Southampton Women's Survey, physical activity levels of 554 4-year-olds and their mothers were measured concurrently by using accelerometry for </=7 days. Two-level mixed-effects linear regression was used to model the association between maternal and children's minutes spent sedentary, in light (LPA) and moderate-to-vigorous physical activity (MVPA). Linear regression was used to investigate correlates of maternal activity. RESULTS: Mother-child daily activity levels were positively associated at all activity intensities (sedentary, LPA, and MVPA; all P < .001). The association for sedentary time was stronger for normal-weight children (versus those who were overweight/obese), and those attending preschool part-time (versus full-time). The mother-child association for LPA differed by maternal education and was stronger at the weekend (versus weekdays). The opposite was true for MVPA. Sedentary time and MVPA were most strongly associated in mornings, with LPA most strongly associated in the evenings. Maternal BMI, age leaving school, number and age of children at home, and working hours were independently associated with maternal daily sedentary time and LPA. CONCLUSIONS: Physical

activity levels in mothers and their 4-year-old children are directly associated, with associations at different activity intensities influenced by temporal and demographic factors. Influences on maternal physical activity levels also differ by activity intensity. Providing targeted interventions for mothers of young children may increase both groups' activity.

Hesketh, Kathryn R.; McMinn, Alison M.; Ekelund, Ulf; Sharp, Stephen J.; Collings, Paul J.; Harvey, Nicholas C. et al. (2014):

Objectively measured physical activity in four-year-old British children: a cross-sectional analysis of activity patterns segmented across the day.

In: *Int J Behav Nutr Phys Act* 11, S. 1. DOI: 10.1186/1479-5868-11-1.

Abstract:

BACKGROUND: Little is known about preschool-aged children's levels of physical activity (PA) over the course of the day. Using time-stamped data, we describe the levels and patterns of PA in a population-based sample of four-year-old British children. METHODS: Within the Southampton Women's Survey the PA levels of 593 4-year-old children (51% female) were measured using (Actiheart) accelerometry for up to 7 days. Three outcome measures: minutes spent sedentary (<20 cpm); in light (LPA: >/=20-399 cpm) and in moderate-to-vigorous activity (MVPA: >/=400 cpm) were derived. Average daily activity levels were calculated and then segmented across the day (morning, afternoon and evening). MVPA was log-transformed. Two-level random intercept models were used to analyse associations between activity level and temporal and demographic factors. RESULTS: Children were active for 67% (mean 568.5 SD 79.5 minutes) of their daily registered time on average, with 88% of active time spent in LPA. All children met current UK guidelines of 180 minutes of daily activity. There were no differences in children's average daily levels of sedentary activity and LPA by temporal and demographic factors: differences did emerge when activity was segmented across the day. Sex differences were largest in the morning, with girls being more sedentary, spending fewer minutes in LPA and 18% less time in MVPA than boys. Children were more sedentary and less active (LPA and MVPA) in the morning if they attended childcare full-time compared to part-time, and on weekend mornings compared to weekdays. The reverse was true for weekend afternoons and evenings. Children with more educated mothers were less active in the evenings. Children were less sedentary and did more MVPA on summer evenings compared to winter evenings. CONCLUSIONS: Preschool-aged children meet current physical activity guidelines, but with the majority of their active time spent in LPA, investigation of the importance of activity intensity in younger children is needed. Activity levels over the day differed by demographic and temporal factors, highlighting the need to consider temporality in future interventions. Increasing girls' morning activity and providing opportunities for daytime activity in winter months may be worthwhile.

Loss of control eating and psychological maintenance in children: an ecological momentary assessment study.

In: *Behav Res Ther* 47 (1), S. 26–33. DOI: 10.1016/j.brat.2008.10.003.

Abstract:

OBJECTIVE\r\nRecent research suggests that binge eating is a common experience in youth. However, it remains largely unknown how children's binge eating presents in everyday life and which psychological factors serve to maintain this binge eating.\r\nMETHODS\r\nChildren aged 8-13 years with binge eating (n=59), defined as at least one episode of loss of control (LOC) over eating within the past three months, and 59 matched children without LOC history were recruited from the community. Following a combined random- and event-sampling protocol, children were interviewed about their day-to-day eating behavior, mood, and eating disorder-specific cognitions using child-specific cell phones during a 4-day assessment period in their natural environment.\r\nRESULTS\r\nLOC episodes led to a significantly greater intake of energy, particularly from carbohydrates, than regular meals of children with and without LOC eating. While LOC episodes were preceded and followed by cognitions about food/eating and body image, there was minimal evidence that negative mood states were antecedents of LOC eating.\r\nCONCLUSIONS\r\nThe results provide support for the construct validity of LOC eating in children. Maintenance theories of binge eating for adults apply to children regarding eating disorder-specific cognitions, but the association with affect regulation difficulties requires further investigation.

Smartphone medical applications useful for the rural practitioner.

In: *W V Med J* 110 (1), S. 40–44.

Abstract:

Like other similarly situated rural states, West Virginia's patients and practitioners often experience access barriers to current medical expertise for multiple disciplines. This article was generated to help bridge this gap and highlights the best-rated mobile medical applications (Apps) for smartphone use. From finding drug interactions and dosing schedules to discussing patients in HIPAA-compliant formats, Apps are becoming integral to the practice of 21st Century medicine. The increased use of these Apps by physicians-in-training and established practitioners highlights the shift from reliance upon the medical library to the easy to use mobile-based technology platforms. This article provides our practitioners, physician extenders, medical trainees, and office staff a guide to access and assess the utility of some of the best rated medical and HIPAA compliant Apps.

Mindfulness and its relationship to emotional regulation.

In: *Emotion* (1528-3542 (Linking)). DOI: 10.1037/a0026355.

Abstract:

Research on the effectiveness and mechanisms of mindfulness training applied in psychotherapy is still in its infancy (Erisman & Roemer, 2010). For instance, little is known about the extent and processes through which mindfulness practice improves emotion regulation. This experience sampling study assessed the relationship between mindfulness, emotion differentiation, emotion lability, and emotional difficulties. Young adult participants reported their current emotional experiences 6 times per day during 1 week on a PalmPilot device. Based on these reports of emotions, indices of emotional differentiation and emotion lability were composed for negative and positive emotions. Mindfulness was associated with greater emotion differentiation and less emotional difficulties (i.e., emotion lability and self-reported emotion dysregulation). Mediational models indicated that the relationship between mindfulness and emotion lability was mediated by emotion differentiation. Furthermore, emotion regulation mediated the relationship between mindfulness and both negative emotion lability and positive emotion differentiation. This experience sampling study indicates that self-reported levels of mindfulness are related to higher levels of differentiation of one's discrete emotional experiences in a manner reflective of effective emotion regulation. User Preferences and Design Recommendations for an mHealth App to Promote Cystic Fibrosis Self-Management.

In: *JMIR Mhealth Uhealth* 2 (4), S. e44. DOI: 10.2196/mhealth.3599.

Abstract:

BACKGROUND: mHealth apps hold potential to provide automated, tailored support for treatment adherence among individuals with chronic medical conditions. Yet relatively little empirical research has guided app development and end users are infrequently involved in designing the app features or functions that would best suit their needs. Self-management apps may be particularly useful for people with chronic conditions like cystic fibrosis (CF) that have complex, demanding regimens. OBJECTIVE: The aim of this mixed-methods study was to involve individuals with CF in guiding the development of engaging, effective, user-friendly adherence promotion apps that meet their preferences and self-management needs. METHODS: Adults with CF (n=16, aged 21-48 years, 50% male) provided quantitative data via a secure Web survey and qualitative data via semi-structured telephone interviews regarding previous experiences using apps in general and for health, and preferred and unwanted features of potential future apps to support CF self-management. RESULTS: Participants were smartphone users who reported sending or receiving text messages (93%, 14/15) or emails (80%, 12/15) on their smartphone or device every day, and 87% (13/15) said it would be somewhat or very hard to give up their smartphone. Approximately one-half (53%, 8/15) reported having health apps, all diet/weight-related, yet many reported that existing nutrition apps were not well-suited for CF management. Participants wanted apps to support CF self-management with characteristics such as having multiple rather than single functions (eg, simple alarms), being specific to CF, and minimizing user burden. Common themes for desired CF app features were having information at one's fingertips, automation of disease management activities such as pharmacy refills, integration with smartphones' technological capabilities, enhancing communication with health care team, and facilitating socialization within the CF community. Opinions were mixed regarding gamification and earning rewards or prizes. Participants emphasized the need for customization options to meet individual preferences and disease management goals. CONCLUSIONS: Unique capabilities of emerging smartphone technologies (eg, social networking integration, movement and location detection, integrated sensors, or electronic monitors) make many of these requests possible. Involving end users in all stages of mHealth app development and collaborating with technology experts and the health care system may result in apps that maintain engagement, improve integration and automation, and ultimately impact self-management and health outcomes.

Assessing Volume of Accelerometry Data for Reliability in Preschool Children.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e3182661478.

Abstract:

PURPOSE: This study examines what volume of accelerometry data (hours/days) is required to reliably estimate preschool children's physical activity and whether it is necessary to include weekday and weekend data. METHODS: Accelerometry data from 493-799 (depending on wear-time) preschool children from the Melbourne-based Healthy Active Preschool Years study were utilized. Percent of wear-time each child spent in total (light-vigorous) physical activity was the main outcome. Hourly increments of daily data were analyzed. T-tests, controlling for age and clustering by centre of recruitment, assessed differences between weekday and weekend physical activity. Intraclass correlation coefficients estimated reliability for an individual day. Spearman-Brown Prophecy Formula estimated number of days required to reach reliability estimates of 0.7, 0.8 and 0.9. RESULTS: Children spent a significantly greater percent of time being physically active on weekend compared with week days regardless of the minimum number of hours included (t=12.49-16.76, P<0.001 for all). The number of days required to reach each of the predetermined reliability estimates increased as the number of hours of data per day decreased. For instance, 2.7-2.8 days of data were required to reach a reliability estimate of 0.7 with 10 or more hours of data per day; 3.3-3.4 days were required to meet the same reliability estimate for days with seven hours of data. CONCLUSIONS: Future studies should ensure they include the minimum amount of data (hours/day and number of days) as identified in this study to meet at least a 0.7 reliability level and should report the level of reliability for their study. In addition to weekdays, at least one weekend day should be included in analyses to reliably estimate physical activity levels for preschool children

Correlates of sedentary behaviours in preschool children: a review.

In: *Int J Behav Nutr Phys Act* 7, S. 66. DOI: 10.1186/1479-5868-7-66.

Abstract:

BACKGROUND\r\nSedentary behaviour has been linked with a number of health outcomes. Preschool-aged children spend significant proportions of their day engaged in sedentary behaviours. Research into the correlates of sedentary behaviours in the preschool population is an emerging field, with most research being published since 2002. Reviews on correlates of sedentary behaviours which include preschool children have previously been published; however, none have reported results specific to the preschool population. This paper reviews articles reporting on correlates of sedentary behaviour in preschool children published between 1993 and 2009.\r\nMETHODS\r\nA literature search was undertaken to identify articles which examined correlates of sedentary behaviours in preschool children. Articles were retrieved and evaluated in 2008 and 2009.\r\nRESULTS\r\nTwenty-nine studies were identified which met the inclusion criteria. From those studies, 63 potential correlates were identified. Television viewing was the most commonly examined sedentary behaviour. Findings from the review suggest that child's sex was not associated with television viewing and had an indeterminate association with sedentary behaviour as measured by accelerometry. Age, body mass index, parental education and race had an indeterminate association with television viewing, and outdoor playtime had no association with television viewing. The remaining 57 potential correlates had been investigated too infrequently to be able to draw robust conclusions about associations.\r\nCONCLUSIONS\r\nThe correlates of preschool children's sedentary behaviours are multi-dimensional and not well established. Further research is required to provide a more comprehensive understanding of the influences on preschool children's sedentary behaviours to better inform the development of interventions.

Using photography in 'The Restaurant of the Future'. A useful way to assess portion selection and plate cleaning?

In: *Appetite* 63, S. 31–35. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-13384-008%26site%3dehost-live;Jeff.Brunstrom@bristol.ac.uk.

Abstract:

Laboratory-based studies of human dietary behaviour benefit from highly controlled conditions; however, this approach can lack ecological validity. Identifying a reliable method to capture and quantify natural dietary behaviours represents an important challenge for researchers. In this study, we scrutinised cafeteria-style meals in the 'Restaurant of the Future.' Self-selected meals

were weighed and photographed, both before and after consumption. Using standard portions of the same foods, these images were independently coded to produce accurate and reliable estimates of (i) initial self-served portions, and (ii) food remaining at the end of the meal. Plate cleaning was extremely common; in 86% of meals at least 90% of self-selected calories were consumed. Males ate a greater proportion of their self-selected meals than did females. Finally, when participants visited the restaurant more than once, the correspondence between selected portions was better predicted by the weight of the meal than by its energy content. These findings illustrate the potential benefits of meal photography in this context. However, they also highlight significant limitations, in particular, the need to exclude large amounts of data when one food obscures another. Hintzen, Anouk; Delespaul, Philippe; van Os, Jim; Myin-Germeys, Inez (2010):

Social needs in daily life in adults with Pervasive Developmental Disorders.

In: *Psychiatry Res* 179 (1), S. 75–80. DOI: 10.1016/j.psychres.2010.06.014.

Abstract:

Although social deficits remain a persistent component of the behavioural phenotype of Pervasive Developmental Disorders (PDD) in adulthood, it remains unclear whether these represent diminished social needs, as is seen in social anhedonia, or rather thwarted social needs, as is seen in social anxiety. This study used the Experience Sampling Method (ESM)--a structured diary technique--to examine social interaction in daily life of 8 adults with PDD, compared to 14 healthy controls. Multilevel linear regression analyses showed that PDD subjects a) did not spend more time alone, b) had no increased preference to be alone when in company, and c) spent more time with familiar people, compared to control subjects. Patients experienced more negative affect and anxiety when in the company of less familiar people compared to when they are alone, whereas no difference in affect could be found between being alone or being with familiar people. All these lines of evidence suggest that PDD subjects do have a desire to interact. However, this may be thwarted as is seen in social anxiety. Therapeutic interventions should aim at decreasing negative affect and anxiety in social interactions possibly by improving social skills to fulfil the existing social needs in adults with PDD.

Acceptability and user satisfaction of a smartphone-based, interactive blood glucose management system in women with gestational diabetes mellitus.

In: *J Diabetes Sci Technol* 9 (1), S. 111–115. DOI: 10.1177/1932296814556506.

Abstract:

The increase in gestational diabetes mellitus (GDM) is challenging maternity services. We have developed an interactive, smartphone-based, remote blood glucose (BG) monitoring system, GDm-health. The objective was to determine women's satisfaction with using the GDm-health system and their attitudes toward their diabetes care. In a service development program involving 52 pregnant women (September 2012 to June 2013), BG was monitored using GDm-health from diagnosis until delivery. Following birth, women completed a structured questionnaire assessing (1) general satisfaction, (2) equipment issues, and (3) relationship with the diabetes care team. Responses were scored on a 7-point Likert-type scale. Reliability and validity of the questionnaire were assessed using statistical methods. Of 52 women, 49 completed the questionnaire; 32 had glucose tolerance test confirmed GDM (gestation at recruitment 29 +/- 4 weeks (mean +/- SD), and 17 women previous GDM recommended for BG monitoring (18 +/- 6 weeks). In all, 45 of 49 women agreed their care was satisfactory and the best for them, 47 of 49 and 43 of 49 agreed the equipment was convenient and reliable respectively, 42 of 49 agreed GDm-health fitted into their lifestyle, and 46 of 49 agreed they had a good relationship with their care team. Written comments supported these findings, with very positive reactions from the majority of women. Cronbach's alpha was .89 with factor analysis corresponding with question thematic trends. This pilot demonstrates that GDm-health is acceptable and convenient for a large proportion of women. Effects on clinical and economic outcomes are currently under investigation in a randomized trial (clinicaltrials.gov NCT01916694).

Comparison of accelerometry cut points for physical activity and sedentary behavior in preschool children: a validation study.

In: *Pediatr.Exerc.Sci.* 24 (4), S. 563–576. Online verfügbar unter PM:23196764.

Abstract:

This study compared accelerometry cut points for sedentary behavior, light and moderate to vigorous intensity activity (MVPA) against a criterion measure, the Children's Activity Rating Scale (CARS), in preschool children. Actigraph accelerometry data were collected from 31 children (4.4 +/- 0.8 yrs) during one hour of free-play. Video data were coded using the CARS. Cut points by Pate et al., van Cauwenberghe et al., Sirard et al. and Puyau et al. were applied to calculate time spent in sedentary, light and MVPA. Repeated-measures ANOVA and paired t tests tested differences between the cut points and the CARS. Bland and Altman plots tested agreement between the cut points and the CARS. No significant difference was found between the CARS and the Puyau et al. cut points for sedentary, light and MVPA or between the CARS and the Sirard et al. cut point for MVPA. The present study suggests that the Sirard et al. and Puyau et al. cut points provide accurate group-level estimates of MVPA in preschool children

Hislop, J. F.; Bulley, C.; Mercer, T. H.; Reilly, J. J. (2012):

Comparison of epoch and uniaxial versus triaxial accelerometers in the measurement of physical activity in preschool children: a validation study.

In: *Pediatr.Exerc.Sci.* 24 (3), S. 450–460. Online verfügbar unter PM:22971560.

Abstract:

The objectives of this study were to explore whether triaxial is more accurate than uniaxial accelerometry and whether shorter sampling periods (epochs) are more accurate than longer epochs. Physical activity data from uniaxial and triaxial (RT3) devices were collected in 1-s epochs from 31 preschool children (15 males, 16 females, 4.4 +/- 0.8 yrs) who were videoed while they engaged in 1-hr of free-play. Video data were coded using the Children's Activity Rating Scale (CARS). A significant difference ($p < .001$) in the number of minutes classified as moderate to vigorous physical activity (MVPA) was found between the RT3 and the CARS ($p < .002$) using the cut point of relaxed walk. No significant difference was found between the GT1M and the CARS or between the RT3 and the CARS using the cut point for light jog. Shorter epochs resulted in significantly greater overestimation of MVPA, with the bias increasing from 0.7 mins at 15-s to 3.2 mins at 60-s epochs for the GT1M and 0 mins to 1.7 mins for the RT3. Results suggest that there was no advantage of a triaxial accelerometer over a uniaxial model. Shorter epochs result in significantly higher number of minutes of MVPA with smaller bias relative to direct observation

An investigation into the minimum accelerometry wear time for reliable estimates of habitual physical activity and definition of a standard measurement day in pre-school children.

In: *Physiol Meas* 35 (11), S. 2213–2228. DOI: 10.1088/0967-3334/35/11/2213.

Abstract:

The purpose of this study was to determine the number of hours and days of accelerometry data necessary to provide a reliable estimate of habitual physical activity in pre-school children. The impact of a weekend day on reliability estimates was also determined and standard measurement days were defined for weekend and weekdays.Accelerometry data were collected from 112 children (60 males, 52 females, mean (SD) 3.7 (0.7)yr) over 7 d. The Spearman-Brown Prophecy formula (S-B prophecy formula) was used to predict the number of days and hours of data required to achieve an intraclass correlation coefficient (ICC) of 0.7. The impact of including a weekend day was evaluated by comparing the reliability coefficient (r) for any 4 d of data with data for 4 d including one weekend day.Our observations indicate that 3 d of accelerometry monitoring, regardless of whether it includes a weekend day, for at least 7 h d(-1) offers sufficient reliability to characterise total physical activity and sedentary behaviour of pre-school children. These findings offer an approach that addresses the underlying tension in epidemiologic surveillance studies between the need to maintain acceptable measurement rigour and retention of a representatively meaningful sample size.

Hjorth, Mads F.; Chaput, Jean Philippe; Damsgaard, Camilla T.; Dalskov, Stine Mathilde; Michaelsen, Kim F.; Tetens, Inge; Sj&#65533;Din, Anders (2012):

Measure of sleep and physical activity by a single accelerometer: Can a waist-worn Actigraph adequately measure sleep in children?

In: *Sleep and Biological Rhythms* 10 (4), S. 328–335. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-27120-011%26site%3dehost-live;madsfiil@life.ku.dk.

Abstract:

Accelerometers could potentially be used to assess physical activity and sleep using the same monitor; however, two different positions are typically used for the assessment of physical activity and sleep (waist and wrist, respectively). The aim of this study is to evaluate the concordance between wrist- and waist-worn Actigraphs for sleep scoring using existing algorithms developed for placement on the wrist. Sixty-two Danish children aged 10.3 -&#65533; 0.6 years (mean -&#65533; standard deviation) wore an accelerometer (Actigraph GT3X+ Tri-Axis Accelerometer Monitor) on the right hip and on the non-dominant wrist for a continuous 7 days and 8 nights. The minute-by-minute sleep–wake agreement was evaluated and the concordance among sleep indicators was assessed using one-way ANOVA, Bland-Altman plots and Pearson correlations. The sensitivity, specificity and accuracy were 98.8–99.7, 29.8–46.9 and 86.6–88.9%, respectively. Total sleep time and sleep efficiency were higher when assessed from the waist compared to the wrist measurement site (73.8 min, P < 0.001; 12.6%, P < 0.001, respectively). In conclusion, the waist-worn and wrist-worn Actigraph monitors cannot be used interchangeably for the measurement of sleep indicators in children using the present algorithms. However, the waist-worn Actigraph monitor can provide a proxy measure of total sleep time for ranking purposes in epidemiologic studies. Ho, V.; Simmons, R. K.; Ridgway, C. L.; van Sluijs, E. M.; Bamber, D. J.; Goodyer, I. M. et al. (2013):

Is wearing a pedometer associated with higher physical activity among adolescents?

In: *Prev.Med* (0091-7435 (Linking)). DOI: 10.1016/j.ypmed.2013.01.015.

Abstract:

OBJECTIVE: To examine whether wearing a pedometer was associated with higher objectively-measured physical activity (PA) among adolescents independent of other behavior change strategies, and whether this association differed by sex or day of wear. METHOD: In a parallel-group population-based cohort study, 892 adolescents (43.4% male, mean+/-SD age, 14.5+/-0.5years) from Eastern England were recruited. PA was measured (in 2005-2006) by accelerometry over four days; a sub-group (n=345) wore a pedometer coterminously with the accelerometer. Three-level (individual, day of wear and school level) multiple linear regression was used to examine the association between accelerometry (counts/min, cpm) and pedometer wear, stratified by sex and adjusted for weekday/weekend. RESULTS: For the entire cohort, there was a significant decline in cpm over four days (p<0.01). Girls wearing pedometers had higher mean cpm than those not wearing a pedometer, independent of BMI z-score, socio-economic status, weekday/weekend, and school clustering (beta=5.1; 95% CI: 0.8 to 9.5, p=0.02). This association was not seen in boys. CONCLUSION: Pedometer wear was associated with higher PA among adolescent girls, but not boys. Findings may support sex-specific intervention strategies. In addition to pedometer monitoring, additional strategies may be required to promote PA levels, especially among boys

Hodgkinson, J. A.; Sheppard, J. P.; Heneghan, C.; Martin, U.; Mant, J.; Roberts, N.; McManus, R. J. (2013):

Accuracy of ambulatory blood pressure monitors: a systematic review of validation studies.

In: *J Hypertens* 31 (2), S. 239–250. DOI: 10.1097/HJH.0b013e32835b8d8b.

Abstract:

BACKGROUND: Recent research and guidelines recommend the routine use of ambulatory blood pressure monitoring for the diagnosis of hypertension, so accuracy of such monitors is more important than ever. AIM: : To systematically review the literature regarding the accuracy of ambulatory monitors currently in use. METHODS: Medline, Embase, Cinahl, the Cochrane database, Medion and the dabl Educational Trust website were searched until February 2011. No language or publication date limits were applied. Data were extracted separately by two independent reviewers. Methodological quality was assessed by whether a validation protocol had been used and followed correctly. RESULTS: From 5420 journal articles identified, 108 met the inclusion criteria. Excluding studies assessing monitors no longer in use, 40 relevant studies were found using 21 different monitors. Thirty-eight (95%) studies used a validation protocol of which 28 studies assessed a monitor in the general population.

Of these, protocols were passed in 24 of 28 studies, but 12 of 24 (50%) found a difference of at least 5 mmHg systolic between the test device and the reference standard for 30% or more of the readings. Of the 10 studies conducted in special population groups (e.g. pregnancy, elderly people), only four devices passed the protocols. Only six (16%) studies correctly adhered to the protocols. CONCLUSION: Published validation studies assessed most ambulatory monitors as accurate, but many failed to adhere to the underlying protocols, undermining this conclusion and peer review standards. Furthermore, most monitors which 'passed' validation showed significant variation in blood pressure from the reference standard, highlighting inadequacies in older validation protocols. Future validation studies should use protocols with simpler methodologies but more rigorous accuracy criteria

Hodgson, Jonathan M.; Woodman, Richard J.; Croft, Kevin D.; Ward, Natalie C.; Bondonno, Catherine P.; Puddey, Ian B. et al. (2014):

Relationships of vascular function with measures of ambulatory blood pressure variation.

In: *Atherosclerosis* 233 (1), S. 48–54. DOI: 10.1016/j.atherosclerosis.2013.12.026.

Abstract:

BACKGROUND: Characteristics of short-term blood pressure (BP) variation may influence cardiovascular disease risk via effects on vascular function. OBJECTIVE: In a cross-sectional study of a group of treated hypertensive and untreated largely normotensive subjects we investigated the relationships of measures of short-term BP variation with brachial artery vasodilator function. METHODS: A total of 163 treated hypertensive (n = 91) and untreated largely normotensive (n = 72) men and women were recruited from the general population. Measures of systolic and diastolic BP variation were calculated from 24 h ambulatory BP assessments and included: (i) rate of measurement-to-measurement BP variation (SBP-var and DBP-var); and (ii) day-to-night BP dip (SBP-dip and DBP dip). Endothelium-dependent vasodilation was assessed as flow-mediated dilation (FMD) and endothelium-independent vasodilation was assessed in response to glyceryl trinitrate (GTN). Relationships were explored using univariate and multivariate linear regression. RESULTS: The relationships of brachial artery vasodilator function with BP variation were not significantly different between treated hypertensive and untreated subjects, therefore these groups were combined for analysis. In univariate analysis, higher SBP-var ($P < 0.001$) and lower DBP-dip ($P = 0.004$) were associated with lower FMD; and higher SBP-var ($P = 0.002$) and lower SBP-dip ($P = 0.003$) and DBP-dip ($P = 0.001$) were associated with lower GTN-mediated dilation. In multivariate analysis, lower SBP-dip ($P = 0.007$) and DBP-dip ($P = 0.03$) were independently associated with lower GTN response. CONCLUSIONS: Our results indicate that a lower day-to-night BP dip is independently associated with impaired smooth muscle cell function. Although rate of BP variation was associated with measures of endothelial and smooth muscle cell function, relationships were attenuated after accounting for age and BP.

Hofmann, W.; Adriaanse, M.; Vohs, K. D.; Baumeister, R. F. (2013):

Dieting and the self-control of eating in everyday environments: An experience sampling study.

In: *Br.J Health Psychol.* (1359-107X (Linking)). DOI: 10.1111/bjhp.12053.

Abstract:

OBJECTIVE: The literature on dieting has sparked several debates over how restrained eaters differ from unrestrained eaters in their self-regulation of healthy and unhealthy food desires and what distinguishes successful from unsuccessful dieters. We addressed these debates using a four-component model of self-control that was tested using ecological momentary assessment, long-term weight change, and a laboratory measure of inhibitory control. DESIGN: A large sample of adults varying in dietary restraint and inhibitory control (as measured by a Stroop task) were equipped with smartphones for a week. They were beeped on random occasions and provided information on their experience and control of healthy and unhealthy food desires in everyday environments. MAIN OUTCOME MEASURES: The main outcome measures were desire strength, experienced conflict, resistance, enactment of desire, and weight change after a 4-month follow-up. RESULTS AND CONCLUSIONS: Dietary restraint was unrelated to desire frequency and strength, but associated with higher conflict experiences and motivation to use self-control with regard to food desires. Most importantly, relationships between dietary restraint and resistance, enactment of desire, and long-term weight change were moderated by inhibitory control: Compared with dieters low in response inhibition, dieters high in response inhibition were more likely to attempt to resist food desires, not consume desired food (especially unhealthy food), and objectively lost more weight over the ensuing 4 months. These results highlight the combinatory effects of aspects of the self-control process in dieters and highlight the value in linking theoretical process frameworks, experience sampling, and laboratory-based assessment in health science. STATEMENT OF CONTRIBUTION: What is already known on this subject? Dieting is a multifaceted process that can be viewed from the lens of self-control. Dietary restraint measures can be used to capture dieting status, but it is relatively unclear what differentiates successful from unsuccessful dieters (e.g., differences in desire frequency, desire strength, motivation, executive functions). What does this study add? A novel four-step conceptual model of self-control is applied to eating behaviour in everyday life. This model allows a fine-grained look at the self-control

process in restrained eaters (dieters) as compared to non-dieters. Dieters and non-dieters do not differ in desire frequency and strength (they are not simply more tempted). Dieters high (as compared to low) in inhibitory control are more likely to engage in self-control. Dieters high (as compared to low) in inhibitory control are more likely to resist unhealthy food desires. Dieters high (as compared to low) in inhibitory control are more likely to loose weight over a 4-month period. Together, the study shows clear differences among successful and unsuccessful dieters that can be linked to differences in executive functioning (inhibitory control). The present article is one of the first studies combining a conceptual model with smartphone experience sampling to study weight control and thus paradigmatic from a methodological perspective

Hofmann, Wilhelm; Baumeister, Roy F.; F+�Rster, Georg; Vohs, Kathleen D. (2011):

Everyday temptations: An experience sampling study of desire, conflict, and self-control.

