mHealth tools may be a feasible modality for delivering evidence-based treatments and principles (EBPs), and may enhance treatment for eating disorders (EDs). However, research on the efficacy of mHealth tools for EDs and the extent to which they include EBPs is lacking. The current study sought to (i) review existing apps for EDs, (ii) determine the extent to which available treatment apps utilize EBPs, and (iii) assess the degree to which existing smartphone apps utilize recent advances in smartphone technology. Overall, existing ED intervention apps contained minimal EBPs and failed to incorporate smartphone capabilities. For smartphone apps to be a feasible and effective ED treatment modality, it may be useful for creators to begin taking utilizing the abilities that set smartphones apart from in-person treatment while incorporating EBPs. Before mHealth tools are incorporated into treatments for EDs, it is necessary that the feasibility, acceptability, and efficacy be evaluated. Judge, Timothy A.; Simon, Lauren S.; Hurst, Charlice; Kelley, Ken (2013):

What I Experienced Yesterday Is Who I Am Today: Relationship of Work Motivations and Behaviors to Within-Individual Variation in the Five-Factor Model of Personality.

In: *J Appl Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-35325-001%26site%3dehost-live.

Abstract:

Historically, organizational and personality psychologists have ignored within-individual variation in personality across situations or have treated it as measurement error. However, we conducted a 10-day experience sampling study consistent with whole trait theory (Fleeson, 2012), which conceptualizes personality as a system of stable tendencies and patterns of intraindividual variation along the dimensions of the Big Five personality traits (Costa & McCrae, 1992). The study examined whether (a) internal events (i.e., motivation), performance episodes, and interpersonal experiences at work predict deviations from central tendencies in trait-relevant behavior, affect, and cognition (i.e., state personality), and (b) there are individual differences in responsiveness to work experiences. Results revealed that personality at work exhibited both stability and variation within individuals. Trait measures predicted average levels of trait manifestation in daily behavior at work, whereas daily work experiences (i.e., organizational citizenship, interpersonal conflict, and motivation) predicted deviations from baseline tendencies. Additionally, correlations of neuroticism with standard deviations in the daily personality variables suggest that, although work experiences influence state personality, people higher in neuroticism exhibit higher levels of intraindividual variation in personality than do those who are more emotionally stable. Advances in remote monitoring of implantable pacemakers, cardioverter defibrillators and cardiac resynchronization therapy systems.

In: *Journal of interventional cardiac electrophysiology : an international journal of arrhythmias and pacing* 23 (1), S. 73–85. DOI: 10.1007/s10840-008-9311-5.

Abstract:

Unlike the standard quarterly or semi-annual direct ambulatory device interrogations procedures, state-of-the-art implantable electronic cardiovascular devices (IECD) enable their wireless remote interrogation and monitoring, and automatically send reports and special alerts on a daily basis. This allows physicians to respond more proactively to changes in patient or device status, more appropriately triage patient care, and more efficiently perform the post-implant ambulatory follow-ups. This review presents the-state-of the-art technology of remote IECD monitoring and summarizes the main clinical observations published through June 2008. Cardiovascular remote monitoring systems made by several manufacturers are currently in various phases of development, clinical investigation, and medical applications. Data collected in several completed and ongoing studies strongly suggest that this new technology will make important contributions, particularly with respect to the facilitation of IECD follow-ups, enhancement of patient safety and quality of life, and lowering of medical costs. Further technological advances and a more clear understanding and appreciation of the clinical and economic benefits of telecardiology, will likely increase sharply the use of remote IECD monitoring in upcoming years.

Paper versus electronic rating scales for pain assessment: a prospective, randomised, cross-over validation study with 200 chronic pain patients.

In: *Current Medical Research and Opinion®* 24 (6), S. 1797–1806.

Abstract:

OBJECTIVE:

Following the recent introduction of hand-held computers to be used by patients instead of conventional pencil-and-paper questionnaires, a validation study under 'real-life' conditions was conducted, in order to compare these two clinical instruments when used by chronic pain patients to describe their pain using visual and numerical rating scales.

METHOD:

Each of 200 chronic pain patients attending a single physician's practice was given two pain questionnaires to complete, one on paper and one on a hand-held computer; completion of these took place directly before and after consultation, in randomised order. The questions asked in the two questionnaires were identical: present pain, average pain, worst pain and those of the painDETECT questionnaire (the latter distinguishes characteristic symptoms of nociceptive pain). In accordance with standard practice, the paper questionnaire used numerical rating scales and the electronic one employed visual analogue scales, with or without a numerical indicator.

RESULTS:

Nearly all patients (99%) of the study population (58% female; aged 57+/-14 years) completed both questionnaires. In spite of the expected substantial intra-individual scatter, overall results from the two questionnaire types were highly consistent. Only a

few differences of potential statistical significance (p<5%) were observed, and none were found that would have led to different interpretations. No difference was seen between results from the electronic visual analogue scales with and without a numerical indicator.

CONCLUSION:

Under conditions of routine clinical practice, the hand-held computer questionnaire can give results equivalent to those obtained with the conventional paper questionnaire.

An experience sampling study of emotional reactions to music: listener, music, and situation.

In: *Emotion* 8 (5), S. 668–683. DOI: 10.1037/a0013505.

Abstract:

The Experience Sampling Method was used to explore emotions to music as they naturally occurred in everyday life, with a focus on the prevalence of different musical emotions and how such emotions are related to various factors in the listener, the music, and the situation. Thirty-two college students, 20 to 31 years old, carried a palmtop that emitted a sound signal seven times per day at random intervals for 2 weeks. When signaled, participants were required to complete a questionnaire on the palmtop. Results showed that music occurred in 37% of the episodes, and in 64% of the music episodes, the participants reported that the music affected how they felt. Comparisons showed that happiness-elation and nostalgia-longing were more frequent in episodes with musical emotions, whereas anger-irritation, boredom-indifference, and anxiety-fear were more frequent in episodes with nonmusical emotions. The prevalence of specific musical emotions correlated with personality measures and also varied depending on the situation (e.g., current activity, other people present), thus highlighting the need to use representative samples of situations to obtain valid estimates of prevalence.

Juth, Vanessa; Dickerson, Sally S.; Zoccola, Peggy M.; Lam, Suman (2014):

Understanding the utility of emotional approach coping: evidence from a laboratory stressor and daily life.

In: *Anxiety Stress Coping*, S. 1–21. DOI: 10.1080/10615806.2014.921912.

Abstract:

Background: Dispositional emotional approach coping (EAC) marks an adaptive tendency to process and express emotions. EAC's association with cognitions, affect, and intra- and interindividual characteristics that may account for its utility was examined in response to an acute stressor and in daily life. Design: This study included a laboratory stress task and ecological momentary assessment. Methods: Healthy undergraduate students (n = 124; mean age: 20; women: 56%) completed a laboratory component (baseline survey, speech stress task, pre- and posttask measures) and five subsequent days of surveys via palm pilot (six surveys/day). Results: Controlling for sex, neuroticism, and social support, greater EAC was associated with more positive cognitive appraisals, personal resources, and positive affect and less-negative affect during the lab stressor, and with more perceived control and positive affect in daily life. Significant EAC x sex interactions were found for poststressor affect: men with high EAC reported more positive affect and women with high EAC reported less negative affect. Conclusions: Findings provide support that EAC's utility may be independent of intra- and interindividual characteristics, and that men and women may benefit from EAC in different ways in regards to affect. The proclivity to use EAC may come with a resiliency that protects against stress and promotes general well-being.

Juth, Vanessa; Smyth, Joshua M.; Santuzzi, Alecia M. (2008):

How do you feel? Self-esteem predicts affect, stress, social interaction, and symptom severity during daily life in patients with chronic illness.

In: *Journal of health psychology* 13 (7), S. 884–894. DOI: 10.1177/1359105308095062.

Abstract:

Self-esteem has been demonstrated to predict health and well-being in a number of samples and domains using retrospective reports, but little is known about the effect of self-esteem in daily life. A community sample with asthma (n = 97) or rheumatoid

arthritis (n = 31) completed a self-esteem measure and collected Ecological Momentary Assessment (EMA) data 5x/day for one week using a palmtop computer. Low self-esteem predicted more negative affect, less positive affect, greater stress severity, and greater symptom severity in daily life. Naturalistic exploration of mechanisms relating self-esteem to physiological and/or psychological components in illness may clarify causal relationships and inform theoretical models of self-care, well-being, and disease management.

Kackar, Hayal Z.; Shumow, Lee; Schmidt, Jennifer A.; Grzetich, Janel (2011):

Age and gender differences in adolescents' homework experiences.

In: *Journal of Applied Developmental Psychology* 32 (2), S. 70–77. DOI: 10.1016/j.appdev.2010.12.005.

Abstract:

Extant data collected through the Experience Sampling Method were analyzed to describe adolescents' subjective experiences of homework. Analyses explored age and gender differences in the time adolescents spend doing homework, and the situational variations (location and companions) in adolescents' reported concentration, effort, interest, positive affect and stress while doing homework. Regarding age differences, middle school students reported more positive experiences when homework was done with companions and in locations other than home, whereas high school students reported more positive experiences when homework was done alone and at home. Regarding gender differences, girls, regardless of age, reported greater stress than boys when doing homework alone, and lower stress when doing homework with friends. High school girls reported lower interest than middle school boys when doing homework alone. Findings provide an understanding of age and gender differences in adolescents' perceptions of homework, which might help educators and parents structure engaging homework environments.

Results of the ALSTER BP real-world registry on renal denervation employing the Symplicity system.

In: *EuroIntervention*.

Abstract:

Aims: To prove the efficacy and safety of renal sympathetic denervation as a new treatment option for patients suffering from resistant hypertension in a real-world setting. Methods and results: This single-centre real-world registry included 93 patients who underwent renal denervation employing the Symplicity system. Patients were followed for six months. The patient cohort was divided into early responders with a reduction of office systolic blood pressure >10 mmHg three months after the procedure (n=53, 57%), late responders (six months after the procedure, n=16, 17%) and non-responders (n=24, 26%). After six months, systolic blood pressure was lowered by 46+/-2.9 mmHg (mean+/-SEM, p<0.001), 31+/-3.4 mmHg (p<0.001) and 7.1+/-3.3 mmHg (p=0.79, ns), respectively. Ambulatory blood pressure monitoring also showed a significant reduction in the early responder group (20+/-5.7 mmHg, p=0.002). We subjected eight patients to a re-do procedure which led to a significant reduction of blood pressure in another five patients after six months (63%). One patient in this cohort developed a one-sided renal artery stenosis associated with an increase in blood pressure. Conclusions: This real-world analysis of renal sympathetic denervation confirms the procedure to be safe and efficient in the majority of patients. Non-responders may profit from a second ablation, arguing in favour of the hypothesis that the procedure did not destroy sufficient amounts of sympathetic innervation in these patients. However, repeated denervations may also increase side effects.

Kaleth, Anthony S.; Ang, Dennis C.; Chakr, Rafael; Tong, Yan (2010):

Validity and reliability of community health activities model program for seniors and short-form international physical activity questionnaire as physical activity assessment tools in patients with fibromyalgia.

In: *Disability and rehabilitation* 32 (5), S. 353–359. DOI: 10.3109/09638280903166352.

Abstract:

PURPOSE\r\nThere currently is a paucity of well-validated instruments to quantitatively measure physical activity (PA) levels in patients with fibromyalgia syndrome (FMS). This study aims to determine the construct validity and test-retest reliability of two self-report physical activity questionnaires [short-form international physical activity questionnaire (s-IPAQ) and community

health activities model program for seniors (CHAMPS)] in a fibromyalgia population.\r\nMETHODS\r\nThirty subjects (mean age 49.1 +/- 9.6 years; 90% females) who met the American College of Rheumatology criteria for FMS were invited to participate in the study. Two-week test-retest reliability was evaluated for the CHAMPS and s-IPAQ. Construct validity was evaluated by comparing PA reported from these questionnaires with data obtained from accelerometry (steps/week, counts/week) and the 6-minute walk test (6-MWT).\r\nRESULTS\r\nCHAMPS showed greater test-retest reliability (r = 0.58; p < 0.001) compared with s-IPAQ (r = 0.18; p = 0.15). No significant correlations were observed between the self-report PA questionnaires and the 6-MWT or accelerometry data (p > 0.05).\r\nCONCLUSIONS\r\nIn a fibromyalgia population, the s-IPAQ does not appear to be a reliable and valid PA assessment tool. CHAMPS displayed moderate test-retest reliability; however, no associations were found between CHAMPS and objectives measures of PA. In view of the known benefits of exercise in patients with FMS, there is a need to develop new measures or validate other existing well-established PA questionnaires.

Kallem, Radhakrishna R.; Meyers, Kevin E. C.; Cucchiara, Andrew J.; Sawinski, Deirdre L.; Townsend, Raymond R. (2014):

Blood pressure variability of two ambulatory blood pressure monitors.

In: *Blood Press Monit* 19 (2), S. 98–102. DOI: 10.1097/MBP.0000000000000019.

Abstract:

OBJECTIVE: There are no data on the evaluation of blood pressure (BP) variability comparing two ambulatory blood pressure monitoring monitors worn at the same time. Hence, this study was carried out to compare variability of BP in healthy untreated adults using two ambulatory BP monitors worn at the same time over an 8-h period. METHODS: An Accutorr device was used to measure office BP in the dominant and nondominant arms of 24 participants.Simultaneous 8-h BP and heart rate data were measured in 24 untreated adult volunteers by Mobil-O-Graph (worn for an additional 16 h after removing the Spacelabs monitor) and Spacelabs with both random (N=12) and nonrandom (N=12) assignment of each device to the dominant arm. Average real variability (ARV), SD, coefficient of variation, and variation independent of mean were calculated for systolic blood pressure, diastolic blood pressure, mean arterial pressure, and pulse pressure (PP). RESULTS: Whether the Mobil-O-Graph was applied to the dominant or the nondominant arm, the ARV of mean systolic (P=0.003 nonrandomized; P=0.010 randomized) and PP (P=0.009 nonrandomized; P=0.005 randomized) remained significantly higher than the Spacelabs device, whereas the ARV of the mean arterial pressure was not significantly different. The average BP readings and ARVs for systolic blood pressure and PP obtained by the Mobil-O-Graph were considerably higher for the daytime than the night-time. CONCLUSION: Given the emerging interest in the effect of BP variability on health outcomes, the accuracy of its measurement is important. Our study raises concerns about the accuracy of pooling international ambulatory blood pressure monitoring variability data using different devices.

Kalpakjian, Claire Z.; Farrell, Debra J.; Albright, Kathie J.; Chiodo, Anthony; Young, Elizabeth A. (2009):

Association of daily stressors and salivary cortisol in spinal cord injury.

In: *Rehabilitation Psychology* 54 (3), S. 288–298. DOI: 10.1037/a0016614.

Abstract:

OBJECTIVE\r\nExamine the diurnal variation of salivary cortisol in adults with spinal cord injury (SCI) and the effect of stressors on cortisol and mood.\r\nMETHOD\r\nEcological momentary assessment (EMA) to capture cortisol, stress, and mood from 25 persons with SCI and 26 without SCI. Data were analyzed using linear mixed models.\r\nRESULTS\r\nThere were no systematic differences between groups on missing data. Diurnal variation of cortisol of participants with SCI reflected an expected pattern. No significant group differences for cortisol diurnal pattern, stress, or mood; when group interactions were significant, results indicated lower cortisol reactivity to stress in participants with SCI. Stress had a significant impact on positive, negative and agitated moods.\r\nCONCLUSIONS\r\nStress in daily life and its association with cortisol and mood were largely similar between persons with and without SCI. A key methodological contribution is the demonstration of using EMA to collect biological and behavioral data in the field from participants with SCI. The use of EMA in rehabilitation psychology research has great potential to advance our understanding of the dynamics of daily life with disability.

Smartphone apps for cardiopulmonary resuscitation training and real incident support: a mixed-methods evaluation study.

In: *J Med Internet Res* 16 (3), S. e89. DOI: 10.2196/jmir.2951.

Abstract:

BACKGROUND: No systematic evaluation of smartphone/mobile apps for resuscitation training and real incident support is available to date. To provide medical, usability, and additional quality criteria for the development of apps, we conducted a mixed-methods sequential evaluation combining the perspective of medical experts and end-users. OBJECTIVE: The study aims to assess the quality of current mobile apps for cardiopulmonary resuscitation (CPR) training and real incident support from expert as well as end-user perspective. METHODS: Two independent medical experts evaluated the medical content of CPR apps from the Google Play store and the Apple App store. The evaluation was based on pre-defined minimum medical content requirements according to current Basic Life Support (BLS) guidelines. In a second phase, non-medical end-users tested usability and appeal of the apps that had at least met the minimum requirements. Usability was assessed with the System Usability Scale (SUS); appeal was measured with the self-developed ReactionDeck toolkit. RESULTS: Out of 61 apps, 46 were included in the experts' evaluation. A consolidated list of 13 apps resulted for the following layperson evaluation. The interrater reliability was substantial (kappa=.61). Layperson end-users (n=14) had a high interrater reliability (intraclass correlation 1 [ICC1]=.83, P<.001, 95% CI 0.75-0.882 and ICC2=.79, P<.001, 95% CI 0.695-0.869). Their evaluation resulted in a list of 5 recommendable apps. CONCLUSIONS: Although several apps for resuscitation training and real incident support are available, very few are designed according to current BLS guidelines and offer an acceptable level of usability and hedonic quality for laypersons. The results of this study are intended to optimize the development of CPR mobile apps. The app ranking supports the informed selection of mobile apps for training situations and CPR campaigns as well as for real incident support.

Kam, H. J.; Lee, K.; Cho, S. M.; Shin, Y. M.; Park, R. W. (2011):

High-Resolution Actigraphic Analysis of ADHD: A Wide Range of Movement Variability Observation in Three School Courses - A Pilot Study.

In: *Healthc.Inform.Res.* 17 (1), S. 29–37. DOI: 10.4258/hir.2011.17.1.29.

Abstract:

OBJECTIVES: This study was conducted to determine whether or not newly proposed high-resolution activity features could provide a superior analytic foundation compared to those commonly used to assess transitions in children's activities, under circumstances in which the types of courses attended exert different situational effects on activity levels. METHODS: From 153 children at a local elementary school, 10 subjects with attention deficit hyperactivity disorder (ADHD) and 7 controls were recruited. Their activity data was collected using an actigraph while they attended school. Ratios of partitioned activity ranges (0.5-2.8 G) during the entire activity were extracted during three classes: art, mathematics, and native language (Korean). Extracted activity features for each participant were compared between the two groups of children (ADHD and control) using graphs and statistical analysis. RESULTS: Activity distributions between ADHD and control groups for each class showed statistically significant differences spread through the entire range in art class compared to native language and mathematics classes. The ADHD group, but not the control group, experienced many significantly different intervals (> 50%) having low to very high activity acceleration regions during the art and languages courses. CONCLUSIONS: Class content appears to influence the activity patterns of ADHD children. Monitoring the actual magnitude and activity counts in a wide range of subjects could facilitate the examination of distributions or patterns of activities. Objective activity measurements made with an actigraph may be useful for monitoring changes in activities in children with ADHD in a timely manner

Kamarck, Thomas W.; Shiffman, Saul; Sutton-Tyrrell, Kim; Muldoon, Matthew F.; Tepper, Ping (2012):

Daily psychological demands are associated with 6-year progression of carotid artery atherosclerosis: The Pittsburgh Healthy Heart Project.

In: *Psychosomatic Medicine* 74 (4), S. 432–439. DOI: 10.1037/t03609-000;

Abstract:

Objective: We examine associations between the perception of ongoing psychological demands by ecological momentary assessment (EMA) and 6-year changes in carotid artery atherosclerosis by ultrasonography. Methods: A total of 270 initially healthy participants collected ambulatory blood pressure (ABP) and recorded their daily experiences, using electronic diaries, during two 3-day periods. Mean intima-media thickness (IMT) and plaque were assessed in the carotid arteries using B-mode ultrasound at baseline and again during a 6-year follow-up (mean follow-up duration = 73 months). Results: Among those who had no exposure to antihypertensive medications during the course of follow-up (n = 192), daily psychological demands were associated with greater progression of IMT as well as plaque, after adjusting for demographic and risk factor covariates. Associations between demands and plaque change were partially accounted for by ABP differences among those reporting high demands. Among those who were employed at baseline (n = 117), 6-year IMT changes were more strongly associated with ratings of daily demands than with traditional measures of occupational stress. Conclusions: These data support the role of psychological demands as a correlate of subclinical atherosclerotic progression, they point to ABP as a potential mechanism

facilitating these effects, and they highlight the utility of EMA measures for capturing daily psychological demands with potential effects on health. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Isolated office hypertension: association with target organ damage and cardiovascular risk indices.

In: *Journal of the National Medical Association* 98 (4), S. 601–606. Online verfügbar unter http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2569228/.

Abstract:

BACKGROUND: Isolated office hypertension (IOH) has been accepted as a benign condition by some researchers, whereas others believe that it is associated with cardiovascular abnormalities and increased cardiovascular risk. The aim of this present study was to evaluate the effects of IOH on target organ damage and cardiovascular risk indices. METHODS: Arterial blood pressure (BP) measured in the office and by 24-hour ambulatory blood pressure measurement (ABMP), carotid intima-media thickness (CIMT), left ventricular mass index (LVMI), cardiothoracic index (CTI), duration of QTc, 24-hour microalbuminuria, fibrinogen, C-reactive protein (CRP), total cholesterol, low-density-lipoprotein (LDL) cholesterol, high-density-lipoprotein (HDL) cholesterol and triglyceride levels were evaluated. Thirty-three subjects with IOH (office BP > or = 140/90 mmHg and daytime ambulatory BP <135/85 mmHg), 17 patients with sustained hypertension (office BP > or = 140/90 mmHg and daytime ambulatory BP > or = 135/85 mmHg), and 17 normotensive control subjects were recruited in the study. The three groups were matched for age, sex and body mass index. RESULTS: CIMT was greater in patients with IOH than in normotensive subjects, and it was significantly lower than that of sustained hypertension patients. Significantly higher LVMI was determined in subjects with IOH compared to normotensive subjects. CTI, QTc, microalbuminuria, fibrinogen, CRP, total cholesterol, LDL cholesterol, HDL cholesterol and triglyceride levels did not differ significantly among the three groups. CONCLUSIONS: IOH causes significant target organ damage and should not be regarded as a benign condition.

Walking Objectively Measured: Classifying Accelerometer Data with GPS and Travel Diaries.

In: *Med Sci Sports Exerc* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e318285f202.

Abstract:

PURPOSE: This study developed and tested an algorithm to classify accelerometer data as walking or non-walking using either GPS or travel diary data within a large sample of adults under free-living conditions. METHODS: Participants wore an accelerometer and a GPS unit, and concurrently completed a travel diary for 7 consecutive days. Physical activity (PA) bouts were identified using accelerometry count sequences. PA bouts were then classified as walking or non-walking based on a decision-tree algorithm consisting of 7 classification scenarios. Algorithm reliability was examined relative to two independent analysts' classification of a 100-bout verification sample. The algorithm was then applied to the entire set of PA bouts. RESULTS: The 706 participants' (mean age 51 years, 62% female, 80% non-Hispanic white, 70% college graduate or higher) yielded 4,702 person-days of data and had a total of 13,971 PA bouts. The algorithm showed a mean agreement of 95% with the independent analysts. It classified physical activity into 8,170 (58.5 %) walking bouts and 5,337 (38.2%) non-walking bouts; 464 (3.3%) bouts were not classified for lack of GPS and diary data. Nearly 70% of the walking bouts and 68% of the non-walking bouts were classified using only the objective accelerometer and GPS data. Travel diary data helped classify 30% of all bouts with no GPS data. The mean duration of PA bouts classified as walking was 15.2 min (SD=12.9). On average, participants had 1.7 walking bouts and 25.4 total walking minutes per day. CONCLUSIONS: GPS and travel diary information can be helpful in classifying most accelerometer-derived PA bouts into walking or non-walking behavior

Kanning, M. (2012):

Using objective, real-time measures to investigate the effect of actual physical activity on affective States in everyday life differentiating the contexts of working and leisure time in a sample with students.

In: *Front Psychol* 3 (1664-1078 (Electronic)), S. 602. DOI: 10.3389/fpsyg.2012.00602.

Abstract:

Multiple studies suggest that physical activity causes positive affective reactions and reduces depressive mood. However, studies and interventions focused mostly on structured activity programs, but rarely on actual physical activity (aPA) in daily life. Furthermore, they seldom account for the context in which the aPA occur (e.g., work, leisure). Using a prospective, real-time assessment design (ambulatory assessment), we investigated the effects of aPA on affective states (valence, energetic arousal, calmness) in real-time during everyday life while controlling for the context. Eighty-seven undergraduates students (Age: M = 24.6; SD = 3.2, females: 54%) participated in this study. aPA was assessed through accelerometers during 24-h. Palmtop devices prompted subjects approximately every 45 min during a 14-h daytime period to assess their affective states and the context. We analyzed within- and between-person effects with hierarchical modeling (HLM 6.0). Multilevel analyses revealed that both aPA and context influenced subsequent affective states. The interaction of aPA and context did predict energetic arousal only. State levels of affects did not differ between men and women. For both men and women, aPA in everyday life has an effect on individual's affective states. For valence and calmness, it seems to be independent of the context in which the aPA occur. For energetic arousal, men reported to have lower feelings of energy and women reported to have more feelings of energy during leisure time compared to working episodes

Kanning, M.; Ebner-Priemer, U.; Brand, R. (2012):

Autonomous regulation mode moderates the effect of actual physical activity on affective States: an ambulant assessment approach to the role of self-determination.

In: *J Sport Exerc.Psychol.* 34 (2), S. 260–269. Online verfügbar unter PM:22605366.

Abstract:

Studies have shown that physical activity influences affective states. However, studies have seldom depicted these associations in ongoing real-life situations, and there is no investigation showing that motivational states (i.e., more or less autonomously regulated) would moderate these effects in situ. To investigate the interaction of autonomous regulation and actual physical activity (aPA) with affective states, we use an ambulatory assessment approach. The participants were 44 university students (mean age: 26.2 +/- 3.2 years). We assessed aPA through 24-hr accelerometry and affective states and autonomous regulation via electronic diaries. Palmtop devices prompted subjects every 45 min during a 14-hr daytime period. We performed hierarchical multilevel analyses. Both aPA and autonomous regulation significantly influenced affective states. The interaction was significant for two affects. The higher the volume of aPA and thereby the more autonomously regulated the preceding bout of aPA was, the more our participants felt energized (r = .16) but agitated (r = -.18)

Use of mobile phone text message reminders in health care services: A narrative literature review.

In: *J Med Internet Res* Vo 16 (10), S. 55–68. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-44170-005%26site%3dehost-live.

Abstract:

Background: Mobile text messages are a widely recognized communication method in societies, as the global penetration of the technology approaches 100% worldwide. Systematic knowledge is still lacking on how the mobile telephone text messaging (short message service, SMS) has been used in health care services. Objective: This study aims to review the literature on the use of mobile phone text message reminders in health care. Methods: We conducted a systematic literature review of studies on mobile telephone text message reminders. The data sources used were PubMed (MEDLINE), CINAHL, Proquest Databases/ PsycINFO, EMBASE, Cochrane Library, Scopus, and hand searching since 2003. Studies reporting the use of SMS intended to remind patients in health services were included. Given the heterogeneity in the studies, descriptive characteristics, purpose of the study, response rates, description of the intervention, dose and timing, instruments, outcome measures, and outcome data from the studies were synthesized using a narrative approach. Results: From 911 initial citations, 60 studies were included in the review. The studies reported a variety of use for SMS. Mobile telephone text message reminders were used as the only intervention in 73% (44/60) of the studies, and in 27% (16/60) of the remaining studies, SMS was connected to another comprehensive health intervention system. SMS reminders were sent to different patient groups: patients with HIV/AIDS (15%, 9/60) and diabetes (13%, 8/60) being the most common groups. The response rates of the studies varied from 22-100%. Typically, the text message reminders were sent daily. The time before the specific intervention to be rendered varied from 10 minutes (eg, medication taken) to 2 weeks (eg, scheduled appointment). A wide range of different evaluation methods and outcomes were used to assess the impact of SMS varying from existing databases (eg, attendance rate based on medical records), questionnaires, and physiological measures. About three quarters of the studies (77%, 46/60) reported improved outcomes: adherence to medication or to treatment reportedly improved in 40% (24/60) of the studies, appointment attendance in 18% (11/60) of the studies, and non-attendance rates decreased in 18% (11/60) of the studies. Other positive impacts were decreased amount of missed medication doses, more positive attitudes towards medication, and reductions in treatment interruptions. Conclusions: We can conclude that although SMS reminders are used with different patient groups in health care, SMS is less systematically studied with randomized controlled trial study design. Although the amount of evidence for SMS application recommendations is still limited, having 77% (46/60) of the studies showing improved outcomes may indicate its use in health care settings. However, more well-conducted SMS studies are still needed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Kanno, Atsuhiro; Metoki, Hirohito; Kikuya, Masahiro; Terawaki, Hiroyuki; Hara, Azusa; Hashimoto, Takanao et al. (2010):

Usefulness of assessing masked and white-coat hypertension by ambulatory blood pressure monitoring for determining prevalent risk of chronic kidney disease: the Ohasama study.

In: *Hypertens Res* 33 (11), S. 1192–1198. DOI: 10.1038/hr.2010.139.

Abstract:

Masked hypertension (MHT) is considered to be associated with organ damage, whereas the association of white-coat hypertension (WCHT) with organ damage remains controversial. Using home blood pressure measurements, we have previously reported that MHT is associated with a risk of chronic kidney disease (CKD) compared with sustained normal blood pressure (SNBP), although WCHT was not significantly related to CKD in a general Japanese population. The objective of this study was to examine CKD risk associated with WCHT and MHT as determined by ambulatory blood pressure (ABP) monitoring. Among 1023 residents in the general Japanese population of Ohasama, ABP and casual blood pressure (CBP) levels were recorded and blood and urine samples were collected. CKD was defined as a positive proteinuria and/or estimated glomerular filtration rate <60 ml min^{-1} per 1.73 m^2. Participants were categorized into four groups using daytime ABP of 140/85 mm Hg and CBP of 140/90 mm Hg as cutoff points: SNBP, 60.0%; WCHT, 15.4%; MHT, 15.0%; and sustained hypertension (SHT), 9.6%. Odds ratios (ORs) for prevalence of CKD were calculated using a multiple logistic regression model. Compared with SNBP, risk of CKD was significantly higher in SHT (OR, 2.81; 95% confidence interval (CI), 1.66-4.75; P=0.0001), MHT (OR, 2.29; 95% CI, 1.45-3.63; P=0.0004) and WCHT (OR, 1.67; 95% CI, 1.03-2.71; P=0.0368). CKD was significantly associated with MHT and WCHT on the basis of ABP monitoring compared with SNBP in the general Japanese population.

Bringing the Laboratory and Clinic to the Community: Mobile Technologies for Health Promotion and Disease Prevention.

In: *Annu.Rev.Psychol.* (0066-4308 (Linking)). DOI: 10.1146/annurev-psych-113011-143736.

Abstract:

Health-related information collected in psychological laboratories may not be representative of people's everyday health. For at least 70 years, there has been a call for methods that sample experiences from everyday environments and circumstances. New technologies, including cell phones, sensors, and monitors, now make it possible to collect information outside of the laboratory in environments representative of everyday life. We review the role of mobile technologies in the assessment of health-related behaviors, physiological responses, and self-reports. Ecological momentary assessment offers a wide range of new opportunities for ambulatory assessment and evaluation. The value of mobile technologies for interventions to improve health is less well established. Among 21 randomized clinical trials evaluating interventions that used mobile technologies, more than half failed to document significant improvements on health outcomes or health risk factors. Theoretical and practical issues for future research are discussed.

Bayesian mixed-effects location and scale models for multivariate longitudinal outcomes: an application to ecological momentary assessment data.

In: *Stat Med. DOI:* 10.1002/sim.6345.

Abstract:

In the statistical literature, the methods to understand the relationship of explanatory variables on each individual outcome variable are well developed and widely applied. However, in most health-related studies given the technological advancement and sophisticated methods of obtaining and storing data, a need to perform joint analysis of multivariate outcomes while explaining the impact of predictors simultaneously and accounting for all the correlations is in high demand. In this manuscript, we propose a generalized approach within a Bayesian framework that models the changes in the variation in terms of explanatory variables and captures the correlations between the multivariate continuous outcomes by the inclusion of random effects at both the location and scale levels. We describe the use of a spherical transformation for the correlations between the random location and scale effects in order to apply separation strategy for prior elicitation while ensuring positive semi-definiteness of the covariance matrix. We present the details of our approach using an example from an ecological momentary assessment study on adolescents. Copyright (c) 2014 John Wiley & Sons, Ltd.

A portable, inexpensive, wireless vital signs monitoring system.

In: *Biomed Instrum Technol* 44 (4), S. 350–353. DOI: 10.2345/0899-8205-44.4.350.

Abstract:

The University of Connecticut, Department of Biomedical Engineering has developed a device to be used by patients to collect physiological data outside of a medical facility. This device facilitates modes of data collection that would be expensive, inconvenient, or impossible to obtain by traditional means within the medical facility. Data can be collected on specific days, at specific times, during specific activities, or while traveling. The device uses biosensors to obtain information such as pulse oximetry (SpO2), heart rate, electrocardiogram (ECG), non-invasive blood pressure (NIBP), and weight which are sent via Bluetooth to an interactive monitoring device. The data can then be downloaded to an electronic storage device or transmitted to a company server, physician's office, or hospital. The data collection software is usable on any computer device with Bluetooth capability, thereby removing the need for special hardware for the monitoring device and reducing the total cost of the system. The modular biosensors can be added or removed as needed without changing the monitoring device software. The user is prompted by easy-to-follow instructions written in non-technical language. Additional features, such as screens with large buttons and large text, allow for use by those with limited vision or limited motor skills.

Evaluation of smartphone sound measurement applications.

In: *J Acoust Soc Am* 135 (4), S. EL186. DOI: 10.1121/1.4865269.

Abstract:

This study reports on the accuracy of smartphone sound measurement applications (apps) and whether they can be appropriately employed for occupational noise measurements. A representative sample of smartphones and tablets on various platforms were acquired, more than 130 iOS apps were evaluated but only 10 apps met our selection criteria. Only 4 out of 62 Android apps were tested. The results showed two apps with mean differences of 0.07 dB (unweighted) and -0.52 dB (A-weighted) from the reference values. Two other apps had mean differences within +/-2 dB. The study suggests that certain apps may be appropriate for use in occupational noise measurements.

Efficacy and Safety of LCZ696, a First-in-Class Angiotensin Receptor Neprilysin Inhibitor, in Asian Patients With Hypertension: A Randomized, Double-Blind, Placebo-Controlled Study.

In: *Hypertension* 63 (4), S. 698–705. DOI: 10.1161/HYPERTENSIONAHA.113.02002.