In: *Journal of Personality and Social Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-28783-001&site=ehost-live.

Abstract:

How often and how strongly do people experience desires, to what extent do their desires conflict with other goals, and how often and successfully do people exercise self-control to resist their desires? To investigate desire and attempts to control desire in everyday life, we conducted a large-scale experience sampling study based on a conceptual framework integrating desire strength, conflict, resistance (use of self-control), and behavior enactment. A sample of 205 adults wore beepers for a week. They furnished 7,827 reports of desire episodes and completed personality measures of behavioral inhibition system/behavior activation system (BIS/BAS) sensitivity, trait self-control, perfectionism, and narcissistic entitlement. Results suggest that desires are frequent, variable in intensity, and largely unproblematic. Those urges that do conflict with other goals tend to elicit resistance, with uneven success. Desire strength, conflict, resistance, and self-regulatory success were moderated in multiple ways by personality variables as well as by situational and interpersonal factors such as alcohol consumption, the mere presence of others, and the presence of others who already had enacted the desire in question. Whereas personality generally had a stronger impact on the dimensions of desire that emerged early in its course (desire strength and conflict), situational factors showed relatively more influence on components later in the process (resistance and behavior enactment). In total, these findings offer a novel and detailed perspective on the nature of everyday desires and associated self-regulatory successes and failures. Hofmann, Wilhelm; Fisher, Rachel R. (2012):

How guilt and pride shape subsequent self-control.

In: *Social Psychological and Personality Science* 3 (6), S. 682–690. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-28528-005%26site%3dehost-live;Wilhelm.Hofmann@ChicagoBooth.edu.

Abstract:

The present research utilized experience sampling data to investigate how guilt and pride experiences in response to self-control failure versus success affect future self-control when encountering the same type of temptation (thematic self-control). Guilt showed signs of a "mixed blessing" such that previous guilt led to an increase in subsequent self-regulatory goal importance and conflict awareness; however, accounting for these beneficial effects, guilt also had a detrimental residual effect on the successful inhibition of recurring temptation. Pride, in contrast, had uniformly positive effects on subsequent self-control in the form of increased goal importance, increased conflict, and increased likelihood to use self-control to resist temptation. These results contrasted in theoretically important ways from an analysis of short-term spillover effects of incidental guilt and pride on thematically unrelated subsequent self-control. Potential mechanisms and implications of these findings are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Hofmann, W.; Fisher, R. R.; Luhmann, M.; Vohs, K. D.; Baumeister, R. F. (2013):

Yes, But Are They Happy? Effects of Trait Self-Control on Affective Well-Being and Life Satisfaction.

In: *J Pers* (0022-3506 (Linking)). DOI: 10.1111/jopy.12050.

Abstract:

OBJECTIVE: Does trait self-control (TSC) predict affective well-being and life satisfaction -positively, negatively, or not? METHOD: We conducted three studies (Study 1: n=414; 64.0% female; Mage =35.0 years; Study 2: n=208; 66.0% female; Mage =25.24 years; Study 3: n=234; 61.0% female; Mage =34.53 years). The key predictor was TSC, with affective well-being and life satisfaction ratings as key outcomes. Potential explanatory constructs including goal conflict, goal balancing, and emotional distress also were investigated. RESULTS: TSC is positively related to affective well-being and life satisfaction, and managing goal conflict is a key as to why. All studies, moreover, showed that the effect of TSC on life satisfaction was at least partially mediated by affect. Study 1's correlational study established the effect. Study 2's experience sampling study demonstrated that compared to those low in TSC, those high in TSC experience higher levels of momentary affect even as they experience desire, an effect partially mediated through experiencing lower conflict and emotional distress. Study 3 found evidence for the proposed mechanism-that TSC may boost well-being by helping people to avoid frequent conflict and balance vice-virtue conflicts by favoring virtues. CONCLUSION: Self-control positively contributes to happiness through avoiding and dealing with motivational conflict

Hofmann, Wilhelm; Kotabe, Hiroki; Luhmann, Maike (2013):

The spoiled pleasure of giving in to temptation.

In: *Motivation and Emotion*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-12452-001%26site%3dehost-live;wilhelm.hofmann@chicagobooth.edu.

Abstract:

Satisfying one’s desires is typically a pleasurable experience and thus a source of momentary happiness. Getting happy in the here and now, however, may be more complicated when people yield to temptations—desires that conflict with personal self-regulatory goals so that they have reason to resist them. Using data from a large experience sampling study on everyday desire, we show that people receive considerably smaller gains in momentary happiness from enacting tempting as compared to nontempting desires. We further demonstrate that this “spoiled pleasure” effect can largely be explained by self-conscious emotions, as statistically accounting for guilt, pride, and regret as mediators reduced the observed hedonic gap to nonsignificance. The present findings challenge the assumption that the costs associated with temptation lie only in the future. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Morality in everyday life.

In: *Science* 345 (6202), S. 1340–1343. DOI: 10.1126/science.1251560.

Abstract:

The science of morality has drawn heavily on well-controlled but artificial laboratory settings. To study everyday morality, we repeatedly assessed moral or immoral acts and experiences in a large (N = 1252) sample using ecological momentary assessment. Moral experiences were surprisingly frequent and manifold. Liberals and conservatives emphasized somewhat different moral dimensions. Religious and nonreligious participants did not differ in the likelihood or quality of committed moral and immoral acts. Being the target of moral or immoral deeds had the strongest impact on happiness, whereas committing moral or immoral deeds had the strongest impact on sense of purpose. Analyses of daily dynamics revealed evidence for both moral contagion and moral licensing. In sum, morality science may benefit from a closer look at the antecedents, dynamics, and consequences of everyday moral experience.

Hohn, P.; Menne-Lothmann, C.; Peeters, F.; Nicolson, N. A.; Jacobs, N.; Derom, C. et al. (2013):

Moment-to-moment transfer of positive emotions in daily life predicts future course of depression in both general population and patient samples.

In: *PLoS.One.* 8 (9), S. e75655. DOI: 10.1371/journal.pone.0075655.

Abstract:

OBJECTIVE: Positive affect (PA) is closely linked to prevention of, and recovery from, depression. Previous studies have investigated PA reactivity to pleasant situations with respect to its protective properties in relation to mood disorder. The purpose of this study was to examine, and replicate, whether moment-to-moment transfer of PA in daily life (PA persistence) is relevant to the prediction of future course of depression. METHOD: Individuals from three different studies (one general population sample (n=540), and two patient samples (n=43 and n=50) with matching controls (n=39 and n=21, respectively)) participated in an Experience Sampling Method (ESM) study. Time-lagged multilevel analyses were used to assess the degree of transfer (or persistence) of momentary positive affective states over time, in relation to naturalistic outcome (study 1) or treatment outcome (studies 2 and 3). Depressive symptoms were measured using the Symptom Checklist (SCL-90R) in sample 1 and the Hamilton Depression Rating Scale (HDRS) in samples 2 and 3. RESULTS: In study 1, participants with greater momentary PA persistence were less likely to show depressive symptoms at follow-up. In study 2, patients were more likely to respond to treatment if they displayed greater momentary PA persistence, particularly in those with recurrent depression. In study 3, patients with greater momentary PA persistence were similarly more likely to respond to treatment, especially when treated with imipramine rather than placebo. CONCLUSION: The ability to transfer PA from one moment to the next is an important factor in the prevention of and recovery from depressive symptoms. Patients with recurrent depression and those who receive antidepressants rather than placebo may benefit most from this effect. The results suggest that treatment-induced improvement in depression is mediated by increased levels of momentary transfer of PA in daily life, acquisition of which may be contingent on duration of exposure to depressive experience

Holden, George W.; Williamson, Paul A.; Holland, Grant W. O. (2014):

Eavesdropping on the family: A pilot investigation of corporal punishment in the home.

In: *Journal of Family Psychology* 28 (3), S. 401–406. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-12893-001%26site%3dehost-live.

Abstract:

This study tested the feasibility of using audio recorders to collect novel information about family interactions. Research into corporal punishment (CP) has relied, almost exclusively, on self-report data; audio recordings have the promise of revealing new insights into the use and immediate consequences of CP. So we could hear how parents respond to child conflicts, 33 mothers wore digital audio recorders for up to 6 evenings. We identified a total of 41 CP incidents, in 15 families and involving 22 parent–child dyads. These incidents were evaluated on 6 guidelines culled from the writings of CP advocates. The results indicated, contrary to advice, CP was not being used in line with 3 of the 6 recommendations and for 2 others, the results were equivocal. The last recommendation could not be assessed with audio. Latency analyses revealed children, after being hit, were misbehaving again within 10 minutes after 73% of the incidents. Mothers' self reports about whether they used CP were found to correspond to the audio data in 81% of the cases. Among the mothers who were hitting, CP occurred at a much higher rate than the literature indicates. These results should be viewed as preliminary because of the small sample of families and the even

smaller number of families who used CP. Nevertheless, this pilot study demonstrates that audio recording naturally occurring momentary processes in the family is a viable method for collecting new data to address important questions about family interactions. Hollier, Carly A.; Harmer, Alison R.; Maxwell, Lyndal J.; Menadue, Collette; Willson, Grant N.; Black, Deborah A.; Piper, Amanda J. (2014):

Validation of respiratory inductive plethysmography (LifeShirt) in obesity hypoventilation syndrome.

In: *Respir Physiol Neurobiol* 194, S. 15–22. DOI: 10.1016/j.resp.2014.01.014.

Abstract:

Validation of respiratory inductive plethysmography (LifeShirt system) (RIPLS) for tidal volume (VT), minute ventilation (V E), and respiratory frequency (fB) was performed among people with untreated obesity hypoventilation syndrome (OHS) and controls. Measures were obtained simultaneously from RIPLS and a spirometer during two tests, and compared using Bland Altman analysis. Among 13 OHS participants (162 paired measures), RIPLS-spirometer agreement was unacceptable for VT: mean difference (MD) 3mL (1%); limits of agreement (LOA) -216 to 220mL (+/-36%); V E MD 0.1Lmin(-1) (2%); LOA -4.1 to 4.3Lmin(-1) (+/-36%); and fB: MD 0.2brmin(-1) (2%); LOA -4.6 to 5.0brmin(-1) (+/-27%). Among 13 controls (197 paired measures), RIPLS-spirometer agreement was acceptable for fB: MD -0.1brmin(-1) (-1%); LOA -1.2 to 1.1brmin(-1) (+/-12%), but unacceptable for VT: MD 5mL (1%); LOA -160 to 169mL (+/-20%) and V E: MD 0.1Lmin(-1) (1%); LOA -1.4 to 1.5Lmin(-1) (+/-20%). RIPLS produces valid measures of fB among controls but not OHS patients, and is not valid for quantifying respiratory volumes among either group.

Holman, R. M.; Carson, V.; Janssen, I. (2011):

Does the fractionalization of daily physical activity (sporadic vs. bouts) impact cardiometabolic risk factors in children and youth?

In: *PLoS.One.* 6 (10), S. e25733. DOI: 10.1371/journal.pone.0025733.

Abstract:

OBJECTIVE: Children and youth accumulate their daily moderate-to-vigorous physical activity (MVPA) in bouts (i.e., >/= 5 consecutive minutes) and in a sporadic manner (i.e., <5 consecutive minutes). The study objective was to determine, within children and youth, whether MVPA accumulated in bouts is more strongly associated with cardiometabolic risk factors than an equivalent volume of MVPA accumulated sporadically. METHODS: Participants consisted of 2754 children and youth aged 6-19 years from the 2003-2006 National Health and Nutrition Examination Survey, a representative cross-sectional study. Bouts and sporadic MVPA were measured objectively over 7 days using Actigraph accelerometers. Thresholds of 5 and 10 consecutive minutes were used to differentiate between bouts and sporadic MVPA. A high cardiometabolic risk factor score (CRS) was created based on measures of waist circumference, non-high-density lipoprotein cholesterol, C-reactive protein, and systolic blood pressure. Associations were examined using logistic regression and controlled for covariates (sex, age, ethnicity, socioeconomic status, dietary fat and sodium, smoking, and accelerometry wear time). RESULTS: The odds of a high CRS decreased in a dose-response for both the sporadic and bout MVPA measures. Relative to quartile 1, the odds ratio (95% confidence interval) for a high CRS in quartile 4 was 0.25 (0.10-0.60) for sporadic MVPA, 0.17 (0.09-0.34) for >/= 5 minute bouts of MVPA, and 0.19 (0.11-0.34) for >/= 10 minute bouts of MVPA. The sporadic and bout MVPA measures had a similar ability to distinguish between participants with high and normal CRS. Relative to 0 minutes of MVPA, an equivalent number of minutes of sporadic MVPA and bouts of MVPA had an almost identical odds ratio for a high CRS. The findings were consistent for 5 and 10 minute bout thresholds. CONCLUSIONS: The relations between sporadic MVPA and bouts of MVPA with cardiometabolic risk factors were remarkably similar in children and youth

Improving prediction of binge episodes by modelling chronicity of dietary restriction.

In: *European Eating Disorders Review* 22 (6), S. 405–411. DOI: 10.1037/t04353-000.

Abstract:

This study evaluates the influences of chronicity of, and time lag between, dietary restriction and binge outcome for predicting binge episode onset. Sixty-two women aged 18 to 40 years old completed an online survey at random intervals seven times daily for a 7-day period. Participants self-reported engagement in dietary restriction and/or binging, and temptation to binge. Consecutive instances of reported dietary restriction better predicted subsequent binges than single instances. As the time lag between the first report of dietary restriction and binge onset increased, a clear linear trend emerged, such that the value of restriction for predicting binges increased with the number of consecutive assessments in which they reported dietary restriction. A similar pattern was found when predicting temptation to binge. Present findings suggest that duration of restriction is a crucial determinant of binge onset. These findings have implications for clinical practice by highlighting the time course from dietary restriction to binging. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Tests of an extension of the dual pathway model of bulimic symptoms to the state-based level.

In: *Eat Behav* 15 (2), S. 280–285. DOI: 10.1016/j.eatbeh.2014.03.011.

Abstract:

The dual pathway model proposes that trait body dissatisfaction leads to bulimic symptoms via two distinct pathways: dieting and trait negative affect. As many of these modelled variables have state-based equivalents, the present study evaluated the generalisability of this model to predict associations between state body dissatisfaction and instances of disordered eating. 124 women aged 18 to 40 years completed an online survey (accessed via a mobile phone device with web access) over a 7-day period. The mobile phone device prompted participants at random intervals seven times daily to self-report their state body dissatisfaction, current mood experiences, dieting attempts, and disordered eating practices. Multi-level mediation modelling revealed that both negative mood states and dieting significantly mediated the state body dissatisfaction-disordered eating relationships, although the strength of these associations depended on the aspect of disordered eating measured and individual differences in trait body dissatisfaction, internalization of appearance standards, tendency towards dieting, and BMI. Collectively, these results not only support adapting the dual pathway model to the state-level, but also suggest that several of the model implied pathways may be more relevant for individuals with more pathological eating- and body-related concerns and behaviours.

Holt, Laura J.; Litt, Mark D.; Cooney, Ned L. (2011):

Prospective analysis of early lapse to drinking and smoking among individuals in concurrent alcohol and tobacco treatment.

In: *Psychology of Addictive Behaviors*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24244-001&site=ehost-live.

Abstract:

The aims of the current study were to examine, prospectively, (a) dynamic changes in affective state, self-efficacy, and urge in the hours before initial smoking and drinking lapses among individuals in concurrent alcohol and smoking treatment, and (b) the extent to which self-efficacy, urge to use, and/or the use of one substance predicted lapse to the other substance. Ninety-six men and women recruited for a clinical trial of concurrent alcohol and tobacco treatment were eligible for inclusion. Only data from those who experienced an initial lapse to drinking (n = 29) or smoking (n = 32) were included. Two outpatient substance abuse clinics provided concurrent alcohol and smoking treatment on a weekly basis for three months. Ecological Momentary Assessment (EMA) methods were employed over a 28-day monitoring period to assess antecedents to first drink, and a 14-day monitoring period was examined for initial smoking lapses. Baseline and EMA measures of positive and negative affect, alcohol/smoking urge, alcohol/smoking abstinence self-efficacy, nicotine withdrawal, and quantity/frequency of alcohol and tobacco use were examined as lapse predictors. Analyses of EMA ratings controlled for the corresponding baseline measure. Smoking lapse among individuals in concurrent alcohol and tobacco treatment was foreshadowed by higher urges to smoke, lower positive mood, and lower confidence to resist smoking. Drinking lapse was preceded by lower confidence to resist smoking, but only among individuals who reported recent smoking. Concurrent alcohol and smoking treatment should focus on the enhancement of abstinence self-efficacy, positive mood, and the curbing of urges in order to offset lapse risk. Holtkamp, Kristian; Herpertz-Dahlmann, Beate; Hebebrand, Kathrin; Mika, Claudia; Kratzsch, Jürgen; Hebebrand, Johannes (2006):

Physical activity and restlessness correlate with leptin levels in patients with adolescent anorexia nervosa.

In: *Biological Psychiatry* 60 (3), S. 311–313.

Abstract:

BACKGROUND:

In food-restricted rats, leptin suppresses semistarvation-induced hyperactivity (SIH) and decreases exploratory behavior. Leptin ameliorates anxiety-related movement in ob/ob mice. In this study, we assessed the relationship between leptin and qualities of physical activity and restlessness in acute anorexia nervosa (AN).

METHODS:

Serum leptin, body mass index (BMI), % body fat, and self- and expert-ratings of qualities of physical activity and restlessness were assessed in 26 inpatients with acute AN. Accelerometry was also performed. Regression analyses were used to predict activity and restlessness using BMI, % body fat, and leptin levels as predictor variables.

RESULTS:

Leptin levels significantly contributed to the prediction of all measures of activity and restlessness.

CONCLUSIONS:

This is the first study linking hypoleptinemia in AN patients to subjective and objective measures of higher physical activity and motor and inner restlessness. Leptin may directly or indirectly (or both) influence behaviors and cognitions contributing to hyperactivity and motor restlessness.

Holt-Lunstad, Julianne; Birmingham, Wendy A.; Light, Kathleen C. (2008):

Influence of a \"warm touch\" support enhancement intervention among married couples on ambulatory blood pressure, oxytocin, alpha amylase, and cortisol.

In: *Psychosomatic Medicine* 70 (9), S. 976–985. DOI: 10.1097/PSY.0b013e318187aef7.

Abstract:

OBJECTIVE\r\nTo investigate whether a support intervention (warm touch enhancement) influences physiological stress systems that are linked to important health outcomes. Growing evidence points to a protective effect of social and emotional support on both morbidity and mortality.\r\nMETHODS\r\nIn this study, 34 healthy married couples (n = 68), aged 20 to 39 years (mean = 25.2 years), were randomly assigned to a \"behavior monitoring\" control group or participated in a 4-week intervention study in which clinic levels of plasma oxytocin, 24-hour ambulatory blood pressure, and salivary cortisol and alpha amylase were obtained pre and post intervention, at the same time salivary oxytocin was taken at home during weeks 1 and 4.\r\nRESULTS\r\nSalivary oxytocin was enhanced both early and late in the intervention group and alpha amylase was reduced at post treatment in intervention group husbands and wives relative to controls. Husbands in the intervention group had

significantly lower post treatment 24-hour systolic blood pressure than the control group.\r\nCONCLUSION\r\nIncreasing warm touch among couples has a beneficial influence on multiple stress-sensitive systems.

Holt-Lunstad, Julianne; Birmingham, Wendy; Jones, Brandon Q. (2008):

Is there something unique about marriage? The relative impact of marital status, relationship quality, and network social support on ambulatory blood pressure and mental health.

In: *Annals of Behavioral Medicine* 35 (2), S. 239–244.

Abstract:

BACKGROUND:

Having close social relationships and being married specifically have been reliably associated with health benefits including lower morbidity and mortality.

PURPOSE:

The purpose of this study was to examine the influence of marital status, relationship quality, and network support on measures of psychological and cardiovascular health.

METHOD:

We examined ambulatory blood pressure (ABP) among 204 married and 99 single males and females (N = 303).

RESULTS:

We found that both marital status and marital quality were important. Married individuals had greater satisfaction with life (SWL) and blood pressure dipping than single individuals. High marital quality was associated with lower ABP, lower stress, less depression, and higher SWL. Importantly, contrasting those who are unmarried with those in low-quality marriages, we find that single individuals had lower ABP-suggesting that single individuals fare better than their unhappily married counterparts. Likewise, having a supportive network did not moderate (i.e., buffer) the effects of being single or unhappily married.

CONCLUSIONS:

Findings indicate being married per se is not universally beneficial, rather, the satisfaction and support associated with such a relationship is important. However, marriage may be distinctive, as evidence further suggests that support from one's network does not compensate for the effect of being single. These results highlight the complexities in understanding the influence of social relationships on long-term health, and they may help clarify the physiological pathways by which such associations exist.

Holtz, Bree; Whitten, Pamela (2009):

Managing asthma with mobile phones: a feasibility study.

In: *Telemed J E Health* 15 (9), S. 907–909. DOI: 10.1089/tmj.2009.0048.

Abstract:

Asthma is a chronic disease and a growing health problem worldwide. The objective of this pilot study was to test the feasibility and utilization of tracking asthma symptoms through an innovative mobile phone application. The subjects for this research project consisted of 4 individuals who are currently receiving treatment for asthma from a primary care physician in Ingham County, Michigan. Participants took their peak flow reading each day and used the short message service (SMS) function on their phone and sent it to a Web server. If they did not send it by 11 AM, they received a reminder via an automated SMS to their phone. The resulting data suggest that this method of management is feasible. The data also demonstrate participants' satisfaction in monitoring their asthma in this manner. Using mobile phones for asthma management could improve compliance with asthma action plans and reduce adverse asthma events. Future research could further demonstrate that mobile phones are a new and effective method for providing healthcare.

Hong, Ryan Y. (2010):

Neuroticism, anxiety sensitivity thoughts, and anxiety symptomatology: Insights from an experience-sampling approach.

In: *Cogn Ther Res* 34 (3), S. 254–262.

Abstract:

Relations among Neuroticism, anxiety sensitivity (AS) thoughts, and anxiety symptoms were examined in this study using an experience-sampling methodology. Daily AS thoughts and anxiety symptoms arising from naturally-occurring negative events were assessed among 100 participants over a 1 month period. Neuroticism moderated the relation between anxiety symptoms and AS thoughts such that individuals high on Neuroticism reported more AS thoughts on days when high (rather than low) anxiety was experienced. Conversely, the relation between anxiety and AS thoughts on a daily basis was weaker for low Neuroticism individuals. Consistent with previous research, elevated levels of AS thoughts on any particular day were associated with increased subsequent anxiety symptoms. The present findings highlight the importance of elucidating psychopathological processes associated with AS and anxiety not only at the interindividual level, but also at the intraindividual level.

Development of the smartphone-based colorimetry for multi-analyte sensing arrays.

In: *Lab Chip. DOI:* 10.1039/c3lc51451j.

Abstract:

Here we report development of a smartphone app (application) that digitizes the colours of a colorimetric sensor array. A conventional colorimetric sensor array consists of multiple paper-based sensors, and reports the detection results in terms of colour change. Evaluation of the colour changes is normally done by the naked eye, which may cause uncertainties due to personal subjectivity and the surrounding conditions. Solutions have been particularly sought in smartphones as they are capable of spectrometric functions. Our report specifically focuses on development of a practical app for immediate point-of-care (POC) multi-analyte sensing without additional devices. First, the individual positions of the sensors are automatically identified by the smartphone; second, the colours measured at each sensor are digitized based on a correction algorithm; and third, the corrected colours are converted to concentration values by pre-loaded calibration curves. All through these sequential processes, the sensor array taken in a smartphone snapshot undergoes laboratory-level spectrometry. The advantages of inexpensive and convenient paper-based colorimetry and the ubiquitous smartphone are tied to achieve a ready-to-go POC diagnosis.

Hopenfeld, Bruce; John, M. Sasha; Fischell, David R.; Medeiros, Paulo; Guimarães, Hélio P.; Piegas, Leopoldo S. (2009):

The Guardian: an implantable system for chronic ambulatory monitoring of acute myocardial infarction.

In: *J Electrocardiol* 42 (6), S. 481–486. DOI: 10.1016/j.jelectrocard.2009.06.017.

Abstract:

The AngelMed Guardian is an implantable medical device that records cardiac data and detects ischemic events using a standard pacemaker intracardiac lead positioned in the right ventricular apex. The Guardian has been implanted in 55 people in the United States and Brazil and is currently undergoing a Food and Drug Administration phase 2 pivotal trial in the United States. The Guardian detects acute ischemic events by analyzing ST-segment shifts. The ST-segment shifts are calculated as the difference between the ST deviation of a current 10-second electrogram window and a baseline ST deviation value. If the ST-segment shift is greater than a heart rate-dependent programmable threshold, then the device generates an emergency alert signal. Results thus far have demonstrated that (i) the intracardiac electrogram is relatively noise-free and (ii) the ST-shift technique used by the Guardian is effective for detecting acute ischemic events.

Hopper, James W.; Su, Zhaohui; Looby, Alison R.; Ryan, Elizabeth T.; Penetar, David M.; Palmer, Christopher M.; Lukas, Scott E. (2006):

Incidence and patterns of polydrug use and craving for ecstasy in regular ecstasy users: an ecological momentary assessment study.

In: *Drug Alcohol Depend* 85 (3), S. 221–235. DOI: 10.1016/j.drugalcdep.2006.04.012.

Abstract:

BACKGROUND\r\nPrevious studies employing retrospective assessments methods found that regular ecstasy users frequently use alcohol, marihuana and other drugs in combination with ecstasy.\r\nMETHODS\r\nTwenty-two participants (13 males, 9 females) wore a wrist actigraph/data recorder to record real-time drug use and ecstasy craving for 6 weeks. Rates of alcohol and drug use on ecstasy use versus non-use nights, and before, during, and after ecstasy use were analyzed with generalized estimation equations (GEE). Craving was modeled with GEE and linear mixed models.\r\nRESULTS\r\nApproximately 70% of ecstasy uses occurred on Friday or Saturday nights. No drug was significantly more likely to be used on ecstasy use nights than comparison Friday and Saturday nights. On nights ecstasy was used, in general across all drugs assessed, use was more likely before and during than after ecstasy intoxication, while alcohol use was also more likely before than during ecstasy intoxication. Though low overall, craving for ecstasy increased over 24 h before use and was higher on Friday nights of weeks ecstasy was used on weekends than weeks it was not used.\r\nCONCLUSIONS\r\nUse of ecstasy on a particular night may not be associated with any greater likelihood of using any other intoxicating drug, and use of other drugs on nights involving ecstasy use may simply reflect a \"natural history\" of drug-use nights that begins with alcohol, progresses to more intoxicating drugs, and ends with little drug use. Confirmation of these findings awaits further advances in the application of ecological momentary assessment methodologies.

Hoppmann, Christiane A.; Gerstorf, Denis; Smith, Jacqui; Klumb, Petra L. (2007):

Linking possible selves and behavior: Do domain-specific hopes and fears translate into daily activities in very old age?

In: *The Journals of Gerontology Series B: Psychological Sciences and Social Sciences* 62 (2), S. P104-P111.

Abstract:

We used time-sampling information from a subsample of the Berlin Aging Study (N=83; M=81.1 years) to investigate the link between possible selves in three domains (health, everyday cognition, and social relations) and performance of daily activities. In the domains of health and social relations, hoped-for selves were associated with higher probabilities of performing daily activities in those domains. There were no associations in the cognitive domain or between feared selves and activities. Individuals who engaged in hope-related activities reported concurrent higher positive affect and subsequently had a higher probability of survival over a 10-year period. These findings speak to important associations between beliefs about possible selves and activities in advanced old age and the value of considering associations between microlevel and macrolevel indicators of successful aging.

Daily goal pursuits predict cortisol secretion and mood states in employed parents with preschool children.

In: *Psychosomatic Medicine* 68 (6), S. 887–894. DOI: 10.1097/01.psy.0000238232.46870.f1.

Abstract:

OBJECTIVE\r\nThis study examined the relationship between the personal relevance of daily activities with respect to self-set work and family goals and affective and neuroendocrine stress reactions.\r\nMETHODS\r\nA total of 53 dual-earner couples with preschool children participated in a 1-week interval-sampling study. At the beginning, participants reported their personal work and family goals. During the time-sampling phase, both partners reported the goal relevance of their daily activities, current mood, and provided saliva samples for cortisol estimation every 3 hours.\r\nRESULTS\r\nHierarchical linear models show that the performance of goal-furthering activities is associated with more positive mood and decreased secretion of cortisol. The relationship between the goal relevance of daily activities and cortisol was partially mediated by affect quality.\r\nCONCLUSIONS\r\nThese findings speak to a person-centered approach in research on stress by showing that knowledge of individual goals is important for an understanding of affective and neuroendocrine stress reactions in employed parents with preschool children.

Hoppmann, Christiane A.; Riediger, Michaela (2009):

Ambulatory assessment in lifespan psychology: An overview of current status and new trends.

In: *European Psychologist* 14 (2), S. 98–108.

Abstract:

Ambulatory assessment represents a powerful research tool in lifespan psychology because it allows assessing the within-person variability of developmental processes as it occurs within context-specific influences of people's natural environments. Following a discussion of historical origins, we review four current research themes in developmentally relevant ambulatory assessment studies that use electronic devices as assessment instruments: (a) affective-motivational development, (b) social contexts of development, (c) age-related challenges and everyday functioning, and (d) cognitive development. Overall, the reviewed research demonstrates that ambulatory assessment complements traditional developmental study designs and laboratory assessments in important ways. Acknowledging the strengths and limitations of ambulatory assessment approaches, we propose that ambulatory assessment will benefit lifespan psychology most if it becomes an integral part of multimethod investigations of developmental phenomena that balance the external and internal validity of findings. Future research should strengthen the lifespan perspective in ambulatory assessment approaches, combine multiple indicators (subjective and objective) of successful development, and attend to the fact that individual development often interacts with significant others. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Horvath, Sylvia; Taylor, David G.; Marsh, Jonathan P.; Kriellaars, Dean J. (2007):

The effect of pedometer position and normal gait asymmetry on step count accuracy.

In: *Applied Physiology, Nutrition, and Metabolism* 32 (3), S. 409–415.

Abstract:

Manufacturers of pedometers recommend wearing a pedometer on the midline of the right thigh and this recommendation is used in research. However, there is conflicting evidence regarding the effect of pedometer position on accuracy. The purpose of this study was to systematically evaluate the effect of pedometer position on accuracy for 3 modes of gait. The Yamax SW200 pedometer was evaluated in 20 subjects in 5 different positions simultaneously: left mid-axillary, left mid-thigh, umbilical, right mid-thigh, and right mid-axillary. Each subject was asked to walk on a treadmill (54, 80, and 107 m.min(-1)), to walk overground (slow, preferred, and fast speeds), and to ascend and descend stairs. Pedometer steps were recorded and compared with actual steps observed. Using the same protocol, instantaneous triaxial accelerometry was used to explain position-dependent differences in accuracy. At slow speeds, the left mid-axillary position demonstrated the lowest net mean (+/-SD) error across all modes of gait (7.7% (+/-11.6%) overground;-0.6% (+/-2.2%) stairs). The right mid-thigh position had significantly ($p<0.01$) higher error for treadmill (18.1% (+/-17.3%)), overground (12.9% (+/-15.2%)), and stairs (2.9% (+/-3.9%)). Pedometer position dependent error was demonstrated, with the left mid-axillary position superior to the recommended position of right mid-thigh. The greater accuracy on the left side was wholly explained by gait asymmetry evident in step-induced accelerations recorded at right and left pedometer positions. A model of absolute error based on the ratio of steps at different gait speeds was generated to demonstrate the importance of this finding in pedometer-based lifestyle intervention studies.

Houtveen, Jan H.; Geus, Eco Jc (2009):

Noninvasive psychophysiological ambulatory recordings: Study design and data analysis strategies.

In: *European Psychologist* 14 (2), S. 132–141.

Abstract:

Rapid technical developments have greatly facilitated noninvasive 24-hour recording of physiological signals at relatively low costs, including blood pressure, activity of the autonomic nervous system, respiratory behavior, and activity of the hypothalamic-pituitary-adrenocortical axis. Ambulatory noninvasive recordings can be used to study the baseline levels of these physiological variables as well as their reactivity to naturalistic stressors. Levels and reactivity can be compared across groups differing in exposure to risk factors (e.g., stress, genotypes) or used to sharpen the clinical profile of individual subjects (e.g., in panic or somatoform disorders). The focus of the current paper is on the importance of a priori choices in study design and data analysis strategies when ambulatory recording specifically targets the reciprocal relationship between physiological and psychological events. These choices are illustrated with ambulatory-assessed indices of the cardiac autonomic nervous system, blood pressure, respiration, and cortisol secretion. Houtveen, Jan H.; Groot, Paul F. C.; de Geus, Eco J C (2006):

Validation of the thoracic impedance derived respiratory signal using multilevel analysis.

In: *International journal of psychophysiology : official journal of the International Organization of Psychophysiology* 59 (2), S. 97–106. DOI: 10.1016/j.ijpsycho.2005.02.003.

Abstract:

The purpose of the current study was to validate the change in thoracic impedance (dZ) derived respiratory signal obtained from four spot electrodes against incidental spirometry. Additionally, a similar validation was performed for a dual respiratory belts signal to compare the relative merit of both methods. Participants were 38 healthy adult subjects (half male, half female). Cross-method comparisons were performed at three (paced) respiration frequencies in sitting, supine and standing postures. Multilevel regression was used to examine the within- and between-subjects structure of the relationship between spirometric volume and the respiratory amplitude signals obtained from either dZ or respiratory belts. Both dZ derived respiratory rate and dual belts derived respiratory rate accurately reflected the pacing frequencies. For both methods, fixed factors indicated acceptable but posture-specific regression on spirometric volume. However, random factors indicated large individual differences, which was supported by variability of gain analyses. It was concluded that both the dZ and dual belts methods can be used for measurement of respiratory rate and within-subjects, posture-specific, changes in respiratory volume. The need for frequent subject-specific and posture-specific calibration combined with relatively large measurement errors may strongly limit the usefulness of both methods to assess absolute tidal volume and minute ventilation in ambulatory designs.

Houtveen, Jan H.; Hamaker, Ellen L.; Van Doornen, Lorenz J P (2010):

Using multilevel path analysis in analyzing 24-h ambulatory physiological recordings applied to medically unexplained symptoms.

In: *Psychophysiology* 47 (3), S. 570–578. DOI: 10.1111/j.1469-8986.2009.00951.x.

Abstract:

A non-clinical group high on heterogeneous medically unexplained symptoms (MUS; n=97) was compared with healthy controls (n=66) on the within-subject relationships between physiological measures using multilevel path analysis. Momentary experienced somatic complaints, mood (tension and depression), cardiac autonomic activity (inter-beat intervals, pre-ejection period (PEP), and respiratory sinus arrhythmia (RSA)) and respiration (rate and partial pressure of CO(2) at the end of a normal expiration) were monitored for 24 h using electronic diary and ambulatory devices. Relationships between measures were controlled for diurnal variation and individual means. Only subtle group differences were found in the diurnal rhythm and in the within-subject relationships between physiological measures. For participants high on MUS, within-subject changes in bodily symptoms were related to changes in mood, but only marginally to the physiological measures. Results of the current path analysis confirm the subordinate role of cardiac autonomic and respiratory parameters in MUS.

Houtveen, Jan H.; Oei, Nicole Y. L. (2007):

Recall bias in reporting medically unexplained symptoms comes from semantic memory.

In: *Journal of Psychosomatic Research* 62 (3), S. 277–282.

Abstract:

OBJECTIVE:

When people report somatic complaints retrospectively, they depend on their memory. Therefore, retrospective reports can be influenced by general beliefs on sickness and health from semantic memory. We hypothesized that individuals with medically unexplained symptoms (MUS) would have recall biases stronger than those of people without complaints when reporting symptoms retrospectively, and that this effect would be a function of time between symptom experience and report.

METHODS:

To compare two time frames, 37 participants who were high and low on MUS reported momentary symptoms combined by daily recall and weekly recall using an electronic diary.

RESULTS:

Both groups reported more symptoms when recalling the entire week than what could be expected from average momentary reports. However, participants high on MUS also reported more symptoms when recalling a week than when recalling a day. For this group, recall bias was not associated with peak heuristic or symptoms variability.

CONCLUSION:

Symptom reports in people high on MUS increases as time passes by, probably as a results of a shift in memory retrieval strategy from using episodic knowledge to using semantic beliefs.

Houtveen, J. H.; Sorbi, M. J. (2013):

Prodromal functioning of migraine patients relative to their interictal state - an ecological momentary assessment study.

In: *PLoS One* 8 (8), S. e72827. DOI: 10.1371/journal.pone.0072827.

Abstract:

Smartphones were used in an online Ecological Momentary Assessment (EMA) design to test prodromal functioning relative to the interictal state in migraine patients. Eighty-seven participants completed an electronic diary 4 times daily during 3-6 weeks to monitor their migraine attacks. Twice daily the diary additionally included 16 multi-answer questions covering physical symptoms (30 items), cognitive-affective functioning (25 items) and external factors (25 items). Eight clustered prodromal features were identified in the current study: sensory sensitivity, pain/stiffness, fatigue, cognitive functioning, positive affect, negative affect, effort spent and stressors encountered. Per feature, individual change scores with interictal control days - excluding 24-hour post-attack recovery - were computed for six 12-hour pre-attack time windows covering three prodromal days. Linear mixed model (fixed-effect) analysis established significant increases in sensory sensitivity, pain/stiffness and fatigue, and a tendency for increased negative affect, in the 12 hours prior to the attack. Positive affect and cognitive functioning were impaired both in the 25-36 hour and - more strongly - in the 12-hour time window before the attack. No effects were found for effort spent and stressors encountered. Exploratory (random effect) analysis revealed significant individual differences in the change scores in sensory sensitivity, pain/stiffness, fatigue and negative affect. It is concluded that the prodromal change in migraine - relative to interictal functioning - predominantly exists within the last 12 hours before attack onset. Individual diversity is large, however. Future research should zoom in to identify prodrome development within the 12 pre-attack hours as well as to isolate individual patterns

Houtveen, Jan H.; van Doornen, Lorenz J. P. (2007):

Medically unexplained symptoms and between-group differences in 24-h ambulatory recording of stress physiology.

In: *Biol Psychol* 76 (3), S. 239–249.

Abstract:

People with medically unexplained symptoms (MUS) often have a comorbid history of stress and negative affect. Although the verbal-cognitive and (peripheral) physiological stress systems have shown a great degree of independence, at the same time it is claimed that chronic stress and negative affect can result in a disregulated physiological stress system, which may lead to MUS. Previous studies could not demonstrate a straightforward between subject relationship between MUS and stress physiology, supporting the view of independence. The aim of the current study was to further explore this relationship using an improved methodology based on ecologically valid 24-h real-life ambulatory recordings. Seventy-four participants (19 male; 55 female) with heterogeneous MUS were compared with 71 healthy controls (26 male; 45 females). Momentary experienced somatic complaints and mood, heart rate, cardiac autonomic activity, respiration and saliva cortisol were monitored using electronic diary and ambulatory registration devices. Participants with MUS reported much more momentary complaints and negative affect as compared to controls. Although MUS seemed to be associated with elevated heart rate and reduced low and very-low frequency heart period variability, these effects disappeared after controlling for differences in sports behaviour. No group differences were found for cardiac autonomic activity, respiration, end-tidal CO(2) and saliva cortisol. Our 24-h real-life ambulatory study did not support the existence of a connection between MUS and disregulated peripheral stress physiology. Future studies may instead focus on central measures to reveal potential abnormalities such as deviant central processing of visceral signals in MUS patients.

Hovi, Petteri; Andersson, Sture; Räikkönen, Katri; Strang-Karlsson, Sonja; Järvenpää, Anna-Liisa; Eriksson, Johan G. et al. (2010):

Ambulatory blood pressure in young adults with very low birth weight.

In: *J Pediatr* 156 (1), S. 54-59.e1. DOI: 10.1016/j.jpeds.2009.07.022.

Abstract:

OBJECTIVE\r\nWe hypothesized that, as compared with a matched control group born at term, young adults with very low birth weight (VLBW <1.5 kg) would have higher 24-hour ambulatory blood pressure.\r\nSTUDY DESIGN\r\nWe studied 118 18- to 27-year-old subjects born with VLBW within the greater Helsinki area and 120 term-born control subjects with similar age, sex, and birth hospital. The mean birth weight for VLBW subjects was 1.1 kg (standard deviation [SD], 0.2) and for controls, 3.6 kg (SD, 0.5). Gestational ages were 29.2 (SD, 2.3) and 40.1 (SD, 1.0) weeks. Current education of higher-educated parents served as an indicator of childhood socioeconomic status. Ambulatory blood pressure was measured during a 24-hour period with an oscillometric device (Spacelabs 90207).\r\nRESULTS\r\nVLBW subjects had, with sex, age, and body mass index adjustment, a 2.4 mm Hg (95% confidence interval, 0.2 to 4.6) higher 24-hour systolic pressure. We found hypertension in 11 VLBW subjects and in 3 term-born subjects, giving an adjusted odds ratio of 4.0 (1.1 to 14.8). When socioeconomic status was taken into account, results remained unchanged.\r\nCONCLUSIONS\r\nHigher rates of hypertension and higher 24-hour blood pressure among young adults with VLBW may indicate higher risk for adverse cardiovascular outcomes.

Howells, Annika; Ivtzan, Itai; Eiroa-Orosa, Francisco Jose (2014):

Putting the 'app' in happiness: A randomised controlled trial of a smartphone-based mindfulness intervention to enhance wellbeing.

In: *Journal of Happiness Studies*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-51006-001%26site%3dehost-live.

Abstract:

Smartphones are revolutionizing approaches to wellbeing investment. Those seeking greater happiness can engage with thousands of downloadable self-help applications instantly, yet their effectiveness remains largely unknown. This investigation explored the viability of delivering a positive psychological intervention in application format to authentic happiness seekers. A smartphone-based randomized-controlled trial was conducted with a diverse self-selecting pool, randomly assigned to engage with an empirically supported mindfulness intervention (n = 57) or a control intervention (n = 64) for 10 days. The study explored smartphone methodology, the importance of empirically based content for wellbeing enhancement and the extent to which user experience related to wellbeing gains. Results of repeated measures ANOVAs showed statistically significant increases in positive affect with a medium effect size and reduced depressive symptoms with a small effect size, although no statistically significant differences in satisfaction with life, flourishing or negative affect were found. No statistically significant gains were observed in the control condition. Ratings of task enjoyment were positively correlated (Pearson's r) with positive affect increase. Findings support the viability of smartphone-based interventions to significantly enhance elements of wellbeing, underscoring the importance of application content and the role of person-activity fit. This investigation presents implications for happiness seeking strategies in the real world whilst showcasing a dynamic method of intervention delivery that can benefit future research and practice. If the greatest mission of positive psychology is to enhance global flourishing, the potential of smartphone-based interventions may play a vital role. Hsieh, Jui-Chien; Yu, Kuo-Chiang; Yang, Chung-Chi (2009):

The realization of ubiquitous 12-lead ECG diagnosis in emergency telemedicine.

In: *Telemed J E Health* 15 (9), S. 898–906. DOI: 10.1089/tmj.2009.0006.

Abstract:

This study presents an e-technology to realize a mobile 12-lead electrocardiography (ECG) information system capable of providing clinicians with ubiquitous 12-lead ECG diagnoses. Until now, there has been limited information on mobile systems that can exchange information with clinically used 12-lead ECG for emergency telemedicine. The development of mobilized 12-lead ECG diagnoses in clinical practice is impeded by the heterogeneous 12-lead ECG file formats and compressed ECG waveform data. In this study, clinically used Standard Communications Protocol ECG and Extensible Markup Language ECG interpreters were developed to extract compressed 12-lead ECG waveform data. A 12-lead ECG database server connecting with a hospital information system was then built to collect 12-lead ECG files and related clinical data. Additionally, a mobile 12-lead ECG database was implemented on mobile phones for remote 12-lead ECG diagnoses. Clinical evaluations confirmed the usefulness of this mobile 12-lead ECG information system, which significantly improves the diagnostic accuracy and the performance of medical treatments in cardio-emergency telemedicine. In summary, this system facilitated ubiquitous 12-lead ECG diagnoses and enhanced the efficiency and service quality of emergency telemedicine.

Huang, Po Hsien; Weng, Li Jen (2012):

Estimating the reliability of aggregated and within-person centered scores in ecological momentary assessment.

In: *Multivariate Behavioral Research* 47 (3), S. 421–441. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-16670-004&site=ehost-live;ljweng@ntu.edu.tw.

Abstract:

A procedure for estimating the reliability of test scores in the context of ecological momentary assessment (EMA) was proposed to take into account the characteristics of EMA measures. Two commonly used test scores in EMA were considered: the aggregated score (AGGS) and the within-person centered score (WPCS). Conceptually, AGGS and WPCS represent the interindividual differences and the intraindividual differences, respectively. The reliability coefficients for AGGS and WPCS were derived using a multilevel factor model with a serial correlation structure framework. Point estimates and confidence intervals of these coefficients were obtained using Mx (Neale, Boker, Xie, & Maes, 2004). A simulation study showed that the proposed procedure performed well empirically. Diary data from Huang (2009), which recorded daily joy level of 110 undergraduate students for 8 days, was used to illustrate the applicability of the proposed method. Huberty, Jennifer L.; Dinkel, Danae M.; Beets, Michael W. (2014):

Evaluation of GoGirlGo!; A practitioner based program to improve physical activity.

In: *BMC Public Health* 14, S. 118. DOI: 10.1186/1471-2458-14-118.

Abstract:

BACKGROUND: GoGirlGo! (GGG) is designed to increase girls' physical activity (PA) using a health behavior and PA-based curriculum and is widely available for free to afterschool programs across the nation. However, GGG has not been formally evaluated. The purpose of this pilot study was to evaluate the effectiveness of the GGG curricula to improve PA, and self-efficacy for and enjoyment of PA in elementary aged girls (i.e., 5-13 years). METHODS: Nine afterschool programs were recruited to participate in the pilot (within subjects repeated measures design). GGG is a 12-week program, with a once a week, one-hour lesson with 30 minutes of education and 30 minutes of PA). Data collection occurred at baseline, mid (twice), post, and at follow-up (3-months after the intervention ended). PA was assessed via accelerometry at each time point. Self-efficacy for and enjoyment of PA was measured using the Self-Efficacy Scale and the Short-PA enjoyment scale and was assessed at baseline, post, and follow-up. Fidelity was assessed at midpoint. RESULTS: Across all age groups there was a statistically significant increase in PA. Overall, on days GGG was offered girls accumulated an average of 11 minutes of moderate-to-vigorous PA compared to 8 minutes during non-GGG days. There was a statistically significant difference in girls' self-efficacy for PA reported between baseline and post, which was maintained at follow-up. An improvement in enjoyment of PA for girls was found between baseline and follow-up. According to fidelity assessment, 89% of the activities within the curriculum were completed each lesson. Girls appeared to respond well to the curriculum but girls 5-7 years had difficulties paying attention and understanding discussion questions. CONCLUSIONS: Even though there were statistically significant differences in self-efficacy for PA and enjoyment of PA, minimal increases in girls' PA were observed. GGG curricula improvements are warranted. Future GGG programming should explore offering GGG every day, modifying activities so that they are moderate-to-vigorous in intensity, and providing additional trainings that allow staff to better implement PA and improve behavior management techniques. With modifications, GGG could provide a promising no-cost curriculum that afterschool programs may implement to help girls achieve recommendations for PA.

Huckvale, K.; Car, M.; Morrison, C.; Car, J. (2012):

Apps for asthma self-management: a systematic assessment of content and tools.

In: *BMC Med* 10 (1741-7015 (Linking)), S. 144. DOI: 10.1186/1741-7015-10-144.

Abstract:

ABSTRACT: BACKGROUND: Apps have been enthusiastically adopted by the general public. They are increasingly recognized by policy-makers as a potential medium for supporting self-management of long-term conditions. We assessed the degree to which current smartphone and tablet apps for people with asthma offer content and tools of appropriate quality to support asthma self-management. METHODS: We adapted systematic review methodology to the assessment of apps. We identified English-language asthma apps for all ages through a systematic search of official app stores. We systematically assessed app content using criteria derived from international guidelines and systematic review of strategies for asthma self-management. We

covered three domains: comprehensiveness of asthma information, consistency of advice with evidence and compliance with health information best practice principles. RESULTS: We identified 103 apps for asthma in English, of which 56 were sources of information about the condition and 47 provided tools for the management of asthma. No apps offered both types of functionality. Only three information apps approached our definition of comprehensiveness of information about asthma. No apps provided advice on lay management of acute asthma that included details of appropriate reliever medication use. In 32 of 72 instances, apps made unequivocal recommendations about strategies for asthma control or prophylaxis that were unsupported by current evidence. Although 90% of apps stated a clear purpose, compliance with other best practice principles for health information was variable. Contact details were located for 55%, funding source for 18% and confidentiality policy for 17%. CONCLUSIONS: No apps for people with asthma combined reliable, comprehensive information about the condition with supportive tools for self-management. Healthcare professionals considering recommending apps to patients as part of asthma self-management should exercise caution, recognizing that some apps like calculators may be unsafe; that no current app will meet the need of every patient; and that ways of working must be adapted if apps are to be introduced, supported and sustained in routine care. Policy-makers need to consider the potential role for assurance mechanisms in relation to apps. There remains much to be done if apps are to find broad use in clinical practice; clinicians cannot recommend tools that are inaccurate, unsafe or lack an evidence base

Hudock, Daniel; Kalinowski, Joseph (2014):

Stuttering inhibition via altered auditory feedback during scripted telephone conversations.

In: *Int J Lang Commun Disord* 49 (1), S. 139–147. DOI: 10.1111/1460-6984.12053.

Abstract:

BACKGROUND: Overt stuttering is inhibited by approximately 80% when people who stutter read aloud as they hear an altered form of their speech feedback to them. However, levels of stuttering inhibition vary from 60% to 100% depending on speaking situation and signal presentation. For example, binaural presentations of delayed auditory feedback (DAF) and frequency-altered feedback (FAF) have been shown to reduce stuttering by approximately 57% during scripted telephone conversations. AIMS: To examine stuttering frequency under monaural auditory feedback with one combination of DAF with FAF (COMBO-2) and two combinations of DAF with FAF (COMBO-4) during scripted telephone conversations. METHODS & PROCEDURES: Nine adult participants who stutter called 15 local businesses during scripted telephone conversations; each condition consisted of five randomized telephone calls. Conditions consisted of (1) baseline (i.e. non-altered feedback), (2) COMBO-2 (i.e. 50-ms delay with a half octave spectral shift up), and (3) COMBO-4 (i.e. 200-ms delay and a half octave spectral shift down in addition to the COMBO-2). Participants wore a supra-aural headset with a dynamic condenser microphone while holding a receiver to their contralateral ear when making telephone calls. OUTCOMES & RESULTS: Stuttering was significantly reduced during both altered auditory feedback (AAF) conditions by approximately 65%. Furthermore, a greater reduction in stuttering was revealed during the COMBO with four effects (74%) as compared with the COMBO with two effects (63%). CONCLUSIONS & IMPLICATIONS: Results from the current study support prior research reporting decreased stuttering under AAF during scripted telephone conversations. Findings that stuttering was significantly reduced to a greater extent under the COMBO with four effects condition suggest that second signals reduce stuttering along a continuum. Additionally, findings support prior research results of decreased stuttering frequency under AAF during hierarchically difficult speaking situations. Clinical application of these findings may be that people who stutter can use specific software or smartphone applications that produce second speech signals to inhibit stuttering frequency effectively during telephone conversations.

Huffziger, Silke; Ebner-Priemer, Ulrich; Zamoscik, Vera; Reinhard, Iris; Kirsch, Peter; Kuehner, Christine (2013):

Effects of mood and rumination on cortisol levels in daily life: An ambulatory assessment study in remitted depressed patients and healthy controls.

In: *Psychoneuroendocrinology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-17752-001%26site%3dehost-live.

Abstract:

The influence of naturally occurring emotional and cognitive experiences on hypothalamic–pituitary–adrenal axis (HPAA) activity is still underinvestigated, particularly in clinical populations. The present study examined effects of mood and rumination on cortisol levels in daily life in remitted depressed patients with recurrent episodes or a chronic precourse (n=31) and healthy controls (n=32). Ambulatory assessment of subjective variables (valence, calmness, energetic-arousal, ruminative self-focus), daily stressors, and saliva cortisol samples was performed five times a day on two consecutive workdays, whereby cortisol was collected 20min after the subjective assessments. In addition, depressive symptoms and trait rumination (brooding, reflection)

were measured retrospectively. Multilevel models revealed that remitted depressed patients showed lower cortisol activity compared to healthy controls. Depressive symptoms and trait rumination did not predict HPAA activity, whereas, by controlling for daily stressors, higher daily means of ruminative self-focus and lower daily means of valence, energetic arousal and calmness were associated with higher daily cortisol levels. Separate analyses per group revealed that mean daily ruminative self-focus predicted higher cortisol in both samples. In contrast, lower daily means of calmness, but also of valence and energetic arousal, were significantly linked to higher cortisol output only in healthy controls, but not in the patient sample. These findings indicate that naturally occurring rumination and low mood are associated with increased activation of the HPAA in daily life. Moreover, our data revealed a potentially reduced mood–cortisol coupling in remitted recurrent depression, possibly indicating that during the course of recurrent depression HPAA activation might become less responsive toward subtle emotional experiences in natural contexts. Huffziger, S.; Ebner-Priemer, U.; Eisenbach, C.; Koudela, S.; Reinhard, I.; Zamoscik, V. et al. (2013):

Induced ruminative and mindful attention in everyday life: An experimental ambulatory assessment study.

In: *J Behav.Ther.Exp.Psychiatry* 44 (3), S. 322–328. DOI: 10.1016/j.jbtep.2013.01.007.

Abstract:

BACKGROUND AND OBJECTIVES: Rumination has been proposed as a risk factor for depression, while mindful attention might be protective. Differential effects of these attention foci have so far only been examined in the laboratory. Therefore, we conducted an experimental ambulatory assessment study using ruminative and mindful attention inductions in everyday life to examine their effects in a natural context. METHODS: Fifty young adults carried palmtops over three weekdays (rumination induction day, mindful attention induction day, noninduction day; randomized cross-over design). Ten times a day, participants rated ruminative self-focus and mood. On the induction days, they were additionally subjected to 3-min inductions of ruminative or mindful attention at each assessment. RESULTS: The two induction modes exhibited differential immediate effects on ruminative self-focus and mood. While induced rumination immediately deteriorated valence and calmness, induced mindful attention specifically enhanced calmness. Depressive symptoms did not moderate these effects. While overall longer term effects of the inductions were missing, the mindful attention day was associated with slightly increasing positive valence over the day. LIMITATIONS: The results need to be replicated in high-risk and patient samples to demonstrate the clinical significance of identified effects. CONCLUSIONS: Results confirm the emotional relevance of rumination and mindful attention in real world settings. Future work may test whether adaptive attention-focusing instructions delivered in daily life can support clinical interventions

Hughes, A. J.; Rutherford, B. J. (2012):

Hemispheric interaction, task complexity, and emotional valence: Evidence from naturalistic images.

In: *Brain Cogn* 81 (2), S. 167–175. DOI: 10.1016/j.bandc.2012.11.004.

Abstract:

Two experiments extend the ecological validity of tests of hemispheric interaction in three novel ways. First, we present a broad class of naturalistic stimuli that have not yet been used in tests of hemispheric interaction. Second, we test whether probable differences in complexity within the class of stimuli are supported by outcomes from measures of hemispheric interaction. Third, we use a procedure that presents target stimuli at fixation rather than at a lateralized location in order to more closely approximate normal viewing behavior. Images of positive or negative valence were presented with a lateralized distractor or no distractor at all. Response time and accuracy to determine whether an image was pleasant or unpleasant was measured. Results found that positive images were more quickly and accurately processed by the left hemisphere alone, while negative images were more quickly processed when the hemispheres interacted, and were more accurately processed when the hemispheres interacted than the left hemisphere alone. The findings support the idea that hemispheric interaction costs the performance of a simple task and benefits the performance of a complex task, and that the respective cost or gain is mediated by the pattern of laterality for emotional processing

Bringing psychosocial support to headache sufferers using information and communication technology: lessons learned from asking potential users what they want.

In: *Pain Res Manag* 19 (1), S. e1-8.

Abstract:

BACKGROUND: Headaches are a major concern for which psychosocial interventions are recommended. However, headache sufferers do not always have ready access to these interventions. Technology has been used to improve access, especially in young people. OBJECTIVES: To examine user preferences to inform the development of an Internet-based psychosocial intervention including smartphone technology, referred to as the Wireless Headache Intervention. METHODS: The methodology followed a participatory design cycle, including 25 headache sufferers (14 to 28 years of age) who informed the prototype design. All participants were familiar with smartphones and the Internet. Through two iterative cycles of focus groups stratified according to age, qualitative data were collected by asking user preferences for the different planned components of the intervention (ie, smartphone pain diary, Internet-based self-management treatment, social support) and other relevant aspects (ie, smartphone versus computer delivery, and ways of reaching target audience). NVivo 8 with content analysis was used to analyze data and reflect themes as guided by the thematic survey. RESULTS: Participants reported a preference for completing the smartphone pain diary on a daily basis. Participants believed that the program should facilitate easy access to information regarding headaches and management strategies. They also wanted access to other headache sufferers and experts. Participants believed that the program should be customizable and interactive. They reinforced the need and value of an integrated smartphone and Internet-based application. CONCLUSIONS: The results provide insight into a participatory design to guide design decisions for the type of intervention for which success relies largely on self-motivation. The results also provide recommendations for design of similar interventions that may benefit from the integration of mobile applications to Internet-based interventions. The present research contributes to the theoretical frameworks that have been formulated for the development of Internet-based applications.