Abstract:

LCZ696 (Japanese adopted name: sucabitril valsartan sodium hydrate), a first-in-class angiotensin receptor neprilysin inhibitor, concomitantly inhibits neprilysin and blocks angiotensin type 1 receptor. This randomized, double-blind, placebo-controlled study, the first in Asia for this drug, evaluated the dose-related efficacy and safety of LCZ696 in patients with hypertension using 24-hour ambulatory blood pressure (BP) monitoring. Asian patients aged >/=18 years (n=389) with hypertension were randomized to receive LCZ696 100 mg (n=100), 200 mg (n=101), 400 mg (n=96), or placebo (n=92) for 8 weeks. The primary end point was mean difference across the 3 single-dose pairwise comparisons of LCZ696 versus placebo in clinic diastolic BP after 8-week treatment. Key secondary efficacy variables included changes in clinic systolic BP and pulse pressure and changes in 24-hour, daytime, and nighttime ambulatory BPs and pulse pressure. Safety assessments included recording all adverse events and serious adverse events. A total of 362 patients completed the study. Reductions in clinic systolic BP, diastolic BP (P<0.0001), and pulse pressure (P<0.001) were significantly greater with all doses of LCZ696 than with placebo. There were also significant reductions in 24-hour, daytime, and nighttime ambulatory systolic BP, diastolic BP, and pulse pressure for all doses of LCZ696 compared with placebo (P<0.0001). LCZ696 was well tolerated, and no cases of angioedema were reported. In conclusion, LCZ696 is effective for the treatment of hypertension in Asian population and, in general, is safe and well tolerated. Clinical Trial Information- URL: http://www.clinicaltrials.gov. Prediction of treatment-induced changes in target-organ damage using changes in clinic, home and ambulatory blood pressure.

In: *Hypertens Res. DOI:* 10.1038/hr.2014.24.

Abstract:

Cross-sectional studies have shown that ambulatory and home blood pressure (ABP and HBP, respectively) measurements are more closely associated with preclinical organ damage than are office measurements. This study investigated the association between treatment-induced changes in BP assessed by the three methods and the corresponding changes in organ damage. Untreated hypertensives were evaluated with office, ABP and HBP measurements and indices of organ damage (echocardiographic left-ventricular mass index (LVMI), pulse wave velocity (PWV), albuminuria) before and after 12 months of treatment. A total of 116 subjects completed the study (mean age 50.7+/-10.5 years, 69 men (59%), mean follow-up 13.4+/-1.4 months). The treatment-induced change in the LVMI was correlated with changes in BP and pulse pressure (PP) assessed by all methods. The change in PWV was correlated with changes in home systolic and ABP and PP and with the change in home diastolic BP. Albuminuria showed no correlations. In linear regression models, changes in home BP and PP had the strongest predictive ability for the change in the LVMI, whereas the change in ABP was the strongest predictor of the change in PWV. The change in office BP had no predictive value. HBP and ABP measurements appear to be superior to office BP measurements and should be considered complementary rather than interchangeable methods for monitoring the effects of antihypertensive treatment on target-organ damage.Hypertension Research advance online publication, 27 February 2014; doi:10.1038/hr.2014.24.

Office, ambulatory and home blood pressure measurement in children and adolescents.

In: *Expert review of cardiovascular therapy* 8 (11), S. 1567–1578.

Abstract:

There is an increasing interest in pediatric hypertension, the prevalence of which is rising in parallel with the obesity epidemic. Traditionally the assessment of hypertension in children has relied on office blood pressure (BP) measurements by the physician. However, as in adults, office BP might be misleading in children mainly due to the white coat and masked hypertension phenomena. Thus, out-of-office BP assessment, using ambulatory or home monitoring, has gained ground for the accurate diagnosis of hypertension and decision-making. Ambulatory monitoring is regarded as indispensable for the evaluation of pediatric hypertension. Preliminary data support the usefulness of home monitoring, yet more evidence is needed. Office, ambulatory and home BP normalcy tables providing thresholds for diagnosis have been published and should be used for the assessment of elevated BP in children.

Karr, T. M.; Crosby, R. D.; Cao, L.; Engel, S. G.; Mitchell, J. E.; Simonich, H.; Wonderlich, S. A. (2012):

Posttraumatic stress disorder as a moderator of the association between negative affect and bulimic symptoms: an ecological momentary assessment study.

In: *Compr.Psychiatry* (0010-440X (Linking)). DOI: 10.1016/j.comppsych.2012.05.011.

Abstract:

OBJECTIVE: The purpose of this study was to examine the potential moderating effect of posttraumatic stress disorder (PTSD) on the emotion-behavior relationship in individuals with bulimia nervosa (BN). METHOD: A total of 119 women with BN were involved in the study. Participants were divided into 2 groups: those with BN and PTSD (n = 20) and those with BN only (n = 99). Ecological momentary assessment procedures were used for the examination of affect, frequency of bulimic behaviors, and the relationship of affect and bulimic behavior over time. The Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Axis I Disorders was conducted for the diagnosis of BN, PTSD, mood disorders, anxiety disorders, and substance use disorders. Mood disorders, anxiety disorders, and substance use disorders functioned as covariates in all analyses. RESULTS: Statistical models showed that those in the PTSD group reported a greater daily mean level of negative affect (NA) and a greater daily frequency of bulimic behaviors than those in the BN-only group. Moderation was found for the association between NA and time in that the PTSD group showed a faster acceleration in NA before purging and faster deceleration in NA after purging. The association between positive affect and time was also moderated by group, indicating that the PTSD group had a faster acceleration in positive affect after purging than the BN-only group. CONCLUSION: These findings highlight the importance of recognizing PTSD when interpreting the emotion-behavior relationship in individuals with BN

Kashdan, Todd B.; Collins, R. Lorraine (2010):

Social anxiety and the experience of positive emotion and anger in everyday life: an ecological momentary assessment approach.

In: *Anxiety Stress Coping* 23 (3), S. 259–272. DOI: 10.1080/10615800802641950.

Abstract:

A few recent studies have found evidence showing that social anxiety is associated with diminished positive affect and elevated anger. However, prior work has relied on trait self-report measures of global positive mood or anger. In this preliminary study, we examined how trait social anxiety relates to moment-to-moment positive and angry emotional states as people navigate through their natural environment in a given day. Of additional interest was whether any associations were limited to social situations or were evident more broadly in non-social situations as well. For 14 days, 38 non-clinical community adults carried electronic diaries to assess their experience of positive emotions, anger, and their current social context and activity. Participants were randomly prompted up to four times per day, leading to 1702 observations. Results showed that social anxiety was associated with less time spent feeling happy and relaxed and more time spent feeling angry throughout the day. In general, people felt happier when they were with other people compared to being alone. Interestingly, people with relatively higher levels of social anxiety reported fewer and less intense positive emotions and greater anger episodes across social and non-social situations.

Kashdan, Todd B.; Farmer, Antonina S. (2014):

Differentiating emotions across contexts: Comparing adults with and without social anxiety disorder using random, social interaction, and daily experience sampling.

In: *Emotion* 14 (3), S. 629–638. DOI: 10.1037/t00532-000.

Abstract:

The ability to recognize and label emotional experiences has been associated with well-being and adaptive functioning. This skill is particularly important in social situations, as emotions provide information about the state of relationships and help guide interpersonal decisions, such as whether to disclose personal information. Given the interpersonal difficulties linked to social anxiety disorder (SAD), deficient negative emotion differentiation may contribute to impairment in this population. We hypothesized that people with SAD would exhibit less negative emotion differentiation in daily life, and these differences would translate to impairment in social functioning. We recruited 43 people diagnosed with generalized SAD and 43 healthy adults to describe the emotions they experienced over 14 days. Participants received palmtop computers for responding to random prompts and describing naturalistic social interactions; to complete end-of-day diary entries, they used a secure online website. We calculated intraclass correlation coefficients to capture the degree of differentiation of negative and positive emotions for each context (random moments, face-to-face social interactions, and end-of-day reflections). Compared to healthy controls, the SAD group exhibited less negative (but not positive) emotion differentiation during random prompts, social interactions, and (at trend level) end-of-day assessments. These differences could not be explained by emotion intensity or variability over the 14 days, or to comorbid depression or anxiety disorders. Our findings suggest that people with generalized SAD have deficits in clarifying specific negative emotions felt at a given point of time. These deficits may contribute to difficulties with effective emotion regulation and healthy social relationship functioning. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Emotion differentiation as resilience against excessive alcohol use: an ecological momentary assessment in underage social drinkers.

In: *Psychological Science* 21 (9), S. 1341–1347. DOI: 10.1177/0956797610379863.

Abstract:

Some people are adept at using discrete emotion categories (anxious, angry, sad) to capture their felt experience; other people merely communicate how good or bad they feel. We theorized that people who are better at describing their emotions might be less likely to self-medicate with alcohol. During a 3-week period, 106 underage social drinkers used handheld computers to self-monitor alcohol intake. From participants' reported experiences during random prompts, we created an individual difference measure of emotion differentiation. Results from a 30-day timeline follow-back revealed that people with intense negative emotions consumed less alcohol if they were better at describing emotions and less reliant on global descriptions. Results from ecological momentary assessment procedures revealed that people with intense negative emotions prior to drinking episodes consumed less alcohol if they were better at describing emotions. These findings provide support for a novel methodology and dimension for understanding the influence of emotions on substance-use patterns.

Laughter with someone else leads to future social rewards: Temporal change using experience sampling methodology.

In: *Personality and Individual Differences*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-36550-001%26site%3dehost-live.

Abstract:

Prior research suggests that laughter is correlated with resilience and well-being. To date, there is little research on the subsequent social benefits following laughter with another person. We hypothesized that laughing with another person would be associated with greater social rewards in subsequent social interactions. Using a two-week daily diary study with 162 people (68% women), we collected data on 5510 face-to-face social interactions in everyday life. We found that laughing with another person during an interaction predicted greater intimacy, positive emotions, and enjoyment in the subsequent social interaction. There was no evidence for the reverse direction, as intimacy, positive emotions, and enjoyment failed to predict laughter in subsequent social interactions. As for specificity, laughter was associated with subsequent intimacy and positive emotions even

after accounting for the variance attributable to enjoyment felt when socializing. As for robustness, laughter with another person had the same effect on subsequent interactions regardless of whether interacting with the same person or a new person. In summary, besides being immediately pleasurable, laughing with social interaction partners influences the likelihood of future social rewards. This study adds to theory and research suggesting that laughing is an important social bonding mechanism. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Telemetry capsule for ambulatory pH monitoring: is it time for a change?

In: *The American journal of gastroenterology* 103 (12), S. 2986–2987. DOI: 10.1111/j.1572-0241.2008.02179.x.

Abstract:

There is currently no clear gold standard for the diagnosis of gastroesophageal reflux disease. The most common practice, a therapeutic trial of antisecretory therapy, falls short of being ideal. Endoscopy is insensitive and impractical as an early diagnostic test for the majority of patient presentations. Ambulatory reflux monitoring offers the most effective means of documenting the presence of abnormal esophageal acid exposure and abnormal reflux frequency and to correlate the association of symptoms and reflux episodes. However, even this diagnostic test has fallen short of being an adequate and reliable standard for diagnosis. Telemetry capsule monitoring offers the opportunity for creative improvement in the diagnostic utility of pH monitoring and is the subject of the study discussed.

Kavanagh, Justin J.; Cross, Troy J.; Newell, Karl M.; Morrison, Steven (2014):

Load-induced changes in older individual's hand-finger tremor are ameliorated with targeting.

In: *J Neurol Sci* 339 (1-2), S. 69–74. DOI: 10.1016/j.jns.2014.01.023.

Abstract:

The purpose of this study was to investigate hand-finger tremor dynamics when a load was applied to the finger in a group of healthy older adults. Moreover, we sought to determine if projecting a representation of the subject's finger tremor on a target was capable of overcoming the effects of loading so that hand-finger interactions returned to a state that was similar to normal tremor. Eight healthy older males (67+/-1year) performed a postural pointing task, where tremor was assessed using lightweight accelerometers attached to the hand and finger. Tremor was then assessed when a laser pointer was attached to the finger and switched off (the load), and then with the laser pointer attached and switched on pointing at targets of 40mm and 20mm in diameter. The main findings of this study were that 1) loading the finger resulted in a reduction in finger tremor amplitude and increased finger tremor regularity, but no change in hand tremor, 2) loading caused increased hand-finger 8-12Hz cross wavelet coherence and phase synchrony, and 3) pointing at different targets while the finger was loaded resulted in an increase in finger tremor amplitude, and changes in inter-segmental coupling to the extent that hand-finger dynamics reflected normal unloaded conditions. Overall, these results illustrate that the damping effects of limb loading can be offset, in part, by altering the accuracy demands of the task to make the pointing action more challenging.

Kavanagh, Justin J.; Menz, Hylton B. (2008):

Accelerometry: a technique for quantifying movement patterns during walking.

In: *Gait Posture* 28 (1), S. 1–15.

Abstract:

The popularity of using accelerometer-based systems to quantify human movement patterns has increased in recent years for clinicians and researchers alike. The benefits of using accelerometers compared to more traditional gait analysis instruments include low cost; testing is not restricted to a laboratory environment; accelerometers are small, therefore walking is relatively unrestricted; and direct measurement of 3D accelerations eliminate errors associated with differentiating displacement and velocity data. However, accelerometry is not without its disadvantages, an issue which is scarcely reported in gait analysis literature. This paper reviews the use of accelerometer technology to investigate gait-related movement patterns, and addresses issues of acceleration measurement important for experimental design. An overview of accelerometer mechanics is provided before illustrating specific experimental conditions necessary to ensure the accuracy of gait-related acceleration measurement. A literature review is presented on how accelerometry has been used to examine basic temporospatial gait parameters, shock attenuation, and segmental accelerations of the body during walking. The output of accelerometers attached to the upper body has provided useful insights into the motor control of normal walking, age-related differences in dynamic postural control, and gait patterns in people with movement disorders.

Sleep parameters in rhesus monkeys by using actigraphy.

In: *Psychopharmacology* 228 (3). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-24823-016%26site%3dehost-live;kawada@nms.ac.jp.

Abstract:

Comments on an article by ML. Andersen et al. (see record 2010-10371-013). Andersen et al. reported the effect of methamphetamine on sleep parameters in rhesus monkeys by using actigraphy. As a conclusion, methamphetamine (0.03 mg/kg) disrupted sleep by producing an increase in sleep latency and sleep fragmentation, in combination with a decrease in sleep efficiency. After concluding the drug experiment, the effect disappeared. Author have two concerns on their study. First, actigraphy cannot become a substitute for sleep polysomnography. Actigraphy is based on an accelerometer for movement, and it does not directly reflect brain activity. They quoted one validation study with Actiwatch-�. Second, they prepared two concentrations of methamphetamine and the effect of methamphetamine treatment was evaluated. Author agree with the simplicity of actigraphy to monitor sleep, but much more trials are needed to establish validation for the application of actigraphy to small nonhuman primates. Activity monitoring and sleep monitoring are different concepts, and special caution should be paid when inferring sleep based on actigraphy. Agreement in regard to total sleep time during a nap obtained via a sleep polygraph and accelerometer: A comparison of different sensitivity thresholds of the accelerometer.

In: *International Journal of Behavioral Medicine* 19 (3), S. 398–401. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-22767-018%26site%3dehost-live;kawada@nms.ac.jp.

Abstract:

Background: Appropriate sensitivity threshold of accelerometer to measure total sleep time during nap is not established. Purpose Actigraphy-derived total sleep times during naps were calculated using three different sensitivity threshold values and compared with polysomnography. Method: The mean age of the 60 subjects (53 men and 7 women) was 22.8, ranging from 22 to 27 years. Determination of the sleep stage by the polygraph and the sleep/wake judgment by the accelerometer obeyed the sleep/wake judgment, and the accelerometer was monitored under different sensitivity threshold settings. The study was carried out during one afternoon with a 3-h nap opportunity. Kappa statistics, correlations, and several indices of accuracy were compared using statistical methods. Results: The mean total sleep times during a nap set for 180 min were 160.4, 151.8, and 140.5 min, respectively, as judged under the low-sensitive, middle-sensitive, high-sensitive settings of an accelerometer worn on the non-dominant wrist. The corresponding mean total sleep time as calculated using a sleep polygraph was 133.0 min. Sleep/wake judgment by three levels of threshold values for the accelerometer showed that high-sensitive threshold showed relatively high specificity (0.452) compared with specificities by the low-sensitive threshold (0.249) or by the middle-sensitive threshold (0.358). The concordance correlation coefficients and 95% confidence intervals (in parenthesis) between the total sleep time judged by polygraph and low-sensitive, middle-sensitive, or high-sensitive accelerometer were 0.40 (0.26–0.51), 0.53 (0.38–0.65), and 0.64 (0.49–0.75), respectively. The Bland–Altman plot of the measurements showed higher agreement between the total sleep time by polygraph and by the accelerometer using the high-sensitive threshold. Conclusions: From the result obtained in this study, the high-sensitive accelerometer showed the strongest agreement of total sleep time and sleep/wake judgment with the calculated value using the sleep polygraph. Estimation of the respiratory ventilation rate of preschool children in daily life using accelerometers.

In: *J Air Waste Manag Assoc* 61 (1), S. 46–54.

Abstract:

Inhalation rate is an essential factor for determining the inhaled dose of air pollutants. Here, accelerometers were used to develop regression equations for predicting the minute ventilation rate (V(E)) to estimate the daily inhalation rate in young children. Body acceleration and heart rate were measured in 29 Japanese preschool children (6 yr of age) during nine different levels of activities (lying down, sitting, standing, playing with plastic bricks, walking, building with blocks, climbing stairs, ball tossing, and running) using the Actical omnidirectional accelerometer, the ActivTracer triaxial accelerometer, and a heart rate monitor. Measurements were calibrated against the V(E) measured by the Douglas bag method. ActivTracer accelerometer measurements gave a strong correlation with V(E) (Pearson's r = 0.913), which was marginally stronger than that for the Actical counts (r = 0.886) and comparable to the correlation between heart rate and logarithmic V(E) (r = 0.909). According to the linear regression equation, the V(E) for lying down, sitting, standing, playing with plastic bricks, walking, and running was overestimated by 14-60% by the Actical and by 14-37% by the ActivTracer. By comparison, for building with blocks, climbing stairs, and ball tossing, the V(E) was underestimated by 19-23% by the Actical and by 13-18% by the ActivTracer. When these three activities were excluded, a stronger correlation was found between the V(E) and ActivTracer measurements (r = 0.949); this correlation was 0.761 for the three excluded activities. Discriminant analysis showed that the ratio between vertical and horizontal acceleration obtained by the ActivTracer could discriminate walking from building with blocks, climbing stairs, and ball tossing with a sensitivity of 75%. The error in estimating V(E) was considerably improved for the ActivTracer measurements by the use of two regression equations developed for each type of activity.

An investigation into non-invasive physical activity recognition using smartphones.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 3340–3343. DOI: 10.1109/EMBC.2012.6346680.

Abstract:

Technology utilized to automatically monitor Activities of Daily Living (ADL) could be a key component in identifying deviations from normal functional profiles and providing feedback on interventions aimed at improving health. However, if activity recognition systems are to be implemented in real world scenarios such as health and wellness monitoring, the activity sensing modality must unobtrusively fit the human environment rather than forcing humans to adhere to sensor specific conditions. Modern smart phones represent a ubiquitous computing device which has already undergone mainstream adoption. In this paper, we investigate the feasibility of using a modern smartphone, with limited placement constraints, as the sensing modality for an activity recognition system. A dataset of 4 subjects performing 7 activities, using varying sensor placement conditions, is utilized to investigate this. Initial experiments show that a decision tree classifier performs activity classification with precision and recall scores of 0.75 and 0.73 respectively. More importantly, as part of this initial experiment, 3 main problems, and subsequently 3 solutions, relating to unconstrained sensor placement were identified. Using our proposed solutions, classification precision and recall scores were improved by +13% and +14.6% respectively

Kelly, Nichole R.; Cotter, Elizabeth W.; Mazzeo, Suzanne E. (2014):

Examining the role of distress tolerance and negative urgency in binge eating behavior among women.

In: *Eat Behav* 15 (3), S. 483–489. DOI: 10.1016/j.eatbeh.2014.06.012.

Abstract:

The current study examined whether distress tolerance and negative urgency moderate the link between depressive symptoms and binge eating frequency, and between disordered eating attitudes and binge eating frequency. Young adult women (N=186) completed questionnaires assessing depressive symptoms, cognitive restraint, eating, shape and weight concerns, distress tolerance, impulsivity (including negative urgency), and binge eating. After controlling for body mass index, race/ethnicity, and other domains of impulsivity, negative urgency was significantly associated with binge eating above and beyond the influence of disordered eating attitudes and depressive symptoms. Distress tolerance, in contrast, was not associated with binge eating. In addition, neither negative urgency nor distress tolerance moderated the associations between disordered eating attitudes and binge eating frequency, or between depressive symptoms and binge eating. Results support the additive role of difficulties responding adaptively to distress in binge eating frequency, above and beyond the influence of emotional distress. Findings highlight the potential value of focusing on negative urgency in targeted treatments for binge eating among women. Importantly, results from the current study differ from those of previous research; these discrepancies could be the result of variations in sample characteristics and approaches to the assessment of binge eating behavior. Additional research, including longitudinal studies and research using "real-time" assessment strategies, such as ecological momentary assessment, is necessary to elucidate further the role of various emotion regulation strategies in maintaining binge eating behavior in adult women.

Kelly, J.; Gooding, P.; Pratt, D.; Ainsworth, J.; Welford, M.; Tarrier, N. (2012):

Intelligent real-time therapy: Harnessing the power of machine learning to optimise the delivery of momentary cognitive-behavioural interventions.

In: *J.Ment.Health* (0963-8237 (Linking)). DOI: 10.3109/09638237.2011.638001.

Abstract:

Background Experience sampling methodology (ESM) [Csikszentmihalyi, M. & Larson, R. (1987). Validity and reliability of the experience-sampling method. Journal of Nervous and Mental Disease, 175(9), 526-536] has been used to elucidate the cognitive-behavioural mechanisms underlying the development and maintenance of complex mental disorders as well as mechanisms involved in resilience from such states. We present an argument for the development of intelligent real-time therapy (iRTT). Machine learning and reinforcement learning specifically may be used to optimise the delivery of interventions by observing and altering the timing of real-time therapies based on ongoing ESM measures. Aims The aims of the present article are to outline the principles of iRTT and to consider how it would be applied to complex problems such as suicide prevention. Methods Relevant literature was identified through use of PychInfo. Results iRTT may provide an important and ecologically valid adjunct to traditional CBT, providing a means of balancing population-based data with individual data, thus addressing the "knowledge-practice gap" [Tarrier, N. (2010b). The cognitive and behavioral treatment of PTSD, what is known and what is known to be unknown: How not to fall into the practice gap. Clinical Psychology: Science and Practice, 17(2), 134-143] and facilitating the delivery of interventions in situ, thereby addressing the "therapy-real-world gap". Conclusions iRTT may provide a platform for the development of individualised and multifaceted momentary intervention strategies that are ecologically valid and aimed at attenuating pathological pathways to complex mental health problems and amplifying pathways associated with resilience

Kenny, P. Pang; Christine, G. Gourin; David, J. Terris (2007):

A comparison of polysomnography and the WatchPAT in the diagnosis of obstructive sleep apnea.

In: *Otolaryngology--Head and Neck Surgery* 137 (4), S. 665–668.

Abstract:

OBJECTIVE:

Our goal was to validate the WatchPAT in the diagnosis of obstructive sleep apnea.

STUDY DESIGN:

We conducted a prospective, blinded, nonrandomized clinical trial.

METHODS:

Patients with suspected obstructive sleep apnea scheduled for an overnight level I polysomnogram were offered enrollment in a study to compare the WatchPAT (Itamar Ltd, Israel) device with polysomnography. Patients wore the WatchPAT device simultaneously while undergoing polysomnography during evaluation in the sleep lab.

RESULTS:

Thirty-seven patients participated in the study. They had a mean age of 50.1 years (range, 31-73 years) and mean body mass index of 34.6 kg/m(2) (range, 21.2-46.8 kg/m(2)). There was high correlation between the polysomnogram and WatchPAT apnea-hypopnea index (r = 0.9288; 95% confidence interval = 0.8579-0.9650, P < 0.0001). The lowest oxygen saturation also showed high correlation (r = 0.989; 95% confidence interval = 0.9773-0.9947, P < 0.0001). The overall polysomnogram and WatchPAT sleep times revealed a correlation of r = 0.5815 (P = 0.005).

CONCLUSION:

The WatchPAT showed a high correlation with the polysomnogram in apnea-hypopnea index, lowest oxygen saturation, and sleep time.

SIGNIFICANCE:

It's use as a reliable tool in the diagnosis of Obstructive Sleep Apnea.

Validity and reliability of cardiorespiratory measurements recorded by the LifeShirt during exercise tests.

In: *Respir Physiol Neurobiol* 167 (2), S. 162–167. DOI: 10.1016/j.resp.2009.03.013.

Abstract:

The LifeShirt is a novel ambulatory monitoring system that records cardiorespiratory measurements outside the laboratory. Validity and reliability of cardiorespiratory measurements recorded by the LifeShirt were assessed and two methods of calibrating the LifeShirt were compared. Participants performed an incremental treadmill test and a constant work rate test (65% peak oxygen uptake) on four occasions (>48 h apart) and wore the LifeShirt, COSMED system and Polar Sport Tester simultaneously. The LifeShirt was calibrated using two methods: comparison to a spirometer; and 800 ml fixed-volume bag. Ventilation, respiratory rate, expiratory time and heart rate recorded by the LifeShirt were compared to measurements recorded by laboratory equipment. Sixteen adults participated (6M:10 F); mean (SD) age 23.1 (2.9) years. Agreement between the LifeShirt and laboratory equipment was acceptable. Agreement for ventilation was improved by calibrating the LifeShirt using a spirometer. Reliability was similar for the LifeShirt and the laboratory equipment. This study suggests that the LifeShirt provides a valid and reliable method of ambulatory monitoring.

The relationship between outdoor activity and health in older adults using GPS.

In: *Int.J.Environ.Res.Public Health* 9 (12), S. 4615–4625. Online verfügbar unter PM:23330225.

Abstract:

Physical activity (PA) provides health benefits in older adults. Research suggests that exposure to nature and time spent outdoors may also have effects on health. Older adults are the least active segment of our population, and are likely to spend less time outdoors than other age groups. The relationship between time spent in PA, outdoor time, and various health outcomes was assessed for 117 older adults living in retirement communities. Participants wore an accelerometer and GPS device for 7 days. They also completed assessments of physical, cognitive, and emotional functioning. Analyses of variance were employed with a main and interaction effect tested for +/-30 min PA and outdoor time. Significant differences were found for those who spent >30 min in PA or outdoors for depressive symptoms, fear of falling, and self-reported functioning. Time to complete a 400 m walk was significantly different by PA time only. QoL and cognitive functioning scores were not significantly different. The interactions were also not significant. This study is one of the first to demonstrate the feasibility of using accelerometer and GPS data concurrently to assess PA location in older adults. Future analyses will shed light on potential causal relationships and could inform guidelines for outdoor activity

Physical activity and the drive to exercise in anorexia nervosa.

In: *Int J Eat Disord. DOI:* 10.1002/eat.22354.

Abstract:

OBJECTIVES: To investigate physical activity (PA) and drive for exercise in anorexia nervosa (AN) in relation to eating disorder (ED) pathology and anxiety. METHOD: Female participants were recruited into four groups: AN outpatients (n = 37), AN inpatients (n = 18), an anxiety group (n = 34), and healthy controls (HCs; n = 30). PA was measured by actigraphy and self-report together with drive/reasons for exercise, ED pathology, anxiety, depression, stress, BMI, and body composition. RESULTS: ED psychopathology, general psychopathology, and physiological measures were consistent with diagnosis. All groups showed a wide range in activity, especially on self-report. No significant group differences were observed in objective PA levels, yet AN groups reported 57-92% higher total activity than HCs. Outpatients reported more walking and moderate exercise than HCs, and inpatients reported more walking but less moderate and vigorous activity than all other groups. AN groups had significantly higher drive to exercise and valued "improving tone" as important and health and enjoyment as less important reasons to exercise. DISCUSSION: Self-perceived activity rather than objective data may partly explain the increased activity reported in AN. Drive to exercise in AN appears to be more related to ED pathology than to anxiety. (c) 2014 Wiley Periodicals, Inc. (Int J Eat Disord 2014).

A modular and programmable development platform for capsule endoscopy system.

In: *J Med Syst* 38 (6), S. 57. DOI: 10.1007/s10916-014-0057-6.

Abstract:

The state-of-the-art capsule endoscopy (CE) technology offers painless examination for the patients and the ability to examine the interior of the gastrointestinal tract by a noninvasive procedure for the gastroenterologists. In this work, a modular and flexible CE development system platform consisting of a miniature field programmable gate array (FPGA) based electronic capsule, a microcontroller based portable data recorder unit and computer software is designed and developed. Due to the flexible and reprogrammable nature of the system, various image processing and compression algorithms can be tested in the design without requiring any hardware change. The designed capsule prototype supports various imaging modes including white light imaging (WLI) and narrow band imaging (NBI), and communicates with the data recorder in full duplex fashion, which enables configuring the image size and imaging mode in real time during examination. A low complexity image compressor based on a novel color-space is implemented inside the capsule to reduce the amount of RF transmission data. The data recorder contains graphical LCD for real time image viewing and SD cards for storing image data. Data can be uploaded to a computer or Smartphone by SD card, USB interface or by wireless Bluetooth link. Computer software is developed that decompresses and reconstructs images. The fabricated capsule PCBs have a diameter of 16 mm. An ex-vivo animal testing has also been conducted to validate the results.

Accuracy, Consistency, and Reproducibility of the Triaxial Accelerometer in the iPod Touch: A Pilot Study.

In: *JMIR Mhealth Uhealth* 2 (4), S. e39. DOI: 10.2196/mhealth.3008.

Abstract:

BACKGROUND: The use of a mobile consumer communicative device as a motion analysis tool for patients has been researched and documented previously, examining the triaxial accelerometer embedded in such devices. However, there have been few reports in the literature testing the sensitivity of an embedded triaxial accelerometer. OBJECTIVE: Our goal in this study was to test the accuracy, consistency, and reproducibility of the triaxial accelerometer in the iPod Touch. METHODS: In this pilot study, we subjected the triaxial accelerometer in the iPod Touch to a free fall from a height of 100 cm in order to test its accuracy, consistency, and reproducibility under dynamic conditions. RESULTS: The resultant vectorial sum acceleration was mean 0.999 g (standard gravity; SD 1.51%; 95% CI 0.99-1.01), indicating very high accuracy and sensitivity under dynamic conditions. CONCLUSIONS: Our results highlighted the reproducibility of the capability of the triaxial accelerometer in the iPod Touch to capture data accurately and consistently. Thus, the device has huge potential as a motion analysis tool for measuring gait and studying balance and mobility in patients before and after surgery.

Feasibility and validity of ecological momentary assessment in adolescents with high-functioning autism and Asperger's disorder.

In: *J.Adolesc.* 37 (1), S. 37–46. DOI: 10.1016/j.adolescence.2013.10.005.

Abstract:

Ecological Momentary Assessment (EMA) may increase accuracy of data compared with retrospective questionnaires by assessing behaviours as they occur, hence decreasing recall biases and increasing ecological validity. This study examined the feasibility and concurrent validity of an EMA tool for adolescents with High-Functioning Autism Spectrum Disorders (HFASD). Thirty-one adolescents with HFASD completed a mobile phone EMA application that assessed stressors and coping for two weeks. Parents and adolescents also completed retrospective measures of the adolescent's coping/stressors. Moderate compliance with the EMA tool was achieved and some concurrent validity was established with the retrospective measure of coping. Concordance was found between the types of stressors reported by parents and adolescents but not the quantity. The results suggest adolescents with HFASD are capable of reporting on their stressors and coping via EMA. EMA has the potential to be a valuable research tool in this population

Khor, A. S.; Melvin, G. A.; Reid, S. C.; Gray, K. M. (2013):

Coping, Daily Hassles and Behavior and Emotional Problems in Adolescents with High-Functioning Autism/Asperger's Disorder.

In: *J Autism Dev.Disord.* (0162-3257 (Linking)). DOI: 10.1007/s10803-013-1912-x.

Abstract:

Although daily hassles and coping are associated with behavior and emotional problems in non-clinical populations, few studies have investigated these relationships in individuals with high-functioning autism/Asperger's Disorder (HFASD). This study examined the relationships between daily hassles, coping and behavior and emotional problems in adolescents with HFASD. Thirty-one adolescents with HFASD completed questionnaires assessing their coping and behavior and emotional problems, and completed an Ecological Momentary Assessment run via a mobile phone application on their coping and daily hassles. Parents completed questionnaires of the adolescents' daily hassles, coping, and behavior and emotional problems. The disengagement coping style was associated with significantly higher levels of behavior and emotional problems regardless of respondent or methodology, suggesting it may be a valuable target for intervention

Kikuchi, H.; Yoshiuchi, K.; Miyasaka, N.; Ohashi, K.; Yamamoto, Y.; Kumano, H. et al. (2006):

Reliability of recalled self-report on headache intensity: investigation using ecological momentary assessment technique.

In: *Cephalalgia* 26 (11), S. 1335–1343. DOI: 10.1111/j.1468-2982.2006.01221.x.

Abstract:

Recalled evaluation of headache intensity is often affected by several factors. Recently, computerized ecological momentary assessment (EMA) has been developed to avoid such problems as recall bias. Here, we compared recalled headache intensity with momentary headache intensity using EMA in tension-type headache (TTH). Forty patients with TTH wore watch-type computers for 1 week to record momentary headache intensity and also rated their headache intensities by recall. We calculated intraclass correlation coefficients between recalled headache intensity and indices from EMA recordings in the whole study population and in two subgroups divided by variability of momentary headache intensity. The results showed that consistency and agreement of momentary and recalled headache intensity were low, and this was especially marked in the subjects whose headache varied widely. These observations suggested that variability of headache intensity may affect recall of headache intensity and this should be taken into consideration in both clinical and research settings.

Kikuchi, H.; Yoshiuchi, K.; Ohashi, K.; Yamamoto, Y.; Akabayashi, A. (2007):

Tension-type headache and physical activity: an actigraphic study.

In: *Cephalalgia* 27 (11), S. 1236–1243.

Abstract:

There have been some studies on the relationship between tension-type headache (TTH) and physical activity. However, most previous studies were not prospective and assessed physical activity by questionnaire. Therefore, this study was aimed to investigate the relationship between TTH intensity and physical activity prospectively utilizing computerized ecological momentary assessment and actigraphy. Thirty-one TTH patients wore watch-type computers equipped with actigraphy inside for 1 week to record momentary headache intensity and physical activity. Multilevel modelling was used to investigate the effect of headache intensity on the simultaneous and subsequent activity level. There were significant negative associations between headache intensity and the simultaneous and subsequent activity level, and activity level was significantly reduced at headache exacerbations. These results provide objective and quantitative evidence suggesting that TTH negatively affects physical activity.

Does sleep aggravate tension-type headache?: An investigation using computerized ecological momentary assessment and actigraphy.

In: *BioPsychoSocial Medicine* 5. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-22750-001&site=ehost-live;kikuchih-tky@umin.ac.jp.

Abstract:

Background: Both insufficient sleep and oversleeping have been reported as precipitating and aggravating factors of tension-type headache (TTH). However, previous studies relied on recalled self-reports, and the relationship has not been confirmed prospectively and objectively in a daily life situation. Recently, ecological momentary assessment (EMA) using electronic diaries, i.e., computerized EMA, is used to record subjective symptoms with the advantages of avoiding recall bias and faked compliance in daily settings. In addition, actigraphy has become an established method to assess sleep outside laboratories. Therefore, the aim of this study was to investigate the within-individual effect of sleep on the following momentary headache intensity in TTH patients during their daily lives utilizing EMA and actigraphy. Methods: Twenty-seven patients with TTH wore watch-type computers as electronic diaries for seven consecutive days and recorded their momentary headache intensity using a visual analog scale of 0-100 approximately every six hours, on waking up, when going to bed, and at the time of headache exacerbations. They also recorded their self-report of sleep quality, hours of sleep and number of awakenings with the computers when they woke up. Physical activity was continuously recorded by an actigraph inside the watch-type computers. Activity data were analyzed by Cole's algorithm to obtain total sleep time, sleep efficiency, sleep latency, wake time after sleep onset and number of awakenings for each night. Multilevel modeling was used to test the effect of each subjective and objective sleep-related variable on momentary headache intensity on the following day. Results: Objectively measured total sleep time was significantly positively associated with momentary headache intensity on the following day, while self-reported sleep quality was significantly negatively associated with momentary headache intensity on the following day. Conclusions: Using computerized EMA and actigraphy, longer sleep and worse sleep quality were shown to be related to more intense headache

intensity on within-individual basis and they may be precipitating or aggravating factors of TTH. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Kim, Hyunna (2013):

Exercise rehabilitation for smartphone addiction.

In: *J Exerc Rehabil* 9 (6), S. 500–505. DOI: 10.12965/jer.130080.

Abstract:

Internet addiction after launching smartphone is becoming serious. Therefore this paper has attempted to sketch out the diverse addiction treatment and then check the feasibility of exercise rehabilitation. The reason to addict the internet or smartphone is personalized individual characters related personal psychological and emotional factors and social environmental factors around them. We have shown that 2 discernible approaches due to 2 different addiction causes: that is behavioral treatment and complementary treatment. In the behavioral treatment, cognitive behavioral approach (CBT) is representative methods for changing additive thoughts and behaviors. Motivational interviewing (MI) is also the brief approach for persons not ready to change their behavior. Mindfulness behavioral cognitive treatment (MBCT) also the adapted treatment based on CBT. There are different types following the emphatic point, mindfulness-based relapse prevention (MBRP) or mindfulness oriented recovery enhancement (MORE). It is apparent that therapeutic recreation, music therapy using drumming activity, and art therapy are useful complementary treatment. Exercise rehabilitation contained the systematic procedures and comprehensive activities compared to previous addiction treatments by contents and techniques. Exercise rehabilitation can treat both physical symptoms at first and mental problems in the next step. So more evidence-based exercise rehabilitation researches need to do, but it is highly probable that exercise rehab can apply for smartphone addiction.

Systematic comparison between ecological momentary assessment and day reconstruction method for fatigue and mood states in healthy adults.

In: *Br.J Health Psychol.* (1359-107X (Linking)). DOI: 10.1111/bjhp.12000.

Abstract:

OBJECTIVES: While both ecological momentary assessment (EMA) and the day reconstruction method (DRM) have been used to overcome recall bias, a full systematic comparison of these methods has not been conducted. This study was aimed to investigate the differences and correlations between momentary fatigue and mood states recorded by EMA and reconstructed ones recorded by simultaneous DRM in healthy adults. DESIGN: Each of two different designs (time-based and episode-based) of EMA and DRM were simultaneously conducted. METHODS: Twenty-five healthy adults recorded momentary fatigue and mood states with EMA, and then, reconstructed them with DRM. Differences between the mean and the variability of momentary and reconstructed recordings, and the correlations between them, are analysed for different EMA designs. RESULTS: No significant differences are found between the mean or the variability of EMA and DRM estimated over the monitoring period. However, correlations between EMA and DRM are low, albeit statistically significant. CONCLUSIONS: Although the overall mean and variability of EMA recordings may be accessible with DRM, detailed changes over time of momentary fatigue and mood states are not retrieved by DRM. Statement of contribution What is already known on this subject? Day reconstruction method (DRM) may be a reliable substitute strategy for the measurement of subjective symptoms instead of ecological momentary assessment (EMA). Remembering the context of daily activities with DRM is assumed to be helpful in reconstructing subjective symptoms without recall bias. What this study adds? We are not able to reconstruct our diurnal time course (i.e. detailed changes over time) of subjective symptoms (e.g. fatigue and mood states in this study) with DRM, while their approximate mean and overall variability during the study period may be accessible with DRM. Reconstructed depression by DRM could be biased when the subjects remembered whether their behaviour was active or inactive

Investigating stage-sequential growth mixture models with multiphase longitudinal data.

In: *Structural Equation Modeling* 19 (2), S. 293–319. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-13451-007&site=ehost-live;suyoung93@gmail.com.

Abstract:

This article investigates three types of stage-sequential growth mixture models in the structural equation modeling framework for the analysis of multiple-phase longitudinal data. These models can be important tools for situations in which a single-phase growth mixture model produces distorted results and can allow researchers to better understand population heterogeneity and growth over multiple phases. Through theoretical and empirical comparisons of the models, the authors discuss strategies with respect to model selection and interpreting outcomes. The unique attributes of each approach are illustrated using ecological momentary assessment data from a tobacco cessation study. Transitional discrepancy between phases as well as growth factors are examined to see whether they can give us useful information related to a distal outcome, abstinence at 6 months postquit. It is argued that these statistical models are powerful and flexible tools for the analysis of complex and detailed longitudinal data. Risk perception and public concerns of electromagnetic waves from cellular phones in Korea.

In: *Bioelectromagnetics* 35 (4), S. 235–244. DOI: 10.1002/bem.21836.

Abstract:

In this study, the difference between the risk perception of electromagnetic waves from cellular phones and the risk perception of other factors such as environment and food was analyzed. The cause of the difference in the psychological and social factors that affect the group with high risk perception of electromagnetic waves was also analyzed. A questionnaire survey on the risk perception of electromagnetic waves from cellular phones was carried out on 1001 subjects (men and women) over the age of 20. In the group with high risk perception of electromagnetic waves from cellular phones, women had higher risk perception than men. Logistic regression analysis, where the group with high risk perception of electromagnetic waves and the group with low risk perception were used as dependent variables, indicated that the risk perception of electromagnetic waves in women was 1.815 times statistically significantly higher than the risk perception of men (95% CI: 1.340-2.457). Also, high risk perception of electromagnetic waves from cellular phones was observed when the subjects considered that they had more personal knowledge (OR: 1.416, 95% CI: 1.216-1.648), that the seriousness of the risk to future generations was high (OR: 1.410, 95% CI: 1.234-1.611), and their outrage for the occurrence of accidents related to electromagnetic waves was high (OR: 1.460, 95% CI: 1.264-1.686). The results of this study need to be sufficiently considered and reflected in designing the risk communication strategies and communication methods for the preventive measures and advice on electromagnetic waves from cellular phones. Bioelectromagnetics. 35:235-244, 2014. (c) 2014 Wiley Periodicals, Inc.

Validation and reliability of a smartphone application for the international prostate symptom score questionnaire: a randomized repeated measures crossover study.

In: *J Med Internet Res* 16 (2), S. e38. DOI: 10.2196/jmir.3042.

Abstract:

BACKGROUND: Smartphone-based assessment may be a useful diagnostic and monitoring tool for patients. There have been many attempts to create a smartphone diagnostic tool for clinical use in various medical fields but few have demonstrated scientific validity. OBJECTIVE: The purpose of this study was to develop a smartphone application of the International Prostate Symptom Score (IPSS) and to demonstrate its validity and reliability. METHODS: From June 2012 to May 2013, a total of 1581 male participants (>/=40 years old), with or without lower urinary tract symptoms (LUTS), visited our urology clinic via the health improvement center at Soonchunhyang University Hospital (Republic of Korea) and were enrolled in this study. A randomized repeated measures crossover design was employed using a smartphone application of the IPSS and the conventional paper form of the IPSS. Paired t test under a hypothesis of non-inferior trial was conducted. For the reliability test, the intraclass correlation coefficient (ICC) was measured. RESULTS: The total score of the IPSS (P=.289) and each item of the IPSS (P=.157-1.000) showed no differences between the paper version and the smartphone version of the IPSS. The mild, moderate, and severe LUTS groups showed no differences between the two versions of the IPSS. A significant correlation was noted in the total group (ICC=.935, P<.001). The mild, moderate, and severe LUTS groups also showed significant correlations (ICC=.616, .549, and .548 respectively, all P<.001).There was selection bias in this study, as only participants who had smartphones could participate. CONCLUSIONS: The validity and reliability of the smartphone application version were comparable to the conventional paper version of the IPSS. The smartphone application of the IPSS could be an effective method for measuring lower urinary tract symptoms.

Kim, J.; Nakamura, T.; Kikuchi, H.; Sasaki, T.; Yamamoto, Y. (2013):

Co-variation of depressive mood and locomotor dynamics evaluated by ecological momentary assessment in healthy humans.

In: *PLoS One* 8 (9), S. e74979. DOI: 10.1371/journal.pone.0074979.

Abstract:

Computerized ecological momentary assessment (EMA) is widely accepted as a "gold standard" method for capturing momentary symptoms repeatedly experienced in daily life. Although many studies have addressed the within-individual temporal variations in momentary symptoms compared with simultaneously measured external criteria, their concurrent associations, specifically with continuous physiological measures, have not been rigorously examined. Therefore, in the present study, we first examined the variations in momentary symptoms by validating the associations among self-reported symptoms measured simultaneously (depressive mood, anxious mood, and fatigue) and then investigated covariant properties between the symptoms (especially, depressive mood) and local statistics of locomotor activity as the external objective criteria obtained continuously. Healthy subjects (N = 85) from three different populations (adolescents, undergraduates, and office workers) wore a watch-type computer device equipped with EMA software for recording the momentary symptoms experienced by the subjects. Locomotor activity data were also continuously obtained by using an actigraph built into the device. Multilevel modeling analysis confirmed convergent associations by showing positive correlations among momentary symptoms. The increased intermittency of locomotor activity, characterized by a combination of reduced activity with occasional bursts, appeared concurrently with the worsening of depressive mood. Further, this association remained statistically unchanged across groups regardless of group differences in age, lifestyle, and occupation. These results indicate that the temporal variations in the momentary symptoms are not random but reflect the underlying changes in psychophysiological variables in daily life. In addition, our findings on the concurrent changes in depressive mood and locomotor activity may contribute to the continuous estimation of changes in depressive mood and early detection of depressive disorders

Geometric Change of a Thiacalix4arene Supramolecular Gel with Volatile Gases and Its Chromogenic Detection for Rapid Analysis.

In: *Inorg Chem* 53 (6), S. 3004–3011. DOI: 10.1021/ic402804p.

Abstract:

A coordination polymer gel that is self-assembled to form a network structure between a thiacalix[4]arene derivative (L) and Co(2+) has been prepared. This gel is capable of selectively changing color in the presence of gases that yield hydrogen chloride

upon hydrolysis. The UV-vis absorption spectrum of a coordination polymer gel derived from Co(NO3)2 exhibits an absorption band at 527 nm and is colored red, indicating the formation of an octahedral Co(2+) complex. Treatment with a small amount of volatile gases containing a chlorine atom (VGCl) causes a red shift of approximately 150 nm, resulting in a new strong band with a maximum at 670 nm and a color change to blue. In addition, the red color of the filter paper coated with a Co(NO3)2 coordination polymer gel changed to blue upon exposure to VGCl, reflecting a change in the coordination geometry. Red and blue colors of single crystals of Co(2+) complexes were obtained from a basic solution. From X-ray crystallographic analysis, the red Co(2+) complex corresponds to an octahedral structure, while the blue Co(2+) complex reflects the presence of a tetrahedral structure. Thus, the induced color change of Co(2+) gel from red to blue upon exposure to VGCl is due to the coordination geometry. The quantitative concentration of VGCl was calculated by employing the RGB histogram available in a smartphone application.

Kim, Junghoon; Tanabe, Kai; Yokoyama, Noriko; Zempo, Hirofumi; Kuno, Shinya (2013):

Objectively measured light-intensity lifestyle activity and sedentary time are independently associated with metabolic syndrome: A cross-sectional study of Japanese adults.

In: *Int J Behav Nutr Phys Act* 10. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-11681-001%26site%3dehost-live;kuno@taiiku.tsukuba.ac.jp.

Abstract:

Background: Reducing sedentary time and increasing lifestyle activities, including light-intensity activity, may be an option to help prevent metabolic syndrome (MetS). The purpose of the present study was to examine whether objectively measured light-intensity lifestyle activity and sedentary time is associated with MetS, independent of moderate–vigorous intensity physical activity (MVPA). Methods: The participants in this cross-sectional study were 483 middle-aged Japanese adults, aged 30–64 years. The participants were divided into those with or without MetS according to the Japanese criteria for MetS. A triaxial accelerometer was used to measure light-intensity lifestyle activity [1.6–2.9 metabolic equivalents (METs)] and sedentary time (≤1.5 METs). Logistic regression was used to predict MetS from the levels of light-intensity lifestyle activity and sedentary time with age, sex, smoking, calorie intake, accelerometer wear time, and MVPA as covariates. Results: The odds ratios (OR) for MetS in the highest and middle tertiles of light-intensity lifestyle activity were 0.44 [95% confidence interval (CI): 0.24 to 0.81] and 0.51 (95% CI: 0.29 to 0.89) relative to the lowest tertile, after adjustment for age, sex, smoking, calorie intake, accelerometer wear time and MVPA (P[sub]trend[/sub] = 0.012). Sedentary time was also associated with the risk of MetS (P[sub]trend[/sub] = 0.018). Among participants in the highest tertile of sedentary time, the risk of MetS was 2.27-times greater than that in the lowest tertile (95% CI: 1.25 to 4.11). The risk of MetS was not significantly increased in subjects in the middle tertile of sedentary time. Conclusions: We found that light-intensity lifestyle activity and sedentary time were significantly associated with the risk of MetS, independent of MVPA. The results of our study suggest that public health messages and guidelines should be refined to include increases in light-intensity lifestyle activity and/or decreases in sedentary time, alongside promoting MVPA, to prevent MetS. Kimhy, David; Delespaul, Philippe; Corcoran, Cheryl; Ahn, Hongshik; Yale, Scott; Malaspina, Dolores (2006):

Computerized experience sampling method (ESMc): assessing feasibility and validity among individuals with schizophrenia.

In: *Journal of Psychiatric Research* 40 (3), S. 221–230. DOI: 10.1016/j.jpsychires.2005.09.007.

Abstract:

The Experience Sampling Method (ESM) is an ecologically valid, time-sampling of self-reports developed to study the dynamic process of person-environment interactions. ESM with digital wristwatch and booklets (paper-based ESM; ESMp) has been used extensively to study schizophrenia. The present study is designed to test the feasibility and validity of using Computerized ESM (ESMc) among individuals with schizophrenia. ESMc is advantageous in allowing for recording of precise time-stamps of responses. We used PDAs (\"Personal Digital Assistant\"; Palm handheld computers) to collect data on momentary psychotic symptoms, mood, and thoughts over a one day period among 10 hospitalized schizophrenia patients and 10 healthy controls. ESMc was equally acceptable to both groups, with similar ratings of comfort carrying the PDAs and operating them, interference with daily activities, as well as response rates. The schizophrenia patients reported significantly higher ratings of auditory and visual hallucinations, suspiciousness, sense of unreality, lack of thought control, fear of losing control, difficulty expressing thoughts, as well as depression/sadness, loneliness and less cheerfulness. Significant inverse relationships were found among both groups between ratings of feeling cheerful and being stressed, irritated, and sad/depressed. Among the schizophrenia subjects, the correlation between ratings of suspiciousness on ESMc and Scale for Assessment of Positive Symptoms (SAPS)

approached significance, as well as the link between suspiciousness and stress. Our results support the feasibility and validity of using ESMc for assessment of momentary psychotic symptoms, mood, and experiences among individuals with schizophrenia. The authors discuss the potential applications of combining ESMc with ambulatory physiological measures.

Kimhy, David; Delespaul, Philippe; Ahn, Hongshik; Cai, Shengnan; Shikhman, Marina; Lieberman, Jeffrey A. et al. (2010):

Concurrent measurement of \"real-world\" stress and arousal in individuals with psychosis: assessing the feasibility and validity of a novel methodology.

In: *Schizophrenia Bulletin* 36 (6), S. 1131–1139. DOI: 10.1093/schbul/sbp028.

Abstract:

BACKGROUND\r\nPsychosis has been repeatedly suggested to be affected by increases in stress and arousal. However, there is a dearth of evidence supporting the temporal link between stress, arousal, and psychosis during \"real-world\" functioning. This paucity of evidence may stem from limitations of current research methodologies. Our aim is to the test the feasibility and validity of a novel methodology designed to measure concurrent stress and arousal in individuals with psychosis during \"real-world\" daily functioning.\r\nMETHOD\r\nTwenty patients with psychosis completed a 36-hour ambulatory assessment of stress and arousal. We used experience sampling method with palm computers to assess stress (10 times per day, 10 AM → 10 PM) along with concurrent ambulatory measurement of cardiac autonomic regulation using a Holter monitor. The clocks of the palm computer and Holter monitor were synchronized, allowing the temporal linking of the stress and arousal data. We used power spectral analysis to determine the parasympathetic contributions to autonomic regulation and sympathovagal balance during 5 minutes before and after each experience sample.\r\nRESULTS\r\nPatients completed 79% of the experience samples (75% with a valid concurrent arousal data). Momentary increases in stress had inverse correlation with concurrent parasympathetic activity (ρ = -.27, P < .0001) and positive correlation with sympathovagal balance (ρ = .19, P = .0008). Stress and heart rate were not significantly related (ρ = -.05, P = .3875).\r\nCONCLUSION\r\nThe findings support the feasibility and validity of our methodology in individuals with psychosis. The methodology offers a novel way to study in high time resolution the concurrent, \"real-world\" interactions between stress, arousal, and psychosis. The authors discuss the methodology's potential applications and future research directions.

Kimhy, David; Myin-Germeys, Inez; Palmier-Claus, Jasper; Swendsen, Joel (2012):

Mobile assessment guide for research in schizophrenia and severe mental disorders.

In: *Schizophrenia Bulletin* 38 (3), S. 386–395. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-15724-007&site=ehost-live;Joel.Swendsen@u-bordeaux2.fr.

Abstract:

Mobile assessment techniques have been used for nearly 3 decades in mental health research, including in investigations of individuals with schizophrenia and other severe disorders. This article reviews the benefits of these data collection strategies relative to traditional self-report or clinician-administered measures administered in hospital or laboratory settings. A detailed discussion of the technical decisions facing researchers in the field is then presented, covering study design issues, questionnaire content development, and choices in hardware and software selection. Following these points, sample recruitment and retention strategies are discussed, as well as the main statistical issues that are necessary to consider in the exploitation of repeated measures data generated by this methodology. Kimhy, David; Vakhrusheva, Julia; Khan, Samira; Chang, Rachel W.; Hansen, Marie C.; Ballon, Jacob S. et al. (2014):

Emotional granularity and social functioning in individuals with schizophrenia: An experience sampling study.

In: *Journal of Psychiatric Research* 53, S. 141–148. DOI: 10.1037/t15180-000;

Abstract:

Previous research has shown that healthy individuals who fail to differentiate among emotional states (i.e., those with low emotional granularity; EG) have poorer social functioning (SF) than those with high EG. It is unknown, however, whether these associations extend to clinical disorders characterized by impaired SF, such as schizophrenia. In the present study, we compared SF and EG in individuals with schizophrenia and healthy controls, and then, within the schizophrenia group, we examined the

links between EG and SF. Employing an Experience Sampling Method approach, 77 individuals with schizophrenia and 27 healthy controls rated their momentary emotions (sadness, anxiety, anger, and happiness) up to 10 times/day over a two-day period using mobile electronic devices. For each participant, we then calculated the within-subject average correlations among the momentary emotion ratings, producing two EG indices—EGIall for all emotions and EGIneg for negative ones. A subsample of participants with schizophrenia also completed self-report, interview, and ability-based measures of SF. Compared to healthy controls, individuals with schizophrenia displayed significantly poorer SF and lower EGIall, but comparable EGIneg. Within the schizophrenia group, hierarchical multiple regression analyses indicated that EGIall, but not EGIneg, significantly predicted social dysfunction after controlling for emotional awareness, symptoms, and emotional intensity and variability. Our findings indicate that individuals with schizophrenia have a relatively intact ability to differentiate among negative emotions in everyday life. However, they experience significant difficulties differentiating between positive and negative emotions, and this may contribute to their social difficulties. Use of mobile assessment technologies in inpatient psychiatric settings.

In: *Asian J Psychiatr* 10, S. 90–95. DOI: 10.1016/j.ajp.2014.04.004.

Abstract:

Mobile electronic devices (i.e., PDAs, cellphones) have been used successfully as part of research studies of individuals with severe mental illness living in the community. More recently, efforts have been made to incorporate such technologies into outpatient treatments. However, few attempts have been made to date to employ such mobile devices among hospitalized psychiatric patients. In this article, we evaluate the potential use of such devices in inpatient psychiatric settings using 33 hospitalized patients with schizophrenia. Employing an Experience Sampling Method approach, we provide support for the feasibility of using such devices, along with examples of potentially clinically-relevant information that can be obtained using such technologies, including assessment of fluctuations in the severity of psychotic symptoms and negative mood in relation to social context, unit location, and time of day. Following these examples, we discuss issues related to the potential use of mobile electronic devices by patients hospitalized at inpatient psychiatric settings including issues related to patients' compliance, assessment schedules, questionnaire development, confidentiality issues, as well as selection of appropriate software/hardware. Finally, we delineate some issues and areas of inquiry requiring additional research and development.

Promoting physical activity through hand-held computer technology.

In: *Am J Prev Med* 34 (2), S. 138–142.

Abstract:

BACKGROUND:

Efforts to achieve population-wide increases in walking and similar moderate-intensity physical activities potentially can be enhanced through relevant applications of state-of-the-art interactive communication technologies. Yet few systematic efforts to evaluate the efficacy of hand-held computers and similar devices for enhancing physical activity levels have occurred. The purpose of this first-generation study was to evaluate the efficacy of a hand-held computer (i.e., personal digital assistant [PDA]) for increasing moderate intensity or more vigorous (MOD+) physical activity levels over 8 weeks in mid-life and older adults relative to a standard information control arm.

DESIGN:

Randomized, controlled 8-week experiment. Data were collected in 2005 and analyzed in 2006-2007.

SETTING/PARTICIPANTS:

Community-based study of 37 healthy, initially underactive adults aged 50 years and older who were randomized and completed the 8-week study (intervention=19, control=18).

INTERVENTION:

Participants received an instructional session and a PDA programmed to monitor their physical activity levels twice per day and provide daily and weekly individualized feedback, goal setting, and support. Controls received standard, age-appropriate written physical activity educational materials.

MAIN OUTCOME MEASURE:

Physical activity was assessed via the Community Healthy Activities Model Program for Seniors (CHAMPS) questionnaire at baseline and 8 weeks.

RESULTS:

Relative to controls, intervention participants reported significantly greater 8-week mean estimated caloric expenditure levels and minutes per week in MOD+ activity ($p<0.04$). Satisfaction with the PDA was reasonably high in this largely PDA-naive sample.

CONCLUSIONS:

Results from this first-generation study indicate that hand-held computers may be effective tools for increasing initial physical activity levels among underactive adults.

Exercise Advice by Humans Versus Computers: Maintenance Effects at 18 Months.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0030646.

Abstract:

Objective: An automated telehealth counseling system, aimed at inactive midlife and older adults, was shown previously to achieve 12-month physical activity levels similar to those attained by human advisors. This investigation evaluated the sustained 18-month impacts of the automated advisor compared with human advisors. Methods: Following the end of the 12-month randomized, controlled trial, participants who had been randomized to either the human advisor (n = 73) or automated advisor (n = 75) arms were followed for an additional 6 months. During that period, human or automated advisor-initiated telephone contacts ceased and participants were encouraged to initiate contact with their advisor as deemed relevant. The primary outcome was moderate-to-vigorous physical activity (MVPA), measured using the Stanford Physical Activity Recall and validated during the major trial via accelerometry. Results: The two arms did not differ significantly in 18-month MVPA or the percentage of participants meeting national physical activity guidelines (ps >.50). No significant within-arm MVPA differences emerged between 12 and 18 months. Evaluation of the trajectory of physical activity change across the 18-month study period indicated that, for both arms, the greatest physical activity increases occurred during the first 6 months of intervention, followed by a relatively steady amount of physical activity across the remaining months. Conclusions: The results provide evidence that an automated telehealth advice system can maintain physical activity increases at a level similar to that achieved by human advisors through 18 months. Given the accelerated use of mobile phones in developing countries, as well as industrialized nations, automated telehealth systems merit further evaluation. Predictors of identity management: An exploratory experience-sampling study of lesbian, gay, and bisexual workers.

In: *Journal of Management*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-26939-001%26site%3dehost-live.

Abstract:

This study examined workplace interactions in which lesbian, gay, and bisexual (LGB) workers faced decisions related to revealing or concealing their LGB identities at work (i.e., identity management situations). Participants were 61 LGB adults who completed a baseline survey about their organization and, over 3 weeks, responded to event-based surveys immediately after identity management situations. Results suggested that LGB workers manage their stigmatized identity strategically according to situational characteristics. Indeed, much of the variance in use of revealing and concealing strategies was due to differences within people from situation to situation. Use of identity management strategies was predicted by interaction partner cues of acceptance or rejection as well as perception of LGB-related organizational climate and policies. Results at the within-person and between-person levels diverged in noteworthy ways. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Kirby, Tony; Thornber-Dunwell, Michelle (2014):

Phone apps could help promote sexual health in MSM.

In: *The Lancet* 384 (9952), S. 1415. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-44639-011%26site%3dehost-live.

Abstract:

This article focuses on promoting sexual health in men who have sex with men (MSM) through phone apps. Since the advent of smartphone technology, people worldwide of all sexualities have been using various downloadable apps to help them meet people for dates, casual sex, and in some cases, group sex. For many (but by no means all) men who have sex with men (MSM), smartphone apps such as Grindr, Hornet, FindFred, Growlr, Scruff , and many others have become part of daily life. These MSM will look at a list of other men in their area, start up a conversation, and can ultimately end up engaging in casual sex. Some of the MSM using apps to meet partners are also using a range of recreational drugs during these sexual encounters. Thus, experts say, it is vital that apps off er links for users to fi nd drug counseling and support as well as promoting good sexual health. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

The exposure assessment in current time study: implementation, feasibility, and acceptability of real-time data collection in a community cohort of illicit drug users.

In: *AIDS Res.Treat.* 2013 (2090-1240 (Linking)), S. 594671. DOI: 10.1155/2013/594671.

Abstract:

Objective. We describe the study design and evaluate the implementation, feasibility, and acceptability of an ecological momentary assessment (EMA) study of illicit drug users. Design. Four sequential field trials targeting observation of 30 individuals followed for a four week period. Participants. Participants were recruited from an ongoing community-cohort of current or former injection drug users. Of 113 individuals enrolled, 109 completed study procedures during four trials conducted from November 2008 to May 2013. Methods. Hand-held electronic diaries used in the initial trials were transitioned to a smartphone platform for the final trial with identical data collection. Random-prompts delivered five times daily assessed participant location, activity, mood, and social context. Event-contingent data collection involved participant self-reports of illicit drug use and craving. Main Outcome Measures. Feasibility measures included participant retention, days of followup, random-prompt response rates, and device loss rate. Acceptability was evaluated from an end-of-trial questionnaire. Sociodemographic, behavioral, clinical, and trial characteristics were evaluated as correlates of weekly random-prompt response rates >/=80% using logistic regression with generalized estimating equations. Results. Study participants were a median of 48.5 years old, 90% African American, 52% male, and 59% HIV-infected with limited income and educational attainment. During a median followup of 28 days, 78% of 11,181 random-prompts delivered were answered (mean of 2.8 responses daily), while 2,798 participant-initiated events were reported (30% drug use events; 70% craving events). Self-reported acceptability to study procedures was uniformly favorable. Device loss was rare (only 1 lost device every 190 person-days of observation). Higher educational attainment was consistently associated with a higher response rate to random-prompts, while an association of HIV infection with lower response rates was not observed after accounting for differences in trial recruitment procedures. Conclusion. Near real-time EMA data collection in the field is feasible and acceptable among community-dwelling illicit drug users. These data provide the basis for future studies of EMA-informed interventions to prevent drug relapse and improve HIV treatment outcomes in this population

Kirwan, Morwenna; Duncan, Mitch J.; Vandelanotte, Corneel; Mummery, W. Kerry (2012):

Using smartphone technology to monitor physical activity in the 10,000 steps program: A matched case-control trial.

In: *J Med Internet Res* 14 (2), S. 176–185. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32352-014%26site%3dehost-live;m.kirwan@cqu.edu.au.

Abstract:

Background: Website-delivered physical activity interventions are successful in producing short-term behavior change. However, problems with engagement and retention of participants in these programs prevent long-term behavior change. New ways of accessing online content (eg, via smartphones) may enhance engagement in these interventions, which in turn may improve the effectiveness of the programs. Objective: To measure the potential of a newly developed smartphone application to improve

health behaviors in existing members of a website-delivered physical activity program (10,000 Steps, Australia). The aims of the study were to (1) examine the effect of the smartphone application on self-monitoring and self-reported physical activity levels, (2) measure the perceived usefulness and usability of the application, and (3) examine the relationship between the perceived usefulness and usability of the application and its actual use. Methods: All participants were existing members of the 10,000 Steps program. We recruited the intervention group (n = 50) via email and instructed them to install the application on their smartphone and use it for 3 months. Participants in this group were able to log their steps by using either the smartphone application or the 10,000 Steps website. Following the study, the intervention group completed an online questionnaire assessing perceived usability and usefulness of the smartphone application. We selected control group participants (n = 150), matched for age, gender, level of self-monitoring, preintervention physical activity level, and length of membership in the 10,000 Steps program, after the intervention was completed. We collected website and smartphone usage statistics during the entire intervention period. Results: Over the study period (90 days), the intervention group logged steps on an average of 62 days, compared with 41 days in the matched group. Intervention participants used the application 71.22% (2210/3103) of the time to log their steps. Logistic regression analyses revealed that use of the application was associated with an increased likelihood to log steps daily during the intervention period compared with those not using the application (odds ratio 3.56, 95% confidence interval 1.72–7.39). Additionally, use of the application was associated with an increased likelihood to log greater than 10,000 steps on each entry (odds ratio 20.64, 95% confidence interval 9.19–46.39). Linear regression analysis revealed a nonsignificant relationship between perceived usability (r = .216, P = .21) and usefulness (r = .229, P = .17) of the application and frequency of logging steps in the intervention group. Conclusion: Using a smartphone application as an additional delivery method to a website-delivered physical activity intervention may assist in maintaining participant engagement and behavior change. However, due to study design limitations, these outcomes should be interpreted with caution. More research, using larger samples and longer follow-up periods, is needed to replicate the findings of this study. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Design, development, and formative evaluation of a smartphone application for recording and monitoring physical activity levels: The 10,000 steps “iStepLog”.

In: *Health Education & Behavior* 40 (2), S. 140–151. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-12138-005%26site%3dehost-live;m.kirwan@uws.edu.au.

Abstract:

Objectives: Limited research exists addressing the development of health-related smartphone apps, a new and potentially effective health promotion delivery strategy. This article describes the development and formative evaluation of a smartphone app associated with a physical activity promotion website. Methods: A combination of qualitative and quantitative techniques (performance measures, direct observation, and subjective participant preferences) were implemented during two usability testing sessions (pre- and postmodification) while participants were completing tasks using the app. Results: Design improvements to the app resulted in a reduction in the problems experienced and a decrease in the time taken to complete tasks. Four usability themes emerged from the data: design, feedback, navigation, and terminology. Conclusion: This study demonstrates the relevance of usability testing to the design and modification of a smartphone app related to a health promotion website. This study resulted in an app with much higher usability, which might increase usage and maintenance of health behavior change in the long term. Practical implications: This study demonstrates the need for formative evaluation in health-related smartphone apps. Attention should be given to basic design principles as well as feedback, navigation, and terminology in order to ensure utility and ease of use of future smartphone app designs. Kirwan, M.; Vandelanotte, C.; Fenning, A.; Duncan, M. J. (2013):

Diabetes self-management smartphone application for adults with type 1 diabetes: randomized controlled trial.

In: *J.Med.Internet.Res.* 15 (11), S. e235. DOI: 10.2196/jmir.2588.

Abstract:

BACKGROUND: Persistently poor glycemic control in adult type 1 diabetes patients is a common, complex, and serious problem initiating significant damage to the cardiovascular, renal, neural, and visual systems. Currently, there is a plethora of low-cost and free diabetes self-management smartphone applications available in online stores. OBJECTIVE: The aim of this study was to examine the effectiveness of a freely available smartphone application combined with text-message feedback from a certified diabetes educator to improve glycemic control and other diabetes-related outcomes in adult patients with type 1 diabetes in a

two-group randomized controlled trial. METHODS: Patients were recruited through an online type 1 diabetes support group and letters mailed to adults with type 1 diabetes throughout Australia. In a 6-month intervention, followed by a three-month follow-up, patients (n=72) were randomized to usual care (control group) or usual care and the use of a smartphone application (Glucose Buddy) with weekly text-message feedback from a Certified Diabetes Educator (intervention group). All outcome measures were collected at baseline and every three months over the study period. Patients' glycosylated hemoglobin levels (HbA1c) were measured with a blood test and diabetes-related self-efficacy, self-care activities, and quality of life were measured with online questionnaires. RESULTS: The mean age of patients was 35.20 years (SD 10.43) (28 male, 44 female), 39% (28/72) were male, and patients had been diagnosed with type 1 diabetes for a mean of 18.94 years (SD 9.66). Of the initial 72 patients, 53 completed the study (25 intervention, 28 control group). The intervention group significantly improved glycemic control (HbA1c) from baseline (mean 9.08%, SD 1.18) to 9-month follow-up (mean 7.80%, SD 0.75), compared to the control group (baseline: mean 8.47%, SD 0.86, follow-up: mean 8.58%, SD 1.16). No significant change over time was found in either group in relation to self-efficacy, self-care activities, and quality of life. CONCLUSIONS: In adjunct to usual care, the use of a diabetes-related smartphone application combined with weekly text-message support from a health care professional can significantly improve glycemic control in adults with type 1 diabetes. Distracted driving and risk of road crashes among novice and experienced drivers.

In: *N Engl J Med* 370 (1), S. 54–59. DOI: 10.1056/NEJMsa1204142.

Abstract:

BACKGROUND: Distracted driving attributable to the performance of secondary tasks is a major cause of motor vehicle crashes both among teenagers who are novice drivers and among adults who are experienced drivers. METHODS: We conducted two studies on the relationship between the performance of secondary tasks, including cell-phone use, and the risk of crashes and near-crashes. To facilitate objective assessment, accelerometers, cameras, global positioning systems, and other sensors were installed in the vehicles of 42 newly licensed drivers (16.3 to 17.0 years of age) and 109 adults with more driving experience. RESULTS: During the study periods, 167 crashes and near-crashes among novice drivers and 518 crashes and near-crashes among experienced drivers were identified. The risk of a crash or near-crash among novice drivers increased significantly if they were dialing a cell phone (odds ratio, 8.32; 95% confidence interval [CI], 2.83 to 24.42), reaching for a cell phone (odds ratio, 7.05; 95% CI, 2.64 to 18.83), sending or receiving text messages (odds ratio, 3.87; 95% CI, 1.62 to 9.25), reaching for an object other than a cell phone (odds ratio, 8.00; 95% CI, 3.67 to 17.50), looking at a roadside object (odds ratio, 3.90; 95% CI, 1.72 to 8.81), or eating (odds ratio, 2.99; 95% CI, 1.30 to 6.91). Among experienced drivers, dialing a cell phone was associated with a significantly increased risk of a crash or near-crash (odds ratio, 2.49; 95% CI, 1.38 to 4.54); the risk associated with texting or accessing the Internet was not assessed in this population. The prevalence of high-risk attention to secondary tasks increased over time among novice drivers but not among experienced drivers. CONCLUSIONS: The risk of a crash or near-crash among novice drivers increased with the performance of many secondary tasks, including texting and dialing cell phones. Capturing intrusive re-experiencing in trauma survivors' daily lives using ecological momentary assessment.