Huh, Jimi; Shin, Heesung; Leventhal, Adam M.; Spruijt-Metz, Donna; Abramova, Zarina; Cerrada, Christian et al. (2014):

Momentary negative moods and being with friends precede cigarette use among Korean American emerging adults.

In: *Nicotine & Tobacco Research* 16 (9), S. 1248–1254. DOI: 10.1037/t04295-000.

Abstract:

Introduction: The objective of this study was to determine contextual antecedents to smoking among Korean American emerging adult (KAEA) smokers using ecological momentary assessment. Based on extant theory and data documenting the importance of negative affect (NA) and social context, we examined the extent to which being with friends and NA independently and concomitantly were associated with the likelihood of subsequent smoking, over and beyond other known situational correlates of smoking. Methods: Twenty-two KAEA daily smokers recorded their smoking events in real time and participated in short surveys implemented on mobile phones for 7 days. Individual, interpersonal, and situational contexts immediately preceding and during smoking events were examined in comparison to nonsmoking events using a within-subject modeling approach. Results: Both NA and being with friends independently were correlated with increased likelihood of smoking. We also found an interaction showing that the effects of NA on smoking were significant only in presence of friends. Conclusions: Unlike more established smokers, these younger smokers may be strongly influenced by peer contexts as well as unpleasant affect. The interaction between social contexts and NA highlights a potential window for intervention for the population of KAEA smokers. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Huisinga, J. M.; Mancini, M.; St George, R. J.; Horak, F. B. (2012):

Accelerometry Reveals Differences in Gait Variability Between Patients with Multiple Sclerosis and Healthy Controls.

In: *Ann.Biomed.Eng* (0090-6964 (Linking)). DOI: 10.1007/s10439-012-0697-y.

Abstract:

Variability of movement reflects important information for the maintenance of the health of the system. For pathological populations, changes in variability during gait signal the presence of abnormal motor control strategies. For persons with multiple sclerosis (PwMS), extensive gait problems have been reported including changes in gait variability. While previous studies have focused on footfall variability, the present study used accelerometers on the trunk to measure variability during

walking. Thus, the purpose of this study was to examine the variability of the acceleration pattern of the upper and lower trunk in PwMS compared to healthy controls. We extracted linear and nonlinear measures of gait variability from 30 s of steady state walking for 15 PwMS and 15 age-matched healthy controls. PwMS had altered variability compared to controls with greater Lyapunov exponent in the ML ($p < 0.001$) and AP ($p < 0.001$) directions, and greater frequency dispersion in the ML direction ($p = 0.034$). PwMS also demonstrated greater mean velocity in the ML direction ($p = 0.045$) and lower root mean square of acceleration in the AP direction ($p = 0.040$). These findings indicate that PwMS have altered structure of variability of the trunk during gait compared to healthy controls and agree with previous findings related to changes in gait variability in PwMS

Humber, N.; Emsley, R.; Pratt, D.; Tarrier, N. (2013):

Anger as a predictor of psychological distress and self-harm ideation in inmates: A structured self-assessment diary study.

In: *Psychiatry Res* (0165-1781 (Linking)). DOI: 10.1016/j.psychres.2013.02.011.

Abstract:

Suicidal ideation and behaviour are common among inmates. Anger is found at exaggerated levels and has been associated with suicidal ideation and behaviour in inmate samples suggesting its possible salience in the prediction of suicide. The study investigated relationships between anger, psychological distress, and self-harm/suicidal ideation among inmates. The principles of Ecological Momentary Assessment were considered and a structured self-assessment diary was utilised to examine relationships between the variables of interest. Participants completed a structured self-assessment diary for six consecutive days which included momentary ratings of items describing psychological states of concurrent affects, thoughts, and appraisals related to anger, psychological distress, and self-harm/suicidal ideation. Psychometric assessment measures were also conducted. Temporal associations between predictors and outcomes were investigated. Multilevel modelling analyses were performed. Increased anger was significantly associated with concurrent high levels of self-harm ideation in inmates, when controlling for depression and hopelessness. Temporal analyses also revealed that anger at one time point did not predict suicidal ideation at the next time point. Elucidating the temporal nature of the relationship between anger, psychological distress, and self-harm/suicidal ideation has advanced understanding of the mechanisms of suicidal behaviour, by demonstrating an increased risk of suicide when a male inmate is angry

Commercially available mobile phone headache diary apps: a systematic review.

In: *JMIR Mhealth Uhealth* 2 (3), S. e36. DOI: 10.2196/mhealth.3452.

Abstract:

BACKGROUND: Headache diaries are often used by headache sufferers to self-monitor headaches. With advances in mobile technology, mobile electronic diary apps are becoming increasingly common. OBJECTIVE: This review aims to identify and evaluate all commercially available mobile headache diary apps for the two most popular mobile phone platforms, iOS and Android. METHODS: The authors developed a priori a set of 7 criteria that define an ideal headache diary app intended to help headache sufferers better understand and manage their headaches, while providing relevant data to health professionals. The app criteria were intended as minimum requirements for an acceptable headache diary app that could be prescribed by health care professionals. Each app was evaluated and scored against each criterion. RESULTS: Of the 38 apps identified, none of the apps met all 7 app criteria. The 3 highest scoring apps, meeting 5 of the app criteria, were iHeadache (developed by Better QOL), ecoHeadache (developed by ecoTouchMedia), and Headache Diary Pro (developed by Froggyware). Only 18% of the apps were created with scientific or clinical headache expertise and none of the apps reported on psychometric properties. CONCLUSIONS: Despite the growing market and demand, there is a concerning lack of scientific expertise and evidence base associated with headache diary apps.

Reinforcement sensitivity theory predicts positive and negative affect in daily life.

In: *Personality and Individual Differences* 54 (3), S. 350–354. DOI: 10.1037/t04113-000;

Abstract:

Laboratory studies of Reinforcement Sensitivity Theory have associated sensitivity to punishment (SP) with negative affect and sensitivity to reward (SR) with positive affect. However, few studies have examined the expression of these systems and their

response to cues of reward in daily life. The current study employed experience sampling methodology (ESM) to assess the association of SP and SR with affect and perceptions of situations in daily life. SP was positively associated with negative affect and negatively associated with positive affect in daily life, whereas SR was associated with positive affect and one aspect of negative affect, irritability/anger. Furthermore, high SP participants experienced smaller increases in positive affect and smaller decreases in negative affect in some situations that were perceived as positive, in comparison to low SP participants. In contrast, high SR participants experienced greater decreases in negative affect in some situations that were perceived as positive, in comparison to low SR participants. Hunter, E. J. (2012):

Teacher response to ambulatory monitoring of voice.

In: *Logoped.Phoniatr.Vocol.* (1401-5439 (Linking)). DOI: 10.3109/14015439.2012.664657.

Abstract:

Voice accumulation and dosimetry devices are used for unobtrusive monitoring of voice use. While numerous studies have used these devices to examine how individuals use their voices, little attention has been paid to how subjects respond to them. Therefore, the purpose of this short communication is to begin to explore two questions: 1) How do voice monitoring devices affect daily communication? and 2) How do participants feel about the physical design and function of these types of voice monitoring devices? One key finding is that most of the subjects remain aware of the dosimeter while wearing it, which may impact the data collected. Further, most subjects have difficulty with the accelerometer and/or the data storage device

Nine clarifications of descriptive experience sampling.

In: *Journal of Consciousness Studies* 18 (1), S. 274–287. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-20325-015&site=ehost-live;russ@unlv.nevada.edu.

Abstract:

Reply by the current author to the comments made by Christopher S. Hill (see record 2011-20325-002); Claire Petitmengin (see record 2011-20325-003); Charles Siewert (see record 2011-20325-004); Eric Klinger (see record 2011-20325-005); Gualtiero Piccinini (see record 2011-20325-006); John Sutton (see record 2011-20325-007); Mark Engelbert and Peter Carruthers (see record 2011-20325-008); Michael J. Kane (see record 2011-20325-009); Maja Spener (see record 2011-20325-010); Terry Horgan and Mark Timmons (see record 2011-20325-011) on the book Describing inner experience? Proponent meets skeptic by Russell T. Hurlburt and Eric Schwitzgebel (see record 2007-14525-000). The commentaries in this symposium reveal nine misconceptions about Descriptive Experience Sampling (DES) that the present paper attempts to clear up: about pristine experience, about the iterative nature of DES, about the term of DES retrospection, about the accuracy of DES, about the diachronic abilities of DES, about the inability of DES to target specific questions, about the worry that DES stifles careful observation, about the difficulty/expense of DES, and about the transformative power of DES to trump a lifetime of observations. (PsycINFO Database Record (c) 2011 APA, all rights reserved)

Hurlburt, Russell T.; Heavey, Christopher L. (2015):

Investigating pristine inner experience: Implications for experience sampling and questionnaires.

In: *Conscious Cogn* 31, S. 148–159. DOI: 10.1016/j.concog.2014.11.002.

Abstract:

We argue that inquiring about directly apprehended ("pristine") inner experience requires four overlapping methodological characteristics: effectively limiting investigation to specific, clearly identified moments; effectively limiting investigation to pristine experience; bracketing presuppositions; and iteratively acquiring skills. We compare and contrast Descriptive Experience Sampling (DES), other (non-DES) experience sampling methods, and questionnaires and conclude that whereas non-DES sampling methods and questionnaires appear to inquire about pristine inner experience, they fall short on all four methodological counts and therefore might be better understood as investigating an ill-defined mixture of presuppositions, judgments about experience, and pristine experience itself. Typical experience sampling studies and questionnaires can be valid and useful, but their validity and utility does not (or at least does not necessarily) arise from their phenomenological fidelity.

Hurst, John R.; Donaldson, Gavin C.; Quint, Jennifer K.; Goldring, James J. P.; Patel, Anant R. C.; Wedzicha, Jadwiga A. (2010):

Domiciliary pulse-oximetry at exacerbation of chronic obstructive pulmonary disease: prospective pilot study.

In: *BMC pulmonary medicine* 10 (1), S. 52.

Abstract:

Background

The ability to objectively differentiate exacerbations of chronic obstructive pulmonary disease (COPD) from day-to-day symptom variations would be an important development in clinical practice and research. We assessed the ability of domiciliary pulse oximetry to achieve this.

Methods

40 patients with moderate-severe COPD collected daily data on changes in symptoms, heart-rate (HR), oxygen saturation (SpO2) and peak-expiratory flow (PEF) over a total of 2705 days. 31 patients had data suitable for baseline analysis, and 13 patients experienced an exacerbation. Data were expressed as multiples of the standard deviation (SD) observed from each patient when stable.

Results

In stable COPD, the SD for HR, SpO2 and PEF were approximately 5 min-1, 1% and 10l min-1. There were detectable changes in all three variables just prior to exacerbation onset, greatest 2-3 days following symptom onset. A composite Oximetry Score (mean magnitude of SpO2 fall and HR rise) distinguished exacerbation onset from symptom variation (area under receiver-operating characteristic curve, AUC = 0.832, 95%CI 0.735-0.929, p = 0.003). In the presence of symptoms, a change in Score of ≥1 (average of ≥1SD change in both HR and SpO2) was 71% sensitive and 74% specific for exacerbation onset.

Conclusion

We have defined normal variation of pulse oximetry variables in a small sample of patients with COPD. A composite HR and SpO2 score distinguished exacerbation onset from symptom variation, potentially facilitating prompt therapy and providing validation of such events in clinical trials.

Hurtig-Wennlöf, Anita; Ruiz, Jonatan R.; Harro, Maarike; Sjöström, Michael (2007):

Cardiorespiratory fitness relates more strongly than physical activity to cardiovascular disease risk factors in healthy children and adolescents: the European Youth Heart Study.

In: *European journal of cardiovascular prevention and rehabilitation : official journal of the European Society of Cardiology, Working Groups on Epidemiology & Prevention and Cardiac Rehabilitation and Exercise Physiology* 14 (4), S. 575–581. DOI: 10.1097/HJR.0b013e32808c67e3.

Abstract:

BACKGROUND\r\nPhysical activity and cardiorespiratory fitness are closely related to health variables in adults, especially those considered to be among risk factors for cardiovascular diseases. The possible tracking of cardiovascular disease risk factors from childhood to adulthood makes it important to increase our understanding of the complex relationships between physical activity, cardiorespiratory fitness and cardiovascular risk factors early in life.\r\nDESIGN\r\nA cross-sectional, school-based study on healthy children and adolescents, aged 9-10 years (295 girls, 295 boys) and 15-16 years (302 girls, 233 boys) was performed during a school year in Sweden and Estonia, as part of the European Youth Heart Study.\r\nMETHODS\r\nTotal physical activity, and minutes spent in inactivity and activity of moderate or higher intensity were measured by accelerometry. A maximal ergometer bike test was used for estimation of cardiorespiratory fitness. The risk factors included blood pressure and fasting blood levels of insulin, glucose, triglycerides, total cholesterol and high-density lipoprotein cholesterol.\r\nRESULTS\r\nCanonical correlations between physical activity and cardiorespiratory fitness versus cardiovascular disease risk factors showed significant associations in both age and sex groups (rc=0.46-0.61, P<0.0001). The cardiorespiratory fitness was found to be the strongest contributor to these relationships. In girls high values of the physical activity variables were also associated with a favourable cardiovascular profile.\r\nCONCLUSIONS\r\nCardiorespiratory fitness relates more strongly to cardiovascular risk factors than components of objectively measured physical activity in children and adolescents. Physical activity becomes more important in the 15-year-old adolescents, indicating that these modifiable lifestyle factors increase in importance with age.

Hurum, Harald; Sulheim, Dag; Thaulow, Erik; Wyller, Vegard Bruun (2011):

Elevated nocturnal blood pressure and heart rate in adolescent chronic fatigue syndrome.

In: *Acta Paediatr* 100 (2), S. 289–292.

Abstract:

AIM:

To compare ambulatory recordings of heart rate (HR) and blood pressure in adolescents with chronic fatigue syndrome (CFS) and healthy controls. We hypothesized both HR and blood pressure to be elevated among CFS patients.

METHODS:

Forty-four CFS patients aged 12-18 years were recruited from our paediatric outpatient clinic. The controls were 52 healthy adolescents having similar distribution of age and gender. 24-h ambulatory blood pressure and HR were recorded using a validated, portable oscillometric device.

RESULTS:

At night (sleep), HR, mean arterial blood pressure and diastolic blood pressure were significantly higher in CFS patients as compared with controls ($p < 0.01$). During daytime, HR was significantly higher among CFS patients ($p < 0.05$), whereas blood pressures were equal among the two groups.

CONCLUSIONS:

The findings support previous experimental evidence of sympathetic predominance of cardiovascular control in adolescent CFS patients. Also, the findings prompt increased focus on cardiovascular risk assessment and suggest a possible target for therapeutic intervention.

Emerging technologies for assessing physical activity behaviors in space and time.

In: *Front Public Health* 2, S. 2. DOI: 10.3389/fpubh.2014.00002.

Abstract:

Precise measurement of physical activity is important for health research, providing a better understanding of activity location, type, duration, and intensity. This article describes a novel suite of tools to measure and analyze physical activity behaviors in spatial epidemiology research. We use individual-level, high-resolution, objective data collected in a space-time framework to investigate built and social environment influences on activity. First, we collect data with accelerometers, global positioning system units, and smartphone-based digital travel and photo diaries to overcome many limitations inherent in self-reported data. Behaviors are measured continuously over the full spectrum of environmental exposures in daily life, instead of focusing exclusively on the home neighborhood. Second, data streams are integrated using common timestamps into a single data structure, the "LifeLog." A graphic interface tool, "LifeLog View," enables simultaneous visualization of all LifeLog data streams. Finally, we use geographic information system SmartMap rasters to measure spatially continuous environmental variables to capture exposures at the same spatial and temporal scale as in the LifeLog. These technologies enable precise measurement of behaviors in their spatial and temporal settings but also generate very large datasets; we discuss current limitations and promising methods for processing and analyzing such large datasets. Finally, we provide applications of these methods in spatially oriented research, including a natural experiment to evaluate the effects of new transportation infrastructure on activity levels, and a study of neighborhood environmental effects on activity using twins as quasi-causal controls to overcome self-selection and reverse causation problems. In summary, the integrative characteristics of large datasets contained in LifeLogs and SmartMaps hold great promise for advancing spatial epidemiologic research to promote healthy behaviors.

Computerized ambulatory monitoring in mood disorders: feasibility, compliance, and reactivity.

In: *Psychiatry Res* 178 (2), S. 440–442. DOI: 10.1016/j.psychres.2010.04.045.

Abstract:

Patients with depression (n=20) or bipolar disorder (n=21) completed computerized ambulatory monitoring for three consecutive days. Results indicate satisfactory rates of acceptance and compliance, with no salient fatigue effects. However, some evidence for reactive effects was found. The findings provide support for this approach in the study of mood disorders.

Husky, Mathilde; Olie, Emilie; Guillaume, Sebastien; Genty, Catherine; Swendsen, Joel; Courtet, Philippe (2014):

Feasibility and validity of ecological momentary assessment in the investigation of suicide risk.

In: *Psychiatry Res. DOI:* 10.1016/j.psychres.2014.08.019.

Abstract:

Ecological Momentary Assessment has been used to investigate a wide range of behaviors and psychiatric conditions. Previous investigations have consistently obtained promising results with high acceptance and compliance rates, and with only minor reactive effects for specific variables. Despite the promise of this methodology for the study of severe psychiatric populations, little is known about its feasibility in samples at risk for suicide. In the present study, four samples at varying risk for suicide completed an Ecological Momentary Assessment study by responding to five electronic assessments per day over a one-week period. Samples included healthy controls (n=13), affective controls (n=21), past suicide attempters (n=20), and recent suicide attempters (n=42). The results demonstrate satisfactory participation rates and high compliance with daily life repeated assessments across all groups. Importantly, negative thoughts or suicidal ideation were not reactive to the duration of the study, indicating that the repeated assessment of such cognitions in daily life have little or no effect on their frequency. The findings provide support for the use of Ecological Momentary Assessment in the study of suicidal ideation and suggest that mobile technologies represent new opportunities for the assessment of high-risk cognitive states experienced by patients in daily life.

Hussong, Andrea M. (2007):

Predictors of drinking immediacy following daily sadness: An application of survival analysis to experience sampling data.

In: *Addict Behav* 32 (5), S. 1054–1065.

Abstract:

Previous studies of daily assessments show modest mood-drinking covariation as a function of gender and coping motives; however previous analyses also assume a fixed interval across all individuals in the onset of drinking following negative mood. The current study used survival analysis and experience sampling methods to test whether gender and coping motives predicted shorter sadness-to-drinking intervals among those with greater alcohol-related drinking consequences. A sample of 85 college students (46% male; 78% Caucasian) completed daily assessments over 28 days. Survival analyses showed that women drank more on days following elevated sadness when they reported being motivated to drink to cope and having experienced alcohol-related consequences. For men, the two groups showing greater drinking risk following days of elevated sadness did not report alcohol-related consequences, with those reporting the presence of coping motives showing the greatest risk. Implications of these findings for self-medication mechanisms are discussed.

Hussong, Andrea M.; Gould, Laura Feagans; Hersh, Matthew A. (2008):

Conduct problems moderate self-medication and mood-related drinking consequences in adolescents.

In: *Journal of Studies on Alcohol and Drugs* 69 (2), S. 296.

Abstract:

OBJECTIVE:

We tested whether conduct problems moderate the relation between negative mood and drinking in adolescents as consistent with either a self-medication or a drinking consequences model.

METHOD:

The sample included 75 rising ninth graders (i.e., in the summer before starting ninth grade) who completed a two-stage, multimethod, multireporter study. We used experience sampling to assess negative mood and drinking across 21 days and hierarchical linear modeling to test our hypotheses.

RESULTS:

Counter to predictions, both self-medication and drinking consequence mechanisms were evident only in youth with fewer conduct problems.

CONCLUSIONS:

Findings provide support for the importance of considering multiple mechanisms as underlying the relation between negative mood and drinking as pertaining to subpopulations of vulnerable youth. Implications for prevention and understanding negative mood-drinking relations in adolescents are discussed.

Hutchesson, Melinda J.; Rollo, Megan E.; Callister, Robin; Collins, Clare E. (2014):

Self-Monitoring of Dietary Intake by Young Women: Online Food Records Completed on Computer or Smartphone Are as Accurate as Paper-Based Food Records but More Acceptable.

In: *J Acad Nutr Diet. DOI:* 10.1016/j.jand.2014.07.036.

Abstract:

Adherence and accuracy of self-monitoring of dietary intake influences success in weight management interventions. Information technologies such as computers and smartphones have the potential to improve adherence and accuracy by reducing the burden associated with monitoring dietary intake using traditional paper-based food records. We evaluated the acceptability and accuracy of three different 7-day food record methods (online accessed via computer, online accessed via smartphone, and paper-based). Young women (N=18; aged 23.4+/-2.9 years; body mass index 24.0+/-2.2) completed the three 7-day food records in random order with 7-day washout periods between each method. Total energy expenditure (TEE) was derived from resting energy expenditure (REE) measured by indirect calorimetry and physical activity level (PAL) derived from accelerometers (TEE=REExPAL). Accuracy of the three methods was assessed by calculating absolute (energy intake [EI]-TEE) and percentage difference (EI/TEEx100) between self-reported EI and TEE. Acceptability was assessed via questionnaire. Mean+/-standard deviation TEE was 2,185+/-302 kcal/day and EI was 1,729+/-249 kcal/day, 1,675+/-287kcal/day, and 1,682+/-352 kcal/day for computer, smartphone, and paper records, respectively. There were no significant differences between absolute and percentage differences between EI and TEE for the three methods: computer, -510+/-389 kcal/day (78%); smartphone, -456+/-372 kcal/day (80%); and paper, -503+/-513 kcal/day (79%). Half of participants (n=9) preferred computer recording, 44.4% preferred smartphone, and 5.6% preferred paper-based records. Most participants (89%) least preferred the paper-based record. Because online food records completed on either computer or smartphone were as accurate as paper-based records but more acceptable to young women, they should be considered when self-monitoring of intake is recommended to young women.

Hutton, J.; Leung, J. (2012):

Treatment of spinal cord compression: are we overusing radiotherapy alone compared to surgery and radiotherapy?

In: *Asia Pac.J Clin.Oncol.* (1743-7555 (Linking)). DOI: 10.1111/j.1743-7563.2012.01568.x.

Abstract:

INTRODUCTION: This article describes how patients with metastatic spinal cord compression (MSCC) were treated from 2005 to 2011 at a single institution. A comparison is made with an international and standardized scoring system which would have predicted which patients would have a better outcome with neurosurgery in addition to radiotherapy in accordance with current best practice standards. METHOD: A retrospective audit of all MSCC patients presenting from 2005 to 2011 was undertaken. An assessment of outcome was made by using ambulatory assessment tool and by comparing overall survival with published standards. RESULTS: In all, 39 patients were identified, of whom 37 received radiotherapy alone and two (5%) received surgery and postoperative radiotherapy. The international standardized scoring system predicted 28 (72%) of the 39 patients might have had a better outcome with neurosurgery in addition to radiotherapy. MSCC patients generally had reasonable outcomes, but selected patients could potentially do better with decompressive surgery. CONCLUSION: There is a subset of MSCC patients who have poor predicted ambulatory rates after radiotherapy alone and who may benefit from decompressive surgery. It is recommended that MSCC patients be categorized according to the international scoring system to identify appropriate candidates for surgical intervention and postoperative radiotherapy or radiotherapy alone

Hynynen, Esa; Konttinen, Niilo; Rusko, Heikki (2009):

Heart rate variability and stress hormones in novice and experienced parachutists anticipating a jump.

In: *Aviation, space, and environmental medicine* 80 (11), S. 976–980.

Abstract:

INTRODUCTION:

Chronic work stress and overtraining are known to influence heart rate (HR) and heart rate variability (HRV) at rest and decreased nocturnal HRV is associated with cardiovascular health and disease. The purpose of this study was to examine whether anticipation of an acute highly stressful event influences HR and HRV during the night and morning.

METHODS:

Nocturnal HR and HRV and urinary stress hormones (cortisol, adrenaline, noradrenaline) as well as HR and HRV responses to an orthostatic test on the morning of a parachute jump day or control day were analyzed from 14 novice and 7 experienced parachute jumpers.

RESULTS:

There were no differences in any HRV indices during the night or the orthostatic test between the jump and control situations. The novices had higher HR than experienced jumpers in the orthostatic test in the morning and also during the jump, but no differences were found between the groups in nocturnal HR and HRV indices or HRV indices during the orthostatic test. There were no differences in nocturnal stress hormone secretions except slightly elevated adrenaline secretion during the jump night compared to the control night (P = 0.014).

CONCLUSIONS:

The parachute jump did not substantially influence HR, HRV, or stress hormones during the night or the orthostatic test in the morning preceding the jump. The results suggest that the parachute jump as an acute highly stressful event had no anticipatory effect on autonomic modulation of the heart even though both the novices and experienced jumpers had markedly accentuated sympathetic activation during the parachuting.

Ibuki, Chikao; Seino, Yoshihiko; Otsuka, Toshiaki; Mizuno, Kyoichi (2014):

The fixed-dose combination of losartan/hydrochlorothiazide elicits potent blood pressure lowering during nighttime in obese hypertensive patients.

In: *J Clin Med Res* 6 (1), S. 8–16. DOI: 10.4021/jocmr1649w.

Abstract:

BACKGROUND: Hypertension is one of the most powerful predictor of the future cardiovascular events, and antihypertensive therapy adopting multiple drug regimen is often needed to obtain the appropriate blood pressure (BP) control. To clarify the blood pressure-lowering effect of the fixed-dose combination (FDC) of an angiotensin receptor blocker (ARB) and diuretic agent in poorly controlled hypertensive patients, we intended a multicenter prospective observational study (Investigation for Normalized Blood pressure control with the Appropriate medication: INBA) by means of the sequential ambulatory blood pressure monitoring (ABPM). METHODS: One hundred and thirteen hypertensive patients who had not achieved the target BP control proposed in the guidelines with medication containing any ARB but without diuretic agents (54 men; mean age, 66 years old; mean office systolic/diastolic BP (SBP/DBP), 158/82 mmHg) were enrolled. Daytime and nighttime blood pressures were assessed with ABPM before and at 12 weeks after switching the ARB to the FDC of 50 mg of losartan, and 12.5 mg of hydrochlorothiazide (HCTZ). RESULTS: Daytime SBP/DBP (mean +/- SD) decreased from 151 +/- 14/88 +/- 8 mmHg to 140 +/- 11/82 +/- 8 mmHg (P < 0.001, P < 0.001, respectively), and nocturnal SBP/DBP from 138 +/- 18/78 +/- 9 mmHg to 125 +/- 14/72 +/- 9 mmHg (P < 0.001, P < 0.001, respectively) during the 12 weeks treatment. Pulse rate did not change irrespective of the time window. Among various parameters (age, history of hypertension, body mass index (BMI), serum potassium, uric acid, estimated glomerular filtration rate, plasma B-type natriuretic peptide), BMI alone showed significant negative correlation with 12-weeks reduction in nocturnal SBP (r = -0.43, P < 0.05). No parameters correlated with reduction in daytime SBP during this period. Patients with BMI >/= median (25.8 kg/m(2)) showed significantly greater reduction in nocturnal SBP for 12 weeks than patients with BMI < median (20.1 +/- 15.6 mmHg vs 6.1 +/- 10.9 mmHg, P < 0.001) although reduction in daytime SBP was comparable between the two groups (8.9 +/- 13.5 mmHg vs 11.9 +/- 12.7 mmHg). CONCLUSIONS: The administration of the FDC of losartan/HCTZ lowers BP both in day- and nighttime, and the nocturnal antihypertensive potency is remarkable in obese patients.

Igic, Ivana; Ryser, Samuel; Elfering, Achim (2013):

Does work stress make you shorter? An ambulatory field study of daily work stressors, job control, and spinal shrinkage.