In: *J.Abnorm.Psychol.* 122 (4), S. 998–1009. DOI: 10.1037/a0034957.

Abstract:

Intrusive memories are common following traumatic events and among the hallmark symptoms of posttraumatic stress disorder (PTSD). Most studies assess summarized accounts of intrusions retrospectively. We used an ecological momentary approach and index intrusive memories in trauma survivors with and without PTSD using electronic diaries. Forty-six trauma survivors completed daily diaries for 7 consecutive days recording a total of 294 intrusions. Participants with PTSD experienced only marginally more intrusions than those without PTSD, but experienced them with more "here and now quality," and responded with more fear, helplessness, anger, and shame than those without PTSD. Most frequent intrusion triggers were stimuli that were perceptually similar to stimuli from the trauma. Individuals with PTSD experienced diary-prompted voluntary trauma memories with the same sense of nowness and vividness as involuntary intrusive trauma memories. The findings contribute to a better understanding of everyday experiences of intrusive reexperiencing in trauma survivors with PTSD and offer clinical treatment implications. Ambulatory assessment in industrial/organizational psychology: Fruitful examples and methodological issues.

In: *European Psychologist* 14 (2), S. 120–131.

Abstract:

In this review, we demonstrate the contribution of ambulatory assessment (AA) research to I/O psychology by reference to four dynamic phenomena, the investigation of which we judge to benefit most from the application of AA techniques: (a) work strain and coping with work stressors, (b) the work/nonwork interface, (c) social interactions at the workplace, and (d) job attitudes and work-related emotions. As we see it, the greatest potential of these studies lies in the analysis of how interindividual differences modulate intraindividual processes. After demonstrating the value of the method, we outline and discuss ways of tackling a number of methodological issues raised in the studies reviewed: selective participation and attrition, altered reporting behavior and reactivity, noncompliance with study instructions, low acceptance, and development of reduced scales or single-item measures. Future studies can pave the way for the broad acceptance and utilization of AA methods by contributing to the resolution of these issues.

Division of Labor in German Dual-Earner Families: Testing Equity Theoretical Hypotheses.

In: *J Marriage and Family* 68 (4), S. 870–882. DOI: 10.1111/j.1741-3737.2006.00301.x.

Abstract:

On the basis of 52 German dual-earner couples with at least 1 child younger than 5 years, we tested the effects of an unequal division of labor on relationship satisfaction. We analyzed diary reports of time allocated to productive activities according to the actor-partner-interdependence model. Hierarchical linear models showed that rather than individual time allocated to household work, the absolute difference in partners' contribution to productive activities influenced relationship satisfaction. This reduction in satisfaction disappeared after accounting for perceived social appreciation of individual contributions. Models with gender-specific slopes showed the effect of input and output to be different for women and men. The findings indicate that a relative equity model best explains the effects of an unequal division of labor.

Work hours affect spouse's cortisol secretion--for better and for worse.

In: *Psychosomatic Medicine* 68 (5), S. 742–746. DOI: 10.1097/01.psy.0000233231.55482.ff.

Abstract:

OBJECTIVE\r\nIn a sample of 52 German dual-earner couples with at least one child under age 5, we examined the bodily costs and benefits of the amount of time each spouse spent on productive activities.\r\nMETHODS\r\nDiary reports of time allocated to formal and informal work activities were analyzed according to the Actor-Partner Interdependence model.\r\nRESULTS\r\nHierarchical linear models showed that each hour an individual allocated to market, as well as household work, increased his or her total cortisol concentration (by 192 and 134 nmol/l, respectively). Unexpectedly, the time the spouse allocated to paid work also raised an individual's total cortisol concentration (by 64 nmol/l). In line with our expectations, there was a tendency for the time the spouse allocated to household work to decrease the individual's cortisol concentration (by 81 nmol/l).\r\nCONCLUSIONS\r\nThis study contributes to the body of evidence on the complex nature of social relationships and complements the literature on specific working conditions and couples' well-being.

Electromagnetic field measurements using personal exposimeters.

In: *Bioelectromagnetics* 29 (2), S. 160–162.

Abstract:

The goal of this brief communication is to call the attention of researchers to possible pit falls when using personal exposimeters (PEM) in epidemiological field studies. One example of problematic handling of PEMs is presented in detail, whereas other possible error sources and other aspects to be considered using such devices are outlined only briefly.

Knatz, Stephanie (2013):

Ecological momentary assessment of shame trends and subtypes throughout the binge-purge cycle.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (9-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99060-374%26site%3dehost-live.

Abstract:

Despite extensive research documenting the role of negative affect in bulimic behaviors, little is known about the specific role that shame plays in relation to these behaviors. The present study examined temporal patterns of shame related to characterological and behavioral features over the course of a binge-purge episode. Thirty women with bulimic symptoms provided momentary self-reports of shame and other negative affect levels during a binge-purge episode. A multi-level factor analysis revealed three distinct subtypes of shame emerging on a momentary basis—shame about the body, and self-judgment (internal shame) and perceived judgment by others (external shame) about engaging in bulimic behaviors. Repeated measures ANOVA was used to identify changes in shame over the course of a bulimic episode. Analysis revealed changes in shame levels throughout a binge-purge episode and distinctive temporal trends for shame subtypes. These findings support the notion that shame is intimately tied to bulimic behaviors and that levels of shame vary depending on the feature or event to which they are tied. Kneipp, Shawn M.; Welch, Dinah P.; Wood, Charles E.; Yucha, Carolyn B.; Yarandi, Hossein (2007):

Psychosocial and physiological stress among women leaving welfare.

In: *Western Journal of Nursing Research*.

Abstract:

Women receiving Temporary Assistance for Needy Families (TANF) report more stress and have poorer health than women in the general population. Studies suggest chronic stress may contribute to poor health via physiological mechanisms, yet little is known about these mechanisms in this population. This study examined psychosocial stress, salivary cortisol, 24-hr ambulatory blood pressure and heart rate, and health among 40 single mothers before and after exiting TANF. As a group, perceived stress decreased after leaving TANF (p = .02), with other measures of psychosocial and physiological stress remaining unchanged. Within participants, changes in psychosocial stress predicted depression and general health over time (adjusted R(2) = .30 and .22; p = .006 and .004, respectively). These findings indicate psychosocial stress is positively associated with depression and

negatively associated with general health as women exit welfare. Psychosocial stress was not associated with changes in physiologic indicators of stress.

Knestel, Andrea (2011):

Religious orientation and naturally occurring stress: Ecological momentary assessment of cardiovascular function.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (2-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-99160-012&site=ehost-live.

Abstract:

Research suggests that religious orientation may impact cardiovascular stress response. Historically, the concept of religious orientation focused on intrinsic and extrinsic religiousness as has research investigating the relationship between religious orientation and cardiovascular stress response. These findings indicate that older intrinsically religious adults demonstrate reduced blood pressure and heart rate reactivity to interpersonal laboratory stressors as compared to older extrinsically religious individuals. A more recent study found that pro-religious adults showed decreased cardiovascular reactivity to laboratory stressors as compared to adults with an intrinsic or non-religious orientation. Although these findings provide valuable information about the religion-health relationship, the study of religious orientation and cardiovascular stress response is still in its early stages. For example, the relationship between religious orientation and cardiovascular response to naturally occurring daily stressors has not been studied. Consequently, this study: (1) explored the relationship between religious orientation and the rate of occurrence of overall stress, interpersonal stress, and non-interpersonal stress, and (2) tested the hypothesis that individuals with a pro-religious orientation would display reduced cardiovascular response to naturally occurring interpersonal stressors as compared to the intrinsic and non-religious groups. Hypotheses were tested using a community sample (n=83) of middle-aged to older adults (40–65 years) with measures of religious orientation, stress, and 24-hour ambulatory blood pressure (ABP) and ambulatory heart rate (AHR). Findings from this study did not reveal statistically significant relationships between religious orientation and cardiovascular response to naturally occurring stress. Visual inspection of these non-significant results does show, however, that the pro-religious group experienced fewer stressors, specifically interpersonal stressors, over the course of a 24-hour period. Surprisingly, the pro-religious group also demonstrated considerable decreases in SBP, DBP, and HR responses to those stressors that they had identified as being the strongest in intensity as compared to the no stress (for SBP and HR), some stress (for SBP, DBP, and HR), and moderate stress (for SBP, DBP, and HR) categories. The intrinsic group showed the largest increases in cardiovascular response to the stressors they identified as being very strong. These observations suggest that religious orientation may be an important variable to consider when examining middle-aged and older adults? cardiovascular responding to stressors in naturalistic environments, particularly, interpersonal stressors. Knols, Ruud H.; Bruin, Eling D.; Aufdemkampe, Geert; Uebelhart, Daniel; Aaronson, Neil K. (2009):

Reliability of ambulatory walking activity in patients with hematologic malignancies.

In: *Arch Phys Med Rehabil* 90 (1), S. 58–65. DOI: 10.1016/j.apmr.2008.06.020.

Abstract:

OBJECTIVES\r\nTo determine the relative and absolute reliability of the assessment of ambulatory walking activity during 2 consecutive weeks in patients with hematologic malignancies recovering at home from their medical treatment and to compare the physical activity level of hematologic cancer patients after high-dose chemotherapy with healthy subjects.\r\nDESIGN\r\nTest-retest study of 2 consecutive 7-day recordings using the microprocessor-based step accelerometer 3 (SAM3).\r\nSETTING\r\nHome and community.\r\nPARTICIPANTS\r\nPatients (n=23) with hematologic malignancies recovering from high-dose chemotherapy and healthy controls (n=30).\r\nINTERVENTIONS\r\nNot applicable.\r\nMAIN OUTCOME MEASURES\r\nThe intraclass correlation coefficient (ICC(3,1)) and its 95% confidence interval (CI), SE of measurement procedure and its 95% CI, the smallest detectable difference (SDD), the coefficient of variation (CV), and t tests for the variables total steps and peak activity.\r\nRESULTS\r\nThe day-to-day and week-to-week CVs for walking activity and peak activity were 35.17% and 13.17% and 18.61% and 6.90%, respectively. For relative reliability, the ICCs for 2 consecutive 7-day recordings including the 95% CI for total steps and peak activity were 0.90 (95% CI, 0.75-0.98) and 0.85 (95% CI, 0.66-0.94), respectively. The absolute reliability for total steps and peak activity including the SE of measurement procedure and the 95% CI were 564 (95% CI, +/-1106) and 2.42 steps (95% CI, +/-4.74), respectively, for 2 consecutive 7-day recordings. The week-to-week SDD was 1564 for total steps and 6.70 for peak activity. The 7-day mean for total step activity was 5355 for the patients with hematologic malignancies and 6364 for healthy subjects (P<0.05).\r\nCONCLUSIONS\r\nThe results of this study indicate that there is good relative reliability for the assessment of 2 consecutive 7-day recordings of ambulatory walking activity, and it showed that the SDD derived from this sample may be useful in detecting changes in daily walking activity in hematologic cancer patients who

are recovering from intensive medical treatment. The study also documented compromised levels of ambulatory walking activity among hematologic cancer patients recovering from high-dose chemotherapy as compared with healthy controls.

The expression of adult ADHD symptoms in daily life: an application of experience sampling methodology.

In: *J Atten Disord* 11 (6), S. 652–663. DOI: 10.1177/1087054707299411.

Abstract:

OBJECTIVE\r\nTo use experience sampling method (ESM) to examine the impact of inattentive and hyperactive-impulsive ADHD symptoms on emotional well-being, activities and distress, cognitive impairment, and social functioning assessed in the daily lives of young adults. The impact of subjective appraisals on their experiences is also examined.\r\nMETHOD\r\nParticipants (n = 206) complete up to 56 in-the-moment assessments of mood and current activities using Personal Digital Assistants for 1 week.\r\nRESULTS\r\nMultilevel modeling techniques reveal that ADHD inattentive and hyperactive-impulsive symptoms differentially relate to daily experiences. Higher inattentive symptoms are associated with indices of general distress, including less positive and more negative mood as well as more concentration problems. Higher hyperactive-impulsive symptoms are associated with reduced sensitivity to contextual factors in perceptions of situations.\r\nCONCLUSION\r\nThese findings demonstrate predictive validity for adult self-report of ADHD symptoms in a general population sample and suggest future research directions using ESM.

Köblitz, Amber R.; Magnan, Renee E.; McCaul, Kevin D.; O'Neill, H. Katherine; Crosby, Ross; Dillard, Amanda J. (2009):

Smokers' thoughts and worries: a study using ecological momentary assessment.

In: *Health Psychol* 28 (4), S. 484–492. DOI: 10.1037/a0014779.

Abstract:

OBJECTIVE\r\nThe purpose of this study was to investigate smokers' thoughts and worries about their smoking behavior. Researchers have sometimes asked smokers to make such self-assessments but typically using retrospective summary judgments.\r\nDESIGN\r\nUsing ecological momentary assessment, community and student smokers reported five times daily during two separate 1-week intervals.\r\nMAIN OUTCOME MEASURES\r\nSmokers reported their thoughts about smoking, worries about smoking, and level of contemplation to quit smoking.\r\nRESULTS\r\nSmokers reported thinking negatively about their smoking 26.8% of the time they had a cigarette. The most frequent thoughts reported by smokers related to immediate reinforcement of smoking (e.g., \"How I smell like cigarettes\"). However, smokers reported more intense worry about thoughts related to health concerns (e.g., \"Symptoms I'm having because of smoking\"). The occurrence of negative thoughts was significantly and positively related to contemplation about quitting, worry about smoking, and risk perceptions. Finally, self-reported worry intensity was more strongly related to contemplation of quitting than negative thought occurrence.\r\nCONCLUSION\r\nOur results show that thoughts about smoking (i.e., cognitions) and feelings about smoking (i.e., worry) are loosely connected and it is feelings rather than cognitions that are most related to contemplation to quit.

Kocyigit, Ismail; Eroglu, Eray; Orscelik, Ozcan; Unal, Aydin; Gungor, Ozkan; Ozturk, Fahir et al. (2014):

Pentraxin 3 as a novel bio-marker of inflammation and endothelial dysfunction in autosomal dominant polycystic kidney disease.

In: *J Nephrol* 27 (2), S. 181–186. DOI: 10.1007/s40620-014-0045-4.

Abstract:

BACKGROUND/AIMS: Cardiovascular disease (CVD) is the main cause of mortality in patients with autosomal dominant polycystic kidney disease (ADPKD). Prior to hypertension early vascular changes and inflammation have been reported. We aimed to investigate long pentraxin 3 (PTX-3), which has been recently described as a biomarker of inflammation, and its relation with endothelial dysfunction in early ADPKD patients. METHODS: Twenty-five ADPKD patients without hypertension and 25 healthy controls were studied cross-sectionally. Hypertension was diagnosed with ambulatory blood pressure monitoring. Plasma concentrations of PTX-3 and proteinuria levels were obtained from each participant. Endothelial dysfunction was assessed using ischemia-induced forearm flow-mediated vasodilation (FMD). RESULTS: PTX-3 levels were higher in ADPKD patients compared to healthy controls (4.2 [1.2-10.1] vs. 1.4 [0.4-3.1] ng/ml, $p < 0.001$). Additionally, C-reactive protein (CRP) and

proteinuria levels were higher in ADPKD patients than in healthy subjects. In the whole cohort, PTX-3 correlated negatively with FMD (r: -0.58, p < 0.001) and positively with proteinuria (r: 0.56, p < 0.001) and uric acid (r: 0.57, p < 0.001). In all subjects, FMD was independently predicted by PTX-3, but not by uric acid, CRP or proteinuria. CONCLUSION: PTX-3 may be a better biomarker of inflammation than CRP to predict endothelial dysfunction in normotensive ADPKD patients with well-preserved kidney function. Hence, inflammation which is demonstrated by PTX-3 may potentially be used to predict future CVD in this population.

Kocyigit, Ismail; Gungor, Ozkan; Unal, Aydin; Orscelik, Ozcan; Eroglu, Eray; Tunca, Onur et al. (2014):

The effect of strict volume control on cardiac biomarker and arterial stiffness in peritoneal dialysis patients.

In: *Clin Nephrol* 81 (4), S. 238–246. DOI: 10.5414/CN108148.

Abstract:

Introduction: Arterial stiffness is a risk marker for cardiovascular events in peritoneal dialysis (PD) patients. Strict volume control strategy has been shown to result in better cardiac functions and control of hypertension in these patients. The aim of the study was to identify the determinants of arterial stiffness and evaluate the changes in cardiac biomarkers in PD patients under strict volume control strategy. Methods: 58 PD patients were enrolled into this prospective observational study. Arterial stiffness determined by aortic pulse wave velocity (PWV), echocardiography, ambulatory blood pressure and NT-pro-BNP levels were measured at baseline and at first year. Results: The mean age of the patients was 46.4 +/- 14 years. 30 patients were on automated PD (APD) and 28 on continuous ambulatory PD (CAPD) group. In both groups, there were significant differences in PWV values at baseline and at the end of the study. A similar decrease was observed with NT-proBNP and PWV levels. In addition, a significant improvement was found in echocardiographic parameters in all patients. Comparison of APD and CAPD groups with respect to change in one year, showed no difference in echocardiographic findings, while the reduction in PWV, NTproBNP and blood pressure values was higher in the CAPD group. Conclusions: In PD patients, strict volume control leads to a reduction in NT-pro-BNP levels, better control of blood pressure and significant improvements in cardiac functions and arterial stiffness.

Kolar, David Raphael; Burger, Arne; Hammerle, Florian; Jenetzky, Ekkehart (2014):

Aversive tension of adolescents with anorexia nervosa in daily course: a case-controlled and smartphone-based ambulatory monitoring trial.

In: *BMJ Open* 4 (4), S. e004703. DOI: 10.1136/bmjopen-2013-004703.

Abstract:

INTRODUCTION: Monitoring and reduction of aversive tension is a core issue in dialectical behaviour therapy of patients. It has been shown that aversive tension is increased in adult borderline personality disorder and is linked to low emotion labelling ability. However, until now there is no documented evidence that patients with anorexia nervosa suffer from aversive tension as well. Furthermore the usability of a smartphone application for ambulatory monitoring purposes has not been sufficiently explored. METHODS AND ANALYSIS: We compare the mean and maximum self-reported aversive tension in 20 female adolescents (12-19 years) with anorexia nervosa in outpatient treatment with 20 healthy controls. They are required to answer hourly, over a 2-day period, that is, about 30 times, four short questions on their smartphone, which ensures prompt documentation without any recall bias. At the close out, the participants give a structured usability feedback on the application and the procedure. ETHICS AND DISSEMINATION: The achieved result of this trial has direct relevance for efficient therapy strategies and is a prerequisite for trials regarding dialectical behaviour therapy in anorexia nervosa. The results will be disseminated through peer-review publications. The ethics committee of the regional medical association in Mainz, Germany approved the study protocol under the reference number 837.177.13. TRIAL REGISTRATION NUMBER: The trial is registered at the German clinical trials registration under the reference number DRKS00005228.

Kolesnik, M.; Sokolova, M. (2014):

Predictors of cardiac arrhythmias in patients with arterial hypertension during exercise stress testing.

In: *Georgian Med News* (227), S. 37–42.

Abstract:

Arterial hypertension is an important risk factor for atrial and ventricular arrhythmias. 203 male patients were examined in order to identify predictors of cardiac arrhythmias in patients with arterial hypertension during exercise stress testing. All participants were studied by 24-hour ambulatory blood pressure monitoring, transthoracic echocardiography, an ultrasound scan of the carotid arteries and treadmill test. 47,3% of patients presented cardiac arrhythmias during exercise stress testing. The left ventricular mass, diastolic function and carotid intima-media thickness were found to be independent predictors of exercise-induced arrhythmias. The use of the exercise stress testing may be reasonable for additional risk stratification in hypertensive patients.

Kollias, Anastasios; Ntineri, Angeliki; Stergiou, George S. (2014):

Is white-coat hypertension a harbinger of increased risk?

In: *Hypertens Res. DOI:* 10.1038/hr.2014.35.

Abstract:

White-coat hypertension is defined by elevated office and normal out-of-office blood pressure (home or ambulatory) in untreated subjects. This condition is common in clinical practice and requires appropriate work-up for detection and management. Many studies have examined the relationship between white-coat hypertension and cardiovascular risk but with marked heterogeneity in the definitions and methodology applied. Thus, the results have been inconsistent leading to confusion in scientific research and clinical practice. Some but not all the relevant studies suggested that white-coat hypertension is associated with subclinical target-organ damage, yet the cross-sectional design of these studies and the fact that these indices are only surrogate end points do not allow firm conclusions to be drawn. In recent years, longitudinal studies have examined the prognostic significance of white-coat hypertension in terms of cardiovascular morbidity and mortality. Most of them indicate that white-coat hypertensive compared with normotensive subjects present a moderate-in most cases not significant-increase in risk. Meta-analyses of raw data from large databases, such as the International Database on Ambulatory blood pressure and Cardiovascular Outcomes (IDACO) and the International Database on HOme blood pressure in relation to Cardiovascular Outcomes (IDHOCO) allowed separate powered analyses in untreated subjects and provided a clearer picture regarding the modest risk associated with white-coat hypertension, especially in the long term. White-coat hypertension is regarded as an intermediate phenotype between normotension and hypertension associated with increased risk of developing sustained hypertension, and therefore requires regular follow-up using nonpharmacological measures.Hypertension Research advance online publication, 6 March 2014; doi:10.1038/hr.2014.35.

Estimation of human circadian phase via a multi-channel ambulatory monitoring system and a multiple regression model.

In: *Journal of biological rhythms* 26 (1), S. 55–67.

Abstract:

Reliable detection of circadian phase in humans using noninvasive ambulatory measurements in real-life conditions is challenging and still an unsolved problem. The masking effects of everyday behavior and environmental input such as physical activity and light on the measured variables need to be considered critically. Here, we aimed at developing techniques for estimating circadian phase with the lowest subject burden possible, that is, without the need of constant routine (CR) laboratory conditions or without measuring the standard circadian markers, (rectal) core body temperature (CBT), and melatonin levels. In this validation study, subjects (N = 16) wore multi-channel ambulatory monitoring devices and went about their daily routine for 1 week. The devices measured a large number of physiological, behavioral, and environmental variables, including CBT, skin temperatures, cardiovascular and respiratory function, movement/posture, ambient temperature, and the spectral composition and intensity of light received at eye level. Sleep diaries were logged electronically. After the ambulatory phase, subjects underwent a 32-h CR procedure in the laboratory for measuring unmasked circadian phase based on the "midpoint" of the salivary melatonin profile. To overcome the complex masking effects of confounding variables during ambulatory measurements, multiple regression techniques were applied in combination with the cross-validation approach to subject-independent prediction of circadian phase. The most accurate estimate of circadian phase was achieved using skin temperatures, irradiance for ambient light in the blue spectral band, and motion acceleration as predictors with lags of up to 24 h. Multiple regression showed statistically significant improvement of variance of prediction error over the traditional approaches to determining circadian phase based on single predictors (motion acceleration or sleep log), although CBT was intentionally not included as the predictor. Compared to CBT alone, our method resulted in a 40% smaller range of prediction errors and a nonsignificant reduction of error variance. The proposed noninvasive measurement method could find applications in sleep

medicine or in other domains where knowing the exact endogenous circadian phase is important (e.g., for the timing of light therapy).

Feasibility and effectiveness of an automated bilingual text message intervention for weight loss: pilot study.

In: *JMIR.Res.Protoc.* 2 (2), S. e48. DOI: 10.2196/resprot.2789.

Abstract:

BACKGROUND: Little is known about the feasibility and acceptability of tailored text message based weight loss programs for English and Spanish-language speakers. OBJECTIVE: This pilot study evaluated the feasibility, acceptability, and estimated impact of a tailored text message based weight loss program for English and Spanish-language speakers. The purpose of this pilot study was to inform the development of a full-scale randomized trial. METHODS: There were 20 overweight or obese participants (mean age 40.10, SD 8.05; 8/20, 40% male; 9/20, 45% Spanish-speakers) that were recruited in San Diego, California, from March to May 2011 and evaluated in a one-group pre/post clinical trial. For 8 weeks, participants received and responded to 3-5 text messages daily sent from a fully automated text messaging system. They also received printed weight loss materials and brief 10-15 minute weekly counseling calls. To estimate the impact of the program, the primary outcome was weight (kg) measured during face-to-face measurement visits by trained research staff. Pre and post differences in weight were analyzed with a one-way repeated measures analysis of variance. Differences by language preference at both time points were analyzed with t tests. Body mass index and weight management behaviors also were examined. Feasibility and acceptability were determined by recruitment success, adherence (ie, percentage of replies to interactive text messages and attrition), and participant satisfaction. RESULTS: Participants who completed the final assessment (N=18) decreased body weight by 1.85 kg (F1,17=10.80, P=.004, CI 0.66-3.03, eta(2)=0.39). At both time points, there were no differences in weight by language preference. Participants responded to 88.04% (986/1120) of interactive text messages, attrition rate was 10% (2/20), and 94% (19/20) of participants reported satisfaction with the program. CONCLUSIONS: This fully automated text message based weight program was feasible with English and Spanish-speakers and may have promoted modest weight loss over an 8-week period. The effect of personality on daily life emotional processes.

In: *PLoS One* 9 (10), S. e110907. DOI: 10.1371/journal.pone.0110907.

Abstract:

Personality features are associated with individual differences in daily emotional life, such as negative and positive affectivity, affect variability and affect reactivity. The existing literature is somewhat mixed and inconclusive about the nature of these associations. The aim of this study was to shed light on what personality features represent in daily life by investigating the effect of the Five Factor traits on different daily emotional processes using an ecologically valid method. The Experience Sampling Method was used to collect repeated reports of daily affect and experiences from 104 healthy university students during one week of their normal lives. Personality traits of the Five Factor model were assessed using NEO Five Factor Inventory. Hierarchical linear modeling was used to analyze the effect of the personality traits on daily emotional processes. Neuroticism predicted higher negative and lower positive affect, higher affect variability, more negative subjective evaluations of daily incidents, and higher reactivity to stressors. Conscientiousness, by contrast, predicted lower average level, variability, and reactivity of negative affect. Agreeableness was associated with higher positive and lower negative affect, lower variability of sadness, and more positive subjective evaluations of daily incidents. Extraversion predicted higher positive affect and more positive subjective evaluations of daily activities. Openness had no effect on average level of affect, but predicted higher reactivity to daily stressors. The results show that the personality features independently predict different aspects of daily emotional processes. Neuroticism was associated with all of the processes. Identifying these processes can help us to better understand individual differences in daily emotional life.

Cognitive benefits of last night's sleep: daily variations in children's sleep behavior are related to working memory fluctuations.

In: *J Child Psychol Psychiatry. DOI:* 10.1111/jcpp.12296.

Abstract:

BACKGROUND: Recent studies have suggested substantial fluctuations of cognitive performance in adults both across and within days, but very little is known about such fluctuations in children. Children's sleep behavior might have an important influence on their daily cognitive resources, but so far this has not been investigated in terms of naturally occurring within-person variations in children's everyday lives. METHODS: In an ambulatory assessment study, 110 elementary school children (8-11 years old) completed sleep items and working memory tasks on smartphones several times per day in school and at home for 4 weeks. Parents provided general information about the children and their sleep habits. RESULTS: We identified substantial fluctuations in the children's daily cognitive performance, self-reported nightly sleep quality, time in bed, and daytime tiredness. All three facets were predictive of performance fluctuations in children's school and daily life. Sleep quality and time in bed were predictive of performance in the morning, and afternoon performance was related to current tiredness. The children with a lower average performance level showed a higher within-person coupling between morning performance and sleep quality. CONCLUSIONS: Our findings contribute important insights regarding a potential source of performance fluctuations in children. The effect of varying cognitive resources should be investigated further because it might impact children's daily social, emotional, and learning-related functioning. Theories about children's cognitive and educational development should consider fluctuations on micro-longitudinal scales (e.g., day-to-day) to identify possible mechanisms behind long-term changes.

Nocturnal blood pressure but not insulin resistance influences endothelial function in treated hypertensive patients.

In: *J Hum Hypertens* 25 (1), S. 18–24.

Abstract:

The impact of insulin sensitivity, casual blood pressure and 24-h ambulatory blood pressure on endothelial function was studied in treated hypertensive subjects. Flow-mediated dilatation of the brachial artery after reperfusion was used to determine endothelial function. Insulin sensitivity indices were obtained by using the homeostasis model assessment, after 75 g Dextrose oral glucose tolerance tests (Matsuda index) and the euglycemic hyperinsulinemic clamp (M-value) in 49 patients with arterial hypertension. The insulin sensitivity indices were compared with healthy controls matched for body weight, age and sex (n=23). Hypertensive patients under therapy were insulin resistant, had higher LDL-cholesterol levels, higher blood pressure and lower endothelial function than healthy controls. Flow-mediated dilatation showed, in the study population being treated for arterial hypertension, no relationships of all insulin sensitivity indices with flow-mediated dilatation, casual blood pressure in the morning before the tests and 24-h ambulatory blood pressure. Flow-mediated dilatation was strongly influenced by nocturnal systolic and diastolic 24-h ambulatory blood pressure (systolic: R^2=0.0943, P<0.05; diastolic: R^2=0.0947, P<0.05). Therefore, endothelial function in these patients is predominantly influenced by nocturnal systolic and diastolic blood pressure and not by insulin sensitivity.

Kööts, Liisi; Realo, Anu; Allik, Jüri (2012):

Relationship between linguistic antonyms in momentary and retrospective ratings of happiness and sadness.

In: *Journal of Individual Differences* 33 (1), S. 43–53. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-30352-006&site=ehost-live;liisi.koots@ut.ee.

Abstract:

Momentary ratings of affective states with a pair of strict antonyms (“happy” vs. “sad”) were studied with an experience-sampling method in a group of 110 participants during 14 consecutive days at 7 randomly determined occasions per day. Before and after the experimental session participants also retrospectively rated how happy or sad they had been during the previous 2 weeks. Multilevel analysis showed that, at the level of single measurement trials, the momentary ratings of happiness and sadness were moderately negatively correlated (r = –.32, p < .001). A between-subject correlation of the two antonyms, however, was in a positive direction (r = .13, p = .123). Participants experienced mixed feelings during a considerable number of measurement

trials, whereas the tendency to feel mixed emotions was predicted by all Big Five personality traits except Agreeableness. A configural frequency analysis (CFA) demonstrated that, although there was no strict bipolarity between momentary ratings of happiness and sadness, they were nevertheless used in an exclusive manner in many occasions. Topography and severity of coronary artery disease in white-coat hypertension.

In: *European journal of internal medicine* 19 (4), S. 280–284.

Abstract:

BACKGROUND:

White-coat hypertension (WCH) has been evaluated as a risk factor for cardiovascular disease. In this study, the role of WCH is evaluated in a cohort of patients with suspected coronary artery disease with both coronary angiography and non-invasive techniques.

METHODS:

One hundred patients with suspected coronary artery disease underwent coronary angiography, 24-h ambulatory blood pressure monitoring (ABPM), and ultrasound imaging of the myocardium and carotids. The lesions in percentage of stenosis in the left coronary artery stem (LM), left anterior descending ramus (LAD), left circumflex artery (LCX), diagonal artery (D1), and right coronary artery (RCA), along with the Gensini score (GS), were recorded. After a series of manual blood pressure measurements, the patients were divided into two groups (patients with and patients without WCH).

RESULTS:

GS was higher in the WCH group (P=0.042), a difference that could be attributed to lesions in the LAD (P=0.007). GS correlated significantly with left ventricular end-diastolic diameter (LVEDD - P=0.041), left ventricular end-systolic diameter (LVESD - P=0.005), end-diastolic volume (EDV - P=0.042), end-systolic volume (ESV - P=0.004), LvMass/BSA (P=0.012), right internal carotid artery intima-media thickness (RICA - P=0.018), left internal carotid artery intima-media thickness (LICA - P=0.021), and their mean (MICA - P=0.005) in the WCH group but not in normotensives.

CONCLUSIONS:

Coronary disease may be more severe among patients with WCH than among those without. In this group, data from myocardial and carotid ultrasound may help to estimate coronary artery disease.

Association of sedentary time with mortality independent of moderate to vigorous physical activity.

In: *PLoS One* 7 (6), S. e37696. DOI: 10.1371/journal.pone.0037696.

Abstract:

BACKGROUND: Sedentary behavior has emerged as a novel health risk factor independent of moderate to vigorous physical activity (MVPA). Previous studies have shown self-reported sedentary time to be associated with mortality; however, no studies have investigated the effect of objectively measured sedentary time on mortality independent of MVPA. The objective our study was to examine the association between objectively measured sedentary time and all-cause mortality. METHODS: 7-day accelerometry data of 1906 participants aged 50 and over from the U.S. nationally representative National Health and Nutrition Examination Survey (NHANES) 2003-2004 were analyzed. All-cause mortality was assessed from the date of examination through December 31, 2006. RESULTS: Over an average follow-up of 2.8 years, there were 145 deaths reported. In a model adjusted for sociodemographic factors, lifestyle factors, multiple morbidities, mobility limitation, and MVPA, participants in third quartile (hazard ratio (HR):4.05; 95%CI:1.55-10.60) and fourth quartile (HR:5.94; 95%CI: 2.49-14.15) of having higher percent sedentary time had a significantly increased risk of death compared to those in the lowest quartile. CONCLUSIONS: Our study suggests that sedentary behavior is a risk factor for mortality independent of MVPA. Further investigation, including studies with longer follow-up, is needed to address the health consequences of sedentary behavior

Koval, P.; Ogrinz, B.; Kuppens, P.; van Den Bergh, O.; Tuerlinckx, F.; Sutterlin, S. (2013):

Affective instability in daily life is predicted by resting heart rate variability.

In: *PLoS.One.* 8 (11), S. e81536. DOI: 10.1371/journal.pone.0081536.

Abstract:

Previous research has shown that being affectively unstable is an indicator of several forms of psychological maladjustment. However, little is known about the mechanisms underlying affective instability. Our research aims to examine the possibility that being prone to extreme fluctuations in one's feelings is related to maladaptive emotion regulation. We investigated this hypothesis by relating affective instability, assessed in daily life using the experience sampling method, to self-reported emotion regulation strategies and to parasympathetically mediated heart rate variability (HRV), a physiological indicator of emotion regulation capacity. Results showed that HRV was negatively related to instability of positive affect (as measured by mean square successive differences), indicating that individuals with lower parasympathetic tone are emotionally less stable, particularly for positive affect

Affect Dynamics in Relation to Depressive Symptoms: Variable, Unstable or Inert?

In: *Emotion* (1528-3542 (Linking)). DOI: 10.1037/a0033579.

Abstract:

Depression not only involves disturbances in prevailing affect, but also in how affect fluctuates over time. Yet, precisely which patterns of affect dynamics are associated with depressive symptoms remains unclear; depression has been linked with increased affective variability and instability, but also with greater resistance to affective change (inertia). In this paper, we argue that these paradoxical findings stem from a number of neglected methodological/analytical factors, which we address using a novel paradigm and analytic approach. Participants (N = 99), preselected to represent a wide range of depressive symptoms, watched a series of emotional film clips and rated their affect at baseline and following each film clip. We also assessed participants' affect in daily life over 1 week using experience sampling. When controlling for overlap between different measures of affect dynamics, depressive symptoms were independently associated with higher inertia of negative affect in the lab, and with greater negative affect variability both in the lab and in daily life. In contrast, depressive symptoms were not independently related to higher affective instability either in daily life or in the lab. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

A portable automatic cough analyser in the ambulatory assessment of cough.

In: *Biomed Eng Online* 9, S. 17. DOI: 10.1186/1475-925X-9-17.

Abstract:

BACKGROUND\r\nCough is one of the main symptoms of advanced lung disease. However, the efficacy of currently available treatment remains unsatisfactory. Research into the new antitussives requires an objective assessment of cough.\r\nMETHODS\r\nThe aim of the study was to test the feasibility of a new automatic portable cough analyser and assess the correlation between subjective and objective evaluations of cough in 13 patients with chronic cough. The patients' individual histories, a cough symptom score and a numeric cough scale (1-10) were used as a subjective evaluation of cough and a computerized audio-timed recorder was used to measure the frequency of coughing.\r\nRESULTS\r\nThe pre-clinical validation has shown that an automated cough analyser is an accurate and reliable tool for the ambulatory assessment of chronic cough. In the clinical part of the experiment for the daytime, subjective cough scoring correlated with the number of all cough incidents recorded by the cough analyser (r = 0.63; p = 0.022) and the number of cough incidents per hour (r = 0.60; p = 0.03). However, there was no relation between cough score and the time spent coughing per hour (r = 0.48; p = 0.1). As assessed for the night-time period, no correlation was found between subjective cough scoring and the number of incidents per hour (r = 0.29; p = 0.34) or time spent coughing (r = 0.26; p = 0.4).\r\nCONCLUSION\r\nAn automated cough analyser seems to be a feasible tool for the ambulatory monitoring of cough. There is a moderate correlation between subjective and objective assessments of cough during the daytime, whereas the discrepancy in the evaluation of night-time coughing might suggest that subjective analysis is unreliable.

Time-Lagged Moment-to-Moment Interplay Between Negative Affect and Paranoia: New Insights in the Affective Pathway to Psychosis.

In: *Schizophr.Bull* (0586-7614 (Linking)). DOI: 10.1093/schbul/sbs194.

Abstract:

Evidence suggests that affect plays a role in the development of psychosis but the underlying mechanism requires further investigation. This study examines the moment-to-moment dynamics between negative affect (NA) and paranoia prospectively in daily life. A female general population sample (n = 515) participated in an experience sampling study. Time-lagged analyses between increases in momentary NA and subsequent momentary paranoia were examined. The impact of childhood adversity, stress sensitivity (impact of momentary stress on momentary NA), and depressive symptoms on these time-lagged associations, as well as associations with follow-up self-reported psychotic symptoms (Community Assessment of Psychic Experiences and the Symptom Checklist-90-Revised) were investigated. Moments of NA increase resulted in a significant increase in paranoia over 180 subsequent minutes. Both stress sensitivity and depressive symptoms impacted on the transfer of NA to paranoia. Stress sensitivity moderated the level of increase in paranoia during the initial NA increase, while depressive symptoms increased persistence of paranoid feelings from moment to moment. Momentary paranoia responses to NA increases were associated with follow-up psychotic symptoms. Examination of microlevel momentary experience may thus yield new insights into the mechanism underlying co-occurrence of altered mood states and psychosis. Knowledge of the underlying mechanism is required in order to determine source and place where remediation should occur

Actigraphic assessment of motor activity in acutely admitted inpatients with bipolar disorder.

In: *PLoS One* 9 (2), S. e89574. DOI: 10.1371/journal.pone.0089574.

Abstract:

INTRODUCTION: Mania is associated with increased activity, whereas psychomotor retardation is often found in bipolar depression. Actigraphy is a promising tool for monitoring phase shifts and changes following treatment in bipolar disorder. The aim of this study was to compare recordings of motor activity in mania, bipolar depression and healthy controls, using linear and nonlinear analytical methods. MATERIALS AND METHODS: Recordings from 18 acutely hospitalized inpatients with mania were compared to 12 recordings from bipolar depression inpatients and 28 healthy controls. 24-hour actigraphy recordings and 64-minute periods of continuous motor activity in the morning and evening were analyzed. Mean activity and several measures of variability and complexity were calculated. RESULTS: Patients with depression had a lower mean activity level compared to controls, but higher variability shown by increased standard deviation (SD) and root mean square successive difference (RMSSD) over 24 hours and in the active morning period. The patients with mania had lower first lag autocorrelation compared to controls, and Fourier analysis showed higher variance in the high frequency part of the spectrum corresponding to the period from 2-8 minutes. Both patient groups had a higher RMSSD/SD ratio compared to controls. In patients with mania we found an increased complexity of time series in the active morning period, compared to patients with depression. The findings in the patients with mania are similar to previous findings in patients with schizophrenia and healthy individuals treated with a glutamatergic antagonist. CONCLUSION: We have found distinctly different activity patterns in hospitalized patients with bipolar disorder in episodes of mania and depression, assessed by actigraphy and analyzed with linear and nonlinear mathematical methods, as well as clear differences between the patients and healthy comparison subjects.

The Role of Location in Everyday Experiences of Music.

In: *Psychology of Popular Media Culture*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-44153-001%26site%3dehost-live.

Abstract:

Mehrabian and Russell's (1974) Pleasure–Arousal–Dominance model states that a propensity to approach/avoid an environment can be conceptualized in terms of the pleasure and arousal it elicits and one's degree of dominance therein. Using the Experience Sampling Method, 177 individuals provided responses concerning Mehrabian and Russell's model throughout 1 wk regarding music experiences that occurred in their daily life (including how the music was heard and how their responses related to the listening location). Results indicate that the time of day and day of week are related to where music is experienced, and

that the consequences of what was heard are related to both time and location. Although music was experienced more often in private locations than in public overall, interesting patterns of music experiences that occurred in public locations demonstrate in detail how music listening varies by location. Specifically, portable devices were associated with positive responses, which contrasted sharply with the responses to music broadcasted publicly in public settings. Participants' ratings of choice, liking, and arousal demonstrated the importance of considering choice as an indication of dominance, such that music usage is consistent with Mehrabian and Russell's model, and has functions that vary according to the specific characteristics of the situation. Sources of variation in habitual physical activity of children and adolescents: the European youth heart study.

In: *Scandinavian Journal of Medicine & Science in Sports* 18 (3), S. 298–308.

Abstract:

The present study examined the influence of gender, maturity state, seasonality, type of measurement day and socioeconomic status (SES) on habitual physical activity in 8-10-year-old children and 14-16-year-old adolescents (n=1318). Physical activity was assessed objectively by accelerometry. The results showed a significant effect of the type of measurement day on physical activity with a general pattern of lower activity levels in weekends compared with weekdays. Furthermore, higher physical activity levels were observed during the months of spring/summer compared with the months of autumn/winter for the 8-10-year-olds, whereas no significant effect of months was observed for the 14-16-year-olds, possibly due to exam preparations and lack of physical activity registration during the months of summer for this cohort. SES was unrelated to physical activity in the 8-10-year-olds, whereas an inverse association was observed in the 14-16-year-olds. However, a post hoc analysis provided strong evidence that this latter result was biased by the accelerometers inability to pick up bicycling activities. Finally, boys were more physically active compared with girls, and maturity state was unrelated to physical activity. The results could prove useful for working out strategies to prevent inactivity and for adjusting for temporal sources of variation in physical activity in future studies.

Kristjánsdóttir ÓB, Fors EA, Eide E, Finset A, Stensrud TL, van Dulmen S, Wigers SH, Eide H. (2013):

A smartphone-based intervention with diaries and therapist feedback to reduce catastrophizing and increase functioning in women with chronic widespread pain. Part 2: 11-month follow-up results of a randomized trial.

In: *J Med Internet Res* 15 (3), S. 152–170. DOI: 10.1037/t00297-000;

Abstract:

Background: Internet-based interventions are increasingly used to support self-management of individuals with chronic illnesses. Web-based interventions may also be effective in enhancing self-management for individuals with chronic pain, but little is known about long-term effects. Research on Web-based interventions to support self-management following participation in pain management programs is limited. Objective: The aim is to examine the long-term effects of a 4-week smartphone-intervention with diaries and therapist-written feedback following an inpatient chronic pain rehabilitation program, previously found to be effective at short-term and 5-month follow-ups. Methods: 140 women with chronic widespread pain, participating in a 4-week inpatient rehabilitation program, were randomized into two groups: with or without a smartphone intervention after the rehabilitation. The smartphone intervention consisted of one face-to-face individual session and 4 weeks of written communication via a smartphone, consisting of three diaries daily to elicit pain-related thoughts, feelings, and activities, as well as daily personalized written feedback based on cognitive behavioral principles from a therapist. Both groups were given access to an informational website to promote constructive self-management. Outcomes were measured with self-reported paper-and-pencil format questionnaires with catastrophizing as the primary outcome measure. Secondary outcomes included daily functioning and symptom levels, acceptance of pain, and emotional distress. Results: By the 11-month follow-up, the favorable between-group differences previously reported post-intervention and at 5-month follow-up on catastrophizing, acceptance, functioning, and symptom level were no longer evident (P > .10). However, there was more improvement in catastrophizing scores during the follow-up period in the intervention group (M = −2.36, SD 8.41) compared to the control group (M = .40, SD 7.20), P = .045. Also, per protocol within-group analysis showed a small positive effect (Cohen's d = .33) on catastrophizing in the intervention group (P = .04) and no change in the control group from the smartphone intervention baseline to 11-month follow-up. A positive effect (Cohen's d = .73) on acceptance was found within the intervention group (P < .001) but not in the control group. Small to large negative effects were found within the control group on functioning and symptom levels, emotional distress, and fatigue (P = .05) from the intervention baseline to the 11-month follow-up. Conclusion: The long-term results of this randomized trial are ambiguous. No significant between-group effect was found on the study variables at 11-

month follow-up. However, the within-group analyses, comparing the baseline for the smartphone intervention to the 11-month data, indicated changes in the desired direction in catastrophizing and acceptance in the intervention group but not within the control group. This study provides modest evidence supporting the long-term effect of the intervention. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

RESULTS: By the 11-month follow-up, the favorable between-group differences previously reported post-intervention and at 5-month follow-up on catastrophizing, acceptance, functioning, and symptom level were no longer evident (P>.10). However, there was more improvement in catastrophizing scores during the follow-up period in the intervention group (M=-2.36, SD 8.41) compared to the control group (M=.40, SD 7.20), P=.045. Also, per protocol within-group analysis showed a small positive effect (Cohen's d=.33) on catastrophizing in the intervention group (P=.04) and no change in the control group from the smartphone intervention baseline to 11-month follow-up. A positive effect (Cohen's d=.73) on acceptance was found within the intervention group (P<.001) but not in the control group. Small to large negative effects were found within the control group on functioning and symptom levels, emotional distress, and fatigue (P=.05) from the intervention baseline to the 11-month follow-up. CONCLUSION: The long-term results of this randomized trial are ambiguous. No significant between-group effect was found on the study variables at 11-month follow-up. However, the within-group analyses, comparing the baseline for the smartphone intervention to the 11-month data, indicated changes in the desired direction in catastrophizing and acceptance in the intervention group but not within the control group. This study provides modest evidence supporting the long-term effect of the intervention. Blood pressure control in hypertensive pediatric renal transplants: role of repeated ABPM following transplantation.

In: *Am J Hypertens* 21 (10), S. 1093–1099. DOI: 10.1038/ajh.2008.251.

Abstract:

BACKGROUND\r\nHypertension in pediatric renal transplants is a widespread condition associated with high mortality risk in early adult life. Ambulatory blood pressure monitoring (ABPM) was found to be superior to office blood pressure (BP) in identifying true hypertensive and responders to treatment. The aim of this study was to investigate the role of repeated ABPM, performed at yearly intervals following transplantation, in the assessment and decision-making processes of post-transplant hypertension.\r\nMETHODS\r\nThirty-seven recipients (23 males; aged 10.5 +/- 4.3 years) who were followed for 4.3 +/- 2.2 years (range 2-9) after transplantation were eligible for analysis. The mean follow-up time between the baseline (1 year post-transplantation) and the most recent ABPM examination was 3.3 +/- 2.2 years (range 1-8).\r\nRESULTS\r\nThroughout the follow-up period, antihypertensive therapy was either started or intensified in 27 recipients. These interventions were decided based on ABPM results obtained on 40 of 44 occasions. At last follow-up, 24 of 29 treated hypertensive recipients displayed controlled BP. This figure was significantly higher compared to our historical hypertensive control recipients in whom ABPM was

applied for the first time in treatment at 6 +/- 3.3 years (range 2-15) after transplantation, while therapeutic decisions were driven by office BP measurements (95 % confidence interval (95% CI) for the difference between proportions (80.6-32 %) 36-60 %, P = 0.001).\r\nCONCLUSIONS\r\nOur study shows that, in a population with high risk for hypertension, repeated ABPM may significantly help to improve BP control.

Facebook use predicts declines in subjective well-being in young adults.

In: *PLoS One* 8 (8), S. e69841. DOI: 10.1371/journal.pone.0069841.

Abstract:

Over 500 million people interact daily with Facebook. Yet, whether Facebook use influences subjective well-being over time is unknown. We addressed this issue using experience-sampling, the most reliable method for measuring in-vivo behavior and psychological experience. We text-messaged people five times per day for two-weeks to examine how Facebook use influences the two components of subjective well-being: how people feel moment-to-moment and how satisfied they are with their lives. Our results indicate that Facebook use predicts negative shifts on both of these variables over time. The more people used Facebook at one time point, the worse they felt the next time we text-messaged them; the more they used Facebook over two-weeks, the more their life satisfaction levels declined over time. Interacting with other people "directly" did not predict these negative outcomes. They were also not moderated by the size of people's Facebook networks, their perceived supportiveness, motivation for using Facebook, gender, loneliness, self-esteem, or depression. On the surface, Facebook provides an invaluable resource for fulfilling the basic human need for social connection. Rather than enhancing well-being, however, these findings suggest that Facebook may undermine it

Application of a full body inertial measurement system in alpine skiing: A comparison with an optical video based system.

In: *J. Appl. Biomech* 26, S. 516–521.

Abstract:

This study aims at determining the accuracy of a full body inertial measurement system in a real skiing environment in comparison with an optical video based system. Recent studies have shown the use of inertial measurement systems for the determination of kinematical parameters in alpine skiing. However, a quantitative validation of a full body inertial measurement system for the application in alpine skiing is so far not available. For the purpose of this study, a skier performed a test-run equipped with a full body inertial measurement system in combination with a DGPS. In addition, one turn of the test-run was analyzed by an optical video based system. With respect to the analyzed angles, a maximum mean difference of 4.9° was measured. No differences in the measured angles between the inertial measurement system and the combined usage with a DGPS were found. Concerning the determination of the skier's trajectory, an additional system (e.g., DGPS) must be used. As opposed to optical methods, the main advantages of the inertial measurement system are the determination of kinematical parameters without the limitation of restricted capture volume, and small time costs for the measurement preparation and data analysis.

Computerized sampling of experiences and behavior. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 124–143. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-007%26site%3dehost-live.

Abstract:

(from the chapter) Conducting experience sampling studies has been made substantively easier over the last two decades with readily available computerized solutions. Our aim in this chapter is to offer the reader advice about which criteria to consider before choosing a particular software package for experience sampling and a current overview of available solutions. The chapter is divided into four parts. First, we give a short overview of currently available platforms. We also dare to venture some—

necessarily subjective—predictions as to which platform is the safest choice for a researcher who seriously wants to engage in computerized experience sampling in the years to come. Second, we will briefly outline criteria one should consider before choosing a particular software solution. In our view, the criteria for software choice should be based largely on the features one needs for a given study. Third, we give an overview of currently available software solutions, with a particular focus on open-source software. Commercial software is included as well. Finally, we give some helpful hints for implementing computerized experience sampling using a given software solution and platform. We conclude this chapter with some final remarks on future trends and possibilities that are to be expected in the field. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Daily hassles and emotional eating in obese adolescents under restricted dietary conditions—The role of ruminative thinking.

In: *Appetite* 51 (1), S. 206–209.

Abstract:

Emotional eating is conceptualized as eating in response to negative affect or distress and is discussed as a mechanism leading to eating binges. Recent evidence suggests that eating may not only be triggered by negative affect, but also ruminative thinking. We report results of an experience sampling study examining the role of rumination for emotional eating in 16 obese adolescents (M=15.5 years, S.D.=1.4; range 14-17, body mass index M = 31.1 kgm(-2), S.D.=5.5) under restricted dietary conditions. We hypothesized that daily hassles type of stress predicted the individuals' desire to eat, with the predictive value further increased when negative affect and rumination were accounted for. The results of mixed regression modeling were in line with our predictions, suggesting a significant contribution of ruminative thinking to the mechanisms of negative affect induced eating.

Continuous glucose monitoring reveals associations of glucose levels with QT interval length.

In: *Diabetes technology & therapeutics* 12 (4), S. 283–286. DOI: 10.1089/dia.2009.0153.

Abstract:

BACKGROUND\r\nQTc interval lengthening during hypoglycemia is discussed as a mechanism linked to sudden death in diabetes patients and the so-called \"dead in bed syndrome.\" Previous research reported a high interindividual variability in the glucose-QTc association. The present study aimed at deriving parameters for direction and strength of the glucose-QTc association on the patient level using combined Holter electrocardiogram (ECG) and continuous glucose monitoring.\r\nMETHODS\r\nTwenty type 1 diabetes patients were studied: mean (SD, range) age, 43.6 (10.8, 22-65) years; gender male (n [%]), 10 (50.0%); mean (SD) hemoglobin A1C, 8.5% (1.0%); and impaired hypoglycemia awareness (n [%]), six (30.0%). Continuous interstitial glucose monitoring and Holter ECG monitoring were performed for 48 h. Hierarchical (mixed) regression modeling was used to account for the structure of the data.\r\nRESULTS\r\nGlucose levels during nighttime were negatively associated with QTc interval length if the data structure was accounted for (b [SE] = -0.76 [0.17], P = 0.000). Exploratory regression analysis revealed hypoglycemia awareness as the only predictor of the individual strength of the glucose-QTc association, with the impaired awareness group showing less evidence for an association of low glucose with QTc lengthening.\r\nCONCLUSIONS\r\nMixed regression allows for deriving parameters for the glucose-QTc association on the patient level. Consistent with previous studies, we found a large interindividual variability in the glucose-QTc association. The finding on impaired hypoglycemia awareness patients has to be interpreted with caution but provides some support for the role of sympathetic activation for the QTc-glucose link.

Kubiak, T.; Zahn, D.; Siewert, K.; Jonas, C.; Weber, H. (2013):

Positive Beliefs about Rumination Are Associated with Ruminative Thinking and Affect in Daily Life: Evidence for a Metacognitive View on Depression.

In: *Behav.Cogn Psychother* (1352-4658 (Linking)), S. 1–9. DOI: 10.1017/S1352465813000325.

Abstract:

Background: Self-regulatory executive function theory (Wells and Matthews, 1994; Wells, 2008) stresses the role of metacognitions in the development of emotional disorders. Within this metacognitive model, positive beliefs about ruminative thinking are thought to be a risk factor for engaging in rumination and subsequently for depression. However, most of the existing research relies on retrospective self-report trait measures. Aims: The aim of the present study was to examine the theory's predictions with an Ecological Momentary Assessment approach capturing rumination as it occurs in daily life. Method: Non-clinical participants (N = 93) were equipped with electronic diaries and completed four signal-contingent momentary self-reports per day for 4 weeks. A multilevel mediation model was computed to examine associations between positive beliefs about rumination and ruminative thinking and negative affect in daily life. Results: Positive beliefs about rumination were significantly associated with ruminative thinking as it occurs in daily life. We further found evidence for a negative association with positive affect that was completely mediated via ruminative thinking in daily life occurring in response to negative emotions. Conclusions: Our results add ecologically valid corroborating evidence for the metacognitive model of emotional disorders within the framework of self-regulatory executive function theory

Circadian cortisol profiles and psychological self-reports in shift workers with and without recent change in the shift rotation system.

In: *Biol Psychol* 74 (1), S. 92–103.

Abstract:

Cortisol profiles including the cortisol rise in the first hour after awakening (CAR) were assessed during shift work and days off (eight saliva samples per shift). Participants were 102 healthy permanent day and night shift workers (comparison groups) and former permanent day and night shift workers after implementation of a new fast-forward rota including morning, evening, and night shifts. Results show that the CAR is detectable in day as well as night shifts. In permanent night workers cortisol profiles appear to be blunted during night work and days off. However, circadian cortisol profiles are not disturbed in former night workers who recently switched to the fast rotating shift schedule. In contrast, implementation of night work in former day workers seems to lead to initially blunted cortisol profiles that normalize after a short adjustment period. Results of a psychological assessment including exhaustion, chronic stress, effort-reward imbalance, and ratings of sleep quality and sleep length are also presented.

Kuepper, R.; Oorschot, M.; Myin-Germeys, I.; Smits, M.; Van, Os J.; Henquet, C. (2013):

Is psychotic disorder associated with increased levels of craving for cannabis? An Experience Sampling study.

In: *Acta Psychiatr.Scand.* (0001-690X (Linking)). DOI: 10.1111/acps.12078.

Abstract:

OBJECTIVE: Although cannabis use among individuals with psychotic disorder is considerable, little is known about patterns of use and factors contributing to continuation of use. Therefore, we investigated craving in relation to cannabis use in patients with psychotic disorder and healthy controls. METHOD: The study included 58 patients with non-affective psychotic disorder and 63 healthy controls; all were frequent cannabis users. Craving was assessed with the Obsessive Compulsive Drug Use Scale (OCDUS) for cannabis, as well as in daily life using the Experience Sampling Method (ESM). RESULTS: Patients scored higher on the OCDUS (B = 1.18, P = 0.022), but did not differ from controls in ESM indices of craving (all P > 0.05). In daily life, ESM craving predicted cannabis use and this was stronger in controls (chi(2) = 4.5, P = 0.033; B(controls) = 0.08, P < 0.001; B(patients) = 0.06, P < 0.001). In both groups ESM craving was predicted by negative affect, paranoia, and hallucinations (B(negativeaffect) = 0.12, P = 0.009; B(paranoia) = 0.13, P = 0.013; B(hallucinations) = 0.13, P = 0.028), and followed by an increase in negative affect at non-cannabis-using moments (B = 0.03, P = 0.002). CONCLUSION: The temporal dynamics of craving as well as craving intensity in daily life appear to be similar in patients and controls. Further research is needed to elucidate the inconsistencies between cross-sectional and daily-life measures of craving in psychosis

Kuerbis, Alexis; Armeli, Stephen; Muench, Frederick; Morgenstern, Jon (2014):

Profiles of confidence and commitment to change as predictors of moderated drinking: A person-centered approach.

In: *Psychology of Addictive Behaviors* 28 (4), S. 1065–1076. DOI: 10.1037/t01528-000.

Abstract:

Identifying who, among problem drinkers, is best suited for moderation and has the greatest likelihood to control drinking has important public health implications. The current study aimed to identify profiles of problem drinkers who may be more or less successful in moderating drinking within the context of a randomized clinical trial of a brief treatment for alcohol use disorder. A person-centered approach was implemented, utilizing composite, baseline daily diary values of confidence and commitment to reduce drinking. Problem drinkers (N = 89) were assessed, provided feedback about their drinking, and randomly assigned to 1 of 3 conditions: 2 brief alcohol use disorder treatments or a third group asked to change on their own. Global self-report assessments were administered at baseline and Week 8 (end of treatment). Daily diary composites were created from data collected via an interactive voice recording system during the week prior to baseline. A K-means cluster analysis identified 3 groups: high, moderate, and low confidence and commitment to change drinking. Group differences were explored, and then group membership was entered into generalized estimating equations to predict drinking trajectories over time. Findings revealed that the groups differentially reduced their drinking, such that the high group had greater reduction in drinking and a faster rate of reduction than the other 2 groups, and the moderate group had greater reduction than the low group. Findings suggest that baseline motivation and self-efficacy are important for predicting prognoses related to successful moderated drinking. Limitations and arenas for future research are discussed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Kuffel, Erin E.; Crouter, Scott E.; Haas, Jere D.; Frongillo, Edward A.; Bassett, David R. J. (2011):

Validity of estimating minute-by-minute energy expenditure of continuous walking bouts by accelerometry.

In: *Int J Behav Nutr Phys Act* 8. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31468-001%26site%3dehost-live;ekuffel@winona.edu.

Abstract:

BACKGROUND:

Objective measurement of physical activity remains an important challenge. For wearable monitors such as accelerometer-based physical activity monitors, more accurate methods are needed to convert activity counts into energy expenditure (EE).

PURPOSE:

The purpose of this study was to examine the accuracy of the refined Crouter 2-Regression Model (C2RM) for estimating EE during the transition from rest to walking and walking to rest. A secondary purpose was to determine the extent of overestimation in minute-by-minute EE between the refined C2RM and the 2006 C2RM.

METHODS:

Thirty volunteers (age, 28 ± 7.7 yrs) performed 15 minutes of seated rest, 8 minutes of over-ground walking, and 8 minutes of seated rest. An ActiGraph GT1M accelerometer and Cosmed K4b2 portable metabolic system were worn during all activities. Participants were randomly assigned to start the walking bout at 0, 20, or 40 s into the minute (according to the ActiGraph clock). Acceleration data were analyzed by two methods: 2006 Crouter model and a new refined model.

RESULTS:

The 2006 Crouter 2-Regression model over-predicted measured kcal kg-1 hr-1 during the first and last transitional minutes of the 20-s and 40-s walking conditions ($P < 0.001$). It also over-predicted the average EE for a walking bout (4.0 ± 0.5 kcal kg-1 hr-1), compared to both the measured kcal kg-1 hr-1 (3.6 ± 0.7 kcal kg-1 hr-1) and the refined Crouter model (3.5 ± 0.5 kcal kg-1 hr-1) ($P < 0.05$).

CONCLUSION:

The 2006 Crouter 2-regression model over-predicts EE at the beginning and end of walking bouts, due to high variability in accelerometer counts during the transitional minutes. The new refined model eliminates this problem and results in a more accurate prediction of EE during walking.

Kuhbeck, Felizian; Engelhardt, Stefan; Sarikas, Antonio (2014):

OnlineTED.com - a novel web-based audience response system for higher education. A pilot study to evaluate user acceptance.

In: *GMS Z Med Ausbild* 31 (1), S. Doc5. DOI: 10.3205/zma000897.

Abstract:

Background and aim: Audience response (AR) systems are increasingly used in undergraduate medical education. However, high costs and complexity of conventional AR systems often limit their use. Here we present a novel AR system that is platform independent and does not require hardware clickers or additional software to be installed. Methods and results: "OnlineTED" was developed at Technische Universitat Munchen (TUM) based on Hypertext Preprocessor (PHP) with a My Structured Query Language (MySQL)-database as server- and Javascript as client-side programming languages. "OnlineTED" enables lecturers to create and manage question sets online and start polls in-class via a web-browser. Students can participate in the polls with any internet-enabled device (smartphones, tablet-PCs or laptops). A paper-based survey was conducted with undergraduate medical students and lecturers at TUM to compare "OnlineTED" with conventional AR systems using clickers. "OnlineTED" received above-average evaluation results by both students and lecturers at TUM and was seen on par or superior to conventional AR systems. The survey results indicated that up to 80% of students at TUM own an internet-enabled device (smartphone or tablet-PC) for participation in web-based AR technologies. Summary and Conclusion: "OnlineTED" is a novel web-based and platform-independent AR system for higher education that was well received by students and lecturers. As a non-commercial alternative to conventional AR systems it may foster interactive teaching in undergraduate education, in particular with large audiences.

Clinician Perceptions of Using a Smartphone App with Prolonged Exposure Therapy.

In: *Adm Policy Ment Health. DOI:* 10.1007/s10488-013-0532-2.

Abstract:

Clinician perceptions of clinical innovations affect their adoption and spread. This study investigated mental health clinicians' (n = 163) perceptions of a patient-facing smartphone application (app) for prolonged exposure (PE) therapy for posttraumatic stress disorder, before its public release. After reading a description of the app, participants rated perceptions of it based on diffusion of innovations theory constructs. Perceptions were generally favorable regarding the app's relative advantage over existing PE practices, compatibility with their values and needs, and complexity. Age (<40 years), smartphone ownership, and having used apps in care related to more favorable perceptions. Smartphone ownership, relative advantage, and complexity significantly predicted intention to use the app if it were available. These findings suggest that clinicians are receptive to using a PE app and that dissemination efforts should target sub-groups of PE clinicians to maximize adoption.

Kuhn, Eric; Greene, Carolyn; Hoffman, Julia; Nguyen, Tam; Wald, Laura; Schmidt, Janet et al. (2014):

Preliminary evaluation of PTSD Coach, a smartphone app for post-traumatic stress symptoms.

In: *Mil Med* 179 (1), S. 12–18. DOI: 10.7205/MILMED-D-13-00271.

Abstract:

PTSD Coach is a mobile application (app) designed to help individuals who have post-traumatic stress disorder (PTSD) symptoms better understand and self-manage their symptoms. It has wide-scale use (over 130,000 downloads in 78 countries) and very favorable reviews but has yet to be evaluated. Therefore, this study examines user satisfaction, perceived helpfulness, and usage patterns of PTSD Coach in a sample of 45 veterans receiving PTSD treatment. After using PTSD Coach for several days, participants completed a survey of satisfaction and perceived helpfulness and focus groups exploring app use and benefit from use. Data indicate that participants were very satisfied with PTSD Coach and perceived it as being moderately to very helpful with their PTSD symptoms. Analysis of focus group data resulted in several categories of app use: to manage acute distress and PTSD symptoms, at scheduled times, and to help with sleep. These findings offer preliminary support for the acceptability and perceived helpfulness of PTSD Coach and suggest that it has potential to be an effective self-management tool for PTSD. Although promising, future research is required to validate this, given study limitations.

Kuhnhausen, J.; Leonhardt, A.; Dirk, J.; Schmiedek, F. (2013):

Physical activity and affect in elementary school children's daily lives.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 456. DOI: 10.3389/fpsyg.2013.00456.

Abstract:

A positive influence of physical activity (PA) on affect has been shown in numerous studies. However, this relationship has not yet been studied in the daily life of children. We present a part of the FLUX study that attempts to contribute to filling that gap. To this end, a proper way to measure PA and affect in the daily life of children is needed. In pre-studies of the FLUX study, we were able to show that affect can be measured in children with self-report items that are answered using smartphones. In the current article, we show that it is feasible to objectively measure children's PA with accelerometers for a period of several weeks and report descriptive information on the amount of activity of 51 children from 3rd and 4th grade. Additionally, we investigate the influence of daily PA on daily affect in children. Mixed effects models show no effect of PA on any of the four measured dimensions of affect. We discuss that this might be due to effects taking place at shorter time intervals, which can be investigated in future analyses

Kumahara, H.; Tanaka, H.; Schutz, Y. (2009):

Are pedometers adequate instruments for assessing energy expenditure?

In: *Eur J Clin Nutr* 63 (12), S. 1425–1432. DOI: 10.1038/ejcn.2009.108.

Abstract:

OBJECTIVE\r\nAssessing energy expenditure (EE) is important for the control of obesity. Daily step counts have become popular and constitute one practical technique for evaluating the physical activity (PA) in large population studies. However, information on the capacity of pedometers to track EE in free-living conditions remains scanty.\r\nSUBJECTS AND METHODS\r\nThe 24-h EE of 71 healthy adults was measured by indirect calorimetry in a large respiratory chamber. Two accelerometers were attached to the waist, one for counting the total daily steps (ACC(STEP)) and another for measuring the anteroposterior whole body acceleration calculated as the root mean square of the acceleration signal at every second (ACC(RMS)).\r\nRESULTS\r\nThe ACC(STEP) was not associated with PA-related EE (PAEE) or 24-h EE. Body weight (BW) was the main determinant of both the values (explaining 30 and 75% of the variance, respectively). Approximately 8% ($P<0.001$) of the variance in PAEE was attributed to the ACC(RMS) after BW was accounted for, whereas the ACC(STEP) did not explain any additional variance. A multiple stepwise regression analysis revealed that BW, height and ACC(RMS) were highly significant determinants of 24-h EE and accounted for as much as 83% of the total variance.\r\nCONCLUSIONS\r\nRecording the number of steps per day does not provide accurate information on EE, and at best is only a crude predictor of the general PA in terms of displacement. In contrast, accelerometry signals are considered to be a more meaningful factor in the assessment of EE rather than step counts under sedentary conditions.

Waiting for Merlot: Anticipatory consumption of experiential and material purchases.

In: *Psychological Science* 25 (10), S. 1924–1931. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-43635-009%26site%3dehost-live.

Abstract:

Experiential purchases (money spent on doing) tend to provide more enduring happiness than material purchases (money spent on having). Although most research comparing these two types of purchases has focused on their downstream hedonic consequences, the present research investigated hedonic differences that occur before consumption. We argue that waiting for experiences tends to be more positive than waiting for possessions. Four studies demonstrate that people derive more happiness from the anticipation of experiential purchases and that waiting for an experience tends to be more pleasurable and exciting than waiting to receive a material good. We found these effects in studies using questionnaires involving a variety of actual planned purchases, in a large-scale experience-sampling study, and in an archival analysis of news stories about people waiting in line to make a purchase. Consumers derive value from anticipation, and that value tends to be greater for experiential than for material purchases. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Kumpula, Mandy J. (2012):

Motivations for sex and sexual behavior among female college students: An event-level analysis.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (6-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-99240-134%26site%3dehost-live.

Abstract:

College-aged women frequently engage in sexual behavior associated with negative physical and psychological outcomes, and understanding factors that promote high-risk sexual behavior is necessary to inform effective interventions. Motivational influences on sexual behavior have been implicated in promoting patterns of sexual risk; however, the precise nature of these relationships is unclear. Event-level associations between motivations for sexual intercourse and sexual risk-taking behavior were examined in an eight-week online electronic diary study from a sample of 241 undergraduate women. Hierarchical linear modeling indicated that situation-specific coping, self-affirmation, and enhancement motives for sex, along with associated contextual and dispositional factors, demonstrated differential influences on indiscriminate sexual behavior and engaging in actions to protect against sexually transmitted diseases and unwanted pregnancy. Women were more likely to engage in sex with a new partner when intercourse was preceded by depressed mood and motivated by a desire to cope with negative emotion. Sexual intercourse resulting from self-affirmation motivation in the context of low self-esteem also was associated with increased likelihood of sex with a new partner, as well as lower probability of condom and contraceptive use. In addition, event-level reports of self-affirmation motives for sex were associated with sex with a less familiar partner when self-esteem ratings were high. Sexual experiences driven by enhancement motives were associated with lower perceived intimacy with a sexual partner, and enhancement motivation interacted with propensity for sensation seeking to predict likelihood of condom use. The results suggest that sexual motivation plays an important role in sexual risk-taking behavior; however, its effects are best understood in the context of other situational and dispositional factors. Kuntsche, Emmanuel; Labhart, Florian (2013):

Using personal cell phones for ecological momentary assessment: An overview of current developments.

In: *European Psychologist* 18 (1), S. 3–11. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-13184-002%26site%3dehost-live;ekuntsche@suchtschweiz.ch.