In: *Journal of Occupational Health Psychology* 18 (4), S. 469–480. DOI: 10.1037/t10391-000;

Abstract:

Body height decreases throughout the day due to fluid loss from the intervertebral disk. This study investigated whether spinal shrinkage was greater during workdays compared with nonwork days, whether daily work stressors were positively related to spinal shrinkage, and whether job control was negatively related to spinal shrinkage. In a consecutive 2-week ambulatory field study, including 39 office employees and 512 days of observation, spinal shrinkage was measured by a stadiometer, and calculated as body height in the morning minus body height in the evening. Physical activity was monitored throughout the 14 days by accelerometry. Daily work stressors, daily job control, biomechanical workload, and recreational activities after work were measured with daily surveys. Multilevel regression analyses showed that spinal disks shrank more during workdays than during nonworkdays. After adjustment for sex, age, body weight, smoking status, biomechanical work strain, and time spent on physical and low-effort activities during the day, lower levels of daily job control significantly predicted increased spinal shrinkage. Findings add to knowledge on how work redesign that increases job control may possibly contribute to preserving intervertebral disk function and preventing occupational back pain. Iida, Masumi; Stephens, Mary Ann Parris; Franks, Melissa M.; Rook, Karen S. (2013):

Daily symptoms, distress and interaction quality among couples coping with type 2 diabetes.

In: *Journal of Social and Personal Relationships* 30 (3), S. 293–300. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-16118-005%26site%3dehost-live;Masumi.Iida@asu.edu.

Abstract:

In this electronic diary study (N = 127 couples), we examined how a diabetic partner's symptoms and distress are associated with relationship interactions over 24 days. Using dyadic multilevel models, we examined the effects of patients' daily diabetes symptom severity and diabetes-specific distress on each partner's evaluations of their daily interaction enjoyment and tension. For both patients and spouses, diabetes symptoms were associated with a decrease in enjoyment and an increase in tension. For spouses, but not for patients, daily diabetes distress was marginally associated with an increase in tension. Among spouses whose patients' diabetes was of longer duration, the negative association of symptoms and spouses' enjoyment was stronger. These findings suggest that the stress of patients' disease and distress affects both partners on a daily basis. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Ilies, Remus; Johnson, Michael D.; Judge, Timothy A.; Keeney, Jessica (2011):

A within-individual study of interpersonal conflict as a work stressor: Dispositional and situational moderators.

In: *J. Organiz. Behav.* 32 (1), S. 44–64. DOI: 10.1002/job.677.

Abstract:

Focusing on interpersonal conflict as a work stressor, the authors used a within-subjects research design to examine the effect of conflict episodes on employees' negative affect on the job. The roles of agreeableness and social support in moderating the negative effects of conflict episodes were also examined. A two-week experience-sampling study revealed that interpersonal conflict influenced employees' intraindividual fluctuations in negative affect. As predicted, agreeableness and social support influenced individuals' patterns of affective responses to conflict, such that conflict was more strongly associated with negative affect for agreeable employees, and for those with lower levels of social support at work. Overall, the results suggest that both personality (agreeableness) and context (social support) significantly moderate the affective implications of interpersonal conflict at work. Work–family interpersonal capitalization: Sharing positive work events at home.

In: *Organizational Behavior and Human Decision Processes* 114 (2), S. 115–126. DOI: 10.1016/j.obhdp.2010.10.008.

Abstract:

In a 3-week experience-sampling study of 52 full-time employees, the authors investigated the within-individual relationships among positive work events, affective states, and job satisfaction. They also examined the influence of work–family interpersonal capitalization (sharing work events with one's spouse or partner at home) on employees' job and relationship satisfaction. Results revealed that positive events influenced job satisfaction through positive affect, and work–family interpersonal capitalization on the most positive work event of the day positively impacted job satisfaction over and above the effects of the event's pleasantness and of the number of other positive work events experienced that day.

A genetic study of ADHD and activity level in infancy.

In: *Genes, brain, and behavior* 9 (3), S. 296–304. DOI: 10.1111/j.1601-183X.2009.00560.x.

Abstract:

It is well known that there are strong genetic influences on attention-deficit hyperactivity disorder (ADHD), with genetic association studies providing good evidence for the involvement of the dopamine neurotransmitter system in its aetiology. Developmental origins of ADHD represent an interesting area of research to understand the genetics that underlie early appearing individual differences. However, understanding the molecular basis of ADHD requires accurate, unbiased, heritable measures that can be used for molecular genetic association analyses. We take two approaches to examine the genetics of ADHD behaviours in infancy. Using quantitative genetic techniques, we explore the relationship between objective measures of activity level (AL) in both home and laboratory environments as well as with parent ratings of ADHD symptoms in a population sample of 2-year-old twins. Molecular association analyses of these measures examine candidate genes previously associated with ADHD. We find that ADHD symptoms, AL in the home and AL in the lab represent heritable phenotypes in 2-year-old infants. AL measured in the home has a strong genetic correlation with symptoms of ADHD, whereas AL in the lab correlates only modestly with the same ADHD measure. Genetic correlations suggest that AL in the home is more comparable than AL in the lab to ADHD behaviour and support the separation of all three for molecular analyses. There was modest evidence for association between DAT1, NET1 and ADHD symptom scores, as well as between DAT1 and AL in the lab.

Attachment and daily sexual goals: A study of dating couples.

In: *Personal Relationships* 15 (3), S. 375–390.

Abstract:

This research provides the first empirical investigation of how both partners' attachment orientations contribute to daily sexual goals. Both members of 84 dating couples who attended a large urban university on the West Coast in the United States completed a measure of attachment orientation, and 1 member completed a measure of sexual goals for 14 consecutive days. Analyses showed that attachment anxiety was associated with engaging in sex to please one's partner and express love, whereas attachment avoidance was associated with engaging in sex to avoid negative relational consequences and was negatively associated with engaging in sex to express love. Daily sexual goals were also associated with the partner's attachment orientation. Gender moderated many of these associations. Theoretical and practical implications are discussed.

The effect of overt and subclinical hypothyroidism on the development of non-dipper blood pressure.

In: *Endokrynol.Pol.* 63 (2), S. 97–103. Online verfügbar unter PM:22538747.

Abstract:

INTRODUCTION: 'Non-dippers' are individuals without the anticipated nocturnal decrease in blood pressure. An increased incidence of target organ damage and a worse outcome in terms of cardiovascular events have been reported in this group of people. The pathogenesis of non-dipper hypertension is not clear at present. We aimed to investigate the effects of overt and subclinical hypothyroidism on the development of a non-dipper blood pressure pattern via 24-hour ambulatory blood pressure monitoring. MATERIAL AND METHODS: 109 normotensive patients with overt and subclinical hypothyroidism were evaluated, and 95 of these patients without reverse dipping and masked hypertension were included in the study. The control group consisted of 75 gender- and age-matched, normotensive, euthyroid healthy individuals. RESULTS: Median serum TSH levels were 7.61 and 1.59 mUmL in patient and control groups, respectively. The number of non-dippers according to systolic, diastolic and mean blood pressure was significantly higher in the patients with hypothyroidism compared to the control group. In linear regression analysis, TSH had a negative effect on the night/day ratio of the systolic, diastolic and mean blood pressures. CONCLUSION: Despite the fact that the effect of hypothyroidism on non-dipper blood pressure pattern is not known, the present study has revealed that elevated TSH levels are likely to increase the risk of non-dipping in normotensive patients with either overt or subclinical hypothyroidism

The interface between core affects and the challenge–skill relationship.

In: *Journal of Happiness Studies*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-24440-001%26site%3dehost-live;Mikko.Inkinen@helsinki.fi.

Abstract:

Different models have been developed to describe human experiences. One of these models is the core affect model, which states that the core of emotional experience is a simple state of feeling good or bad, energized or drowsy. Another model is the experience fluctuation model (EFM), which has been developed to map how emotions and other experiences fluctuate along with the relationship between challenges and skills. In this study, we first mathematically refined the EFM. Second, we tested if fluctuations in core affect could be modeled with a continuous wave-like sine function (Study 1). Third, we applied the sine function to our own experience-sampling data, which we collected via mobile phones from 55 university students, and located each challenge–skill relationship in a two-dimensional core affect space (Study 2). The results were consistent in both studies and showed that fluctuations in core affect dimensions, measured as a function of the relationship between challenges and skills, can be modeled with the sine function. The results also indicated that there is a systematic link between challenge–skill relationships and core affect: High challenge–high skill situations were connected to a very active and pleasant core affect, whereas high challenge–low skill situations were connected to a quite active but unpleasant core affect, low challenge–low skill situations to a very passive and unpleasant core affect, and low challenge–high skill situations to a quite passive and pleasant core affect. Compared to previous studies, this study presents a more fine-grained and comprehensive level of information on the relationship between core affect and challenges and skills. Inoue, Ryusuke; Ohkubo, Takayoshi; Kikuya, Masahiro; Metoki, Hirohito; Asayama, Kei; Obara, Taku et al. (2006):

Predicting stroke using 4 ambulatory blood pressure monitoring-derived blood pressure indices: the Ohasama Study.

In: *Hypertension* 48 (5), S. 877–882. DOI: 10.1161/01.HYP.0000242285.83728.ee.

Abstract:

We investigated the association between stroke and blood pressure (BP) indices (systolic BP [SBP], diastolic BP [DBP], mean BP [MBP], and pulse pressure [PP]) determined by ambulatory BP monitoring. The predictive power for stroke of these indices was compared in the general Japanese population. We obtained ambulatory BP data in 1271 subjects (40% men) aged > or = 40 (mean: 61) years. During a mean follow-up of 11 years, 113 strokes were observed. The multivariate adjusted relative hazard and likelihood ratio for a 1-SD increase for each BP index was determined by Cox proportional hazard regression. Comparison of the likelihood ratio between Cox models including 2 indices and those including 1 index indicated that PP was significantly less informative than other indices ($P<0.01$ when adding MBP, SBP, or DBP to the PP model; $P>0.09$ when adding PP to the model including another index). However, after removing age from covariates, PP became more informative than DBP and MBP ($P<0.0001$ when adding PP to the MBP or DBP model, whereas SBP was more informative than PP even after removing age; $P<0.05$ when adding SBP to the PP model). In conclusion, PP was the weakest predictor of stroke. Exclusion of age from covariates increased the predictive power of PP, suggesting that the stroke risk associated with PP reflected the risk of aging per se.

Characteristics of Accelerometry Respondents to a Mail-Based Surveillance Study.

In: *Journal of Epidemiology* 20 (6), S. 446–452. DOI: 10.2188/jea.JE20100062.

Abstract:

Background

Differences in the characteristics of respondents and nonrespondents to a survey can be a cause of selection bias. The aim of this study was to determine the sociodemographic and lifestyle characteristics of respondents to a field-based accelerometry survey.

Methods

A cross-sectional mail survey was sent to 4000 adults (50% male; age 20 to 69 years) who were randomly selected from the registries of residential addresses of 4 cities in Japan. There were 1508 respondents (responding subsample) to the initial questionnaire. A total of 786 participants from the responding subsample also agreed to wear an accelerometer for 7 days (accelerometer subsample). Age, sex, and city of residence were compared between the accelerometer subsample and all 3214 nonrespondents, including those who did not respond to the initial questionnaire. In addition, multiple logistic regression analyses were used to compare the sociodemographic and lifestyle characteristics of the accelerometer subsample and the 722 respondents who participated in the questionnaire survey but not the accelerometry (questionnaire-only subsample).

Results

As compared with all nonrespondents, the accelerometer subsample included significantly more women, middle-aged and older adults, and residents of specific cities. Multiple logistic regression analyses comparing the accelerometer and questionnaire-only subsamples revealed that participation in the accelerometry survey was greater among nonsmokers (odds ratio, 1.35; 95% confidence interval, 1.02–1.79) and persons who reported a habit of leisure walking (1.56, 1.21–2.01).

Conclusions

Sex, age, city of residence, smoking status, and leisure walking were associated with participation in accelerometry. This response pattern reveals potential selection bias in mail-based accelerometry studies.

Emerging technology for studying daily life. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 267–282. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-015%26site%3dehost-live.

Abstract:

(from the chapter) This chapter explores emerging developments in the use of technology for studying daily life. The rapid adoption of sensor-enabled mobile technologies, especially phones, will create new opportunities for researchers interested in measurement of behavior. Innovations in technology will also make possible novel forms of real-time, computer-driven interventions, in which the computer presents information at automatically determined and behaviorally based "teachable moments." This chapter highlights measurement and intervention opportunities that will emerge as sensor-enabled mobile devices become more computationally powerful and commonplace. These phones make possible a new fusion of ecological momentary assessment (EMA) and ambulatory monitoring, in which triggering of self-report, data collection, or feedback related to encouraging participant compliance is based on automatic analysis of the ambulatory monitoring data in real time by the mobile device. Researchers will no longer be limited to systematic, stratified, or purposive EMA sampling methods. Context-sensitive ecological momentary assessment (CS-EMA; Intille, 2007; Intille et al., 2003) creates a fourth option: purposive sampling in response to automatically detected user behavior, context, or physiological response, as measured passively or semiautomatically using sensors. Development and decline of upright gait stability.

In: *Front Aging Neurosci* 6, S. 14. DOI: 10.3389/fnagi.2014.00014.

Abstract:

Upright gait is a peculiar characteristic of humans that requires the ability to manage upper body dynamic balance while walking, despite the perturbations that are generated by movements of the lower limbs. Most of the studies on upright gait stability have compared young adults and the elderly to determine the effects of aging. In other studies, the comparison was between healthy subjects and patients to examine specific pathologies. Fewer researches have also investigated the development of upright gait stability in children. This review discusses these studies in order to provide an overview of this relevant aspect of human locomotion. A clear trend from development to decline of upright gait stability has been depicted across the entire lifespan, from toddlers at first steps to elderly. In old individuals, even if healthy, the deterioration of skeletal muscle, combined with sensorial and cognitive performance, reduces the ability to maintain an upright trunk during walking, increasing the instability and the risk of falls. Further, the pathological causes of altered development or of a sudden loss of gait stability, as well as the environmental influence are investigated. The last part of this review is focused on the control of upper body accelerations during walking, a particularly interesting topic for the recent development of low-cost wearable accelerometers.

Iosa, Marco; Morelli, Daniela; Nisi, Enrica; Sorbara, Carlo; Negrini, Stefano; Gentili, Paola et al. (2014):

Assessment of upper body accelerations in young adults with intellectual disabilities while walking, running, and dual-task running.

In: *Hum Mov Sci. DOI:* 10.1016/j.humov.2014.02.005.

Abstract:

There is an increasing interest about upper body accelerations during locomotion and how they are altered by physical impairments. Recent studies have demonstrated that cognitive impairments affect gait stability in the elderly (i.e., their capacity for smoothing upper body accelerations during walking) but little attention has been paid to young adults with intellectual disabilities. The purpose of this study was to examine upright stability in young adults with intellectual disabilities during walking, running, and dual-task running (playing soccer). To this aim a wearable trunk-mounted device that permits on-field assessment was used to quantify trunk acceleration of 18 male teenagers with intellectual disabilities (IDG) and 7 mental-age-matched healthy children (HCG) who participated in the same soccer program. We did not find any significant difference during walking in terms of speed, whereas speed differences were found during running (p=.001). Upper body accelerations were altered in a pathology-specific manner during the dual task: the performance of subjects with autistic disorders was compromised while running and controlling the ball with the feet. Differences in upright locomotor patterns between IDG and HCG emerged during more demanding motor tasks in terms of a loss in the capacity of smoothing accelerations at the trunk level.

Ireland, A. M.; Wiklund, I.; Hsieh, R.; Dale, P.; O'Rourke, E. (2012):

An electronic diary is shown to be more reliable than a paper diary: results from a randomized crossover study in patients with persistent asthma.

In: *J Asthma* 49 (9), S. 952–960. DOI: 10.3109/02770903.2012.724754.

Abstract:

OBJECTIVES: Test-retest reliability of an asthma paper diary versus an electronic diary (e-diary) with an integrated peak flow meter was investigated. The equivalence of the two modes was also evaluated. METHODS: Prospective, randomized crossover study design in adolescents (12-17 years) and adults (>/=18 years). Key inclusion criteria were persistent asthma, Asthma Control Test (ACT) scores >/=16, use of inhaled corticosteroid with or without long-acting beta-agonist for >/=12 weeks, nocturnal awakenings <2 times in the past week, and activity limitations <1 per week. Participants were randomized to either paper then e-diary or e-diary then paper, to be completed for 14 days each. RESULTS: Forty-seven participants completed all study visits. Weekly percentage of symptom-free days (SFDs) and rescue-free days (RFDs) were calculated. Intraclass correlation coefficients (ICCs) of Week 1 mean SFD and RFD (test) and Week 2 mean SFD and RFD (retest), respectively, were estimated in three groups defined as stable: (i) minimal changes in asthma symptoms, as measured by the global patient reported symptom change question, (ii) less than 15% change (absolute value) in 1 second FEV(1) at adjacent study visits, and (iii) changes in ACT scores less than three points for each mode. SFD demonstrated acceptable ICC (>/=0.70) using all three definitions of asthma stability for both modes. CONCLUSION: Acceptable reproducibility of the percentage of RFD (ICC = 0.78) was only observed for the e-diary using the FEV(1) stability criterion. The ICCs for SFD and RFD were acceptable, 0.84 and 0.70, respectively, suggesting better reliability for the e-diary

Ishikawa, Joji; Carroll, Deirdre J.; Kuruvilla, Sujith; Schwartz, Joseph E.; Pickering, Thomas G. (2008):

Changes in home versus clinic blood pressure with antihypertensive treatments: a meta-analysis.

In: *Hypertension* 52 (5), S. 856–864. DOI: 10.1161/HYPERTENSIONAHA.108.115600.

Abstract:

Home blood pressure (HBP) monitoring is recommended for assessing the effects of antihypertensive treatment, but it is not clear how the treatment-induced changes in HBP compare with the changes in clinic blood pressure (CBP). We searched PubMed using the terms \"home or self-measured blood pressure,\" and selected articles in which the changes in CBP and HBP (using the upper arm oscillometric method) induced by antihypertensive drugs were presented. We performed a systematic review of 30 articles published before March 2008 that included a total of 6794 subjects. As there was significant heterogeneity in most of the outcomes, a random effects model was used for the meta-analyses. The mean changes (+/-SE) in CBP and HBP (systolic/diastolic) were -15.2+/-0.03/-10.3+/-0.03 mm Hg and -12.2+/-0.04/-8.0+/-0.04 mm Hg respectively, although there were wide varieties of differences in the reduction between HBP and CBP. The reductions in CBP were correlated with those of HBP (systolic BP; r=0.66, B=0.48, diastolic BP; r=0.71, B=0.52, P<0.001). In 7 studies that also included 24-hour BP monitoring, the reduction of HBP was greater than that of 24-hour BP in systolic (HBP; -12.6+/-0.06 mm Hg, 24-hour BP; -11.9+/-0.04 mm Hg, P<0.001). In 5 studies that included daytime and nighttime systolic BP separately, HBP decreased 15% more than daytime ambulatory BP and 30% more than nighttime ambulatory BP. In conclusion, HBP falls approximately 20% less than CBP with antihypertensive treatments. Daytime systolic BP falls 15% less and nighttime systolic BP falls 30% less than home systolic BP.

The Role of Physical Acivity in Bone Health in Peripubertal Boys.

In: *Pediatr Int. DOI:* 10.1111/ped.12337.

Abstract:

BACKGROUND: The aim of the present cross-sectional study was to investigate the relationship of different physical activity levels to bone mineral parameters in 11-13 year old boys. METHODS: In total, 264 boys, divided into normal-weight (n=154) and overweight (n=110), participated in this study. Physical activity was measured with a 7-day accelerometry and bone mineral parameters by DXA. RESULTS: In overweight boys, vigorous physical activity was associated with total bone mineral density (BMD), total bone mineral component (BMC), while moderate to vigorous physical activity MVPA was associated with femoral neck BMD. However, in normal weight boys only vigorous physical activity was associated with femoral neck BMD. Dividing the normal weight group into tertiles by MVPA levels indicated that femoral neck BMD was higher in the highest tertile compared to the lowest tertile. No more significant differences were found in bone mineral parameters according to the tertiles of MVPA. CONCLUSIONS: Our results suggest that in overweight peribubertal boys, physical activity is more associated with bone mineral parameters compared to normal-weight subjects. In addition to vigorous physical activity, already moderate physical activity levels have had significant impact to bone mineral parameters in overweight subjects.

Ivuskans, Arturs; Maestu, Jarek; Jurimae, Toivo; Latt, Evelin; Purge, Priit; Saar, Meeli et al. (2014):

Sedentary time has a negative influence on bone mineral parameters in peripubertal boys: a 1-year prospective study.

In: *J Bone Miner Metab. DOI:* 10.1007/s00774-013-0556-4.

Abstract:

One of the key determinants of adult skeletal health is the maximization of bone mass during the growth period. Physical activity (PA) in combination with lean mass and fat mass contribute to a great extent to bone mineral accrual; however, PA changes significantly during puberty. The aim of the present study was to examine PA exposure relative to bone mass acquisition during a longer observation period. Daily PA was measured with 7-day accelerometry and bone mineral parameters by DXA in 11- to 13-year-old peripubertal boys (n = 169). Similar testing was done after 1 calendar year. Changes in sedentary time were negatively related to changes in whole-body bone mineral density (BMD), lumbar spine bone mineral content (BMC), lumbar spine bone area (BA), femoral neck (FN) BMD, and FN BMC ($r > -0.157$; $p < 0.05$). Sedentary time emerged as the main PA level in predicting changes in FN BMC ($p = 0.027$) and in combination with vigorous PA predicting changes in FN BMD ($p < 0.024$). In addition to the effect of body composition on the skeleton, increase in sedentary time emerged as one main physical activity predictor (in addition to vigorous PA) of bone mineral acquisition during a 12-month period in peripubertal boys.

A statistical test to determine the quality of accelerometer data.

In: *Physiol Meas* 27 (4), S. 413. Online verfügbar unter http://stacks.iop.org/0967-3334/27/i=4/a=007.

Abstract:

Accelerometer data quality can be inadequate due to data corruption or to non-compliance of the subject with regard to study protocols. We propose a simple statistical test to determine if accelerometer data are of good quality and can be used for analysis or if the data are of poor quality and should be discarded. We tested several data evaluation methods using a group of 105 subjects who wore Motionlogger actigraphs (Ambulatory Monitoring, Inc.) over a 15 day period to assess sleep quality in a study of health outcomes associated with stress among police officers. Using leave-one-out cross-validation and calibration-testing methods of discrimination statistics, error rates for the methods ranged from 0.0167 to 0.4046. We found that the best method was to use the overall average distance between consecutive time points and the overall average mean amplitude of consecutive time points. These values gave us a classification error rate of 0.0167. The average distance between points is a measure of smoothness in the data, and the average mean amplitude between points gave an average reading. Both of these values were then normed to determine a final statistic, K , which was then compared to a cut-off value, K C , to determine data quality.

Effects of daily intake of yoghurt enriched with bioactive components on chronic stress responses: a double-blinded randomized controlled trial.

In: *Int J Food Sci Nutr. DOI:* 10.3109/09637486.2014.880669.

Abstract:

Abstract Chronic stress has a negative influence on health. The aim was to determine stress reducing effects of yoghurt enriched with bioactive components as compared to normal yoghurt. High-trait anxiety individuals (n = 67) aged 18-63 years participated in a randomized, placebo-controlled, double-blinded intervention with parallel groups. They received either yoghurt enriched with alpha-lactalbumin, casein tripeptides and B vitamins (active) or isoenergetic standard yoghurt (control). To detect changes in psychological and physiological stress, State-Trait Anxiety Inventory, Profile of Mood States, salivary cortisol, inflammatory markers, blood pressure, heart rate variability (HRV) and actigraphy were monitored. We observed higher ratings of vigor (p = 0.047) and reduced feeling of inefficiency (p = 0.048) in the active group. HRV (baseline adjusted mean 49.1 +/- 2.3 ms) and recovery index (106.6 +/- 33.4) were higher in the active group than in controls (42.5 +/- 2.2 ms and 80.0 +/- 29.3) (p = 0.046 and p = 0.02, respectively). In conclusion, daily intake of yoghurt enriched with bioactive components may aid in stress coping.

Wearable interrupter module for home-based applications in a telemedical system dedicated to respiratory mechanics measurements.

In: *Biomedical Engineering, IEEE Transactions on* 58 (3), S. 785–789.

Abstract:

The mobile interrupter module, dedicated to the enhanced interrupter (EIT) measurement of respiratory mechanics in a home environment and capable of cooperation with a telemedical system, is presented. Characterized by noninvasiveness and minimal requirements regarding patient cooperation, the EIT algorithm is especially suitable for newborns, preschool children, and patients suffering from respiratory muscle impairment. Furthermore, this device enables access to raw data--without initial preprocessing--in a fully flexible measurement protocol (which is not available in any commercial apparatus), and the EIT procedure improves insight (the number and precision of assessed parameters) into the physiological system with respect to the classical occlusive methods.

Jackson, Diane M.; Djafarian, Kurosh; Stewart, Joanne; Speakman, John R. (2009):

Increased television viewing is associated with elevated body fatness but not with lower total energy expenditure in children.

In: *Am J Clin Nutr* 89 (4), S. 1031–1036. DOI: 10.3945/ajcn.2008.26746.

Abstract:

BACKGROUND\r\nTelevision (TV) viewing in children is associated with a higher body mass index, but it is unknown whether this reflects body fatness, and, if it does, why.\r\nOBJECTIVE\r\nThe objective was to investigate whether TV viewing is associated with body fatness, physical activity, and total energy expenditure in preschool children.\r\nDESIGN\r\nEighty-nine children were recruited into a cross-sectional study. Total daily energy expenditure (TEE) was measured by doubly labeled water, body composition by dual-energy X-ray absorptiometry, and physical activity by accelerometry.\r\nRESULTS\r\nThere was a significant positive association between fat mass (corrected for fat-free body mass) and TV viewing (F = 9.05, P = 0.004). Each extra hour of watching TV was associated with an extra 1 kg of body fat. Children who watched more TV were also significantly less physically active (F = 5.16, P = 0.026). Independent of body composition and sex, children with greater physical activity levels had higher TEE (F = 5.15, P = 0.029); however, physical activity did not mediate the relation between TV viewing and adiposity (P > 0.05).\r\nCONCLUSIONS\r\nPreschool children who watch more TV are fatter and are less active, and activity influences TEE. However, despite TV viewing being linked to lower physical activity, the relation between TV viewing and fatness is not mediated by physical activity. The results suggest that a relation between TV viewing and fatness is more likely to be due to an effect on food intake.

Remote monitoring of pain and symptoms using wireless technology in children and adolescents with sickle cell disease.

In: *Journal of the American Academy of Nurse Practitioners* 25 (1), S. 42–54. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-00006-007%26site%3dehost-live;ejacob@sonnet.ucla.edu.

Abstract:

Purpose: The purpose of this study was to examine (a) symptoms, (b) pain characteristics (intensity, location, quality), (c) pain medications and non-pharmacological strategies used for pain, (d) thoughts and feelings, and (e) healthcare visits. We also examined the relationship between pain and sleep. Data sources: Pain and symptoms were entered on an electronic e-Diary using a smartphone and were remotely monitored by an advanced practice registered nurse (APRN). Sixty-seven children and adolescents (10–17 years) reported mild to severe pain at home that did not require healthcare visits. Symptoms reported were (a) general symptoms such as tiredness/fatigue (34.7%), headache (20.8%), yellowing of the eyes (28.4%); (b) respiratory symptoms such as sniffling (32.9%), coughing (19.1%), changes in breathing (10.0%); and (c) musculoskeletal symptoms such as stiffness in joints (15.8%). A significant negative correlation was found between pain and sleep (r = −.387, p = .024). Factors that predict pain included previous history of sickle cell disease (SCD) related events, symptoms, and negative thoughts. Conclusion: Pain and multiple symptoms entered on a web-based e-Diary were remotely monitored by an APRN and prompted communications, further evaluation, and recommendations. Implications for practice: Remote monitoring using wireless technology may facilitate timely management of pain and symptoms and minimize negative consequences in SCD. Jacobi, David; Charles, Marie-Aline; Tafflet, Muriel; Lommez, Agnès; Borys, Jean-Michel; Oppert, Jean-Michel (2009):

Relationships of self-reported physical activity domains with accelerometry recordings in French adults.

In: *European Journal of Epidemiology* 24 (4), S. 171–179. DOI: 10.1007/s10654-009-9329-8.

Abstract:

The objective was to examine the relationships of self-reported physical activity (PA) by domain (leisure, occupational, other) with PA and sedentary time as measured objectively by accelerometry. Subjects were adults with low habitual PA levels from a community in northern France. Among subjects in the lowest tertile of a PA score from a screening questionnaire, 160 (37% males, age: 41.0 +/- 10.8 years, BMI: 25.1 +/- 4.1 kg/m(2), mean +/- SD) completed a detailed instrument (Modifiable Activity Questionnaire), and wore an accelerometer (Actigraph) for seven consecutive days. Relationships between questionnaire domains (occupational, leisure, and \"non-occupational non-leisure\") and accelerometry measures (total activity and sedentary

time) were assessed using Spearman correlation coefficients. In this population, the highest contributor to total reported PA (h/week) was occupational PA. Time spent in non-occupational non-leisure PA ranked second in women and third in men. The most frequent non-occupational non-leisure PA were shopping and household chores. In women, non-occupational non-leisure PA contributed more than occupational or leisure-time PA to total PA energy expenditure (median: 18.0, 9.1, and 4.9 MET-h/week, respectively). Total PA by accelerometry (count/day) was correlated to leisure-time PA in women ($r = 0.22$, $P < 0.05$) and to occupational ($r = 0.43$, $P < 0.01$) and total reported PA ($r = 0.39$, $P < 0.01$) in men (all in MET-h/week). There was an inverse relationship between accelerometry sedentary time (h/day) and non-occupational non-leisure PA (MET-h/week, $r = -0.30$, $P < 0.001$). These findings indicate the importance of assessing non-occupational non-leisure PA for a better understanding of how individuals partition their time between active or sedentary occupations.

Jacobs, K.; Foley, G.; Punnett, L.; Hall, V.; Gore, R.; Brownson, E. et al. (2011):

University students' notebook computer use: lessons learned using e-diaries to report musculoskeletal discomfort.

In: *Ergonomics* 54 (2), S. 206–219. DOI: 10.1080/00140139.2010.544764.

Abstract:

The objective of this pilot study was to identify if notebook accessories (ergonomic chair, desktop monitor and notebook riser) combined with a wireless keyboard, mouse and participatory ergonomics training would have the greatest impact on reducing self-reported upper extremity musculoskeletal discomfort in university students. In addition to pre-post computing and health surveys, the Ecological Momentary Assessment was used to capture change in discomfort over time using a personal digital assistant (PDA) as the e-diary. The PDA was programmed with a survey containing 45 questions. Four groups of university students were randomised to either intervention (three external computer accessories) or to control. Participants reported less discomfort with the ergonomic chair and notebook riser based on the pre-post survey data and the e-diary/PDA ANOVA analysis. However, the PDA data, adjusted for the effect of hours per day of computer use, showed no benefit of the chair and limited benefit from the riser. Statement of Relevance:University students' use of notebook computers has increased. This study found evidence of a positive effect of an adjustable chair or notebook riser when combined with ergonomic training on reducing discomfort. Daily notebook computer use of 4 h was confirmed as a risk factor. Without some form of ergonomic intervention, these students are likely to enter the workforce with poor computing habits, which places them on the road to future injuries as technology continues to play a dominant role in their lives.

Jacobs, N.; Menne-Lothmann, C.; Derom, C.; Thiery, E.; Van, Os J.; Wichers, M. (2012):

Deconstructing the familiality of variability in momentary negative and positive affect.

In: *Acta Psychiatr.Scand.* (0001-690X (Linking)). DOI: 10.1111/j.1600-0447.2012.01924.x.

Abstract:

Jacobs N, Menne-Lothmann C, Derom C, Thiery E, van Os J, Wichers M. Deconstructing the familiality of variability in momentary negative and positive affect. Objective: The daily life, affective phenotypes of momentary negative affect (NA), positive affect (PA) variability and NA variability are associated with future depressive symptomatology. This study investigates the extent to which genetic and environmental factors contribute to the inter-individual differences in these daily life, affective phenotypes. Method: Two hundred and seventy-nine female twins from the Flemish (Belgium) general population participated in an experience sampling study measuring affect in daily life. Structural equation modelling was used to fit univariate and bivariate models. Results: Genetic factors explained, respectively, 18%, 18% and 35% of the inter-individual differences in momentary NA, PA variability and NA variability. Non-shared environmental factors were found to explain the remaining inter-individual variation. In addition, 41% of the association between positive and NA variability was attributed to shared genetic factors. Conclusion: Results of this study show that daily life patterns of affective expression are subject to substantial environmental influence. Prospective assessments of the effect of interventions on these expressions may therefore represent a powerful tool to prevent transition from subclinical depressive symptomatology to a clinical outcome or to reduce symptomatology in those with clinical depression

Jacobs, N.; van Os, J.; Derom, C.; Thiery, E.; Delespaul, P.; Wichers, M. (2011):

Neuroticism explained? From a non-informative vulnerability marker to informative person-context interactions in the realm of daily life.

In: *British Journal of Clinical Psychology* 50 (1), S. 19–32. DOI: 10.1348/014466510X491397.

Abstract:

OBJECTIVES\r\nDespite the well-replicated finding that neuroticism is associated with increased susceptibility for psychopathology, it remains unclear what 'vulnerability as indexed by neuroticism' represents in terms of everyday life emotional processes. This study examined the association between neuroticism and six phenotypes of daily life emotional responses: positive affect (PA), negative affect (NA), PA variability, NA variability, stress sensitivity, and reward experience, and investigated the contribution of genetic and environmental factors to these associations.\r\nDESIGN\r\nA prospective cohort study in a population-based sample of 416 adult female twins.\r\nMETHOD\r\nA momentary assessment approach (experience sampling method) was used to collect multiple assessments of affect in daily life. Neuroticism was assessed with the Eysenck Personality Scale. Multi-level regression analyses were carried out to examine the association between neuroticism and the phenotypes of daily life emotional responses. Cross-twin, cross-trait analyses, and bivariate structural equation modelling (SEM) were performed in order to investigate the nature of these associations.\r\nRESULTS\r\nA high neuroticism score was associated with lower momentary PA levels and increased NA variability, independent of momentary NA, PA variability, stress sensitivity, and reward experience. Both the cross-twin, cross-trait analyses, and the bivariate SEM showed that unique, non-shared environmental factors drive the association between neuroticism and PA and that the association between neuroticism and increased NA variability is based on shared genetic factors as well as individual-specific environmental factors.\r\nCONCLUSIONS\r\nNeuroticism as measured by Eysenck questionnaire may index an environmental risk for decreased daily life PA levels and a genetic as well as an environmental risk for increased NA variability. Decomposing the broad measure of neuroticism into measurable persons-context interactions increases its 'informative' value in explaining psychopathology.

Jacobson, Judith S.; Lieblein, Andrea; Fierman, Arthur H.; Fishkin, Edward R.; Hutchinson, Vincent E.; Rodriguez, Luis et al. (2009):

Randomized trial of an electronic asthma monitoring system among New York City children.

In: *The American journal of managed care* 15 (11), S. 809–814.

Abstract:

OBJECTIVES: To test the efficacy of an electronic asthma monitoring system (AMS) to reduce pediatric emergency department (ED) visits and hospitalizations for asthma.

STUDY DESIGN: Randomized clinical trial.

METHODS: Families of pediatric patients with asthma aged 8 to 17 years were recruited at 6 medical centers. Children were randomly assigned to the American Medical Alert Corporation pediatric AMS or a paper diary. The numbers of and costs associated with ED visits and hospitalizations for the 2 groups in the year following randomization were compared using t tests of statistical significance.

RESULTS: Of 59 children recruited to the trial, 29 were randomized to the AMS and 30 to the diary. The 2 groups were similar in demographic and clinical characteristics. During their study year, 24 AMS group members logged on a mean (SD) of 211.0 (117.3) days; 13 diary group members provided data on a mean (SD) of 136.6 (128.0) days. During the 32 months that the study was in progress, the case managers logged on a mean (SD) of 171.0 (97.2) days. Overall, 35 children had at least 1 ED visit, but only 7 children were hospitalized. The 2 groups had no statistically significant differences in the numbers of or charges associated with ED visits or hospitalizations.

CONCLUSION: Electronic devices are being developed to make chronic disease management easier for patients and their families, but they should not be adopted without careful study, including randomized trials, to ascertain their use, costs, and benefits.

Jafari, B.; Austin, N.; Lemke, R.; Poojary, S. (2013):

An audit of the prevalence and characteristics of advance care planning for patients from residential aged care facilities (racfs) referred to the mobile assessment and treatment service (mats).

In: *BMJ Support Palliat Care* 3 (2), S. 280. DOI: 10.1136/bmjspcare-2013-000491.143.

Abstract:

BACKGROUND: Advance Care Planning (ACP) ensures recognition of a person's wishes and promotes autonomy, however, completion and implementation has been a challenge. AIM: To assess the prevalence of ACP in patients from Residential Aged Care Facilities (RACFs) referred to the 'Residential In-reach' service of Alfred Health known as Mobile Assessment and Treatment Service (MATS), and to assess how the process of ACP has been approached by the mangers of those facilities. METHODS: Part A: Prospective audit of documentation of ACP for 100 patients referred to MATS Part B: De-identified, paper-based surveys of the managers of the RACFs where the patients from part A of the study were residing. RESULTS: Part A: The prevalence of ACP, Medical Enduring Power Of Attorney and 'Not for Resuscitation' form were 38%, 37% and 35%, respectively. Patients with ACP or a separate 'NFR' form were significantly more likely to be living in high care compared to low care facilities (79% vs 21%, p=0.049 and 80% vs 20%, p=0.032, respectively). Part B: There was a significant inconsistency between the facilities with regards to 'facility requirements' for ACP, 'person responsible', 'documentation' and 'GP involvement'. DISCUSSION: This study found a low prevalence of ACP, MEPOA and 'NFR' form in patients from RACFs referred to MATS. There was also lack of a systematic approach in the process of ACP. CONCLUSION: There is a need for structured policy coupled with appropriate funding as well as further education of both public and health professionals.

Jagannathan, Mukund (2013):

Efficacy of communication amongst staff members at plastic and reconstructive surgery section using smartphone and mobile Whats App.

In: *Indian J Plast Surg* 46 (3), S. 506–507.

Abstract:

Objective: The objective of this study is to assess the efficacy of smartphone and its WhatsApp application as a communication method amongst the staff of plastic and reconstructive surgery section at tertiary care health facility. Materials and Methods: From January 2012 onwards, the authors used smartphones and its WhatsApp application as a communication method amongst their team for various aspects of patient management and as a tool for academic endorsements. Results: During the period of this study, there were 116 episodes regarding patient management, which were handled, in a timely fashion by using this application. In addition opinion of rotating residents in the section was sought regarding the efficacy of this method of communication. Overall majority of residents were satisfied with this mode of communication. Conclusions: This new method of communication is an effective method for clinical and academic endorsements. The method is cheap and quick and easy to operate.

Jago, Russell; Baranowski, Tom; Baranowski, Janice C. (2006):

Observed, GIS, and self-reported environmental features and adolescent physical activity.

In: *Am J Health Promot* 20 (6), S. 422–428.

Abstract:

Purpose. Examine associations among observed, self-reported, and Geographical Information Systems (GIS) environmental features and physical activity among adolescent males.

Design. Cross-sectional study.

Setting. Boy Scout troops and neighborhoods in Houston, Texas.

Subjects. Two hundred and ten 10- to 14-year-old Boy Scouts.

Measures. Accelerometry to obtain minutes of sedentary, light, and moderate to vigorous activity per day. GIS sources were used to identify the numbers of parks, gymnasiums, trails, bus stops, grocery stores, and restaurants within a 1-mile radius of participant residences as well as residential density, connectivity, and crime. Participants provided a self-report of their environment.

Analysis. Principal component analysis was used to reduce the number of GIS and self-reported items. Four factors were previously obtained from direct observations of the neighborhoods. Correlations were conducted among factors and physical activity. Regression models were run in which minutes of sedentary behavior, light, or moderate to vigorous physical activity were the dependent variables and environmental factors were the independent variables. Nonsignificant variables were removed in a backward deletion process.

Results. Three GIS factors, Parks, Crime, and Gyms, were obtained as were two self-reported factors: difficulty and access and safety. Factor scores were interrelated and associated with the four observed factors. Only observed sidewalk characteristics were correlated with physical activity and were retained in the regression models.

Conclusion. Environmental factors were interrelated. Only sidewalk characteristics were associated with sedentary behavior and light intensity physical activity. (Am J Health Promot 2006;20[6]:422–428.)

Physical activity and sedentary behaviour typologies of 10-11 year olds.

In: *Int J Behav Nutr Phys Act* 7. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32462-001%26site%3dehost-live;russ.jago@bris.ac.uk.

Abstract:

Background: Targeted interventions may be more effective at increasing children's physical activity. The aim of this study was to identify clusters of children based on physical activity and sedentary patterns across the week. Methods: Participants were 761, 10-11 year old children. Participants self-reported time spent in eight physical activity and sedentary contexts and wore an accelerometer. Cluster analysis was conducted on the time spent in the self-reported physical activity and sedentary contexts. Mean minutes of accelerometer derived of moderate to vigorous physical activity (MVPA) and sedentary time were derived for the entire week, weekdays only, weekend days and four different time periods across each type (weekend or weekday) of days. Differences in the physical activity patterns of the groups derived from the cluster analysis were assessed for overall physical activity as well as for the four time periods on weekdays and weekend days. Results: Three clusters emerged: 1) High active/Low sedentary; 2) Low active/Moderate sedentary; and 3) High Active/High sedentary. Patterns of activity differed across the week for each group and the High Active/High sedentary obtained the most minutes of MVPA. Conclusions: Patterns of physical activity and sedentary time differed across the week for each cluster. Interventions could be targeted to the key periods when each group is inactive. Jahng, Seungmin (2012):

Multilevel models for intensive longitudinal data with heterogeneous error structure: Covariance transformation and variance function models.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (2-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-99160-591%26site%3dehost-live.

Abstract:

Recent developments in data collection methods in the behavioral and social sciences, such as Ecological Momentary Assessment (EMA) enables researchers to gather intensive longitudinal data (ILD) and to examine more detailed features of intraindividual variation of a variable(s) over time. Due to its high intensity of assessments within individuals, ILD often has different characteristics from traditional longitudinal data with a few measurement occasions and requires different assumptions of statistical models in use. In the present thesis, issues in the analysis of ILD and problems of current use of statistical models for the analysis of ILD are discussed and investigated. Specifically, the issue of heterogeneity of autocorrelation and variance across individuals in ILD is extensively studied for multilevel models (MLMs). In chapter 2, a brief introduction to multilevel models and issues in modeling residual covariance structure in MLMs are provided and discussed. In chapter 3, it is shown that bias in estimation of parameters in MLMs under homogeneity assumption is not ignorable when autocorrelation differs across individuals and its average is high. It is also shown that a transformation method, which multiplies variables in the model by the inverse of Cholesky factor of individual-specific error covariance, attenuates the bias for ILD. Chapter 4 reviews variance function models for heterogeneous variance and introduces a two-step MLM approach for modeling heterogeneous variance using squared residuals. A simulation study showed that the two-step MLM does not suffer from non-convergence and is applicable to ILD. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Jahng, Seungmin; Wood, Phillip K.; Trull, Timothy J. (2008):

Analysis of affective instability in ecological momentary assessment: Indices using successive difference and group comparison via multilevel modeling.

In: *Psychological methods* 13 (4), S. 354–375. DOI: 10.1037/a0014173.

Abstract:

Temporal instability of affect is a defining characteristic of psychological disorders such as borderline personality disorder (BPD) and mood cycling disorders. Ecological momentary assessment (EMA) enables researchers to directly assess such frequent and extreme fluctuations over time. The authors examined 4 operationalizations of such temporal instability: the within-person variance (WPV), the first-order autocorrelation, the mean square successive difference (MSSD), and the probability of acute change (PAC). It is argued that the MSSD and PAC measures are preferred indices of affective instability because they capture both variability and temporal dependency in a time series. Additionally, the performance of these 2 measures in capturing within- and between-day instability is discussed. To illustrate, the authors present EMA data from a study of negative mood in BPD and major depressive disorder patients. In this study, MSSD and PAC captured affective instability better than did WPV. Given that MSSD and PAC are individual difference measures, the authors propose that group differences on these indices be explored using generalized multilevel models. Versions of MSSD and PAC that adjust for randomly elapsed time interval between assessments are also presented.

James, Kirstyn; Dolan, Eamon; O'Brien, Eoin (2014):

Making ambulatory blood pressure monitoring accessible in pharmacies.

In: *Blood Press Monit. DOI:* 10.1097/MBP.0000000000000034.

Abstract:

OBJECTIVES: Ambulatory blood pressure measurement (ABPM), although recommended for the diagnosis and management of hypertension, has limited availability. The objective of this study was to show that if the characteristics of patients attending pharmacies for ABPM are similar to those attending primary care, the technique can be made more widely available to patients through pharmacies. PATIENTS AND METHODS: A comparative study using a software program that allowed central collection, analysis and comparison of ABPM data from patients attending primary care and pharmacies for assessment of hypertension in Ireland. RESULTS: ABPM data from 46 978 patients attending primary care were compared with 1698 attending pharmacies between 2007 and 2013. The age, sex and blood pressure characteristics of patients attending primary care and pharmacies were similar. The mean pressures in all categories, except for systolic blood pressure recorded in primary care, were higher in men. The first ABPM measurements recorded in pharmacies were slightly higher than those in primary care (150.8+/-19.5/88.7+/-13.7 vs. 149.6+/-20.7/88.0+/-14.4 mmHg). More patients attending primary care were normotensive than those attending pharmacies (19.5 vs. 16.4%), whereas more patients attending pharmacies were hypertensive than those attending primary care (62.8 vs. 60.7%), particularly female patients (61.0 vs. 56.4%). White-coat hypertension was similar in patients attending primary care and pharmacies (19.8 vs. 20.8%), but it was more prevalent in men attending pharmacies (22.0 vs. 17.4%) and in women attending primary care (21.9 vs. 19.7%). There were more dippers in pharmacy then primary care ABPMs (84.7 vs. 79.4%). A preference for having ABPM on Fridays and Saturdays was evident in patients attending pharmacies (19.6 vs. 6.6%), whereas there was a preference for early morning recording in primary care (4.1 vs. 1.1%). CONCLUSION: This study, which is the first to report on ABPM data from the pharmacy setting, shows that the blood pressure characteristics of patients with ABPMs recorded in pharmacies are similar to those recorded in primary care practices. It is feasible, therefore, to perform ABPM in pharmacies, which can be utilized to make ABPM more accessible to the large number of patients in the population with hypertension.

Janney, C. A.; Fagiolini, A.; Swartz, H. A.; Jakicic, J. M.; Holleman, R. G.; Richardson, C. R. (2014):

Are adults with bipolar disorder active? Objectively measured physical activity and sedentary behavior using accelerometry.

In: *J.Affect.Disord.* 152-154 (0165-0327 (Linking)), S. 498–504. DOI: 10.1016/j.jad.2013.09.009.

Abstract:

BACKGROUND: Little is known about physical activity and sedentary behavior of adults with bipolar disorder (BP). Physical activity and sedentary behaviors may be modifiable factors associated with elevated rates of obesity, diabetes, cardiovascular disease, metabolic syndrome, and mortality in adults with BP. METHODS: Sixty adult outpatients treated for BP (>18yr) wore accelerometers for seven consecutive days. Each minute epoch was assigned an activity level based on the number of counts per minute; sedentary(<100 counts), light(101-1951 counts), or moderate/vigorous(>1952 counts). Adults with BP were matched 1:1 to users and non-users of mental health services (MHS) (NHANES 2003-2004) by gender, closest BMI, and age. RESULTS: On average, adults with BP wore actigraphs over 17h/day. The majority of monitoring time (78%) was classified as sedentary (approximately 13.5h/day). Light physical activity accounted for 21% of the monitoring time/day (215min/day). None achieved 150min/wk of moderate/vigorous activity as recommended by national guidelines. Adults with BP were significantly less active and more sedentary than MHS users and non-users in NHANES 2003-2004 ($p<0.01$). LIMITATIONS: Majority of the participants were relatively asymptomatic with most (87%) having no more than mild depressive symptoms and none experiencing severe manic symptoms. The sedating effects of medications on physical activity were not investigated. CONCLUSION: From clinical

perspectives, these findings justify physical activity interventions targeting adults with BP as a possible means to improve their physical and mental health and to reduce the elevated risk of commonly observed medical comorbidities in this high-risk population

Janney, C. A.; Ganguli, R.; Richardson, C. R.; Holleman, R. G.; Tang, G.; Cauley, J. A.; Kriska, A. M. (2013):

Sedentary behavior and psychiatric symptoms in overweight and obese adults with schizophrenia and schizoaffective disorders (WAIST Study).

In: *Schizophr.Res* 145 (1-3), S. 63–68. DOI: 10.1016/j.schres.2013.01.010.

Abstract:

OBJECTIVE: Examine the association between sedentary behavior and psychiatric symptoms among overweight and obese adults with schizophrenia or schizoaffective disorders (SZO/SA). DESIGN: Randomized clinical trial; Weight Assessment and Intervention in Schizophrenia Treatment (WAIST) Study: baseline data collected 2005-2008. SETTING: University of Pittsburgh Medical Center, Pittsburgh, PA, USA. PARTICIPANTS: Community-dwelling adults diagnosed with SZO/SA, with mild symptom severity [Positive and Negative Syndrome Scale (PANSS)<90], who were interested in losing weight, age 18-70years, BMI>27kg/m. MEASUREMENTS: Objectively measured sedentary behavior by accelerometry, and psychopathology assessed by PANSS. Participants wore the actigraphs for 7 consecutive days during their waking hours. Sedentary behavior was defined as </=100 counts per minute during wear-time and excluded sleep and non-wear time. RESULTS: On average, 81% of the participant's monitoring time or 756min/day was classified as sedentary behavior using accelerometry. No association was observed between sedentary behaviors and PANSS psychiatric symptoms [total (p>/=0.75), positive (p>/=0.81), negative (p>/=0.59) and general psychopathology (p>/=0.65) subscales]. No association was observed between sedentary behaviors and age, race, gender and BMI. CONCLUSION: From a clinical and public health perspective, the amount of time (approximately 13h) and percentage of time (81% excluding non-wear time associated with sleeping) engaged in sedentary behavior among overweight and obese adults in this population is alarming, and points to an urgent need for interventions to decrease sedentary behaviors. The lack of associations between sedentary behavior and psychiatric symptoms may be due to a ceiling effect for sedentary behavior

Janssen, Wim G. M.; Külcü, Duygu Geler; Horemans, Herwin L. D.; Stam, Henk J.; Bussmann, Johannes B. J. (2008):

Sensitivity of accelerometry to assess balance control during sit-to-stand movement.

In: *IEEE Trans Neural Syst Rehabil Eng* 16 (5), S. 479–484. DOI: 10.1109/TNSRE.2008.2003386.

Abstract:

Accelerometry has the potential to measure balance, defined as high-frequency body sway, ambulatorily in a simple and inexpensive way. The aim of this study was to determine and compare the sensitivity of accelerometric balance parameters during the sit-to-stand (STS) movement. Eleven healthy subjects (four males, 28.2 +/-7.9 years) and 31 patients with stroke (21 males; 63.3+/-12.8 years) were included. The healthy subjects performed STS movements in four conditions with different levels of difficulty. Data of the patients were compared 1) with healthy subjects, 2) between patient subgroups, and 3) between different phases of recovery to assess the sensitivity of accelerometry for differences in balance control. Accelerometers were attached to the trunk, and force plate measurements were simultaneously done in the healthy subjects. Main outcome measures were root mean square (rms) and area under the curve (AUC) derived from the high-frequency component of the transversal acceleration signal of the trunk. In all comparisons there was a significant difference in AUC data ($p < 0.05$), and AUC appeared to be more sensitive than rms. Variability in AUC was not completely or mainly the result of changes and differences in the duration of the STS movement. As a conclusion, accelerometry is a potentially valuable technique to measure balance during the STS movement.

Janssens, M.; Lataster, T.; Simons, C. J.; Oorschot, M.; Lardinois, M.; Van, Os J.; Myin-Germeys, I. (2012):

Emotion recognition in psychosis: no evidence for an association with real world social functioning.

In: *Schizophr.Res* 142 (1-3), S. 116–121. DOI: 10.1016/j.schres.2012.10.003.

Abstract:

BACKGROUND: Patients with psychotic disorders show impairments in the recognition of emotions in other people. These impairments have been associated with poor social functioning as measured by self-report questionnaires, clinical interviews and

laboratory-based tests of social skills. The ecological validity of these tests, however, is low. Associations were examined between emotion recognition and daily life social interactions in 50 patients diagnosed with a non-affective psychotic disorder and 67 healthy controls. METHODS: All participants were assessed with the Degraded Facial Affect Recognition Task (DFAR), a computer test measuring the recognition of emotional facial expressions. Social functioning in daily life was assessed using the Experience Sampling Method (a random time sampling technique) with focus on measures of social context and appraisal of the social situation. RESULTS: Groups differed significantly in the recognition of angry faces, whereas no differences existed for other emotions. There were no associations between emotion recognition and social functioning in daily life and there was no evidence for differential associations in patients as compared to controls. DISCUSSION: Social functioning, when assessed in an ecologically valid fashion, is not sensitive to variation in the traditional experimental assessment of emotion recognition. Real life measures of functioning should guide research linking the handicaps associated with psychosis to underlying cognitive and emotional dysregulation

Janz, Kathleen F.; Kwon, Soyang; Letuchy, Elena M.; Eichenberger Gilmore, Julie M.; Burns, Trudy L.; Torner, James C. et al. (2009):

Sustained effect of early physical activity on body fat mass in older children.

In: *Am J Prev Med* 37 (1), S. 35–40. DOI: 10.1016/j.amepre.2009.03.012.

Abstract:

BACKGROUND\r\nPhysical activity is assumed to reduce excessive fatness in children. This study examined whether the benefits of early childhood moderate-to-vigorous physical activity (MVPA) on fatness are sustained throughout childhood.\r\nMETHODS\r\nMVPA minutes per day (min/d) and fat mass (kilograms; kg) were measured using accelerometry and dual-energy x-ray absorptiometry in 333 children aged 5, 8, and 11 years who were participating in the Iowa Bone Development Study. Mixed regression models were used to test whether MVPA at age 5 years had an effect on fat mass at age 8 years and age 11 years, after adjustment for concurrent height, weight, age, maturity, and MVPA. The analysis was repeated to control for fat mass at age 5 years. Using mixed-model least-squares means, adjusted means of fat mass at age 8 years and age 11 years were compared between the highest and lowest quartiles of MVPA at age 5 years. Data were collected between 1998 and 2006 and analyzed in 2008.\r\nRESULTS\r\nFor boys and girls, MVPA at age 5 years was a predictor of adjusted fat mass at age 8 years and age 11 years ($p<0.05$). In girls, the effect of MVPA at age 5 years was not significant when fat mass at age 5 years was included. Boys and girls in the highest quartile of MVPA at age 5 years had a lower fat mass at age 8 years and age 11 years than children in the lowest MVPA quartile at age 5 years ($p<0.05$; mean difference 0.85 kg at age 8 years and 1.55 kg at age 11 years).\r\nCONCLUSIONS\r\nSome effects of early-childhood MVPA on fatness appear to persist throughout childhood. Results indicate the potential importance of increasing MVPA in young children as a strategy to reduce later fat gains.

Janz, Kathleen F.; Medema-Johnson, H. C.; Letuchy, Elena M.; Burns, Trudy L.; Gilmore, J. Eichenbergerm; Torner, James C. et al. (2008):

Subjective and objective measures of physical activity in relationship to bone mineral content during late childhood: the Iowa Bone Development Study.

In: *British Journal of Sports Medicine* 42 (8), S. 658–663.

Abstract:

OBJECTIVE:

This study compared accelerometry to self-report for the assessment of physical activity (PA) in relation to bone mineral content (BMC). In addition, we compared the ability of these measures to assess PA in boys versus girls.

METHODS:

Participants in this cross-sectional study included 449 children (mean age 11 years) from the Iowa Bone Development Study. PA was measured via 3-5 days of accelerometry using the Actigraph and 7 day self-report questionnaire using the Physical Activity Questionnaire for Children (PAQ-C). Hip, spine, and whole body BMC were measured via dual energy x ray absorptiometry (DXA).

RESULTS:

Partial correlation analysis (controlling for height, weight, and maturity) showed the Actigraph was significantly associated with hip ($r = 0.40$), spine ($r = 0.20$), and whole body ($r = 0.33$) BMC in boys, as was the PAQ-C ($r = 0.28$ hip, $r = 0.19$ spine, and $r = 0.22$ whole body). Among girls, only the Actigraph was significantly associated with hip ($r = 0.18$) and whole body ($r = 0.16$) BMC. Both the Actigraph and PAQ-C were significant in hip, spine, and whole body multivariable linear regression models (after controlling for body size and maturity) in boys. Only the Actigraph entered hip BMC regression model in girls.

CONCLUSIONS:

Our study supports previous work showing associations between everyday PA and BMC in older children. These associations are more likely to be detected with an objective versus subjective measure of PA, particularly in girls.

Jappe, L. M.; Cao, L.; Crosby, R. D.; Crow, S. J.; Peterson, C. B.; Le, Grange D. et al. (2013):

Stress and eating disorder behavior in anorexia nervosa as a function of menstrual cycle status.

In: *Int.J.Eat.Disord.* (0276-3478 (Linking)). DOI: 10.1002/eat.22211.

Abstract:

OBJECTIVE: Fluctuations in ovarian hormones during the menstrual cycle and psychosocial stress contribute to eating disorder (ED) behavior. METHOD: Using ecological momentary assessment techniques, this study examined relationships between stress and binge eating, self-induced vomiting, and dietary restriction based on menstrual cycle status in anorexia nervosa (AN). One hundred nine females with full and subthreshold AN (17-45 years old) recorded ED behavior and stress ratings over 2 weeks. Using hierarchical linear modeling, individuals with eumenorrhea and those with amenorrhea or oligomenorrhea were compared. RESULTS: Following episodes of meal skipping, momentary stress decreased in individuals with normal menstrual cycles and increased in those with irregular menstrual cycles. DISCUSSION: Results suggest that changes in stress severity in response to food restriction may differ based on ovarian hormonal status and may be a mechanism by which AN is maintained in individuals without menstrual disturbance. Do smokers know what we're talking about? The construct validity of nicotine dependence questionnaire measures.