Abstract:

Ecological Momentary Assessment (EMA) is a way of collecting data in people's natural environments in real time and has become very popular in social and health sciences. The emergence of personal digital assistants has led to more complex and sophisticated EMA protocols but has also highlighted some important drawbacks. Modern cell phones combine the functionalities of advanced communication systems with those of a handheld computer and offer various additional features to

capture and record sound, pictures, locations, and movements. Moreover, most people own a cell phone, are familiar with the different functions, and always carry it with them. This paper describes ways in which cell phones have been used for data collection purposes in the field of social sciences. This includes automated data capture techniques, for example, geolocation for the study of mobility patterns and the use of external sensors for remote health-monitoring research. The paper also describes cell phones as efficient and user-friendly tools for prompt manual data collection, that is, by asking participants to produce or to provide data. This can either be done by means of dedicated applications or by simply using the web browser. We conclude that cell phones offer a variety of advantages and have a great deal of potential for innovative research designs, suggesting they will be among the standard data collection devices for EMA in the coming years. Kuppens, Peter; Allen, Nicholas B.; Sheeber, Lisa B. (2010):

Emotional inertia and psychological maladjustment.

In: *Psychological Science* 21 (7), S. 984–991. DOI: 10.1177/0956797610372634.

Abstract:

In this article, we examine the concept of emotional inertia as a fundamental property of the emotion dynamics that characterize psychological maladjustment. Emotional inertia refers to the degree to which emotional states are resistant to change. Because psychological maladjustment has been associated with both emotional underreactivity and ineffective emotion-regulation skills, we hypothesized that its overall emotion dynamics would be characterized by high levels of inertia. We provide evidence from two naturalistic studies that, using different methods, showed that the emotional fluctuations of individuals who exhibited low self-esteem (Study 1) and depression (Study 2) were characterized by higher levels of inertia in both positive and negative emotions than the emotional fluctuations of people who did not exhibit low self-esteem and depression. We also discuss the usefulness of the concept of emotional inertia as a hallmark of maladaptive emotion dynamics.

The dynamic interplay between appraisal and core affect in daily life.

In: *Front Psychol* 3. DOI: 10.1037/t01286-000;

Abstract:

Appraisals and core affect are both considered central to the experience of emotion. In this study we examine the bidirectional relationships between these two components of emotional experience by examining how core affect changes following how people appraise events and how appraisals in turn change following how they feel in daily life. In an experience sampling study, participants recorded their core affect and appraisals of ongoing events; data were analyzed using cross-lagged multilevel modeling. Valence-appraisal relationships were found to be characterized by congruency: the same appraisals that were associated with a change in pleasure-displeasure (motivational congruency, other-agency, coping potential, and future expectancy), changed themselves as a function of pleasure-displeasure. In turn, mainly secondary appraisals of who is responsible and how one is able to cope with events were associated with changes in arousal, which itself is followed by changes in the future appraised relevance of events. These results integrate core affect and appraisal approaches to emotion by demonstrating the dynamic interplay of how appraisals are followed by changes in core affect which in turn change our basis for judging future events. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Feelings change: accounting for individual differences in the temporal dynamics of affect.

In: *Journal of Personality and Social Psychology* 99 (6), S. 1042.

Abstract:

People display a remarkable variability in the patterns and trajectories with which their feelings change over time. In this article, we present a theoretical account for the dynamics of affect (DynAffect) that identifies the major processes underlying individual differences in the temporal dynamics of affective experiences. It is hypothesized that individuals are characterized by an affective home base, a baseline attractor state around which affect fluctuates. These fluctuations vary as the result of internal or external processes to which an individual is more or less sensitive and are regulated and tied back to the home base by the attractor strength. Individual differences in these 3 processes--affective home base, variability, and attractor strength--are proposed to underlie individual differences in affect dynamics. The DynAffect account is empirically evaluated by means of a diffusion modeling approach in 2 extensive experience-sampling studies on people's core affective experiences. The findings show that the model is capable of adequately capturing the observed dynamics in core affect across both large (Study 1) and shorter time scales (Study 2) and illuminate how the key processes are related to personality and emotion dispositions. Implications for the understanding of affect dynamics and affective dysfunctioning in psychopathology are also discussed.

Kuppens, Peter; van Mechelen, Iven; Nezlek, John B.; Dossche, Dorien; Timmermans, Tinneke (2007):

Individual differences in core affect variability and their relationship to personality and psychological adjustment.

In: *Emotion* 7 (2), S. 262.

Abstract:

How people's feelings change across time can be represented as trajectories in a core affect space defined by the dimensions of valence and activation. In this article, the authors analyzed individual differences in within-person affective variability defined as characteristics of core affect trajectories, introducing new ways to conceptualize affective variability. In 2 studies, participants provided multiple reports across time describing how they were feeling in terms of core affect. From these data, characteristics of participants' core affect trajectories were derived. Across both studies, core affect variability was negatively related to average valence, self-esteem, and agreeableness, and it was positively related to neuroticism and depression. Moreover, spin, a measure of how much people experienced qualitatively different feelings within the core affect space, was related more consistently to trait measures of adjustment and personality than other measures of within-person variability, including widely used measures of within-person single-dimension standard deviations.

Kurti, Allison N.; Logan, Henrietta; Manini, Todd; Dallery, Jesse (2014):

Physical Activity Behavior, Barriers to Activity, and Opinions About a Smartphone-Based Physical Activity Intervention Among Rural Residents.

In: *Telemed J E Health. DOI:* 10.1089/tmj.2014.0034.

Abstract:

Abstract Background: Rural Americans engage in less physical activity (PA) and experience higher rates of consequent health problems (i.e., obesity, cardiovascular disease) than urban Americans. Although geographic barriers have historically made this population hard to reach, rural individuals are increasingly gaining access to smartphones. Thus, the purpose of this study was to evaluate PA behavior and barriers to PA among rural residents and to gauge their receptiveness to a smartphone-based PA intervention that is currently in the development stage. Materials and Methods: Rural Floridian adults (n=113), 18 years of age and older, completed surveys to assess PA behavior, PA barriers, and opinions about an intervention to increase PA. Specifically, they were asked to imagine a program that would require them to do PA with their mobile phones and whether they viewed intended aspects of the program as helpful. The present work is therefore formative research that sought to determine the

feasibility and acceptability of a smartphone-based intervention among rural residents. Results of the survey will inform the development of a tailored, smartphone-based PA intervention. Results: The 37.2% of participants with low PA levels (<600 metabolic equivalent [MET]-min per week) were more likely to report personal and environmental barriers to PA than the 47.8% of participants with moderate PA levels (>/=600 MET-min per week). More barriers were reported among participants who self-reported as white and among participants of older age, lower education level, and lower socioeconomic status. Additionally, 75.9% of participants reported features of the intervention as at least somewhat helpful. Conclusions: The growing ubiquity of smartphones among rural residents, combined with participants' positive response to the program description, supports the acceptability of a smartphone-based PA intervention for rural communities. Given the participants' receptiveness, future research should evaluate the efficacy of smartphone-delivered health behavior interventions among this population.

Urinary angiotensinogen, related factors and clinical implications in normotensive autosomal dominant polycystic kidney disease patients.

In: *Ren Fail. DOI:* 10.3109/0886022X.2014.890857.

Abstract:

Abstract Background: Although several lines of evidence suggest that renin angiotensin system (RAS) proteins are synthesized by cyst epithelium and dilated tubules, role of intrarenal RAS in the progression of otozomal dominant polycystic kidney disease (ADPKD) is not well known. We aimed to study the levels and clinical correlations of urinary angiotensinogen (UAGT) in normotensive ADPKD patients compared with age- and sex-matched healthy subjects. Methods: The study included 20 normotensive ADPKD patients (F/M: 11/9) and 20 age and sex matched healthy controls (F/M: 9/11). Diagnosis of ADPKD was made based on Ravine criteria. Twenty-four hours ambulatory blood pressure monitoring (ABPM) was performed. Serum concentrations of creatinine, Na, K, uric acid, and urinary concentrations of Na, K, uric acid, creatinine, protein and albumin were measured. UAGT were measured via commercially available ELISA kit. Results: ADPKD patients had higher urinary albumin:creatinine ratio (UAlb/UCrea) than healthy controls ($p < 0.01$). UAGT/UCrea levels significantly positively correlated with urinary protein: creatinine ratio (UPro/UCrea) ($r = 0.785$, $p = 0.01$), and UAlb/UCrea ($r = 0.681$, $p = 0.01$) in normotensive ADPKD patients. Conclusion: This pilot study demonstrates that UAGT levels tend to be elevated and are correlated with proteinuria and albuminuria in normotensive ADPKD patients during relatively early stages of the disease.

Monitoring stage fright outside the laboratory: an example in a professional musician using wearable sensors.

In: *Med.Probl.Perform.Art.* 27 (1), S. 21–30. Online verfügbar unter PM:22543319.

Abstract:

We implemented and tested a wearable sensor system to measure patterns of stress responses in a professional musician under public performance conditions. Using this sensor system, we monitored the cellist's heart activity, the motion of multiple body parts, and their gradual changes during three repeated performances of a skill-demanding piece in front of a professional audience. From the cellist and her teachers, we collected stage fright self-reports and performance ratings that were related to our sensor data analysis results. Concomitant to changes in body motion and heart rate, the cellist perceived a reduction in stage fright. Performance quality was objectively improved, as technical playing errors decreased throughout repeated renditions. In particular, from performance 1 to 3, the wearable sensors measured a significant increase in the cellist's bowing motion dynamics of approximately 6% and a decrease in heart rate. Bowing motion showed a marginal correlation to the observed heart rate patterns during playing. The wearable system did not interfere with the cellist's performance, thereby allowing investigation of stress responses during natural public performances

Effects of Azilsartan Compared to Other Angiotensin Receptor Blockers on Left Ventricular Hypertrophy and the Sympathetic Nervous System in Hemodialysis Patients.

In: *Ther Apher Dial. DOI:* 10.1111/1744-9987.12168.

Abstract:

Hypertension is a major risk factor for cardiovascular and cerebrovascular events, and most patients with hypertension are administered antihypertensive drugs. However, not all patients achieve normal blood pressure levels. The new angiotensin receptor blocker azilsartan (Takeda Pharmaceutical Company Limited, Osaka, Japan) has been reported to have a strong hypotensive effect. Our study investigated the efficacy of azilsartan compared with other angiotensin receptor blockers. This study included 17 hypertensive patients on HD, who had been administered angiotensin receptor blockers, except for azilsartan, for more than 6 months before enrolling, and after enrollment, they were switched to azilsartan. Blood tests, Holter electrocardiogram, ambulatory blood pressure monitoring, and echocardiography were performed at baseline and at the 6-month follow-up. The blood pressure from baseline to 6 months had significantly decreased (24-h systolic blood pressure from 150.9 +/- 16.2 mm Hg to 131.3 +/- 21.7 mm Hg, P = 0.008), awakening time systolic blood pressure from 152.1 +/- 16.9 mm Hg to 131.7 +/- 23.2 mm Hg, P = 0.01, sleep-time systolic blood pressure from 148.1 +/- 19.7 mm Hg to 130.0 +/- 20.1 mm Hg, P = 0.005). There was a significant reduction in serum noradrenaline levels as well as left ventricular mass index after switching to azilsartan (from 550.1 +/- 282.9 pg/mL, to 351.7 +/- 152.3 pg/mL, P = 0.002; from 117.0 +/- 26.4 g/m2 to 111.3 +/- 23.9 g/m2 , P = 0.01, respectively). Azilsartan had a significantly stronger hypotensive effect than other angiotensin receptor blockers. Thus, the switch to azilsartan might improve prognosis of hemodialysis patients. We suggest that the strong anti-hypertensive effect of azilsartan originated from a combination of primary angiotensin receptor blocker class-effect and a stronger suppression of sympathetic nervous system.

Kwapil, T. R.; Brown, L. H.; Silvia, P. J.; Myin-Germeys, I.; Barrantes-Vidal, N. (2012):

The expression of positive and negative schizotypy in daily life: An experience sampling study.

In: *Psychological Medicine* 42 (12), S. 2555–2566. DOI: 10.1037/t02328-000;

Abstract:

Background: Psychometrically identified positive schizotypy and negative schizotypy are differentially related to psychopathology, personality and social functioning. However, little is known about the experience and expression of schizotypy in daily life and the psychological mechanisms that trigger psychotic-like experiences. Method: The present study employed experience sampling methodology (ESM) to assess positive and negative schizotypy in daily life in a non-clinical sample of 412 young adults. ESM is a structured diary technique in which participants are prompted at random times during the day to complete assessments of their current experiences. Results: As hypothesized, positive schizotypy was associated with increased negative affect, thought impairment, suspiciousness, negative beliefs about current activities and feelings of rejection, but not with social disinterest or decreased positive affect. Negative schizotypy, on the other hand, was associated with decreased positive affect and pleasure in daily life, increased negative affect, and decreases in social contact and interest. Both positive schizotypy and negative schizotypy were associated with the desire to be alone when with others. However, this was moderated by anxiety in positive schizotypy and by diminished positive affect in negative schizotypy Conclusions: The results support the construct validity of a multidimensional model of schizotypy and the ecological validity of the positive and negative schizotypy dimensions. ESM appears to be a promising method for examining the daily life experiences of schizotypic individuals. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Kwon, S.; Burns, T. L.; Levy, S. M.; Janz, K. F. (2011):

Breaks in Sedentary Time during Childhood and Adolescence: Iowa Bone Development Study.

In: *Med.Sci.Sports Exerc.* (0195-9131 (Linking)). DOI: 10.1249/MSS.0b013e318245ca20.

Abstract:

PURPOSE: The frequency of interruptions in sedentary time (sedentary breaks) is an aspect of sedentary behaviors which may be associated with metabolic health outcomes. The aim of this study was to describe the change in the frequency of sedentary breaks over a 10-year period from ages 5 to 15. METHODS: The longitudinal Iowa Bone Development Study has collected accelerometry data at approximately 5, 8, 11, 13, and 15 years of age. Data from participants who wore an accelerometer at least 10 hours per day and three days per data collection episode were used (423 children at age 5, 550 at age 8, 520 at age 11, 454 at age 13, and 344 at age 15). The frequency of sedentary breaks was determined based on accelerometry data and compared by weekday/weekend, time period during the day, gender, and data collection episode. RESULTS: The frequency of sedentary breaks decreased by > 200 times/day over a 10-year period from ages 5 to 15. Linear regression models estimated a 1.84 times/hour decrease per year for boys and a 2.04 times/hour decrease per year for girls (Ps < 0.0001). Both boys and girls showed significantly fewer breaks on weekdays from morning to 3:00 PM than on weekends from morning to 3:00 PM (Ps < 0.0001). The frequency of sedentary breaks was slightly higher among boys than girls (gender difference </= 2 times/hour; Ps <

0.01 at ages 11, 13, and 15). CONCLUSION: Breaks in sedentary time notably decrease during childhood and adolescence. During school hours, boys and girls have fewer breaks in sedentary time than during any other time period of weekday or weekend day

Kwon, Yongjin; Kang, Kyuchang; Bae, Changseok; Chung, Hee-Joon; Kim, Ju Han (2014):

Lifelog agent for human activity pattern analysis on health avatar platform.

In: *Healthc Inform Res* 20 (1), S. 69–75. DOI: 10.4258/hir.2014.20.1.69.

Abstract:

OBJECTIVES: To provide accurate personalized medical care, it is necessary to gather individual-related data or contextual information regarding the target person. Nowadays a large number of people possess smartphones, which enables sensors in the smartphones to be used for lifelogging. The objective of the study is to analyze human activity pattern by using lifelog agent cooperating with the Health Avatar platform. METHODS: Using the lifelog measured by accelerometer and gyroscope in a smartphone at a 50 Hz rate, the agent reveals how long the user walks, runs, sits, stands, and lies down, and this information is summarized by hours. The summaries are sent to the Health Avatar platform and finally are written in the Continuity of Care Record (CCR) format. RESULTS: The lifelog agent is successfully operated with the Health Avatar platform. In addition, we implement an application that displays the user's activity patterns in a graph and calculates the metabolic equivalent of task based calorie burned by hour or by day using the lifelog of the CCR form to show that the lifelog can be used as medical records. CONCLUSIONS: The agent shows how lifelogs are analyzed and summarized to help activity recognition. We believe that our agent demonstrates a way of incorporating lifelogs into medical care and a way of exploiting lifelogs in a medical format.

Kwon, S.; Kim, H.; Park, K. S. (2012):

Validation of heart rate extraction using video imaging on a built-in camera system of a smartphone.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 2174–2177. DOI: 10.1109/EMBC.2012.6346392.

Abstract:

As a smartphone is becoming very popular and its performance is being improved fast, a smartphone shows its potential as a low-cost physiological measurement solution which is accurate and can be used beyond the clinical environment. Because cardiac pulse leads the subtle color change of a skin, a pulsatile signal which can be described as photoplethysmographic (PPG) signal can be measured through recording facial video using a digital camera. In this paper, we explore the potential that the reliable heart rate can be measured remotely by the facial video recorded using smartphone camera. First, using the front facing-camera of a smartphone, facial video was recorded. We detected facial region on the image of each frame using face detection, and yielded the raw trace signal from the green channel of the image. To extract more accurate cardiac pulse signal, we applied independent component analysis (ICA) to the raw trace signal. The heart rate was extracted using frequency analysis of the raw trace signal and the analyzed signal from ICA. The accuracy of the estimated heart rate was evaluated by comparing with the heart rate from reference electrocardiogram (ECG) signal. Finally, we developed FaceBEAT, an iPhone application for remote heart rate measurement, based on this study

Kwon, Min; Kim, Dai-Jin; Cho, Hyun; Yang, Soo (2013):

The smartphone addiction scale: development and validation of a short version for adolescents.

In: *PLoS One* 8 (12), S. e83558. DOI: 10.1371/journal.pone.0083558.

Abstract:

OBJECTIVE: This study was designed to investigate the revised and short version of the smartphone addiction scale and the proof of its validity in adolescents. In addition, it suggested cutting off the values by gender in order to determine smartphone addiction and elaborate the characteristics of smartphone usage in adolescents. METHOD: A set of questionnaires were provided to a total of 540 selected participants from April to May of 2013. The participants consisted of 343 boys and 197 girls, and their average age was 14.5 years old. The content validity was performed on a selection of shortened items, while an internal-consistency test was conducted for the verification of its reliability. The concurrent validity was confirmed using SAS, SAPS and

KS-scale. Receiver operating characteristics analysis was conducted to suggest cut-off. RESULTS: The 10 final questions were selected using content validity. The internal consistency and concurrent validity of SAS were verified with a Cronbach's alpha of 0.911. The SAS-SV was significantly correlated with the SAS, SAPS and KS-scale. The SAS-SV scores of gender (p<.001) and self-evaluation of smartphone addiction (p<.001) showed significant difference. The ROC analysis results showed an area under a curve (AUC) value of 0.963(0.888-1.000), a cut-off value of 31, sensitivity value of 0.867 and specificity value of 0.893 in boys while an AUC value of 0.947(0.887-1.000), a cut-off value of 33, sensitivity value of 0.875, and a specificity value of 0.886 in girls. CONCLUSIONS: The SAS-SV showed good reliability and validity for the assessment of smartphone addiction. The smartphone addiction scale short version, which was developed and validated in this study, could be used efficiently for the evaluation of smartphone addiction in community and research areas.

CardioGuard: A Brassiere-Based Reliable ECG Monitoring Sensor System for Supporting Daily Smartphone Healthcare Applications.

In: *Telemed J E Health* 20 (12), S. 1093–1102. DOI: 10.1089/tmj.2014.0008.

Abstract:

Abstract We propose CardioGuard, a brassiere-based reliable electrocardiogram (ECG) monitoring sensor system, for supporting daily smartphone healthcare applications. It is designed to satisfy two key requirements for user-unobtrusive daily ECG monitoring: reliability of ECG sensing and usability of the sensor. The system is validated through extensive evaluations. The evaluation results showed that the CardioGuard sensor reliably measure the ECG during 12 representative daily activities including diverse movement levels; 89.53% of QRS peaks were detected on average. The questionnaire-based user study with 15 participants showed that the CardioGuard sensor was comfortable and unobtrusive. Additionally, the signal-to-noise ratio test and the washing durability test were conducted to show the high-quality sensing of the proposed sensor and its physical durability in practical use, respectively.

Kwon, Hyung-Min; Lim, Jae-Sung; Kim, Young Seo; Moon, Jangsup; Park, Hyeri; Kim, Hyun Young et al. (2014):

Cerebral microbleeds are associated with nocturnal reverse dipping in hypertensive patients with ischemic stroke.

In: *BMC Neurol* 14, S. 8. DOI: 10.1186/1471-2377-14-8.

Abstract:

BACKGROUND: Abnormalities in nocturnal blood pressure dipping are well known for its relationship to cardiovascular diseases. Cerebral microbleeds are frequently observed in patients with hypertension and are known to be potent risk factors for stroke. However, there are scanty reports about the relationship between nocturnal dipping and cerebral microbleeds. METHODS: We recruited consecutive patients with both hypertension and ischemic stroke within 7 days after symptom onset, and those with cardioembolism were excluded. We applied 24-hour ambulatory blood pressure monitoring two weeks after stroke onset, and we used brain MRI to detect cerebral microbleeds. Various blood pressure parameters such as mean 24-hour blood pressure, awake/sleep blood pressure, and morning surge were compared between cerebral microbleeds (+) vs. (-) groups. Subjects were further classified according to nocturnal dipping status and were analyzed by logistic regression to determine its association with cerebral microbleeds with adjustment for age, gender, and cardiovascular risk factors. RESULTS: A total of 162 patients (100 males, age 65.33 +/- 10.32 years) were included. Cerebral microbleeds were detected in 65 patients (40.1%). Most ambulatory blood pressure parameters except morning surge were significantly higher in those who had cerebral microbleeds. After adjusting for the confounding factors, the reverse dippers were prone to have cerebral microbleeds (odds ratio, 3.81; 95% confidential interval, 1.36-10.65; p-value = 0.01). CONCLUSION: Cerebral microbleeds are independently associated with reverse dipping on ambulatory blood pressure monitoring in hypertensive stroke patients.

La Sierra, Alejandro; Redon, Josep; Banegas, José R.; Segura, Julián; Parati, Gianfranco; Gorostidi, Manuel et al. (2009):

Prevalence and factors associated with circadian blood pressure patterns in hypertensive patients.

In: *Hypertension* 53 (3), S. 466–472. DOI: 10.1161/HYPERTENSIONAHA.108.124008.

Abstract:

Ambulatory blood pressure (BP) monitoring has become useful in the diagnosis and management of hypertensive individuals. In addition to 24-hour values, the circadian variation of BP adds prognostic significance in predicting cardiovascular outcome. However, the magnitude of circadian BP patterns in large studies has hardly been noticed. Our aims were to determine the prevalence of circadian BP patterns and to assess clinical conditions associated with the nondipping status in groups of both treated and untreated hypertensive subjects, studied separately. Clinical data and 24-hour ambulatory BP monitoring were obtained from 42,947 hypertensive patients included in the Spanish Society of Hypertension Ambulatory Blood Pressure Monitoring Registry. They were 8384 previously untreated and 34,563 treated hypertensives. Twenty-four-hour ambulatory BP monitoring was performed with an oscillometric device (SpaceLabs 90207). A nondipping pattern was defined when nocturnal systolic BP dip was <10% of daytime systolic BP. The prevalence of nondipping was 41% in the untreated group and 53% in treated patients. In both groups, advanced age, obesity, diabetes mellitus, and overt cardiovascular or renal disease were associated with a blunted nocturnal BP decline (P<0.001). In treated patients, nondipping was associated with the use of a higher number of antihypertensive drugs but not with the time of the day at which antihypertensive drugs were administered. In conclusion, a blunted nocturnal BP dip (the nondipping pattern) is common in hypertensive patients. A clinical pattern of high cardiovascular risk is associated with nondipping, suggesting that the blunted nocturnal BP dip may be merely a marker of high cardiovascular risk.

Development and testing of Painometer: a Smartphone app to assess pain intensity.

In: *J Pain. DOI:* 10.1016/j.jpain.2014.04.009.

Abstract:

The so-called electronic and information technologies (EITs) are increasingly being used to assess pain. This study aims (1) to introduce Painometer, a Smartphone app that helps users to assess pain intensity, and (2) to report on its usability (i.e., user performance and satisfaction) and acceptability (i.e. the willingness to use it) when it is used by healthcare professionals and non-professionals. Painometer includes four well-known pain intensity scales: the Faces Pain Scale-Revised, the Numerical Rating Scale-11, the Coloured Analogue Scale, and the Visual Analogue Scale. Scores reported with these scales, when used in its traditional format, have demonstrated to be valid and reliable. The app was tested in a sample of 24 healthcare professionals, and 30 non-professionals. Two iterative usability cycles were conducted with a qualitative usability testing approach and a semi-structured interview. The participants had an average of 10 years' experience in using computers. The domains measured were ease of use, errors in usage, most popular characteristics, suggested changes and acceptability. Adding instructions and changing format and layout details solved the usability problems reported in cycle 1. No further problems were reported in cycle 2. Painometer has been found to be a useful, user-friendly app that may help to improve the accuracy of pain intensity assessment. PERSPECTIVE: Painometer, a Smarphone application to assess pain intensity, shows good usability and acceptability properties when used by healthcare professionals and non-professional users.

Labinson, Paul T.; Giacco, Sharon; Gift, Henry; Mansoor, George A.; White, William B. (2008):

The importance of the clinical observer in the development of a white-coat effect in African–American patients with hypertension.

In: *Blood Press Monit* 13 (3), S. 139–142.

Abstract:

INTRODUCTION:

As the office-awake blood pressure (BP) difference (white-coat effect) in African-Americans has not been evaluated, we studied the ethnicity, professional status (nurse versus doctor) and sex of the observer on the white-coat effect in African-American patients with hypertension.

METHODS:

Seated clinical BP measurements were obtained in random order by an African-American male research physician, a Caucasian male research physician, and a Caucasian female nurse who is of similar age and clinical experience. Within 1 week, ambulatory BP recordings were performed.

RESULTS:

A total of 65 African-American patients [54+/-13 years, 55% women, body mass index (BMI) 31+/-6 kg/m, 62% on drug therapy, 28% current smokers] participated in the study. Twenty-two percent had a systolic white-coat effect >20 mmHg and 49% had a diastolic white-coat effect >10 mmHg (average of all observers). Although there were no differences in the magnitude of the

white-coat effect among the three study observers, the primary physician's diastolic white-coat effect was significantly greater than that of the African-American physician (14+/-12 vs. 9+/-12, P=0.05), but not the systolic white-coat effect (16+/-16 vs. 10+/-16 mmHg, P=0.09). BMI positively correlated with the systolic and diastolic white-coat effect (r=0.30, P=0.02 and r=0.41, P=0.0001), but this correlation was true only for female patients in multiple regression analyses. BMI significantly predicted the systolic (P=0.043) and diastolic (P=0.004) white-coat effects.

CONCLUSION:

A white-coat effect is relatively common in African-American patients with hypertension and is the largest when the observer is their usual doctor. The clinical observer's ethnicity or sex does not play an important role in generating a white-coat effect in African-American patients with hypertension.

Lackner, J. M.; Jaccard, J.; Keefer, L.; Firth, R.; Carosella, A. M.; Sitrin, M.; Brenner, D. (2014):

The accuracy of patient-reported measures for GI symptoms: a comparison of real time and retrospective reports.

In: *Neurogastroenterol Motil* 26 (12), S. 1802–1811. DOI: 10.1111/nmo.12466.

Abstract:

BACKGROUND: Obtaining accurate information about gastrointestinal (GI) symptoms is critical to achieving the goals of clinical research and practice. The accuracy of patient data is especially important for functional GI disorders (e.g., IBS) whose symptoms lack a biomarker and index illness severity and treatment response. Retrospective patient-reported data are vulnerable to forgetting and various cognitive biases whose impact has not been systematically studied in patients with GI disorders. The aim of this study was to document the accuracy of patient-reported GI symptoms over a reporting period (1 week) most representative of the time frame used in research and clinical care. METHODS: Subjects were 273 Rome III-diagnosed IBS patients (mean age = 39 years, 89% F) who completed end of day GI symptom ratings for 7 days using an electronic diary. On Day 8, Subjects recalled the frequency and/or intensity of IBS symptoms over the past 7 days. Reports were then compared against a validation criterion based on aggregated end of day ratings. KEY RESULTS: At the group level, subjects recalled most accurately abdominal pain and urgency intensity at their worst, urgency days, and stool frequency. When data were analyzed at the individual level, a subgroup of subjects had difficulty recalling accurately symptoms that showed convergence between recall and real time reports at the group level. CONCLUSIONS & INFERENCES: Although many patients' recollection for specific GI symptoms (e.g., worst pain, stool frequency) is reasonably accurate, a non-trivial number of other symptoms (e.g., typical pain) are vulnerable to distortion from recall biases that can reduce sensitivity of detecting treatment effects in clinical and research settings.

Laing, Brian Yoshio; Mangione, Carol M.; Tseng, Chi-Hong; Leng, Mei; Vaisberg, Ekaterina; Mahida, Megha et al. (2014):

Effectiveness of a smartphone application for weight loss compared with usual care in overweight primary care patients: a randomized, controlled trial.

In: *Ann Intern Med* 161 (10 Suppl), S. S5-12. DOI: 10.7326/M13-3005.

Abstract:

BACKGROUND: Many smartphone applications (apps) for weight loss are available, but little is known about their effectiveness. OBJECTIVE: To evaluate the effect of introducing primary care patients to a free smartphone app for weight loss. DESIGN: Randomized, controlled trial. (ClinicalTrials.gov: NCT01650337). SETTING: 2 academic primary care clinics. PATIENTS: 212 primary care patients with body mass index of 25 kg/m2 or greater. INTERVENTION: 6 months of usual care without (n = 107) or with (n = 105) assistance in downloading the MyFitnessPal app (MyFitnessPal). MEASUREMENTS: Weight loss at 6 months (primary outcome) and changes in systolic blood pressure and behaviors, frequency of app use, and satisfaction (secondary outcomes). RESULTS: After 6 months, weight change was minimal, with no difference between groups (mean between-group difference, -0.30 kg [95% CI, -1.50 to 0.95 kg]; P = 0.63). Change in systolic blood pressure also did not differ between groups (mean between-group difference, -1.7 mm Hg [CI, -7.1 to 3.8 mm Hg]; P = 0.55). Compared with patients in the control group, those in the intervention group increased use of a personal calorie goal (mean between-group difference, 2.0 d/wk [CI, 1.1 to 2.9 d/wk]; P < 0.001), although other self-reported behaviors did not differ between groups. Most users reported high satisfaction with MyFitnessPal, but logins decreased sharply after the first month. LIMITATIONS: Despite being blinded to the name of the app, 14 control group participants (13%) used MyFitnessPal. In addition, 32% of intervention group participants and 19% of control group participants were lost to follow-up at 6 months. The app was given to patients by research assistants, not by physicians. CONCLUSION: Smartphone apps for weight loss may be useful for persons who are ready to self-monitor calories, but introducing a smartphone app is unlikely to produce substantial weight change for most patients. "There's a Pain App for That": Review of Patient-Targeted Smartphone Applications for Pain Management.

In: *Clin J Pain. DOI:* 10.1097/AJP.0000000000000171.

Abstract:

OBJECTIVES:: There are a growing number of pain self-management apps available for users to download on personal smartphones. The purpose of this study was to critically appraise the content and self-management functionality of currently available pain apps. METHODS:: An electronic search was conducted between May and June 2014 of the official stores for the four major operating systems. Two authors independently identified patient-focused apps with a stated goal of pain management. Discrepancies regarding selection were resolved through discussion with a third party. Metadata from all included apps were abstracted into a standard form. The content and functionality of each app as it pertained to pain self-management was rated. RESULTS:: A total of 279 apps met the inclusion criteria. Pain self-care skill support was the most common self-management function (77.4%). Apps also purported providing patients with the ability to engage in pain education (45.9%), self-monitoring (19%), social support (3.6%) and goal-setting (0.72%). No apps were comprehensive in terms of pain self-management, with the majority of apps including only a single self-management function (58.5%). Additionally, only 8.2% of apps included a healthcare professional in their development, not a single app provided a theoretical rationale, and only 1 app underwent scientific evaluation. DISCUSSION:: Currently available pain self-management apps for patients are simplistic, lack the involvement of healthcare professionals in their development, and have not been rigorously tested for effectiveness on pain-related health outcomes. There is a need to develop and test theoretically- and evidence-based apps to better support patients with accessible pain care self-management.

Electronic and paper diary recording of infant and caregiver behaviors.

In: *Journal of Developmental & Behavioral Pediatrics* 31 (9), S. 685–693.

Abstract:

OBJECTIVES:

To assess (1) preference of parental use of an electronic diary (e-diary) over a paper diary to record continuous infant and caregiver behaviors over 7 days; (2) whether e-diary recordings would differ in systematic ways from those obtained by paper diaries, and (3) frequency of diary entries when parents provide entries when convenient.

METHODS:

Mothers of normal newborns were randomized at 5 weeks infant age to a paper diary first (n = 34) or e-diary first (n = 35) group. With 3 days between, mothers completed 7-day recordings on both the paper Baby's Day Diary and an analogous personal digital assistant e-diary for infant (sleep, awake alert, feeding, fussing, crying, inconsolable crying) and caregiver (carrying/holding, moving) behaviors, and completed post diary ease-of-use ratings and poststudy preference ratings.

RESULTS:

Mothers found e-diaries less bothersome but similarly disruptive and enjoyable to paper diaries. At study end, more found e-diaries easier to use, less bothersome and more efficient. E-diary behaviors were consistently more frequent, but rarely different in duration, then paper diary behaviors. Time-stamped e-diary entries (1) generally declined across weeks, (2) were higher if e-diaries were used first, and (3) settled at a modal 2 to 3 entries/day by the second week.

CONCLUSIONS:

For behavioral recording of infant and caregiver behaviors, mothers generally expressed more approval for e-diaries than paper diaries, but neither was considered onerous. E-diaries consistently report more frequent but similar durations of behaviors. If recording when convenient, daily diary entries trend toward 2 to 3 entries a day. The e-diary results provide convergent evidence that paper diary recordings of common infant and caregiver behavior durations provide good estimates of durations, but that behavioral frequencies may be underestimated.

Lam, C. Y.; Businelle, M. S.; Aigner, C. J.; McClure, J. B.; Cofta-Woerpel, L.; Cinciripini, P. M.; Wetter, D. W. (2013):

Individual and Combined Effects of Multiple High-Risk Triggers on Postcessation Smoking Urge and Lapse.

In: *Nicotine.Tob.Res.* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt190.

Abstract:

INTRODUCTION: Negative affect, alcohol consumption, and presence of others smoking have consistently been implicated as risk factors in smoking lapse and relapse. What is not known, however, is how these factors work together to affect smoking outcomes. This paper uses ecological momentary assessment (EMA) collected during the first 7 days of a smoking cessation attempt to test the individual and combined effects of high-risk triggers on smoking urge and lapse. METHODS: Participants were 300 female smokers who enrolled in a study that tested an individually tailored smoking cessation treatment. Participants completed EMA, which recorded negative affect, alcohol consumption, presence of others smoking, smoking urge, and smoking lapse, for 7 days starting on their quit date. RESULTS: Alcohol consumption, presence of others smoking, and negative affect were, independently and in combination, associated with increase in smoking urge and lapse. The results also found that the relationship between presence of others smoking and lapse and the relationship between negative affect and lapse were moderated by smoking urge. CONCLUSIONS: The current study found significant individual effect of alcohol consumption, presence of other smoking, and negative affect on smoking urge and lapse. Combing the triggers increased smoking urge and the risk of lapse to varying degrees and the presence of all 3 triggers resulted in the highest urge and lapse risk

Lam, Cho Y.; Businelle, Michael S.; Cofta-Woerpel, Ludmila; McClure, Jennifer B.; Cinciripini, Paul M.; Wetter, David W. (2014):

Positive smoking outcome expectancies mediate the relation between alcohol consumption and smoking urge among women during a quit attempt.

In: *Psychol Addict Behav* 28 (1), S. 163–172. DOI: 10.1037/a0034816.

Abstract:

Social learning models of addiction hypothesize that situational factors interact with cognitive determinants to influence a person's motivation to use substances. Ecological momentary assessment was used to examine the association between alcohol consumption, smoking outcome expectancies, and smoking urge during the first 7 days of a smoking quit attempt. Participants were 113 female smokers who enrolled in a study that tested an individually tailored smoking cessation treatment. Participants carried a palm-top personal computer for 7 days and were instructed to complete 4 random assessments each day and to initiate an assessment when they were tempted to smoke. Multilevel mediational analyses were used to examine (a) the effects of alcohol consumption before time j and positive smoking outcome expectancies at time j on smoking urge at time j + 1 (Model 1) and (b) the effects of alcohol consumption before time j and smoking urge at time j on positive smoking outcome expectancies at time j + 1 (Model 2). Model 1 found a significant effect of alcohol consumption before time j on smoking urge at time j + 1 ($p = .04$), and this effect was significantly mediated by positive smoking outcome expectancies at time j ($p < .0001$). Model 2 failed to find a significant effect of alcohol consumption before time j on positive smoking outcome expectancies at time j + 1. The findings suggest that alcohol consumption is significantly associated with increased positive smoking outcome expectancies that, in turn, are associated with increased smoking urge in women seeking to quit smoking.

Challenges to the four-channel model of flow: Primary assumption of flow support the moderate challenging control channel.

In: *The Journal of Positive Psychology* 8 (5), S. 395–403. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-29305-004%26site%3dehost-live;jl185872@sju.edu.

Abstract:

Flow theory postulates that the psychological state of flow emerging when one engages in activities where skill level and challenge are both high, results in ‘optimal’ subjective experiences relative to other psychological states, and is intrinsically motivated. The experience sampling method was used on a sample of college students to compare daily activities associated with flow (high skill, high challenge) to the psychological state of control (high skill, moderate challenge) in relation to the subjective experiences of enjoyment, happiness, intrinsic motivation, and cognitive involvement. Contrary to flow theory, enjoyment, happiness, and intrinsic motivation were characteristic of activities associated with being in ‘control,’ as opposed to flow. Flow activities were associated with being cognitively involved in the task at hand. We believe such theoretically important

findings have been masked when using the original four-channel model of flow, but are clarified with use of the revised experience fluctuation model. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Morning Surge in Blood Pressure Is Associated With Reactivity of the Sympathetic Nervous System.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpt273.

Abstract:

BACKGROUND: An exaggerated morning surge in blood pressure (BP) closely relates to target organ damage and cardiovascular risk, but whether the causative mechanism involves greater reactivity of the sympathetic nervous system (SNS) is unknown. We determined whether the response of the SNS to a cold pressor test predicted the BP morning surge. METHODS: Ambulatory BP recordings were obtained from 14 men and 19 women (age = 41+/-4 years), and the amplitude (day-night difference), rate of rise (RoR), rate by amplitude product (BPPower), and morning BP surge (MBPS; post-awake minus pre-awake) of morning mean arterial pressure (MAP) were determined. The reactivity of the SNS to CPT was assessed by recording of muscle sympathetic nerve activity (MSNA). RESULTS: CPT induced a marked increase in MAP and all parameters of MSNA, including burst amplitude. Log-normalized BPPower positively correlated with the overall average CPT-induced increases in total MSNA (r = 0.38; P = 0.04) and burst amplitude (r = 0.43; P = 0.02) but was not related to the increase in MSNA frequency. Furthermore, a strong positive linear trend in the CPT-induced changes in burst amplitude across tertiles of BPPower and RoR was observed. BPPower and RoR were not related to CPT-induced hemodynamic changes. The MBPS did not correlate with any of the CPT-induced changes in vascular or MSNA variables. CONCLUSIONS: These results suggest that the central nervous system mechanisms influencing the increase in MSNA burst amplitude during arousal may also be fundamental in determining the rate and power of BP rise during the morning period.

Lamont, Alexandra; Webb, Rebecca (2009):

Short-and long-term musical preferences: what makes a favourite piece of music?

In: *Psychology of Music*.

Abstract:

Within the growing field of music preferences, little is currently known about the concept of a favourite piece of music. The current study explores listeners' nominated favourite pieces of music over short and longer time-spans, combining diary and interview methods to uncover what a favourite means, how stable it is, and what factors influence the development of favourites. Nine undergraduate students participated in a diary study spanning one month, with follow-up interviews conducted with two participants. Results indicate that musical favourites are subject to rapid change and highly context-dependent. Most daily favourites were heard on the day, either deliberately or by chance. 'Magpie' listeners collected a large number of relatively transient favourites, while 'squirrel' listeners had a large catalogue of music stored from which to select. Long-term favourites differed from daily favourites, being associated with intense emotional events in listeners' lives. In this small-scale study, diary methods successfully captured fluctuations in music preferences over time for most listeners, while interviews revealed more about listeners' motivations and personal stories connected with their favourite music. Future research is required with larger samples to tease out the complexities of developing music preferences over time and engagement with music in everyday life settings.

Lamoth, Claudine J. C.; van Lummel, Rob C.; Beek, Peter J. (2009):

Athletic skill level is reflected in body sway: a test case for accelometry in combination with stochastic dynamics.

In: *Gait Posture* 29 (4), S. 546–551. DOI: 10.1016/j.gaitpost.2008.12.006.

Abstract:

Recent studies on postural control have shown that the variability of body sway during quiet standing may provide valuable information to characterize changes in postural control due to age, pathology, skill and task. The aim of the present study was to determine - as spade work for possible clinical applications - whether body sway measured with a three-axial accelerometer at the trunk can differentiate between three healthy young populations that differ in athletic skill level. The three groups in

question (group size: n=22) consisted of regular bachelor students, physical education students and physical education students specialized in gymnastics. Data were recorded during tandem stance with eyes open or closed and while standing on foam. The acceleration time-series were analysed in anteriorposterior and mediolateral direction. Differences in postural control were quantified in terms of variability, spectral properties and stochastic dynamical measures, i.c., regularity (sample entropy, long-range correlations) and local stability (largest Lyapunov exponent). The results were clear-cut. Standing with eyes closed and on foam increased variability. Compared to standing with eyes open, standing with eyes closed resulted in less regular sway patterns but with greater local stability, whereas standing on foam had an opposite effect. With greater gymnastic skills, acceleration time-series were less variable, less regular and more stable. These results imply that quantifying the stochastic-dynamical structure of postural sway using ambulant accelerometry may provide a useful diagnostic tool.

Lampert, Rachel; Bremner, J. Douglas; Su, Shaoyong; Miller, Andrew; Lee, Forrester; Cheema, Faiz et al. (2008):

Decreased heart rate variability is associated with higher levels of inflammation in middle-aged men.

In: *Am Heart J* 156 (4), S. 759.e1-7. DOI: 10.1016/j.ahj.2008.07.009.

Abstract:

BACKGROUND\r\nMany traditional risk factors for coronary artery disease (CAD) are associated with altered autonomic function. Inflammation may provide a link between risk factors, autonomic dysfunction, and CAD. We examined the association between heart rate variability (HRV), a measure of autonomic function, and inflammation, measured by C-reactive protein (CRP) and interleukin-6 (IL-6).\r\nMETHODS\r\nWe examined 264 middle-aged male twins free of symptomatic CAD. All underwent ambulatory electrocardiogram monitoring and 24-hour ultra low, very low, low, and high-frequency power were calculated using power spectral analysis. C-reactive protein and IL-6 were measured, and risk factors including age, smoking, hypertension, lipids, diabetes, body mass index (BMI), depression, and physical activity were assessed.\r\nRESULTS\r\nPhysical activity, BMI, high-density lipoprotein cholesterol, smoking, depression, and hypertension were directly associated with CRP and IL-6 and inversely associated with one or more HRV variables. There was a graded inverse relationship between all HRV parameters (except high frequency) and CRP and IL-6. After adjustment for age, BMI, activity, high-density lipoprotein, smoking, hypertension, depression, and diabetes, ultra low frequency and very low frequency remained significant predictors of CRP ($P < .01$).\r\nCONCLUSIONS\r\nC-reactive protein is associated with decreased HRV, even after controlling for traditional CAD risk factors. Autonomic dysregulation leading to inflammation may represent one pathway through which traditional risk factors promote development of CAD.

Lamprecht, Marnie L.; Bradley, Andrew P.; Tran, Tommy; Boynton, Alison; Terrill, Philip I. (2015):

Multisite accelerometry for sleep and wake classification in children.

In: *Physiol Meas* 36 (1), S. 133–147. DOI: 10.1088/0967-3334/36/1/133.

Abstract:

Actigraphy is a useful alternative to the gold standard polysomnogram for non-invasively measuring sleep and wakefulness. However, it is unable to accurately assess sleep fragmentation due to its inability to differentiate restless sleep from wakefulness and quiet wake from sleep. This presents significant limitations in the assessment of sleep-related breathing disorders where sleep fragmentation is a common symptom. We propose that this limitation may be caused by hardware constraints and movement representation techniques. Our objective was to determine if multisite tri-axial accelerometry improves sleep and wake classification. Twenty-four patients aged 6-15 years (median: 8 years, 16 male) underwent a diagnostic polysomnogram while simultaneously recording motion from the left wrist and index fingertip, upper thorax and left ankle and great toe using a custom accelerometry system. Movement was quantified using several features and two feature selection techniques were employed to select optimal features for restricted feature set sizes. A heuristic was also applied to identify movements during restless sleep. The sleep and wake classification performance was then assessed and validated against the manually scored polysomnogram using discriminant analysis. Tri-axial accelerometry measured at the wrist significantly improved the wake detection when compared to uni-axial accelerometry (specificity at 85% sensitivity: 71.3(14.2)% versus 55.2(24.7)%, $p < 0.01$). Multisite accelerometry significantly improved the performance when compared to the single wrist placement (specificity at 85% sensitivity: 82.1(12.5)% versus 71.3(14.2)%, $p < 0.05$). Our results indicate that multisite accelerometry offers a significant performance benefit which could be further improved by analysing movement in raw multisite accelerometry data.

Beginning the workday yet already depleted? Consequences of late-night smartphone use and sleep.

In: *Organizational Behavior and Human Decision Processes* 124 (1), S. 11–23. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-09380-003%26site%3dehost-live.

Abstract:

Smartphones have become a prevalent technology as they provide employees with instant access to work-related information and communications outside of the office. Despite these advantages, there may be some costs of smartphone use for work at night. Drawing from ego depletion theory, we examined whether smartphone use depletes employees' regulatory resources and impairs their engagement at work the following day. Across two studies using experience sampling methodology, we found that smartphone use for work at night increased depletion the next morning via its effects on sleep. Morning depletion in turn diminished daily work engagement. The indirect effects of smartphone use on depletion and engagement the next day were incremental to the effects of other electronic devices (e.g., computer, tablet, and television use). We also found some support that the negative effects of morning depletion on daily work engagement may be buffered by job control, such that depletion impairs work engagement only for employees who experience low job control. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Lanata, Antonio; Valenza, Gaetano; Nardelli, Mimma; Gentili, Claudio; Scilingo, Enzo Pasquale (2015):

Complexity index from a personalized wearable monitoring system for assessing remission in mental health.

In: *IEEE J Biomed Health Inform* 19 (1), S. 132–139. DOI: 10.1109/JBHI.2014.2360711.

Abstract:

This study discusses a personalized wearable monitoring system, which provides information and communication technologies to patients with mental disorders and physicians managing such diseases. The system, hereinafter called the PSYCHE system, is mainly comprised of a comfortable t-shirt with embedded sensors, such as textile electrodes, to monitor electrocardiogram-heart rate variability (HRV) series, piezoresistive sensors for respiration activity, and triaxial accelerometers for activity recognition. Moreover, on the patient-side, the PSYCHE system uses a smartphone-based interactive platform for electronic mood agenda and clinical scale administration, whereas on the physician-side provides data visualization and support to clinical decision. The smartphone collects the physiological and behavioral data and sends the information out to a centralized server for further processing. In this study, we present experimental results gathered from ten bipolar patients, wearing the PSYCHE system, with severe symptoms who exhibited mood states among depression (DP), hypomania(HM), mixed state (MX), and euthymia (EU), i.e., the good affective balance. In analyzing more than 400 h of cardiovascular dynamics, we found that patients experiencing mood transitions from a pathological mood state (HM, DP, or MX-where depressive and hypomanic symptoms are simultaneously present) to EU can be characterized through a commonly used measure of entropy. In particular, the SampEn estimated on long-term HRV series increases according to the patients' clinical improvement. These results are in agreement with the current literature reporting on the complexity dynamics of physiological systems and provides a promising and viable support to clinical decision in order to improve the diagnosis and management of psychiatric disorders.

Lande, Marc B.; Carson, Nancy L.; Roy, Jason; Meagher, Cecilia C. (2006):

Effects of childhood primary hypertension on carotid intima media thickness: a matched controlled study.

In: *Hypertension* 48 (1), S. 40–44. DOI: 10.1161/01.HYP.0000227029.10536.e8.

Abstract:

To determine whether carotid intima media thickness is increased in children with primary hypertension, the current study compared carotid intima media thickness in hypertensive children with that of normotensive control subjects matched closely for body mass index and determined the relationship between carotid intima media thickness and hypertension severity determined by ambulatory blood pressure monitoring. Children with newly diagnosed office hypertension (n=28) had carotid intima media thickness, left ventricular mass index, and ambulatory blood pressure monitoring performed. Carotid intima media thickness was performed in normotensive control subjects (n=28) matched pairwise to hypertensive subjects for age (+/-1 year), gender, and body mass index (+/-10%). Eighty-two percent of subjects were overweight or obese (body mass index > or =85th

percentile). The median carotid intima media thickness of hypertensive subjects was greater than that of matched controls (0.67 versus 0.63 mm; P=0.045). In the hypertensive subjects, carotid intima media thickness correlated strongly with several ambulatory blood pressure monitoring parameters, with the strongest correlation for daytime systolic blood pressure index (r=0.57; P=0.003). In the hypertensive group, the prevalence of left ventricular hypertrophy was 32%, but unlike carotid intima media thickness, left ventricular mass index did not correlate with ambulatory blood pressure monitoring. Together, the findings that hypertensive subjects had increased carotid intima media thickness compared with matched controls and that higher carotid intima media thickness correlated with more severe hypertension by ambulatory blood pressure monitoring provide strong evidence that carotid intima media thickness is increased in childhood primary hypertension, independent of the effects of obesity.

Landon, Chris (2009):

Novel methods of ambulatory physiologic monitoring in patients with neuromuscular disease.

In: *Pediatrics* 123 Suppl 4, S. S250-2. DOI: 10.1542/peds.2008-2952L.

Abstract:

This is a summary of the presentation on novel methods of ambulatory physiologic monitoring in patients with neuromuscular disease, presented as part of the program on pulmonary management of pediatric patients with neuromuscular disorders at the 30th annual Carrell-Krusen Neuromuscular Symposium on February 20, 2008.

Job strain and ambulatory blood pressure: a meta-analysis and systematic review.

In: *Am J Public Health* 103 (3), S. e61-e71. DOI: 10.2105/AJPH.2012.301153.

Abstract:

We reviewed evidence of the relationship between job strain and ambulatory blood pressure (ABP) in 29 studies (1985-2012). We conducted a quantitative meta-analysis on 22 cross-sectional studies of a single exposure to job strain. We systematically reviewed 1 case-control study, 3 studies of cumulative exposure to job strain, and 3 longitudinal studies. Single exposure to job strain in cross-sectional studies was associated with higher work systolic and diastolic ABP. Associations were stronger in men than women and in studies of broad-based populations than those with limited occupational variance. Biases toward the null were common, suggesting that our summary results underestimated the true association. Job strain is a risk factor for blood pressure elevation. Workplace surveillance programs are needed to assess the prevalence of job strain and high ABP and to facilitate workplace cardiovascular risk reduction interventions

Lane, Andrew M.; Wilson, Mathew (2011):

Emotions and trait emotional intelligence among ultra-endurance runners.

In: *Journal of Science and Medicine in Sport* 14 (4), S. 358–362.

Abstract:

OBJECTIVES:

The aim of this study was to investigate relationships between trait emotional intelligence and emotional state changes over the course of an ultra-endurance foot race covering a route of approximately 175 miles (282 km) and held in set stages over six days.

DESIGN:

A repeated measures field design that sought to maintain ecological validity was used. Trait emotional intelligence was defined as a relatively stable concept that should predict adaptive emotional states experienced over the duration of the race and therefore associate with pleasant emotions during a 6-stage endurance event.

METHOD:

Thirty-four runners completed a self-report measure of trait emotional intelligence before the event started. Participants reported emotional states before and after each of the six races.

RESULTS:

Repeated measures ANOVA results showed significant variations in emotions over time and a main effect for trait emotional intelligence. Runners high in self-report trait emotional intelligence also reported higher pleasant and lower unpleasant emotions than runners low in trait emotional intelligence.

CONCLUSIONS:

Findings lend support to the notion that trait emotional intelligence associates with adaptive psychological states, suggesting that it may be a key individual difference that explains why some athletes respond to repeated bouts of hard exercise better than others. Future research should test the effectiveness of interventions designed to enhance trait emotional intelligence and examine the attendant impact on emotional responses to intense exercise during multi-stage events.

Lange, Stefanie; Suss, Heinz-Martin (2014):

Measuring slips and lapses when they occur - ambulatory assessment in application to cognitive failures.

In: *Conscious Cogn* 24, S. 1–11. DOI: 10.1016/j.concog.2013.12.008.

Abstract:

Cognitive failures are lapses in attention, cognition, and actions that everybody experiences in everyday life. Self-reports are mainly used for assessment but those instruments are memory-biased and more related to personality aspects than to actual behavior. Ambulatory assessment is already used for capturing emotions or addictive behavior, but not yet for cognitive failures. The newly developed Questionnaire for Cognitive Failures in Everyday Life (KFA) was applied via mobile phones (electronic KFA) wherein an acoustic signal asked participants (N=91, 60-76 years) 4 times daily to answer 13 questions for 1 week. The new instrument showed satisfying reliability and was compared with a self-report method (Cognitive Failures Questionnaire; Broadbent, Cooper, Fitzgerald, and Parkes, 1982) in terms of correlations with cognitive abilities (working memory capacity, short-term memory, switching ability, and reasoning), personality traits, and demographical aspects. Although further validation is needed, first results are promising and eKFA enriches cognitive failures research.

Langrish, Jeremy P.; Mills, Nicholas L.; Chan, Julian Kk; Leseman, Daan Lac; Aitken, Robert J.; Fokkens, Paul Hb et al. (2009):

Beneficial cardiovascular effects of reducing exposure to particulate air pollution with a simple facemask.

In: *Particle and fibre toxicology* 6, S. 8. DOI: 10.1186/1743-8977-6-8.

Abstract:

BACKGROUND\r\nExposure to air pollution is an important risk factor for cardiovascular morbidity and mortality, and is associated with increased blood pressure, reduced heart rate variability, endothelial dysfunction and myocardial ischaemia. Our objectives were to assess the cardiovascular effects of reducing air pollution exposure by wearing a facemask.\r\nMETHODS\r\nIn an open-label cross-over randomised controlled trial, 15 healthy volunteers (median age 28 years) walked on a predefined city centre route in Beijing in the presence and absence of a highly efficient facemask. Personal exposure to ambient air pollution and exercise was assessed continuously using portable real-time monitors and global positional system tracking respectively. Cardiovascular effects were assessed by continuous 12-lead electrocardiographic and ambulatory blood pressure monitoring.\r\nRESULTS\r\nAmbient exposure (PM2.5 86 +/- 61 vs 140 +/- 113 mug/m3; particle number 2.4 +/- 0.4 vs 2.3 +/- 0.4 x 104 particles/cm3), temperature (29 +/- 1 vs 28 +/- 3 degrees C) and relative humidity (63 +/- 10 vs 64 +/- 19%) were similar (P > 0.05 for all) on both study days. During the 2-hour city walk, systolic blood pressure was lower (114 +/- 10 vs 121 +/- 11 mmHg, P < 0.01) when subjects wore a facemask, although heart rate was similar (91 +/- 11 vs 88 +/- 11/min; P > 0.05). Over the 24-hour period heart rate variability increased (SDNN 65.6 +/- 11.5 vs 61.2 +/- 11.4 ms, P < 0.05; LF-power 919 +/- 352 vs 816 +/- 340 ms2, P < 0.05) when subjects wore the facemask.\r\nCONCLUSION\r\nWearing a facemask appears to abrogate the adverse effects of air pollution on blood pressure and heart rate variability. This simple intervention has the potential to protect susceptible individuals and prevent cardiovascular events in cities with high concentrations of ambient air pollution.

Activity-promoting video games and increased energy expenditure.

In: *J Pediatr* 154 (6), S. 819–823. DOI: 10.1016/j.jpeds.2009.01.009.

Abstract:

OBJECTIVES\r\nTo test the hypothesis that both children and adults would expend more calories and move more while playing activity-promoting video games compared with sedentary video games.\r\nSTUDY DESIGN\r\nIn this single-group study, 22 healthy children (12 +/- 2 years; 11 male, 11 female) and 20 adults (34 +/- 11 years; 10 male, 10 female) were recruited. Energy expenditure and physical activity were measured while participants were resting, standing, watching television seated, sitting and playing a traditional sedentary video game, and while playing an activity-promoting video game (Nintendo Wii Boxing). Physical activity was measured with accelerometers, and energy expenditure was measured with an indirect calorimeter.\r\nRESULTS\r\nEnergy expenditure was significantly greater than all other activities when children or adults played Nintendo Wii (mean increase over resting, 189 +/- 63 kcal/hr, P < .001, and 148 +/- 71 kcal/hr, P < .001, respectively). When examining movement with accelerometry, children moved significantly more than adults (55 +/- 5 arbitrary acceleration units and 23 +/- 2 arbitrary acceleration units, respectively, P < .001) while playing Nintendo Wii.\r\nCONCLUSION\r\nActivity-promoting video games have the potential to increase movement and energy expenditure in children and adults.

Larkin, K. T.; Schauss, S. L.; Elnicki, D. M.; Goodie, J. L. (2007):

Detecting white coat and reverse white coat effects in clinic settings using measures of blood pressure habituation in the clinic and patient self-monitoring of blood pressure.

In: *J Hum Hypertens* 21 (7), S. 516–524.

Abstract:

To examine the utility of blood pressure (BP) habituation within and across multiple clinic visits and patient-determined home BP monitoring for detecting white coat (WCE) and reverse white coat effects (RWCE) commonly observed in medical settings, 54 patients undergoing evaluation for hypertension in an internal medicine group practice were categorized according to the magnitude of differences between systolic BP (SBP) and diastolic BP (DBP) obtained in the clinic and through ambulatory BP monitoring. BPs were measured four times during three separate clinic visits, during a 1-week home BP monitoring period, and during a single 24-h ambulatory monitoring period. Patients whose mean clinic and average daytime BPs were within +/-5 mm Hg were categorized as having stable BP; patients whose clinic BPs were >5 mm Hg of their daytime BPs were categorized as showing a WCE and patients whose average daytime BPs were >5 mm Hg of their clinic BPs were categorized as showing a RWCE. Results revealed that degree of habituation occurring between the first and third clinic visits significantly predicted magnitude of both the WCE and RWCE for SBP, with greater habituation being associated with the WCE and lesser habituation associated with the RWCE. Greater SBP habituation within clinic visits was associated with the WCE for SBP and greater DBP habituation within clinic visits was associated with the WCE for DBP. Lesser DBP habituation within clinic visits was associated with the RWCE for both SBP and DBP. Home BP monitoring did not contribute to predicting either WCE or RWCE.

Larsen, H.; Overbeek, G.; Granic, I.; Engels, R. C. (2012):

The strong effect of other people's drinking: two experimental observational studies in a real bar.

In: *Am.J.Addict.* 21 (2), S. 168–175. DOI: 10.1111/j.1521-0391.2011.00200.x.

Abstract:

Research has demonstrated that when people are with heavy-drinking peers, they consume more alcohol than when they are in the company of light-drinking peers. This social influence process has usually been investigated in clinical laboratories or seminaturalistic drinking settings such as laboratory bars. The question remains whether these robust effects can be replicated in real-life drinking settings. The aim of these experimental studies was to examine social influence processes in real bars. In Study 1 a two (confederate drank alcoholic vs. nonalcoholic drinks) by two (male vs. female participant) between-participant design was used to test imitation in same-sex dyads (N = 79). Study 2 tested differences in imitation between same- and other-sex dyads with a two (confederate drank alcoholic vs. nonalcoholic drinks) by two (male vs. female confederate) between-participant design (N = 60). Both studies showed that participants consumed more alcohol in the alcohol condition than the nonalcohol condition. No sex differences emerged in the extent to which participants imitated their drinking partners. Study 2 demonstrated no difference in imitation between same-sex and other-sex dyads. Results support the ecological validity of research on imitation of alcohol consumption conducted in laboratory bars

Larsson, Bo; Stinson, Jennifer N. (2011):

Commentary: On the importance of using prospective diary data in the assessment of recurrent headaches, stressors, and health behaviors in children and adolescents.

In: *Journal of Pediatric Psychology* 36 (8), S. 863–867. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-18469-003&site=ehost-live;bo.larsson@ntnu.no.

Abstract:

Comments on an article by M. Connelly, and J. Bickel (see record 2011-18469-002). The authors explore the stress and health behavior triggers of primary headaches in children using a daily process evaluation that is captured using a handheld electronic diary (e-diary). They reported on the evaluation of stress and health behavior triggers in a small sample of children aged 8–17 years referred to a pediatric clinic because of frequent headaches. The authors' innovative use of prospective measurement of headaches and potential triggers three times a day during two weeks in an electronic computer diary is a clear advancement of previous research and provided an opportunity for conducting statistical analyses of temporal and casual relationships between new headache episodes and the included triggers. The study provide encouraging data on potential triggers of frequent headaches in a selected clinic and small sample of children and adolescents based on prospective electronic diary measurement. The use of prospective event recordings in diaries will certainly help advance our knowledge and understanding of important triggers behind recurrent migraine and tension-type headaches in children and adolescents but also provide more solid grounds in evaluating treatment approaches focusing on coping strategies to improve headaches in these age groups. Cerebellum involvement in post-stroke mood: A combined ecological and MRI study.

In: *Psychiatry Research: Neuroimaging* 212 (2), S. 158–160. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-15482-004%26site%3dehost-live;igor.sibon@chu-bordeaux.fr.

Abstract:

This study evaluated a new approach combining magnetic resonance imaging and the experience sampling method in the understanding of post-stroke mood pathophysiology. Findings revealed that emotional cognition after stroke may be related to phenotypic characteristics such as cerebellar volume, thereby suggesting that this combined approach could provide new insights into the pathophysiology of post-stroke mood disorders as well as other forms of comorbidity. Lataster, T.; Collip, D.; Lardinois, M.; van Os, J.; Myin-Germeys, I. (2010):

Evidence for a familial correlation between increased reactivity to stress and positive psychotic symptoms.

In: *Acta Psychiatrica Scandinavica* 122 (5), S. 395–404.

Abstract:

OBJECTIVE:

This study tested the hypothesis that stress-reactivity may represent an intermediary phenotype underlying positive psychotic symptoms. It was examined whether: (i) stress-reactivity clusters within families of psychotic patients and (ii) stress-reactivity in relatives cosegregates with positive symptoms in patients.

METHOD:

The sample consisted of 40 patients and 47 siblings of these patients. The Experience Sampling Method (ESM - a structured diary technique) was used to measure stress-reactivity. Positive symptoms in patients were measured with the Comprehensive Assessment of Symptoms and History.

RESULTS:

Within-trait, cross-sib associations showed a significant association between stress-reactivity in the patient and stress-reactivity in their siblings. Significant cross-trait, cross-sib associations were established showing a significant association between positive psychotic symptoms in the patient and stress-reactivity in the sibling.

CONCLUSION:

The findings show familial clustering of increased stress-reactivity, suggesting common aetiological influences, probably both genetic and environmental, underlying stress-reactivity in the siblings and patients. In addition, the results underscore the hypothesis that increased stress-reactivity is an unconfounded mechanism of risk underlying the positive symptoms of psychotic disorders.

Lataster, T.; Valmaggia, L.; Lardinois, M.; Van, Os J.; Myin-Germeys, I. (2012):

Increased stress reactivity: a mechanism specifically associated with the positive symptoms of psychotic disorder.

In: *Psychol.Med.* (0033-2917 (Linking)), S. 1–12. DOI: 10.1017/S0033291712002279.

Abstract:

BACKGROUND: An increased reactivity to stress in the context of daily life is suggested to be an independent risk factor underlying the positive symptoms of psychotic disorder. The aim of this study was to investigate whether positive symptoms moderate the association between everyday stressful events and negative affect (NA), known as stress reactivity. This hypothesis was put to the test in patients with a diagnosis of psychotic disorder. Method The Comprehensive Assessment of Symptoms and History (CASH) and the Positive and Negative Syndrome Scale (PANSS) were used to assess positive and negative symptoms. The experience sampling method (ESM), a structured diary technique, was used to measure stress reactivity and psychotic symptoms in daily life. RESULTS: Higher levels of positive symptoms (CASH: B = 0.14, p = 0.005; PANSS: B = 0.05, p = 0.000; ESM: B = 0.03, p = 0.000) and lower levels of negative symptoms (PANSS: B = - 0.05, p = 0.001) significantly moderate the association between unpleasant events and NA. No significant moderating effect was found for CASH negative symptoms. Moreover, the moderating effect of lifetime and current symptoms on the stress-NA association was significantly larger for those patients with predominantly positive symptoms (CASH: B = 0.09, p = 0.000; PANSS: B = 0.08, p = 0.000; ESM: B = 0.13, p = 0.000). CONCLUSIONS: Patients with a 'psychotic syndrome' with high levels of positive symptoms and low levels of negative symptoms show increased reactivity to stress in daily life, indicating that stress reactivity is a possible risk factor underlying this syndrome

Lau, Hong-Yin; Tong, Kai-Yu; Zhu, Hailong (2009):

Support vector machine for classification of walking conditions of persons after stroke with dropped foot.

In: *Hum Mov Sci* 28 (4), S. 504–514. DOI: 10.1016/j.humov.2008.12.003.

Abstract:

Walking with dropped foot represents a major gait disorder, which is observed in hemiparetic persons after stroke. This study explores the use of support vector machine (SVMs) to classify different walking conditions for hemiparetic subjects. Seven participants with dropped foot (category 4 of functional ambulatory category) walked in five different conditions: level ground, stair ascent, stair descent, upslope, and downslope. The kinematic data were measured by two portable sensor units, each comprising an accelerometer and gyroscope attached to the lower limb on the shank and foot segments. The overall classification accuracy of stair ascent, stair descent, and other walking conditions was 92.9% using input features from the sensor attached to the shank. It was further improved to 97.5% by adding two more inputs from the sensor attached to the foot. Stair ascent was also classified by the inputs from the foot sensor unit with 96% accuracy. The performance of an SVM was shown to be superior to that of other machine learning methods using artificial neural networks (ANN) and radial basis function neural networks (RBF). The results suggested that the SVM classification method could be applied as a tool for pathological gait analysis, pattern recognition, control signals in functional electrical stimulation (FES) and rehabilitation robot, as well as activity monitoring during rehabilitation of daily activities.

Laurenceau, Jean-Philippe; Hayes, Adele M.; Feldman, Greg C. (2007):

Some methodological and statistical issues in the study of change processes in psychotherapy.

In: *Clinical Psychology Review* 27 (6), S. 682–695.

Abstract:

As the number of psychotherapies with demonstrated efficacy accumulates, an important task is to identify principles and processes of change. This information can guide treatment refinement, integration, and future development. However, the standard randomized control trial (RCT) design can limit the questions that can be asked and the statistical analyses that can be conducted. We discuss the importance of examining the shape of change, in addition to the importance of identifying mediators and moderators of change. We suggest methodological considerations for longitudinal data collection that can improve the kinds of therapy process questions that can be examined. We also review some data analytic approaches that are being used in other areas of psychology that have the potential to capture the complexity and dynamics of change in psychotherapy.

Night/day ratio as predictor of preeclampsia in normoalbuminuric, diabetic women: early signs of blood pressure disorders.

In: *Archives of gynecology and obstetrics* 279 (6), S. 829–834. DOI: 10.1007/s00404-008-0840-z.

Abstract:

PURPOSE\r\nDay/night ratio from diurnal ambulatory blood pressure (AMBP) in pregnant women with type 1 diabetes mellitus (T1DM) and in non-diabetic women was evaluated for its association with preeclampsia, retinopathy, HbA1c, and birth weight.\r\nMETHODS\r\nOne hundred and sixty-one women were recruited for AMBP performed with a Spacelab 90207 monitor. The pregnant women were 50 non-diabetic women and 111 T1DM women with normoalbuminuria and no hypertension. ANOVA, regression, and ROC curves analysis were applied.\r\nRESULTS\r\nWomen with simplex retinopathy had higher night/day ratio and lower birth weight than those without retinopathy. Women who developed preeclampsia had night/day ratio similar to those with simplex retinopathy. In first trimester they had higher blood pressure than those who did not develop preeclampsia.\r\nCONCLUSIONS\r\nSimplex retinopathy and preeclampsia are associated with a reduced night/day ratio even with normal blood pressure but night/day ratio provides no better prediction of preeclampsia than the absolute values.

Lavender, J. M.; Wonderlich, S. A.; Crosby, R. D.; Engel, S. G.; Mitchell, J. E.; Crow, S. et al. (2013):

A naturalistic examination of body checking and dietary restriction in women with anorexia nervosa.

In: *Behav.Res Ther.* 51 (8), S. 507–511. DOI: 10.1016/j.brat.2013.05.004.

Abstract:

Body checking has been conceptualized as a behavioral manifestation of the core overvaluation of eating, shape, and weight concerns underlying eating disorder psychopathology. Cognitive-behavioral theories suggest that body checking behaviors may function to maintain dietary restriction. The current study examined the association between body checking frequency and dietary restriction among women with anorexia nervosa (AN) in the natural environment. Women (N = 118) with full or partial AN completed baseline clinical interviews and a two-week ecological momentary assessment protocol, during which they reported on body checking behaviors (i.e., checking whether one's thighs touch; checking joints/bones for fat) and dietary restriction (i.e., 8 waking hours without eating; consuming less than 1200 calories per day). Average daily body checking frequency was positively associated with baseline eating disorder symptoms and body mass index. Daily body checking frequency was associated with both forms of dietary restriction on the same day, as well as the following day. Results support the theorized association between body checking and overvaluation of shape and weight, and suggest that targeting such behaviors in treatment may have utility in reducing dietary restriction

Lavender, J. M.; Wonderlich, S. A.; Crosby, R. D.; Engel, S. G.; Mitchell, J. E.; Crow, S. J. et al. (2013):

Personality-based subtypes of anorexia nervosa: Examining validity and utility using baseline clinical variables and ecological momentary assessment.

In: *Behav.Res Ther.* 51 (8), S. 512–517. DOI: 10.1016/j.brat.2013.05.007.