In: *Psychological Assessment* 21 (4), S. 595–607. DOI: 10.1037/a0017312.

Abstract:

Few studies have examined whether nicotine dependence self-report questionnaires can predict specific behaviors and symptoms at specific points in time. The present study used data from a randomized clinical trial (N = 608; M. E. Piper et al., 2007) to assess the construct validity of scales and items from 3 nicotine dependence measures: the Fagerström Test for Nicotine Dependence (T. F. Heatherton, L. T. Kozlowski, R. C. Frecker & K.-O. Fagerström, 1991), the Nicotine Dependence Syndrome Scale (S. Shiffman, A. J. Waters, & M. Hickcox, 2004), and the Wisconsin Inventory of Smoking Dependence Motives (M. E. Piper et al., 2004). Scales from these measures were used to predict participants' reports on real-time measures of withdrawal symptoms and smoking behavior and retrospective self-report questionnaires to assess convergent and discriminative validity. The nicotine dependence measures' scales and items generally predicted the real-time measures of similar constructs, but the percent of variance accounted for was low. The nicotine dependence measures did, however, show evidence of discriminative validity. Thus, this study provides modest support for the construct validity of these nicotine dependence scales.

Sub-typing daily fatigue progression in chronic fatigue syndrome.

In: *J Ment.Health* (0963-8237 (Linking)). DOI: 10.3109/09638237.2012.670879.

Abstract:

Background Activity logs involve patients writing down their activities and symptoms over 1 or more days. Aims This study sought to classify daily fatigue patterns among patients with chronic fatigue syndrome (CFS) using activity logs. Method Fatigue intensity was self-reported every 30 min in a sample of 90 patients with CFS over 1 day. A cluster analysis using fatigue intensity, variability and slope was conducted. Results Three clusters emerged involving patients with different trajectories. One group evidenced high fatigue intensity, low variability, and fatigue intensity stayed the same over time. A second group had moderate fatigue intensity, high variability, and fatigue intensity decreased over time. A third group had moderate fatigue intensity, high variability, but fatigue intensity increased over time. The three clusters of patients differed on measures of actigraphy, pain and immune functioning. Conclusions Activity logs can provide investigators and clinicians with valuable sources of data for understanding patterns of fatigue and activity among patients with CFS

The affective response to health-related information and its relationship to health anxiety: An ambulatory approach.

In: *Cogn Emot*, S. 1–9. DOI: 10.1080/02699931.2014.930022.

Abstract:

Affective reactions to health-related information play a central role in health anxiety. Therefore, using ambulatory assessment, we analysed the time course of negative affect in a control group (CG, n = 60) which only rated their negative affect and an experimental group (EG, n = 97) which also rated the presence of somatic symptoms (e.g., back pain). By means of mixed regression models, we observed a decline of negative affect following the symptom self-ratings in the EG and a stable affect in the CG. The decline of negative affect was not moderated by the degree of health anxiety. Our findings might indicate that evaluating one's health status leads to a general reduction of negative affect in healthy individuals. The results of the study are in line with a bidirectional symptom perception model and underline the crucial role of affect regulation in the processing of health-related information.

Information Technology in Mental Health Research: Impediments and Implications in One Chronic Pain Study Population.

In: *Pain Medicine* 8 (s3), S. S176-S181.

Abstract:

Objective. The Department of Veterans Affairs and Veterans' Administration hospitals began using the electronic medical record in 1994, streamlining provider-to-provider communication of vital clinical information, and simultaneously providing investigators access to vast amounts of clinical data for research purposes. Administrative and coded data, including symptoms and diagnoses as derived from chart content, are one of the most ready substrates for analysis of these massive databases to answer various research-related inquiries. We evaluated the capability of this type of coded data to accurately identify patients with schizophrenia from a group of 819 patients taking opioids for chronic pain in the primary care clinic of the Philadelphia Veterans' Administration Medical Center.

Methods. Patients were identified for inclusion in this analysis by their sequential enrollment in an Opioid Renewal Clinic as referred by their primary care providers, as well as a nonreferred cohort of chronic pain patients maintained on opioids by their primary care providers (N = 819). The prevalence of schizophrenia obtained by coded diagnostic labeling by computerized chart review was compared with the prevalence of schizophrenia obtained by systematic independent manual chart review of all cases by a research psychiatrist.

Results. Based purely on coded diagnostic labeling, the prevalence of schizophrenia in this population was 14%, nearly 14 times the estimated general population prevalence. However, manual independent chart review of the identified cases by a research psychiatrist (N = 119) resulted in the actual prevalence in this group to be estimated at 1.8%. None of the patients with three or less incidents of diagnostic labeling by code had schizophrenia. Of those with four or more incidents, 74% had schizophrenia.

Conclusions. Better accuracy is obtained when cases of schizophrenia are identified by multiple coding incidents derived from longitudinal clinical encounters. These findings suggest that the extraction of up to three coding incidents for schizophrenia alone is not an accurate means of identifying this clinical population for research and epidemiological purposes. Further, when designing automated, information technology-based approaches to the identification of subjects for clinical research and extracting their data from electronic medical records using International Classification of Disease, Ninth Revision, Clinical Modification (ICD-9-CM) codes, mental health diagnoses must be uniquely considered on a disease-by-disease basis.

Telemonitoring with respect to mood disorders and information and communication technologies: overview and presentation of the PSYCHE project.

In: *Biomed Res Int* 2014, S. 104658. DOI: 10.1155/2014/104658.

Abstract:

This paper reviews what we know about prediction in relation to mood disorders from the perspective of clinical, biological, and physiological markers. It then also presents how information and communication technologies have developed in the field of mood disorders, from the first steps, for example, the transition from paper and pencil to more sophisticated methods, to the

development of ecological momentary assessment methods and, more recently, wearable systems. These recent developments have paved the way for the use of integrative approaches capable of assessing multiple variables. The PSYCHE project stands for Personalised monitoring SYstems for Care in mental HEalth.

Jeffrey Kao, Ming-Chih; Jarosz, Renata; Goldin, Michael; Patel, Amy; Smuck, Matthew (2014):

Determinants of Physical Activity in America: A First Characterization of Physical Activity Profile using National Health and Nutrition Examination Survey (NHANES).

In: *PM R. DOI:* 10.1016/j.pmrj.2014.03.004.

Abstract:

OBJECTIVE: To develop and implement methodologies for characterizing accelerometry-derived patterns of physical activity (PA) in the United States in relation to demographics, anthropometrics, behaviors, and co-morbidities using the NHANES dataset. DESIGN: Retrospective analysis of nationally representative database SETTING: Computer-generated modeling in silico PARTICIPANTS: 6,329 adults in the U.S. from NHANES 2003-2004 database. METHODS: In order to discover subtle multivariate signal in the dynamic and noisy accelerometry data, we develop a novel approach, termed discretized multiple adaptive regression (DMAR), and implement the algorithm in SAS. Main Outcome Measurements: Demographic, anthropometric, co-morbidity, and behavioral variables. RESULTS: The intensity of PA decreases with both increased age and increased BMI. Both higher education and greater income correlate with increased activity over short durations and reduced activity intensity over long durations. Numerous predictors that demonstrated effects that may be masked by use of these larger intervals were found. This includes age, one of the most robust variables, where we discovered decreasing activities particularly in the moderate activity range. It also includes gender where women compared to men have increased proportions of active times upto the center of light activity range; and income greater than $45,000 where a complex effect is seen with little correspondence to existing cut-points. CONCLUSIONS: The results presented in this study suggest that the method of multiple regression and heat map visualization can generate insights otherwise hidden in large datasets such as NHANES. A review of the provided heat maps reveals the trends discussed above involving demographic, anthropometric, co-morbidity, and behavioral variables. It also demonstrates the power of accelerometry to expose alterations in PA. Ultimately, this study provides a U.S. population-based norm to use in future studies of PA.

An Intelligent Tool for Activity Data Collection.

In: *Sensors.(Basel)* 11 (4), S. 3988–4008. DOI: 10.3390/s110403988.

Abstract:

Activity recognition systems using simple and ubiquitous sensors require a large variety of real-world sensor data for not only evaluating their performance but also training the systems for better functioning. However, a tremendous amount of effort is required to setup an environment for collecting such data. For example, expertise and resources are needed to design and install the sensors, controllers, network components, and middleware just to perform basic data collections. It is therefore desirable to have a data collection method that is inexpensive, flexible, user-friendly, and capable of providing large and diverse activity datasets. In this paper, we propose an intelligent activity data collection tool which has the ability to provide such datasets inexpensively without physically deploying the testbeds. It can be used as an inexpensive and alternative technique to collect human activity data. The tool provides a set of web interfaces to create a web-based activity data collection environment. It also provides a web-based experience sampling tool to take the user's activity input. The tool generates an activity log using its activity knowledge and the user-given inputs. The activity knowledge is mined from the web. We have performed two experiments to validate the tool's performance in producing reliable datasets

Jehle, Sigrid; Lardi, Alessia; Felix, Barbara; Hulter, Henry N.; Stettler, Christoph; Krapf, Reto (2014):

Effect of large doses of parenteral vitamin D on glycaemic control and calcium/phosphate metabolism in patients with stable type 2 diabetes mellitus: a randomised, placebo-controlled, prospective pilot study.

In: *Swiss Med Wkly* 144, S. w13942. DOI: 10.4414/smw.2014.13942.

Abstract:

OBJECTIVE: Vitamin D (D(3)) status is reported to correlate negatively with insulin production and insulin sensitivity in patients with type 2 diabetes mellitus (T2DM). However, few placebo-controlled intervention data are available. We aimed to assess the effect of large doses of parenteral D3 on glycosylated haemoglobin (HbA((1)c)) and estimates of insulin action (homeostasis model assessment insulin resistance: HOMA-IR) in patients with stable T2DM. MATERIALS AND METHODS: We performed a prospective, randomised, double-blind, placebo-controlled pilot study at a single university care setting in Switzerland. Fifty-five patients of both genders with T2DM of more than 10 years were enrolled and randomised to either 300,000 IU D(3) or placebo, intramuscularly. The primary endpoint was the intergroup difference in HbA((1)c) levels. Secondary endpoints were: changes in insulin sensitivity, albuminuria, calcium/phosphate metabolism, activity of the renin-aldosterone axis and changes in 24-hour ambulatory blood pressure values. RESULTS: After 6 months of D(3) supply, there was a significant intergroup difference in the change in HbA((1)c) levels (relative change [mean +/- standard deviation] +2.9% +/- 1.5% in the D(3) group vs +6.9% +/- 2.1% the in placebo group, p = 0.041) as HOMA-IR decreased by 12.8% +/- 5.6% in the D(3) group and increased by 10% +/- 5.4% in the placebo group (intergroup difference, p = 0.032). Twenty-four-hour urinary albumin excretion decreased in the D(3) group from 200 +/- 41 to 126 +/- 39, p = 0.021). There was no significant intergroup difference for the other secondary endpoints. CONCLUSIONS: D(3) improved insulin sensitivity (based on HOMA-IR) and affected the course of HbA((1)c) positively compared with placebo in patients with T2DM.

Jentzsch, N. S.; Camargos, P. A. M.; Colosimo, E. A.; Bousquet, J. (2009):

Monitoring adherence to beclomethasone in asthmatic children and adolescents through four different methods.

In: *Allergy* 64 (10), S. 1458–1462. DOI: 10.1111/j.1398-9995.2009.02037.x.

Abstract:

BACKGROUND\r\nSuboptimal adherence to inhaled steroids is a known problem in children and adolescents, even when medications are administered under parental supervision. This study aimed to verify the adherence rate to beclomethasone dipropionate (BDP) by four currently available methods.\r\nMETHODS\r\nIn this concurrent cohort study, 102 randomly selected asthmatic children and adolescents aged 3-14 years were followed for 12 months. Adherence rate was assessed every 2 months by self and/or parent report, pharmacy dispensing data, electronic device (Doser); Meditrack Products, Hudson, MA, USA) monitor, and canister weight.\r\nRESULTS\r\nMean adherence rates to BDP by self and/or parent report, pharmacy records, Doser, and canister weight were 97.9% (95% CI 88.0-98.6), 70.0% (95% CI 67.6-72.4), 51.5% (95% CI 48.3-54.6), and 46.3% (95% CI 44.1-48.4), respectively. Agreement analysis between (Doser) and canister weight revealed a weighted kappa equal to 0.76 (95% CI 0.65-0.87).\r\nCONCLUSIONS\r\nAdherence was a dynamic event and rates decreased progressively for all methods over the 12-month follow-up. Canister weight and electronic monitoring measures were more accurate than self/parent reports and pharmacy records. Rates obtained by these two methods were very close and statistical analysis also showed a substantial agreement between them. As measurements by canister weight are less costly compared with currently available electronic devices, it should be considered as an alternative method to assess adherence in both clinical research and practice.

Jeon, Eunjoo; Park, Hyeoun-Ae; Min, Yul Ha; Kim, Hyun-Young (2014):

Analysis of the information quality of korean obesity-management smartphone applications.

In: *Healthc Inform Res* 20 (1), S. 23–29. DOI: 10.4258/hir.2014.20.1.23.

Abstract:

OBJECTIVES: This study analyzed smartphone obesity-management applications developed in Korea and the quality of the information that they provide. METHODS: Obesity-management smartphone applications were searched using the keywords 'obesity + management,' 'weight + management,' 'weight + loss,' 'weight + exercise,' 'weight + diet,' 'weight + calories,' and 'diet,' with a search application programming interface (provided by Apple) between September 23 and September 27, 2013. These applications were then classified according to their main purpose, type of interventions used, price, type of developer, and user ratings. The information quality of the applications was analyzed using the Silberg scale. RESULTS: In total, 148 smartphone applications for obesity management were found. The main purpose of most of these applications (70.95%) was to provide information regarding weight control. The most frequently used intervention (34.62%) was to provide information on exercise management. More than half of the applications (58.78%) were free of charge. The mean of users' rating of these applications was 3.68 out of 5. The quality of information provided by these applications was evaluated as 4.55 out of 9: specifically, 1.79 out of 3 for authorship, 0.22 out of 2 for attribution, 1.29 out of 2 for disclosure, and 1.25 out of 2 for currency. Only three of the applications (2.88%) had a score on the Silberg scale greater than or equal to 7 points. CONCLUSIONS: The findings of this study

suggest that the quality of information provided by smartphone applications in the healthcare domain urgently need to be evaluated to prevent users being misinformed by these applications.

Jern, Patrick; Gunst, Annika; Sandqvist, Felicia; Sandnabba, N. Kenneth; Santtila, Pekka (2011):

Using Ecological Momentary Assessment to investigate associations between ejaculatory latency and control in partnered and non-partnered sexual activities.

In: *Journal of sex research* 48 (4), S. 316–324. DOI: 10.1080/00224499.2010.518293.

Abstract:

Ecological Momentary Assessment (EMA) was used to investigate associations between, and variations in, ejaculatory control and ejaculation latency time (ELT) over repeated measurements of sexual activities. Differences between measures recorded in partnered or non-partnered settings were also investigated. The sample consisted of 21 male Finns aged 18 years or above, contributing a total of 158 reports of partnered and non-partnered sexual activities over a six-week period. In the context of non-partnered sexual activities, after controlling for within-subjects dependence, ELTs between events were predictive of one another, but ELT did not predict ejaculatory control when measured simultaneously, nor at subsequent events. Also, ejaculatory control could not predict simultaneously measured ELT or ejaculatory control at subsequent events. During partnered sexual activities, both ejaculatory control and ELT could be accurately predicted by observing ejaculatory control at prior events. In this context, ejaculatory control could also reliably predict simultaneously measured ELT. ELT or ejaculatory control during partnered sexual activity could not be predicted by observing ELT at prior events. Between-event correlations were generally low, indicating considerable variation in ejaculatory functioning over time. EMA is a thrifty assessment method for studying variations in ejaculatory function, and is likely suitable for studying sexual dysfunctions in general.

Ji, Jun; Ling, Xuefeng B.; Zhao, Yingzhen; Hu, Zhongkai; Zheng, Xiaolin; Xu, Zhening et al. (2014):

A data-driven algorithm integrating clinical and laboratory features for the diagnosis and prognosis of necrotizing enterocolitis.

In: *PLoS One* 9 (2), S. e89860. DOI: 10.1371/journal.pone.0089860.

Abstract:

BACKGROUND: Necrotizing enterocolitis (NEC) is a major source of neonatal morbidity and mortality. Since there is no specific diagnostic test or risk of progression model available for NEC, the diagnosis and outcome prediction of NEC is made on clinical grounds. The objective in this study was to develop and validate new NEC scoring systems for automated staging and prognostic forecasting. STUDY DESIGN: A six-center consortium of university based pediatric teaching hospitals prospectively collected data on infants under suspicion of having NEC over a 7-year period. A database comprised of 520 infants was utilized to develop the NEC diagnostic and prognostic models by dividing the entire dataset into training and testing cohorts of demographically matched subjects. Developed on the training cohort and validated on the blind testing cohort, our multivariate analyses led to NEC scoring metrics integrating clinical data. RESULTS: MACHINE LEARNING USING CLINICAL AND LABORATORY RESULTS AT THE TIME OF CLINICAL PRESENTATION LED TO TWO NEC MODELS: (1) an automated diagnostic classification scheme; (2) a dynamic prognostic method for risk-stratifying patients into low, intermediate and high NEC scores to determine the risk for disease progression. We submit that dynamic risk stratification of infants with NEC will assist clinicians in determining the need for additional diagnostic testing and guide potential therapies in a dynamic manner. ALGORITHM AVAILABILITY: http://translationalmedicine.stanford.edu/cgi-bin/NEC/index.pl and smartphone application upon request.

Jiang, Li (2012):

Absence makes the heart grow fonder, behaviors adaptive and perceptions idealized: The effects of geographic separation and interpersonal media on intimacy process.

In: *Dissertation Abstracts International Section A: Humanities and Social Sciences* 73 (2-A). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99150-106&site=ehost-live.

Abstract:

Many people assume that it is challenging to maintain a romantic relationship when the partners are separated by a considerable distance. Recent research on long-distance relationships, however, suggests that long-distance romantic

relationships are equally or even more intimate and satisfied than geographically close counterparts. The present study examined whether the everyday intimacy process unfolds differently in long-distance versus geographically close dating relationships and whether the use of interpersonal media interplays with geographic separation to affect intimacy in specific interactions. Drawing on the Interpersonal Process Model of Intimacy (IPMI; Reis & Shaver, 1988), the study tested an intimacy enhancement mechanism in which long-distance couples engage in more adaptive self-disclosure behaviors and form more idealized relationship perceptions than do geographically close couples for the pursuit of intimacy across various interpersonal media. These predictions were examined with a novel electronic diary method. Long-distance and geographically close dating couples completed a 7-day diary study in which both members of the couple independently reported their interactions that took place each day. The results provide support for the behavioral adaptation and perceptual idealization effects proposed, and suggest that the two effects vary along the media dimensions of cue multiplicity, synchronicity and mobility. These findings offer a contextual extension to the IPMI and advance the understanding of communication and relational processes in long-distance and mixed-mode relationships. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Patient compliance with assessing and monitoring of asthma.

In: *J Asthma* 46 (10), S. 1027–1031. DOI: 10.3109/02770900903229685.

Abstract:

BACKGROUND\r\nThe current asthma guidelines encourage use of a diary for assessing and monitoring symptoms and airway function. However, patient compliance and acceptability are usually poor owing to the burden of frequent and prolonged assessment.\r\nOBJECTIVE\r\nWe investigated whether better patient compliance could be ensured if a study was more relevant to patient convenience and had less impact on their daily life.\r\nMETHODS\r\nA total of 106 patients with symptomatic asthma underwent a fixed-time thrice-daily assessment schedule for a period lasting 2 weeks, and they were assigned to a doctor visit after the assessment. Symptoms and medication use were recorded in a booklet (paper diary) and airway function measured by a portable spirometer (electronic diary).\r\nRESULTS\r\nOf 4,452 expected entries, the paper diary yielded 3,186 compliant entries and the electronic diary yielded 3,557 compliant entries; 71% of patients completed at least 30 compliant entries in the paper diary and 79% in the electronic diary. Use of an electronic device was associated with better compliance compared with paper technique (80.0% vs. 71.7%, $p < 0.0001$). Patient compliance decreased in the second week compared with the first week of diary keeping for both types of diaries (paper diary: 68.6% vs. 74.8%, $p < 0.0001$; electronic diary: 76.7% vs. 83.4%, $p < 0.0001$). The morning compliance was the least good, the afternoon better, and the evening best (paper diary: 68.2% vs. 71.0% vs. 75.9%, $p < 0.0001$; electronic diary: 77.2% vs. 79.0% vs. 83.9%, $p < 0.0001$). Among demographics and clinical factors, higher anxiety levels were linked to lower patient compliance.\r\nCONCLUSION\r\nGood patient compliance and acceptability can be achieved when a study takes into account patient convenience, uses user friendly electronic devices, and is less disruptive to patients' daily life.

Jiang, Li; Mancuso, Matthew; Lu, Zhengda; Akar, Gunkut; Cesarman, Ethel; Erickson, David (2014):

Solar thermal polymerase chain reaction for smartphone-assisted molecular diagnostics.

In: *Sci Rep* 4, S. 4137. DOI: 10.1038/srep04137.

Abstract:

Nucleic acid-based diagnostic techniques such as polymerase chain reaction (PCR) are used extensively in medical diagnostics due to their high sensitivity, specificity and quantification capability. In settings with limited infrastructure and unreliable electricity, however, access to such devices is often limited due to the highly specialized and energy-intensive nature of the thermal cycling process required for nucleic acid amplification. Here we integrate solar heating with microfluidics to eliminate thermal cycling power requirements as well as create a simple device infrastructure for PCR. Tests are completed in less than 30 min, and power consumption is reduced to 80 mW, enabling a standard 5.5 Wh iPhone battery to provide 70 h of power to this system. Additionally, we demonstrate a complete sample-to-answer diagnostic strategy by analyzing human skin biopsies infected with Kaposi's Sarcoma herpesvirus (KSHV/HHV-8) through the combination of solar thermal PCR, HotSHOT DNA extraction and smartphone-based fluorescence detection. We believe that exploiting the ubiquity of solar thermal energy as demonstrated here could facilitate broad availability of nucleic acid-based diagnostics in resource-limited areas.

A smartphone-based pain management app for adolescents with cancer: establishing system requirements and a pain care algorithm based on literature review, interviews, and consensus.

In: *JMIR Res Protoc* 3 (1), S. e15. DOI: 10.2196/resprot.3041.

Abstract:

BACKGROUND: Pain that occurs both within and outside of the hospital setting is a common and distressing problem for adolescents with cancer. The use of smartphone technology may facilitate rapid, in-the-moment pain support for this population. To ensure the best possible pain management advice is given, evidence-based and expert-vetted care algorithms and system design features, which are designed using user-centered methods, are required. OBJECTIVE: To develop the decision algorithm and system requirements that will inform the pain management advice provided by a real-time smartphone-based pain management app for adolescents with cancer. METHODS: A systematic approach to algorithm development and system design was utilized. Initially, a comprehensive literature review was undertaken to understand the current body of knowledge pertaining to pediatric cancer pain management. A user-centered approach to development was used as the results of the review were disseminated to 15 international experts (clinicians, scientists, and a consumer) in pediatric pain, pediatric oncology and mHealth design, who participated in a 2-day consensus conference. This conference used nominal group technique to develop consensus on important pain inputs, pain management advice, and system design requirements. Using data generated at the conference, a prototype algorithm was developed. Iterative qualitative testing was conducted with adolescents with cancer, as well as pediatric oncology and pain health care providers to vet and refine the developed algorithm and system requirements for the real-time smartphone app. RESULTS: The systematic literature review established the current state of research related to nonpharmacological pediatric cancer pain management. The 2-day consensus conference established which clinically important pain inputs by adolescents would require action (pain management advice) from the app, the appropriate advice the app should provide to adolescents in pain, and the functional requirements of the app. These results were used to build a detailed prototype algorithm capable of providing adolescents with pain management support based on their individual pain. Analysis of qualitative interviews with 9 multidisciplinary health care professionals and 10 adolescents resulted in 4 themes that helped to adapt the algorithm and requirements to the needs of adolescents. Specifically, themes were overall endorsement of the system, the need for a clinical expert, the need to individualize the system, and changes to the algorithm to improve potential clinical effectiveness. CONCLUSIONS: This study used a phased and user-centered approach to develop a pain management algorithm for adolescents with cancer and the system requirements of an associated app. The smartphone software is currently being created and subsequent work will focus on the usability, feasibility, and effectiveness testing of the app for adolescents with cancer pain.

Farmers' market use is associated with fruit and vegetable consumption in diverse southern rural communities.

In: *Nutr J* 13, S. 1. DOI: 10.1186/1475-2891-13-1.

Abstract:

BACKGROUND: While farmers' markets are a potential strategy to increase access to fruits and vegetables in rural areas, more information is needed regarding use of farmers' markets among rural residents. Thus, this study's purpose was to examine (1) socio-demographic characteristics of participants; (2) barriers and facilitators to farmers' market shopping in southern rural communities; and (3) associations between farmers' market use with fruit and vegetable consumption and body mass index (BMI). METHODS: Cross-sectional surveys were conducted with a purposive sample of farmers' market customers and a representative sample of primary household food shoppers in eastern North Carolina (NC) and the Appalachian region of Kentucky (KY). Customers were interviewed using an intercept survey instrument at farmers' markets. Representative samples of primary food shoppers were identified via random digit dial (RDD) cellular phone and landline methods in counties that had at least one farmers' market. All questionnaires assessed socio-demographic characteristics, food shopping patterns, barriers to and facilitators of farmers' market shopping, fruit and vegetable consumption and self-reported height and weight. The main outcome measures were fruit and vegetable consumption and BMI. Descriptive statistics were used to examine socio-demographic characteristics, food shopping patterns, and barriers and facilitators to farmers' market shopping. Linear regression analyses were used to examine associations between farmers' market use with fruit and vegetable consumption and BMI, controlling for age, race, education, and gender. RESULTS: Among farmers' market customers, 44% and 55% (NC and KY customers, respectively) reported shopping at a farmers' market at least weekly, compared to 16% and 18% of NC and KY RDD respondents. Frequently reported barriers to farmers' market shopping were market days and hours, "only come when I need something", extreme weather, and market location. Among the KY farmers' market customers and NC and KY RDD respondents, fruit and vegetable consumption was positively associated with use of farmers' markets. There were no associations between use

of farmers' markets and BMI. CONCLUSIONS: Fruit and vegetable consumption was associated with farmers' market shopping. Thus, farmers' markets may be a viable method to increase population-level produce consumption.

Improving inertial Pedestrian Dead-Reckoning by detecting unmodified switched-on lamps in buildings.

In: *Sensors (Basel)* 14 (1), S. 731–769. DOI: 10.3390/s140100731.

Abstract:

This paper explores how inertial Pedestrian Dead-Reckoning (PDR) location systems can be improved with the use of a light sensor to measure the illumination gradients created when a person walks under ceiling-mounted unmodified indoor lights. The process of updating the inertial PDR estimates with the information provided by light detections is a new concept that we have named Light-matching (LM). The displacement and orientation change of a person obtained by inertial PDR is used by the LM method to accurately propagate the location hypothesis, and vice versa; the LM approach benefits the PDR approach by obtaining an absolute localization and reducing the PDR-alone drift. Even from an initially unknown location and orientation, whenever the person passes below a switched-on light spot, the location likelihood is iteratively updated until it potentially converges to a unimodal probability density function. The time to converge to a unimodal position hypothesis depends on the number of lights detected and the asymmetries/irregularities of the spatial distribution of lights. The proposed LM method does not require any intensity illumination calibration, just the pre-storage of the position and size of all lights in a building, irrespective of their current on/off state. This paper presents a detailed description of the light-matching concept, the implementation details of the LM-assisted PDR fusion scheme using a particle filter, and several simulated and experimental tests, using a light sensor-equipped Galaxy S3 smartphone and an external foot-mounted inertial sensor. The evaluation includes the LM-assisted PDR approach as well as the fusion with other signals of opportunity (WiFi, RFID, Magnetometers or Map-matching) in order to compare their contribution in obtaining high accuracy indoor localization. The integrated solution achieves a localization error lower than 1 m in most of the cases.

Johansson, E.; Ekelund, U.; Nero, H.; Marcus, C.; Hagstromer, M. (2014):

Calibration and cross-validation of a wrist-worn Actigraph in young preschoolers.

In: *Pediatr Obes. DOI:* 10.1111/j.2047-6310.2013.00213.x.

Abstract:

OBJECTIVE: To calibrate the Actigraph GT3X+ accelerometer for wrist-worn placement in young preschoolers by developing intensity thresholds for sedentary, low- and high-intensity physical activity. Furthermore, to cross-validate the developed thresholds in young preschoolers. METHODS: Actigraph GT3X+ was used to measure physical activity during structured activities and free play in 38 children (15-36 months). Activity was video recorded and scored into sedentary, low- and high-intensity physical activity based on Children's Activity Rating Scale (CARS) and combined with accelerometer data using a 5 s epoch. Receiver operating characteristic analysis was used to develop intensity thresholds in 26 randomly selected children. The remaining 12 children were used for cross-validation. RESULTS: Intensity thresholds for sedentary were </=89 vertical counts (Y) and </=221 vector magnitude (VM) counts per 5 s and >/=440 Y counts and >/=730 VM counts per 5 s for high-intensity physical activity. Sensitivity and specificity were 60-100% for the developed intensity thresholds. Strong correlations (Spearman rank correlation 0.69-0.91) were found in the cross-validation sample between the developed thresholds for the accelerometer and CARS scoring time in all intensity categories. CONCLUSION: The developed intensity thresholds appear valid to categorize sedentary behaviour and physical activity intensity categories in children 2 years of age.

Simple to complex modeling of breathing volume using a motion sensor.

In: *Sci.Total Environ.* 454-455 (0048-9697 (Linking)), S. 184–188. DOI: 10.1016/j.scitotenv.2013.02.092.

Abstract:

PURPOSE: To compare simple and complex modeling techniques to estimate categories of low, medium, and high ventilation (VE) from ActiGraph activity counts. METHODS: Vertical axis ActiGraph GT1M activity counts, oxygen consumption and VE were measured during treadmill walking and running, sports, household chores and labor-intensive employment activities. Categories of low (<19.3 l/min), medium (19.3 to 35.4 l/min) and high (>35.4 l/min) VEs were derived from activity intensity classifications

(light <2.9 METs, moderate 3.0 to 5.9 METs and vigorous >6.0 METs). We examined the accuracy of two simple techniques (multiple regression and activity count cut-point analyses) and one complex (random forest technique) modeling technique in predicting VE from activity counts. RESULTS: Prediction accuracy of the complex random forest technique was marginally better than the simple multiple regression method. Both techniques accurately predicted VE categories almost 80% of the time. The multiple regression and random forest techniques were more accurate (85 to 88%) in predicting medium VE. Both techniques predicted the high VE (70 to 73%) with greater accuracy than low VE (57 to 60%). Actigraph cut-points for light, medium and high VEs were <1381, 1381 to 3660 and >3660 cpm. CONCLUSIONS: There were minor differences in prediction accuracy between the multiple regression and the random forest technique. This study provides methods to objectively estimate VE categories using activity monitors that can easily be deployed in the field. Objective estimates of VE should provide a better understanding of the dose-response relationship between internal exposure to pollutants and disease

Computerized ambulatory monitoring in psychiatry: a multi-site collaborative study of acceptability, compliance, and reactivity.

In: *International Journal of Methods in Psychiatric Research* 18 (1), S. 48–57. DOI: 10.1002/mpr.276.

Abstract:

Computerized ambulatory monitoring overcomes a number of methodological and conceptual challenges to studying mental disorders, however concerns persist regarding the feasibility of this approach with severe psychiatric samples and the potential of intensive monitoring to influence data quality. This multi-site investigation evaluates these issues in four independent samples. Patients with schizophrenia (n = 56), substance dependence (n = 85), anxiety disorders (n = 45), and a non-clinical sample (n = 280) were contacted to participate in investigations using computerized ambulatory monitoring. Micro-computers were used to administer electronic interviews several times per day for a one-week period. Ninety-five percent of contacted individuals agreed to participate in the study, and minimum compliance was achieved by 96% of these participants. Seventy-eight percent of all programmed assessments were completed overall, and only 1% of micro-computers were not returned to investigators. There was no evidence that missing data or response time increased over the duration of the study, suggesting that fatigue effects were negligible. The majority of variables investigated did not change in frequency as a function of study duration, however some evidence was found that socially sensitive behaviors changed in a manner consistent with reactivity.

The Dispositional Flow Scale-2 as a Measure of Autotelic Personality: An Examination of Criterion-Related Validity.

In: *J Pers Assess. DOI:* 10.1080/00223891.2014.891524.

Abstract:

The Dispositional Flow Scale-2 (DFS-2; Jackson & Eklund, 2002) may be one of the most promising measures for assessing Csikszentmihalyi's (1990) construct of "autotelic personality." Despite strong internal validity, external validity of the DFS-2 remains open. We used 2 methods to provide evidence for external validity: (1) multiple-time assessments of experience sampling (1,856 entries generated over 7 days) to derive aggregate indices of criterion validity; and (2) single-time assessments of flow and personality for additional criterion-related validity. For single-time assessments of flow, we used a modified version of the Flow Questionnaire (Csikszentmihalyi & Larson, 1984). To assess personality, we included a measure of the Five-factor traits using the Revised NEO Personality Inventory (Costa & McCrae, 1992). A path model of NEO domains, DFS-2 global scores, and experience sampling aggregates fit the data well.

The Good and Bad of Being Fair: Effects of Procedural and Interpersonal Justice Behaviors on Regulatory Resources.

In: *J Appl Psychol. DOI:* 10.1037/a0035647.

Abstract:

The justice literature has paid considerable attention to the beneficial effects of fair behaviors for recipients of such behaviors. It is possible, however, that exhibiting fair behaviors may come at a cost for actors. In this article, we integrate ego depletion

theory with organizational justice research in order to examine the consequences of justice behaviors for actors. We used an experience-sampling method in a sample of managerial employees to examine the relations of performing procedural justice and interpersonal justice behaviors with subsequent changes in actors' regulatory resources. Our results indicate that procedural justice behaviors are draining, whereas interpersonal justice behaviors are replenishing for actors. Depletion, in turn, adversely affected the performance of citizenship behavior, and depletion mediated relations of justice behavior with citizenship. Furthermore, 2 traits that impact self-regulatory skills-extraversion and neuroticism-moderated the replenishing effects of engaging in interpersonal justice behaviors. We conclude by discussing implications and avenues for future research. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Johnson, Jarrod A.; Miller, Michelle L.; Lynam, Donald R.; South, Susan C. (2012):

Five-factor model facets differentially predict in-the-moment affect and cognitions.

In: *Journal of Research in Personality* 46 (6), S. 752–759. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-30580-012%26site%3dehost-live;ssouth@purdue.edu;dlynam@psych.purdue.edu;johns468@purdue.edu.

Abstract:

The facets of the Five-Factor Model (FFM) of personality are presumed to represent distinct, biologically-based tendencies to act, think, and behave; yet they have received little behaviorally-based empirical validation. In this study, FFM facets were used to examine individual differences in affective and cognitive responses to stressors as they are experienced in daily life. Participants (N = 79) completed the NEO-PI-R followed by a week-long experience sampling procedure. As expected, hierarchical linear modeling showed that FFM facets captured affective and cognitive tendencies that were missed at the domain level. They additionally demonstrated convergent and divergent validity in predicting momentary affect. These results provide evidence that facets are distinct, non-interchangeable predictors of daily thoughts and emotions. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Johnson, E. I.; Sibon, I.; Renou, P.; Rouanet, F.; Allard, M.; Swendsen, J. (2009):

Feasibility and validity of computerized ambulatory monitoring in stroke patients.

In: *Neurology* 73 (19), S. 1579–1583. DOI: 10.1212/WNL.0b013e3181c0d466.

Abstract:

BACKGROUND\r\nComputerized ambulatory monitoring provides real-time assessments of clinical outcomes in natural contexts, and it has been increasingly applied in recent years to investigate symptom expression in a wide range of disorders. The purpose of this study was to examine the feasibility and validity of this data collection strategy with adult stroke patients.\r\nMETHODS\r\nForty-eight individuals (75% of the contacted sample) agreed to participate in the current study and were instructed to complete electronic interviews using a personal digital assistant 5 times per day over a 1-week period.\r\nRESULTS\r\nMore than 80% of programmed assessments were completed by the sample, and no evidence was found for fatigue effects. Expected patterns of associations were observed among daily life variables, and data collected through ambulatory monitoring were significantly correlated with standard clinic-based measures of similar constructs.\r\nCONCLUSION\r\nSupport was found for the feasibility and validity of computerized ambulatory monitoring with stroke patients. The application of these novel methods with stroke patients should provide complementary information that is inaccessible to standard hospital-based assessments and permit increased understanding of the significance of clinical results and test scores for daily life experience.

Stress in Nurses: Stress-Related Affect and Its Determinants Examined Over the Nursing Day.

In: *Ann.Behav.Med* (0883-6612 (Linking)). DOI: 10.1007/s12160-012-9458-2.

Abstract:

BACKGROUND: Nurses are a stressed group and this may affect their health and work performance. The determinants of occupational stress in nurses and other occupational groups have almost invariably been examined in between subject studies. PURPOSE: This study aimed to determine if the main determinants of occupation stress, i.e. demand, control, effort and reward, operate within nurses. METHODS: A real time study using personal digital-assistant-based ecological momentary assessment to

measure affect and its hypothesised determinants every 90 min in 254 nurses over three nursing shifts. The measures were negative affect, positive affect, demand/effort, control and reward. RESULTS: While the effects varied in magnitude between people, in general increased negative affect was predicted by high demand/effort, low control and low reward. Control and reward moderated the effects of demand/effort. High positive affect was predicted by high demand/effort, control and reward. CONCLUSIONS: The same factors are associated with variations in stress-related affect within nurses as between

Detection of COPD Exacerbations and Compliance with Patient Reported Daily Symptom Diaries Using a BlackBerry-Based Information System.

In: *Chest* (0012-3692 (Linking)). DOI: 10.1378/chest.12-2308.

Abstract:

ABSTRACT BACKGROUND: Paper-based diaries and self-report of symptom worsening in COPD studies may lead to under-detection of exacerbations. Epidemiologically, COPD exacerbations exhibit seasonal patterns peaking at year-end. We examined whether use of a BlackBerry-based daily symptom diary would detect 95% or more of exacerbations and enable characterization of seasonal differences between them. METHODS: Fifty participants with GOLD stage I to IV COPD began a community-based study in December 2007. Another 30 began in December 2008. Participants transmitted daily symptom diaries using a BlackBerry. Alerts were triggered when symptom changes, missed diary transmissions or medical care for a respiratory problem occurred. Participant encounters were initiated if COPD exacerbations were suspected. Participants reported returns to normal breathing using their BlackBerry. RESULTS: Participants transmitted 99.9% of 28,514 possible daily diaries. All 191 (2.5/participant-year) COPD exacerbations meeting Anthonisen criteria were detected. During 148/191 exacerbations (78%; 1.97/participant-year) patients were hospitalized and/or ordered prednisone, an antibiotic or both. Respiratory viruses were detected in 78/191 (41%) of exacerbations. Those coinciding with a respiratory viral infection averaged 12.0 days, those without averaged 8.9 days (P <.04), with no difference in Anthonisen score. Respiratory symptom scores before exacerbations and after normal breathing return showed no differences. Exacerbations were more frequent during the Christmas period than the rest of the year but not than the rest of winter alone. CONCLUSIONS: Smartphone-based collection of COPD symptom diaries enables near complete identification of exacerbations at inception. Exacerbation rates in the Christmas season do not reach levels that necessitate changes in disease management

Jokerst, Nan M.; Brooke, Martin A.; Cho, Sang-Yeon; Shang, Allan B. (2007):

Chip-scale sensor system integration for portable health monitoring.

In: *Anesthesia & Analgesia* 105 (6), S. S42-S47.

Abstract:

The revolution in integrated circuits over the past 50 yr has produced inexpensive computing and communications systems that are powerful and portable. The technologies for these integrated chip-scale sensing systems, which will be miniature, lightweight, and portable, are emerging with the integration of sensors with electronics, optical systems, micromachines, microfluidics, and the integration of chemical and biological materials (soft/wet material integration with traditional dry/hard semiconductor materials). Hence, we stand at a threshold for health monitoring technology that promises to provide wearable biochemical sensing systems that are comfortable, inauspicious, wireless, and battery-operated, yet that continuously monitor health status, and can transmit compressed data signals at regular intervals, or alarm conditions immediately. In this paper, we explore recent results in chip-scale sensor integration technology for health monitoring. The development of inexpensive chip-scale biochemical optical sensors, such as microresonators, that are customizable for high sensitivity coupled with rapid prototyping will be discussed. Ground-breaking work in the integration of chip-scale optical systems to support these optical sensors will be highlighted, and the development of inexpensive Si complementary metal-oxide semiconductor circuitry (which makes up the vast majority of computational systems today) for signal processing and wireless communication with local receivers that lie directly on the chip-scale sensor head itself will be examined.

Jola, C.; Grosbras, M. H. (2013):

In the here and now: Enhanced motor corticospinal excitability in novices when watching live compared to video recorded dance.

In: *Cogn Neurosci* 4 (2), S. 90–98. DOI: 10.1080/17588928.2013.776035.

Abstract:

Enhanced motor corticospinal excitability (MCE) in passive action observation is thought to signify covert motor resonance with the actions seen. Actions performed by others are an important social stimulus and thus, motor resonance is prevalent during social interaction. However, most studies employ simple/short snippets of recorded movements devoid of any real-life social context, which has recently been criticized for lacking ecological validity. Here, we investigated whether the co-presence of the actor and the spectator has an impact on motor resonance by comparing novices' MCE for the finger (FDI) and the arm (ECR) with single-pulse transcranial magnetic stimulation when watching five-minute solos of ballet dance, Bharatanatyam (Indian dance) and an acting control condition either live or on video. We found that (1) MCE measured in the arm muscle was significantly enhanced in the live compared to the video condition, (2) differences across performances were only evident in the live condition, and (3) our novices reported enjoying the live presentations significantly more. We suggest that novice spectators' MCE is susceptible to the performers' live presence

Jones, Helen; Atkinson, Greg; Leary, Andrew; George, Keith; Murphy, Michael; Waterhouse, Jim (2006):

Reactivity of ambulatory blood pressure to physical activity varies with time of day.

In: *Hypertension* 47 (4), S. 778–784. DOI: 10.1161/01.HYP.0000206421.09642.b5.

Abstract:

Blood pressure (BP) fluctuates over a 24-hour period, but it is unclear to what extent this variation is governed completely by changes in physical activity. Our aim was to use a BP \"reactivity index\" to investigate whether the BP response to a given level of physical activity changes during a normal sleep-wake cycle. Hypertensive patients (n=440) underwent simultaneous 24-hour ambulatory BP, heart rate (HR), and activity monitoring. BP and HR were measured every 20 minutes. Actigraphy data were averaged over the 15 minutes that preceded a BP measurement. Individual BP and HR reactivity indices were calculated using least-squares regression for twelve 2-hour periods. These indices were then analyzed for time-of-day differences using a general linear model. Systolic BP and HR were generally more reactive to physical activity than diastolic BP. The highest reactivity of systolic BP (mean+/-SE=4+/-1 mm Hg per logged unit change in activity) was observed between 8:00 AM and 10:00 AM (P=0.014). Between 10:00 AM and 12:00 PM, BP reactivity then decreased (P=0.048) and showed a secondary rise in the early afternoon. These 24-hour changes in BP reactivity did not differ significantly between groups formed on the basis of early and late wake times (P=0.485), medication use, age, and sex (P>0.350). In conclusion, under conditions of normal living, the reactivity of BP and HR to a given unit change in activity is highest in the morning and shows a secondary rise in the afternoon.

Jones, Michelle D.; Crowther, Janis H.; Ciesla, Jeffrey A. (2014):

A naturalistic study of fat talk and its behavioral and affective consequences.

In: *Body Image* 11 (4), S. 337–345. DOI: 10.1016/j.bodyim.2014.05.007.

Abstract:

Fat talk is a style of verbal expression among young women involving negative self-statements, complaints about physical appearance, and weight management. This research used ecological momentary assessment to examine the impact of naturalistic fat talk experiences on body dissatisfaction, body checking, negative affect, and disordered eating behaviors. We examined trait self-objectification as a moderator. Sixty-five female college students completed a baseline questionnaire and responded to questions when randomly prompted by palm pilot devices for five days. Results indicated fat talk is common and associated with greater body dissatisfaction, body checking, negative affect, and disordered eating behaviors. Fat talk participation was associated with greater body checking than overhearing fat talk. Greater trait self-objectification was associated with greater body dissatisfaction and body checking following fat talk. These results suggest that fat talk negatively impacts the cognitions, affect, and behavior of young women and has increased negative effects for women higher in self-objectification.

Jones, Helen; George, K.; Edwards, Benjamin; Atkinson, Greg (2009):

Exercise intensity and blood pressure during sleep.

In: *Int J Sports Med* 30 (2), S. 94–99.

Abstract:

Exercise, of appropriate intensity and duration, could help maintain normotension if post-exercise hypotension persists over subsequent everyday activities. Therefore, we monitored ambulatory blood pressure (BP) for 24 h following four separate

exercise bouts which differed in intensity, duration and total work completed. At 08:00 h, six normotensive males completed a no exercise control and, in two further trials, 30 min of cycling at 70 % V O (2 peak) and 40 % V O (2 peak). A fourth trial involved cycling at 40 % V O (2 peak) for a time which equated total work with that in the most intense exercise trial. Between 20 min and 24 h after exercise, ambulatory BP, heart rate (HR) and wrist-activity were compared between trials using general linear models. Participants slept normally at night. Post-exercise changes in BP and HR were not affected by exercise intensity or total work completed from 20 min after exercise until nocturnal sleep-onset (p > 0.21). During sleep, mean arterial BP was lower following exercise at 70 % V O (2 peak) compared to the other trials (p = 0.03), including the 40 % V O (2 peak) trial equated for total work (90 % CI for difference = - 22.1 to - 0.1). We conclude that daytime exercise can elicit a physiologically meaningful lower BP during sleep and exercise intensity is the most important factor in this phenomenon.

Jones, Deborah P.; Richey, Phyllis A.; Alpert, Bruce S. (2008):

Validation of the AM5600 ambulatory blood pressure monitor in children and adolescents.

In: *Blood Press Monit* 13 (6), S. 349–351. DOI: 10.1097/MBP.0b013e3283102cfe.

Abstract:

OBJECTIVE\r\nWe measured ambulatory blood pressure using the AM5600 in children and adolescents participating in a research study to assess the relationship of blood pressure to risk factors for cardiovascular disease. Although the use of this monitor has been previously reported in adults, it has not been validated in pediatric patients.\r\nPARTICIPANTS AND METHODS\r\nIn this study, we assess the accuracy of the monitor as compared with the mercury sphygmomanometer in children of 7-18 years of age.\r\nRESULTS\r\nWe found that the mean of the difference between the monitor and the mercury device was 0.29+/-3.5 and 0.045+/-3.7 mmHg for systolic and diastolic blood pressure, respectively, which fulfills the Advancement of Medical Instrumentation standard for use of a device. The cumulative percentage of readings between the two devices which differed by 5, 10 and 15 mmHg or more assigned a grade of A grade to the device according to the British Hypertension Society.\r\nCONCLUSION\r\nThe AM5600 ambulatory blood pressure device is valid for measurement of blood pressure in children and adolescents.

Jones, Nathan; Youngs, Peter (2012):

Attitudes and affect: Daily emotions and their association with the commitment and burnout of beginning teachers.

In: *Teachers College Record* 114 (2), S. 1–36. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-16299-001%26site%3dehost-live.

Abstract:

Background/Context: The increasing number of districts implementing mentoring and induction programs suggests that policymakers are aware of the need to increase the support available to new teachers. The argument underlying many of these programs is based, at least partly, on assumptions about beginning teachers' emotional responses to their work. Yet while considerable research has studied the effects of induction programs, few researchers have rigorously collected data on how beginning teachers' affective experiences seem to impact their career plans. Purpose of the Study: We tested a framework developed in the organizational behavior literature known as affective events theory (AET), which proposes that emotional responses to work, coupled with abstract beliefs about one's job, can influence overall judgments about job satisfaction. Specifically, we drew on research from education and organizational behavior to test whether mean levels of positive affect, negative affect, skill, and fatigue are associated with intentions to remain in teaching (i.e., commitment to one's teaching assignment), commitment to one's school, and levels of burnout. Research Design: Sources of data in this study include survey data collected at two time points (fall 2007 and spring 2008) from 42 beginning general and special education teachers in three districts in Michigan and Indiana, as well as data collected using the experience sampling method (ESM), a time sampling method for gaining information about individuals' immediate experiences. The inclusion of both data sources allowed us to capitalize on the richness of the ESM data—which accounts for variation in teachers' momentary affective states—while also supporting the data with more traditional survey measures. Conclusions/Recommendations: We found that mean levels of positive affect and skill are positively associated with commitment, even when controlling for prior commitment. Similarly, negative affect and tiredness seem to be predictive of teacher burnout. These results suggest that, by taking account of teachers' emotional reactions to their work (in addition to features of their work environments), researchers, policymakers, and district administrators will be better positioned to support special and general educators during their early years of teaching. Jonge, Peter; Mangano, Dennis; Whooley, Mary A. (2007):

Differential association of cognitive and somatic depressive symptoms with heart rate variability in patients with stable coronary heart disease: findings from the Heart and Soul Study.

In: *Psychosomatic Medicine* 69 (8), S. 735.

Abstract:

Objective

To determine if depression associated with low heart rate variability (HRV) in patients post myocardial infarction (MI), but not in patients with stable coronary heart disease (CHD), may be the result of differential associations of somatic and cognitive depressive symptoms with HRV.

Methods

To examine the association of somatic and cognitive depressive symptoms with 24-hour HRV, we performed a cross-sectional study of 863 outpatients with stable CHD. The severity of somatic and cognitive depressive symptoms was determined using factor analysis of items of the Patient Health Questionnaire (PHQ-9). Time-domain (SDNN, SDANN) and frequency-domain (VLF, LF, HF, WBF) indices of HRV were derived using ambulatory monitoring.

Results

Unadjusted analyses revealed that somatic symptom scores were significantly associated with HRV (r = −.09 for SDNN; r = −.08 for SDANN; r = −.08 for LnVLF; r = −.08 for LnLF; r = −.10 for LnHF; r = −.08 for LnWBF). After adjustment for demographic variables, comorbidities, and lifestyle factors, somatic symptom scores were no longer associated with lower HRV, with the possible exception of LnWBF (r = −.06). Cognitive depressive symptom scores were not associated with HRV using either unadjusted or adjusted analyses.

Conclusions

We found that somatic depressive symptoms were associated with lower HRV, although cognitive depressive symptoms were not. The inverse association of somatic symptoms with HRV was largely explained by differences in comorbidities and lifestyle factors. These results suggest that individual symptoms of depression may have differential associations with HRV.

Daily telemonitoring of exhaled nitric oxide and symptoms in the treatment of childhood asthma.

In: *American journal of respiratory and critical care medicine* 179 (2), S. 93–97. DOI: 10.1164/rccm.200807-1010OC.

Abstract:

RATIONALE\r\nAsthma treatment might improve when inhaled steroids are titrated on airway inflammation. Fractional exhaled nitric oxide (FeNO0.05), a marker of eosinophilic airway inflammation, can be measured at home.\r\nOBJECTIVES\r\nWe assessed daily FeNO0.05 telemonitoring in the management of childhood asthma.\r\nMETHODS\r\nChildren with atopic asthma (n = 151) were randomly assigned to two groups: FeNO0.05 plus symptom monitoring, or monitoring of symptoms only. All patients scored asthma symptoms in an electronic diary over 30 weeks; 77 received a portable nitric oxide (NO) analyzer. Data were transmitted daily to the coordinating centers. Patients were phoned every 3 weeks and their steroid dose was adapted according to FeNO0.05 and symptoms, or according to symptoms. Children were seen at 3, 12, 21, and 30 weeks for examination and lung function testing. The primary end point was the proportion of symptom-free days in the last 12 study weeks.\r\nMEASUREMENTS AND MAIN RESULTS\r\nTelemonitoring was feasible with reliable FeNO0.05 data for 86% of days, and valid diary entries for 79% of days. Both groups showed an increase in symptom-free days, improvement of FEV1 and quality of life, and a reduction in steroid dose. None of the changes from baseline differed between groups. The difference in symptom-free days over the last 12 weeks was 0.3% (P = 0.95; 95% confidence interval, -10 to 11%). There was a trend for fewer exacerbations in the FeNO0.05 group.\r\nCONCLUSIONS\r\nThirty weeks of daily FeNO0.05 and symptom telemonitoring was associated with improved asthma control and a lower steroid dose. We found no added value of daily FeNO0.05 monitoring compared with daily symptom monitoring only.

Does savoring increase happiness? A daily diary study.

In: *The Journal of Positive Psychology* 7 (3), S. 176–187. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-11218-002&site=ehost-live;paul.jose@vuw.ac.nz.

Abstract:

Bryant and Veroff (2007, Savoring: A new model of positive experience. Mahwah, NJ: Lawrence Erlbaum Associates) have proposed that savoring, namely, regulating the emotional impact of positive events by one's cognitive or behavioral responses, increases happiness. The present study was designed to determine whether and how savoring influences daily happiness. Experience sampling methodology was used with 101 participants, who provided self-reports of their momentary positive events, savoring responses, and positive affect daily over a period of 30 days. Multilevel modeling analyses verified that (a) these three constructs were positively related to each other within a given day, (b) momentary savoring both mediated and moderated the impact of daily positive events on momentary happy mood, and (c) levels of trait savoring moderated the observed mediational pattern. These results provide support for the hypothesis that savoring is an important mechanism through which people derive happiness from positive events. Telephotography in trauma: a 2-year clinical experience.

In: *Telemed J E Health* 20 (4), S. 342–345. DOI: 10.1089/tmj.2013.0190.

Abstract:

Abstract Introduction: Smartphones can be used to record and transmit high-quality clinical photographs. The aim of this study was to describe our experience with smartphone telephotography in the care of trauma patients. We hypothesized that smartphone telephotography can be safely and effectively implemented on a trauma service. Subjects and Methods: We performed a 2-year (January 2011-December 2012) prospective analysis of all patient photographs recorded by members of our trauma team at our Level I trauma center. All members of the trauma team recorded patient photographs and e-mailed them to a secure e-mail account. An administrative assistant uploaded a copy of each photgrapho into the patient's electronic medical record. We assessed the number of photographs collected and uploaded, as well as the success, failure, and complication rates. Results: Our trauma team sent 7,200 photographs to a secure e-mail account. Of those, 6,120 (85%) were considered, after an initial review, to be of good quality. Of these, 3,320 photographs (54%) were successfully uploaded into a patient's electronic medical record; the remaining 2,800 photographs lacked adequate labeling and could not be uploaded. The average interval to uploading was 3 months. In total, 10 photographs were uploaded into the wrong patient's electronic medical record, for an error rate of 0.003%. We received only three complaints during the study period. Conclusions: Telephotography can be safely and effectively implemented in trauma clinical practice. Fears of Health Insurance Portability and Accountability Act violations are not valid, as the incidence of patient complaints is minimal when telephotography is implemented under strict guidelines and rules. Dedicated administrative personnel are essential for effective implementation of smartphone photography.

Rapid tremor frequency assessment with the iPhone accelerometer.

In: *Parkinsonism & related disorders* 17 (4), S. 288–290. DOI: 10.1016/j.parkreldis.2011.01.001.

Abstract:

The physician is often seeking more efficient ways of performing patient assessments. Currently, measuring tremor frequency requires expensive and bulky equipment. We propose the use of the in-built accelerometer of the iPhone via the iSeismo application for rapid measurement of tremor frequency. We use this device in a series of 7 different tremor cases, and show that the frequency measurements on the iSeismo graph closely match the more sophisticated EMG analysis during tremor. This is a preliminary confirmation of the usefulness of this device in the clinical setting for quick assessment of the dominant frequency component in a variety of tremors.

Guest editorial. Body sensor networks: from theory to emerging applications.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 13 (6), S. 859–863. DOI: 10.1109/TITB.2009.2034564.

Abstract:

The use of sensor networks for healthcare, well-being, and working in extreme environments has long roots in the engineering sector in medicine and biology community. With the maturity of wireless sensor networks, body area networks (BANs), and wireless BANs (WBANs), recent efforts in promoting the concept of body sensor networks (BSNs) aim to move beyond sensor connectivity to adopt a system-level approach to address issues related to biosensor design, interfacing, and embodiment, as well as ultralow-power processing/communication, power scavenging, autonomic sensing, data mining, inferencing, and integrated wireless sensor microsystems. As a result, the system architecture based on WBAN and BSN is becoming a widely accepted method of organization for ambulatory and ubiquitous monitoring systems. This editorial paper presents a snapshot of the current research and emerging applications and addresses some of the challenges and implementation issues.

Accelerometry and self-report in sedentary populations.

In: *Am J Health Behav* 35 (1), S. 71–80.

Abstract:

OBJECTIVES: To determine whether self-reported exercise duration and intensity matched accelerometer data in sedentary endometrial cancer survivors and age-matched controls. METHODS: Participants were asked to wear an accelerometer and self-report exercise bouts, duration, and intensity for one week. Self-reported duration was compared with accelerometer data. RESULTS: Self-reported exercise-bout duration matched accelerometer duration 93% for survivors and 99% for controls. Self-reported exercise-bout intensity matched accelerometer intensity 70% for survivors and 66% for controls. There were no significant differences between groups. CONCLUSIONS: Sedentary endometrial cancer survivors and controls self-reported duration and intensity of physical activity consistent with accelerometer data.