Abstract:

OBJECTIVE: This study sought to empirically derive and validate clinically relevant personality-based subtypes of anorexia nervosa (AN). METHODS: Women (N = 116) with full or subthreshold AN completed baseline measures of personality, clinical variables, and eating disorder (ED) symptoms, followed by two weeks of ecological momentary assessment (EMA). A latent profile analysis was conducted to identify personality subtypes, which were compared on baseline clinical variables and EMA variables. RESULTS: The best-fitting model supported three subtypes: underregulated, overregulated, and low psychopathology. The underregulated subtype (characterized by high Stimulus Seeking, Self-Harm, and Oppositionality) displayed greater baseline ED symptoms, as well as lower positive affect and greater negative affect, self-discrepancy, and binge eating in the natural environment. The overregulated subtype (characterized by high Compulsivity and low Stimulus Seeking) was more likely to have a lifetime obsessive-compulsive disorder diagnosis and exhibited greater perfectionism; levels of negative affect, positive affect, and self-discrepancy in this group were intermediate between the other subtypes. The low psychopathology subtype (characterized by normative personality) displayed the lowest levels of baseline ED symptoms, co-occurring disorders, and ED behaviors measured via EMA. CONCLUSIONS: Findings support the validity of these personality-based subtypes, suggesting the potential utility of addressing within-diagnosis heterogeneity in the treatment of AN

Lavender, Jason M.; Young, Kyle P.; Wonderlich, Stephen A.; Crosby, Ross D.; Engel, Scott G.; Mitchell, James E. et al. (2013):

Daily Patterns of Anxiety in Anorexia Nervosa: Associations With Eating Disorder Behaviors in the Natural Environment.

In: *Journal of Abnormal Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-15420-001%26site%3dehost-live.

Abstract:

The role of anxiety has been emphasized in etiological/maintenance models of anorexia nervosa. This study identified daily patterns of anxiety in anorexia nervosa and examined the likelihood of the occurrence of eating disorder behaviors in each trajectory, the daily temporal distribution of eating disorder behaviors in each trajectory, and the extent to which the tendency to exhibit particular anxiety trajectories was associated with baseline diagnostic and trait-level personality variables. Women with full or subthreshold anorexia nervosa (N = 118) completed a 2-week ecological momentary assessment (EMA) protocol during which they reported on a variety of behavioral and affective variables, including anxiety and eating disorder behaviors. Using latent growth mixture modeling to classify EMA days (N = 1,526) based on anxiety ratings, we identified 7 distinct daily anxiety trajectories. Overall differences between trajectories were found for rates of binge eating, self-induced vomiting, body checking, skipping meals, and dietary restriction. Furthermore, distinct daily temporal distributions of eating disorder behaviors were found across the trajectories, with peaks in the probability of behaviors frequently coinciding with high levels of anxiety. Finally, traits of personality pathology (affective lability, self-harm, social avoidance, and oppositionality) and the presence of a co-occurring mood disorder were found to be associated with the tendency to experience particular daily anxiety trajectories (e.g., stable high anxiety). Findings support the presence of within-person variability in daily anxiety patterns in anorexia nervosa and also provide evidence for an association between these anxiety patterns and eating disorder behaviors. Lawman, Hannah G.; Wilson, Dawn K.; van Horn, M. Lee; Resnicow, Ken; Kitzman-Ulrich, Heather (2011):

The relationship between psychosocial correlates and physical activity in underserved adolescent boys and girls in the ACT trial.

In: *J Phys Act Health* 8 (2), S. 253.

Abstract:

BACKGROUND:

Previous research suggests motivation, enjoyment, and self-efficacy may be important psychosocial factors for understanding physical activity (PA) in youth. While previous studies have shown mixed results, emerging evidence indicates relationships between psychosocial factors and PA may be stronger in boys than girls. This study expands on previous research by examining

the effects of motivation, enjoyment and self-efficacy on PA in underserved adolescent (low income, ethnic minorities) boys and girls. Based on previous literature, it was hypothesized the effects of motivation, enjoyment and self-efficacy on moderate-to-vigorous PA (MVPA) would be stronger in boys than in girls.

METHODS:

Baseline cross-sectional data were obtained from a randomized, school-based trial (Active by Choice Today; ACT) in underserved 6th graders (N=771 girls, 651 boys). Intrapersonal variables for PA were assessed via self-report and confirmatory factor analyses were conducted for each predictor. MVPA was assessed with 7-day accelerometry estimates.

RESULTS:

Multivariate regression analyses stratified by sex demonstrated a significant positive main effect of self-efficacy and motivation on MVPA for girls. Boys also showed a positive trend for the effect of motivation on MVPA.

CONCLUSIONS:

The results from this study suggest motivation and self-efficacy should be better integrated to facilitate the development of more effective interventions for increasing PA in underserved adolescents.

Layne, Charles S.; Mama, Scherezade K.; Banda, Jorge A.; Lee, Rebecca E. (2011):

Development of an ecologically valid approach to assess moderate physical activity using accelerometry in community dwelling women of color: A cross-sectional study.

In: *Int J Behav Nutr Phys Act* 8 (1), S. 21.

Abstract:

BACKGROUND:

Women of color report the lowest levels of physical activity and highest rates of overweight and obesity in the US. The purpose of this study was to develop an individualized, ecologically valid, field based method to assess physical activity over seven days for community dwelling women of color using accelerometers.

METHODS:

Accelerometer-measured physical activity, Borg perceived exertion, demographics, blood pressure, heart rate, and anthropometric measures were collected from African American and Hispanic or Latina women (N = 209). A threshold for increased physical activity was determined for each participant by calculating the average count per minute (plus one standard deviation) for each participant collected during a self-selected pace that corresponded to a 'recreational' walk about their neighborhood. The threshold was then used to calculate the amount of time spent doing increased intensity physical activity during a typical week.

RESULTS:

Women were middle-aged and obese (M BMI = 34.3 ± 9.3). The average individual activity counts per day ranged from 482-1368 in African American women and 470-1302 in Hispanic or Latina women. On average, African American women spent significantly more time doing what was labeled 'increased' physical activity than Hispanic and Latino women. However neither group approached recommended physical activity levels, as African American women, averaged 1.73% and Hispanic and Latino women averaged 0.83% of their day engaged in increased physical activity ($p < 0.05$).

CONCLUSIONS:

This study presents a simple field-based method for developing accelerometer thresholds that identify personalized thresholds of moderate intensity physical activity that can be used by in community-based settings. Findings highlight a need for physical activity programs whose starting points are based upon the individual's typical baseline physical activity level, which is likely to be well below the minimum recommended published guidelines.

Lazarescu, A.; Sifrim, D. (2008):

Ambulatory monitoring of GERD: current technology.

In: *Gastroenterology clinics of North America* 37 (4), S. 793-805, viii. DOI: 10.1016/j.gtc.2008.09.006.

Abstract:

Various techniques have been devised to diagnose, characterize, and classify gastroesophageal reflux (GER). Stationary techniques, such as fluoroscopy and scintigraphy, provide interesting anatomic and functional information related to GER but

are not sensitive enough and are usually performed in nonphysiologic conditions. Ambulatory techniques for GER monitoring have been developed and used since 1974. The current available techniques include catheter and wireless pH-metry, Bilitec, and impedance-pH monitoring. Prolonged wireless pH monitoring can be useful to evaluate patients off and on proton pump inhibitor (PPI) treatment. Impedance-pH monitoring is being used increasingly in patients who have persistent symptoms on PPI therapy because it can establish an association between symptoms and weakly acidic or nonacid reflux. Bilitec is performed in patients suspected to have increased duodenogastroesophageal reflux (DGER). This article discusses the technical details, clinical indications, and applications of these diagnostic techniques.

Le, Grange D.; Crosby, R. D.; Engel, S. G.; Cao, L.; Ndungu, A.; Crow, S. J. et al. (2012):

DSM-IV-Defined Anorexia Nervosa Versus Subthreshold Anorexia Nervosa (EDNOS-AN).

In: *Eur.Eat.Disord.Rev.* (1072-4133 (Linking)). DOI: 10.1002/erv.2192.

Abstract:

OBJECTIVES: Eating disorder not otherwise specified (EDNOS) is the most prevalent eating disorder, yet its heterogeneity begs less reliance on this broad diagnostic category. The purpose of this study was to compare women with anorexia nervosa (AN) and EDNOS, AN type (EDNOS-AN) from a multisite study on eating-related and general psychopathology measures. METHODS: One hundred eighteen participants (n = 59 with DSM-IV AN, n = 59 with EDNOS-AN) completed structured interviews, questionnaires and a physical examination at baseline. In addition, participants carried a handheld palm pilot computer for 2 weeks to provide ecological momentary assessment (EMA) information about mood and eating disorder behaviours. RESULTS: No significant differences between AN and EDNOS-AN were found on the self-report and interview measures, or on the EMA mood assessments. The only differences to emerge were that participants with AN reported higher rates of binge eating and purging on EMA compared with those with EDNOS-AN, whereas EDNOS-AN reported higher rates of checking thighs and joints on EMA compared with those with AN. For the physiological parameters, AN presented with lower white blood cell counts compared with EDNOS-AN. CONCLUSIONS: Findings highlight the clinical significance of EDNOS-AN and support a closer look at the definition of AN as proposed by the Diagnostic and Statistical Manual of Mental Disorders, 5th Edition. Copyright (c) 2012 John Wiley & Sons, Ltd and Eating Disorders Association

An online diary for tracking epilepsy.

In: *Epilepsy Behav* 22 (4), S. 705–709. DOI: 10.1016/j.yebeh.2011.08.035.

Abstract:

My Epilepsy Diary is a free Web-based application on the public website epilepsy.com, available for patients to track epilepsy and to aid clinicians with data-based, individualized management. The first aim of this descriptive study was to outline electronic diary functions. Second, the study retrospectively profiled a large cohort of 2010 calendar year diary users including demographics, seizure types, temporal distribution of seizures, triggers, and use and side effects of antiepileptic drugs (AEDs). A total of 1944 users provided demographic information and 1877 recorded seizure data. Most (64%) users were women. Average age was 29.9+/-16.0years. A total of 70,990 seizure entries and 15,630 AED entries were logged. Events were apportioned as 79% seizures and 21% seizure clusters. Specific AEDs were detailed in 7331 entries: monotherapy was used in 18% and polytherapy in 82%. Mood-related side effects were most commonly reported in 19% of 1027 users

Leahey, Tricia M.; Crane, Melissa M.; Pinto, Angela Marinilli; Weinberg, Brad; Kumar, Rajiv; Wing, Rena R. (2010):

Effect of teammates on changes in physical activity in a statewide campaign.

In: *Prev Med* 51 (1), S. 45–49. DOI: 10.1016/j.ypmed.2010.04.004.

Abstract:

OBJECTIVE\r\nMost Americans do not meet physical activity recommendations. Statewide campaigns can effectively increase activity levels. Reported herein are physical activity outcomes from Shape Up Rhode Island (SURI) 2007, a statewide campaign to increase steps through team-based competition. Given the importance of social networks in behavior change, this paper focused on the effects of team and team characteristics on activity outcomes.\r\nMETHOD\r\nFor 16weeks, 5333 adults comprising 652 teams wore pedometers and reported their steps online.\r\nRESULTS\r\nParticipants' daily steps increased from 7029(3915) at baseline to 9393(5976) at SURI end (p<0.001). There was a significant intraclass correlation for step change among team members (ICC=0.09); thus, an individual's change in steps was influenced by what team they were on. Moreover, baseline team

characteristics predicted individual step change; being on a more active team was associated with greater increases in activity for individual members (p<0.001), whereas being on a team with a broad range of steps was associated with smaller changes in activity for individual members (p=0.02).\r\nCONCLUSION\r\nThese findings are the first to suggest that team members influence individual activity outcomes in team-based statewide campaigns. Future research should explore ways to use social network factors to enhance team-based physical activity programs.

Leahey, Tricia M.; Crowther, Janis H. (2008):

An ecological momentary assessment of comparison target as a moderator of the effects of appearance-focused social comparisons.

In: *Body Image* 5 (3), S. 307–311.

Abstract:

This research examined whether comparison target moderates the effects of naturally occurring appearance-focused social comparisons on women's affect, appearance esteem, and dieting thoughts. During daily activities, body-satisfied (BS) women and body-dissatisfied (BD) women recorded their comparison targets and reactions to comparison information. For BS women, upward comparisons with peers were associated with more positive affect (PA) and appearance esteem and less guilt than upward comparisons with media images and downward comparisons with peers were associated with less PA than downward comparisons with media images. For BD women, upward comparisons with peers were associated with more appearance esteem and diet thoughts than upward comparisons with media images and downward comparisons with peers were associated with less PA, appearance esteem, and diet thoughts and more guilt than downward comparisons with media images.

Leahey, Tricia M.; Crowther, Janis H.; Ciesla, Jeffrey A. (2011):

An ecological momentary assessment of the effects of weight and shape social comparisons on women with eating pathology, high body dissatisfaction, and low body dissatisfaction.

In: *Behav Ther* 42 (2), S. 197–210.

Abstract:

This research examined the effects of naturally occurring appearance comparisons on women's affect, body satisfaction, and compensatory cognitions and behaviors. Using ecological momentary assessment, women with high body dissatisfaction and eating pathology (EPHB), high body dissatisfaction (HB), or low body dissatisfaction (LB) recorded their reactions to appearance-focused social comparisons. EPHB and HB women made more upward appearance comparisons than LB women. All women experienced negative emotions and cognitions after upward comparisons, including increased guilt, body dissatisfaction, and thoughts of dieting. EPHB women were most negatively affected by comparisons; they experienced more intense negative emotions, more thoughts of dieting/exercising, and an increase in eating-disordered behavior after upward comparisons. HB women experienced more negative affective consequences and thoughts of dieting than LB women. Results are consistent with social comparison theory and provide important information that may be used to inform eating disorder treatment and prevention efforts.

Leblanc, A. G.; Janssen, I. (2010):

Difference between self-reported and accelerometer measured moderate-to-vigorous physical activity in youth.

In: *Pediatric Exercise Science* 22, S. 523–534.

Abstract:

We examined differences between objective (accelerometer) and subjective (self-report) measures of moderate-to-vigorous physical activity (MVPA) in youth. Participants included 2761 youth aged 12–19 years. Within each sex and race group, objective and self-reported measures of MVPA were poorly correlated (R2 = .01–.10). Self-reported MVPA values were higher than objective values (median: 42.4 vs. 15.0 min/d). 65.4% of participants over-reported their MVPA by >/=5 min/d. The difference between self-reported and objective measures was not influenced by sex, age, or race. There was, however, a systematic difference such that inactive participants over-reported their MVPA to the greatest extent.

Leclerc, Jocelyne; Rahn, Michelle; Linden, Wolfgang (2006):

Does personality predict blood pressure over a 10-year period?

In: *Personality and Individual Differences* 40 (6), S. 1313–1321.

Abstract:

We posited that if personality traits were to influence disease development, then there would have to exist a stable link between personality and certain indicators of health status. This hypothesis was evaluated by measuring the stability of blood pressure (BP)–personality associations over a 10-year interval.

One hundred and twelve participants completed ambulatory blood pressure monitoring (ABPM) and personality questionnaires twice, over a 10-year time interval. Stability coefficients (r) for measures of depression, hostility, self-deception and impression management were 0.35, 0.55, 0.26 and 0.41, respectively. BP was also fairly stable (r = .44 and r = .59 for systolic/diastolic BP). Associations between personality indicators and BP were noted for depression, hostility, and impression management at baseline. Hostility additionally correlated with diastolic BP 10 years later. Further analyses revealed differential results for men and women, as well as a more pronounced linkage in individuals with a positive family history of hypertension. Multiple regression analyses were utilized to assess gender differences. High self-deception was found to predict significant variance in 10-year BP. Higher age and low hostility were both independent predictors of 10-year BP in women. These results support the hypothesis that personality traits can play a role in disease development.

Lee, P. H. (2013):

Data imputation for accelerometer-measured physical activity: the combined approach.

In: *Am J Clin.Nutr.* 97 (5), S. 965–971. DOI: 10.3945/ajcn.112.052738.

Abstract:

BACKGROUND: Accelerometers are gaining popularity for the assessment of the physical activity level; however, compliance is a problem that results in missing data. Data from study days in which the accelerometer is not worn for a number of hours that are sufficient to reach a predetermined cutoff value are considered invalid and discarded. The problem of missing data is commonly handled by imputation; however, all traditional imputation methods ignore the available information from invalid days. OBJECTIVE: In this study, I propose a new approach to the imputation of missing accelerometer data that takes into account the data available from invalid days. DESIGN: A total of 4069 participants in NHANES waves 2003-2004 and 2005-2006 who provided 7 d of valid accelerometer data were used to illustrate this new approach. The method of imputation was a combined approach that combined the available data from valid days and invalid days to impute missing values. Simulation studies were carried out to compare this new combined approach with the traditional imputation method for 1) accuracy and 2) effect-size estimation of the sex-physical activity relation by using the root mean squared error (RMSE). RESULTS: The combined approach performed significantly better than traditional imputation method (all t tests $P < 0.001$), with the percentage reduction of the RMSE for accuracy and effect-size estimation that ranged from 12.4% to 17.3% and 19.8% to 32.9%, respectively. CONCLUSION: The combined approach significantly outperforms the traditional imputation algorithm

The SAMS: Smartphone Addiction Management System and Verification.

In: *J Med Syst* 38 (1), S. 1. DOI: 10.1007/s10916-013-0001-1.

Abstract:

While the popularity of smartphones has given enormous convenience to our lives, their pathological use has created a new mental health concern among the community. Hence, intensive research is being conducted on the etiology and treatment of the condition. However, the traditional clinical approach based surveys and interviews has serious limitations: health professionals cannot perform continual assessment and intervention for the affected group and the subjectivity of assessment is questionable. To cope with these limitations, a comprehensive ICT (Information and Communications Technology) system called SAMS (Smartphone Addiction Management System) is developed for objective assessment and intervention. The SAMS system consists of an Android smartphone application and a web application server. The SAMS client monitors the user's application usage together with GPS location and Internet access location, and transmits the data to the SAMS server. The SAMS server stores the usage data and performs key statistical data analysis and usage intervention according to the clinicians' decision. To verify the reliability and efficacy of the developed system, a comparison study with survey-based screening with the K-SAS (Korean Smartphone Addiction Scale) as well as self-field trials is performed. The comparison study is done using usage data from 14 users who are 19 to 50 year old adults that left at least 1 week usage logs and completed the survey questionnaires. The field trial fully verified the accuracy of the time, location, and Internet access information in the usage measurement and the

reliability of the system operation over more than 2 weeks. The comparison study showed that daily use count has a strong correlation with K-SAS scores, whereas daily use times do not strongly correlate for potentially addicted users. The correlation coefficients of count and times with total K-SAS score are CC = 0.62 and CC =0.07, respectively, and the t-test analysis for the contrast group of potential addicts and the values for the non-addicts were p = 0.047 and p = 0.507, respectively.

Portable activity monitoring system for temporal parameters of gait cycles.

In: *J Med Syst* 34 (5), S. 959–966.

Abstract:

A portable and wireless activity monitoring system was developed for the estimation of temporal gait parameters. The new system was built using three-axis accelerometers to automatically detect walking steps with various walking speeds. The accuracy of walking step-peak detection algorithm was assessed by using a running machine with variable speeds. To assess the consistency of gait parameter analysis system, estimated parameters, such as heel-contact and toe-off time based on accelerometers and footswitches were compared for consecutive 20 steps from 19 individual healthy subjects. Accelerometers and footswitches had high consistency in the temporal gait parameters. The stance, swing, single-limb support, and double-limb support time of gait cycle revealed ICCs values of 0.95, 0.93, 0.86, and 0.75 on the right and 0.96, 0.86, 0.93, 0.84 on the left, respectively. And the walking step-peak detection accuracy was 99.15% (±0.007) for the proposed method compared to 87.48% (±0.033) for a pedometer. Therefore, the proposed activity monitoring system proved to be a reliable and useful tool for identification of temporal gait parameters and walking pattern classification.

A smartphone-based driver safety monitoring system using data fusion.

In: *Sensors.(Basel)* 12 (12), S. 17536–17552. DOI: 10.3390/s121217536.

Abstract:

This paper proposes a method for monitoring driver safety levels using a data fusion approach based on several discrete data types: eye features, bio-signal variation, in-vehicle temperature, and vehicle speed. The driver safety monitoring system was developed in practice in the form of an application for an Android-based smartphone device, where measuring safety-related data requires no extra monetary expenditure or equipment. Moreover, the system provides high resolution and flexibility. The safety monitoring process involves the fusion of attributes gathered from different sensors, including video, electrocardiography, photoplethysmography, temperature, and a three-axis accelerometer, that are assigned as input variables to an inference analysis framework. A Fuzzy Bayesian framework is designed to indicate the driver's capability level and is updated continuously in real-time. The sensory data are transmitted via Bluetooth communication to the smartphone device. A fake incoming call warning service alerts the driver if his or her safety level is suspiciously compromised. Realistic testing of the system demonstrates the practical benefits of multiple features and their fusion in providing a more authentic and effective driver safety monitoring

Lee, Jong-Hyuk; Jung, Han-Kil; Lee, Gang-Geun; Kim, Han-Young; Park, Sun-Gyoo; Woo, Seong-Chang (2013):

Effect of behavioral intervention using smartphone application for preoperative anxiety in pediatric patients.

In: *Korean J Anesthesiol* 65 (6), S. 508–518. DOI: 10.4097/kjae.2013.65.6.508.

Abstract:

BACKGROUND: Children and parents experience significant anxiety and distress during the preoperative period. This is important because preoperative anxiety in children is associated with adverse postoperative outcome. So we suggest behaviorally oriented preoperative anxiety intervention program based on the anesthesia and psychology with smartphone application, world-widely used. METHODS: A total 120 patients (aged 1-10 years old) who were scheduled for elective surgery under general anesthesia was included in this randomized controlled trial. We randomized the patients into three groups, with using intravenous (IV) midazolam sedation (M group), with using smartphone application program (S group), and with using low dose IV midazolam plus smartphone application program (SM group). And the child anxiety was assessed using the modified Yale Preoperative Anxiety Scale (mYPAS) at holding area, 5 min after intervention, entrance to operating room. RESULTS: In all three groups, mYPAS after intervention were lower than the preoperative holding area (M group 52.8 +/- 11.8 vs 41.0 +/- 7.0, S

group 59.2 +/- 17.6 vs 36.4 +/- 7.3, SM group 58.3 +/- 17.5 vs 26.0 +/- 3.4). A comparison of mYPAS scores between each group showed that the S group reduced anxiety lower than M group (P < 0.01), and the SM group exhibited significantly lower anxiety than the two other groups (P < 0.01). CONCLUSIONS: The preoperative preparation program using smartphone application is simple and customized by individual development that effective in the reduction of preoperative anxiety.

Online Learning for Classification of Alzheimer Disease based on Cortical Thickness and Hippocampal Shape Analysis.

In: *Healthc Inform Res* 20 (1), S. 61–68. DOI: 10.4258/hir.2014.20.1.61.

Abstract:

OBJECTIVES: Mobile healthcare applications are becoming a growing trend. Also, the prevalence of dementia in modern society is showing a steady growing trend. Among degenerative brain diseases that cause dementia, Alzheimer disease (AD) is the most common. The purpose of this study was to identify AD patients using magnetic resonance imaging in the mobile environment. METHODS: We propose an incremental classification for mobile healthcare systems. Our classification method is based on incremental learning for AD diagnosis and AD prediction using the cortical thickness data and hippocampus shape. We constructed a classifier based on principal component analysis and linear discriminant analysis. We performed initial learning and mobile subject classification. Initial learning is the group learning part in our server. Our smartphone agent implements the mobile classification and shows various results. RESULTS: With use of cortical thickness data analysis alone, the discrimination accuracy was 87.33% (sensitivity 96.49% and specificity 64.33%). When cortical thickness data and hippocampal shape were analyzed together, the achieved accuracy was 87.52% (sensitivity 96.79% and specificity 63.24%). CONCLUSIONS: In this paper, we presented a classification method based on online learning for AD diagnosis by employing both cortical thickness data and hippocampal shape analysis data. Our method was implemented on smartphone devices and discriminated AD patients for normal group.

Lee, Rebecca E.; Mama, Scherezade K.; Adamus-Leach, Heather J.; Soltero, Erica G. (2014):

Contribution of Neighborhood Income and Access to Quality Physical Activity Resources to Physical Activity in Ethnic Minority Women Over Time.

In: *Am J Health Promot. DOI:* 10.4278/ajhp.130403-QUAN-148.

Abstract:

Abstract Purpose . To create and test an index to indicate both availability and quality of physical activity (PA) resources (PARs), to examine associations between access to quality PARs and changes in PA, and to determine whether this association differed in lower- and higher-income neighborhoods. Design . Longitudinal, 6-month intervention. Setting . Houston and Austin, Texas. Subjects . African-American and Hispanic or Latina women. Measures . Women (N = 410) completed a questionnaire and accelerometry to measure PA. Neighborhoods (N = 163) were classified as lower- or higher-income by median household income at the census-tract level. PARs were audited using the PARA (physical activity resource assessment). Access to quality PARs was determined by a composite index (QPAR) of features, amenities, and incivilities. Analysis . Repeated measures analyses of variance were used to examine changes in PA by (1) neighborhood income (lower/higher) and QPAR (lower/higher) groups, and (2) neighborhood income (lower/higher) and number of PARs (lower/higher) groups, adjusting for ethnicity, household income, and body mass index. Results . Women in neighborhoods with lower QPAR scores had small increases in self-reported vigorous PA (M Delta = 327.8 metabolic equivalent of task [MET]-min/wk) and decreases in accelerometer PA (M = -3.4 min/d), compared to those with higher QPAR scores who had larger increases in self-reported vigorous PA (M Delta = 709.8 MET-min/wk) and increased accelerometer PA (M = 3.9 min/d). There was a significant interaction between changes in leisure-time PA, QPAR score, and number of PARs (p = .049). Women with both more PARs and higher QPAR scores reported greater increases in leisure-time PA than women with fewer PARs and lower QPAR scores. Conclusion . Access to higher-quality PARs can help increase or maintain PA over time regardless of neighborhood income. PAR quality is a separate and distinct, important determinant of PA in ethnic minority women.

Lee, J.; Matsumura, K.; Yamakoshi, T.; Rolfe, P.; Tanaka, N.; Kim, K.; Yamakoshi, K. (2013):

Validation of normalized pulse volume in the outer ear as a simple measure of sympathetic activity using warm and cold pressor tests: towards applications in ambulatory monitoring.

In: *Physiol Meas* 34 (3), S. 359–375. DOI: 10.1088/0967-3334/34/3/359.

Abstract:

Normalized pulse volume (NPV) derived from the ear has the potential to be a practical index for monitoring daily life stress. However, ear NPV has not yet been validated. Therefore, we compared NPV derived from an index finger using transmission photoplethysmography as a reference, with NPV derived from a middle finger and four sites of the ear using reflection photoplethysmography during baseline and while performing cold and warm water immersion in ten young and six middle-aged subjects. The results showed that logarithmically-transformed NPV (lnNPV) during cold water immersion as compared with baseline values was significantly lower, only at the index finger, the middle finger and the bottom of the ear-canal. Furthermore, lnNPV reactivities (DeltalnNPV; the difference between baseline and test values) from an index finger were significantly related to DeltalnNPV from the middle finger and the bottom of the ear-canal (young: r = 0.90 and 0.62, middle-aged: r = 0.80 and 0.58, respectively). In conclusion, these findings show that reflection and transmission photoplethysmography are comparable methods to derive NPV in accordance with our theoretical prediction. NPV derived from the bottom of the ear-canal is a valid approach, which could be useful for evaluating daily life stress

Lee, Matthew R.; Okazaki, Sumie; Yoo, Hyung Chol (2006):

Frequency and intensity of social anxiety in Asian Americans and European Americans.

In: *Cultural Diversity and Ethnic Minority Psychology* 12 (2), S. 291.

Abstract:

Asian American students have typically reported greater levels of social anxiety than European American students on self-report measures (e.g., Okazaki, 1997; Norasakkunkit & Kalick, 2002). This study employed an event-contingent experience sampling methodology to examine whether Asian American university students experienced social anxiety more often and more intensely than European Americans in their daily lives. Forty-five Asian American and 38 European American students participated in a two-week diary study. The results showed that on average, Asian Americans and European Americans reported a similar number of events that evoked anxiety in social situations, but Asian Americans reported more negative emotions on average in social situations than did European Americans.

Lee, Seoho; Oncescu, Vlad; Mancuso, Matt; Mehta, Saurabh; Erickson, David (2014):

A smartphone platform for the quantification of vitamin D levels.

In: *Lab Chip* 14 (8), S. 1437–1442. DOI: 10.1039/c3lc51375k.

Abstract:

Vitamin D deficiency has been linked to a number of diseases and adverse outcomes including: osteoporosis, infections, diabetes, cardiovascular diseases, and even cancer. At present the vast majority of vitamin D testing is performed in large-scale laboratories at the request of a physician as part of an annual panel of blood tests. Here we present a system for rapid quantification of vitamin D levels on a smartphone. The system consists of a smartphone accessory, an app, and a test strip that allows the colorimetric detection of 25-hydroxyvitamin D using a novel gold nanoparticle-based immunoassay. We show that the system can be used to accurately measure physiological levels of 25-hydroxyvitamin D with accuracy better than 15 nM and a precision of 10 nM. We compare our system with well-established ELISA test kits for serum samples of unknown concentration and demonstrate equivalency of the results. We envision this as the first step towards the development of the NutriPhone, a comprehensive system for the analysis of multiple vitamins and micronutrients on a smartphone.

Lee, Christine M.; Patrick, Megan E.; Neighbors, Clayton; Lewis, Melissa A.; Tollison, Sean J.; Larimer, Mary E. (2010):

Exploring the role of positive and negative consequences in understanding perceptions and evaluations of individual drinking events.

In: *Addict Behav* 35 (8), S. 764–770. DOI: 10.1016/j.addbeh.2010.03.003.

Abstract:

While research has established that drinking more alcohol is associated with experiencing more positive and negative alcohol-related consequences, less is known about how college students evaluate their drinking experiences. Evaluations of drinking events may vary with factors such as how much one drinks, which consequences one experiences, and the context (i.e., where and with whom) one drinks on a given occasion. This research used daily data (Level 2: N=166 students, 61% female; Level 1: N=848 person drinking days) to explore the relationship between quantity of alcohol consumed and experience of specific domains of positive and negative consequences and to examine how the experience of specific consequences related to overall evaluation of the drinking experience. Drinking on a given day was positively associated with experiencing more negative (social and personal) and more positive (image, fun/social, and relaxation) consequences. With respect to the formation of overall impressions, negative (social and personal) consequences were associated with less favorable evaluations whereas positive (image, fun/social, and relaxation) consequences were associated with more favorable evaluations of the drinking experience. Indirect effects analyses suggested that consequences (negative personal, negative social, positive fun/social, and positive relaxation) significantly mediated the relationship between drinking and overall evaluation at the daily level. These results underscore the importance of considering both positive and negative consequences in understanding students' choices to drink and how they evaluate their experiences.

Lee, Joon; Steele, Catriona M.; Chau, Tom (2009):

Swallow segmentation with artificial neural networks and multi-sensor fusion.

In: *Med Eng Phys* 31 (9), S. 1049–1055. DOI: 10.1016/j.medengphy.2009.07.001.

Abstract:

Swallow segmentation is a critical precursory step to the analysis of swallowing signal characteristics. In an effort to automatically segment swallows, we investigated artificial neural networks (ANN) with information from cervical dual-axis accelerometry, submental MMG, and nasal airflow. Our objectives were (1) to investigate the relationship between segmentation performance and the number of signal sources and (2) to identify the signals or signal combinations most useful for swallow segmentation. Signals were acquired from 17 healthy adults in both discrete and continuous swallowing tasks using five stimuli. Training and test feature vectors were constructed with variances from single or multiple signals, estimated within 200 ms moving windows with 50% overlap. Corresponding binary target labels (swallow or non-swallow) were derived by manual segmentation. A separate 3-layer ANN was trained for each participant-signal combination, and all possible signal combinations were investigated. As more signal sources were included, segmentation performance improved in terms of sensitivity, specificity, accuracy, and adjusted accuracy. The combination of all four signal sources achieved the highest mean accuracy and adjusted accuracy of 88.5% and 89.6%, respectively. A-P accelerometry proved to be the most discriminatory source, while the inclusion of MMG or nasal airflow resulted in the least performance improvement. These findings suggest that an ANN, multi-sensor fusion approach to segmentation is worthy of further investigation in swallowing studies.

Lee, Hopin; Sullivan, S. John; Schneiders, Anthony G.; Ahmed, Osman Hassan; Balasundaram, Arun Prasad; Williams, David et al. (2014):

Smartphone and tablet apps for concussion road warriors (team clinicians): a systematic review for practical users.

In: *Br J Sports Med. DOI:* 10.1136/bjsports-2013-092930.

Abstract:

BACKGROUND: Mobile technologies are steadily replacing traditional assessment approaches for the recognition and assessment of a sports concussion. Their ease of access, while facilitating the early identification of a concussion, also raises issues regarding the content of the applications (apps) and their suitability for different user groups. AIM: To locate and review apps that assist in the recognition and assessment of a sports concussion and to assess their content with respect to that of internationally accepted best-practice instruments. METHODS: A search of international app stores and of the web using key terms such as 'concussion', 'sports concussion' and variants was conducted. For those apps meeting the inclusion criteria, data were extracted on the platform, intended users and price. The content of each app was benchmarked to the Sport Concussion Assessment Tool 2 (SCAT2) and Pocket SCAT2 using a custom scoring scheme to generate a percentage compliance statistic.

RESULTS: 18 of the 155 apps identified met the inclusion criteria. Almost all (16/18) were available on an iOS platform and only five required a payment to purchase. The apps were marketed for a wide range of intended users from medical professionals to the general public. The content of the apps varied from 0% to 100% compliance with the selected standard, and 'symptom evaluation' components demonstrated the highest level of compliance. CONCLUSIONS: The surge in availability of apps in an unregulated market raises concerns as to the appropriateness of their content for different groups of end users. The consolidation of best-practice concussion instruments now provides a framework to inform the development of future apps.

Lee, Jwy; Yan, Sj; Chan, Hck; Yau, Qkc; Shyung, P.; Chan, Km (2014):

A novel mobile device based hamstring strength test result can predict isokinetic hamstring strength in professional football players: a study of reliability and validity.

In: *Br J Sports Med* 48 (7), S. 623–624. DOI: 10.1136/bjsports-2014-093494.172.

Abstract:

BACKGROUND: Isokinetic hamstring strength test is considered as a golden standard for identifying players with increased risk of hamstring strain injuries. However, those testing protocols were time consuming and inconvenient. OBJECTIVE: The aim of this study is to examine the reliability and validity of a novel mobile device based hamstring strength test in soccer players. It is hypothesized that a greater forward flexion angle is associated a greater isokinetic hamstring strength. DESIGN: Cross-sectional study. SETTING: A physical test of hamstring strength in clinical setting. PARTICIPANTS: 30 first team players were recruited from professional football clubs. MAIN OUTCOME MEASUREMENTS: In the CUHK hamstring strength test (CUHK test), a smartphone was attached on subject's lower back. Subjects were instructed to lower the upper body from a kneeling position until the point he cannot sustain. Trunk forward flexion angle and angular velocity were recorded by the device. In the isokinetic hamstring strength test, it examined subjects' concentric and eccentric hamstring peak torque. Pearson Correlation, linear regression and intra-class correlation coefficient (ICC) were used to examine the validity and reliability. RESULTS: Result shown that the reliability was good, R=0.845. The CUHK strength test result was highly correlated with isokinetic hamstring peak torque at ecc. 30 degree/second, con. 60 degree/second, con. 240 degree/second respectively, i.e. R=0.81, 0.73 and 0.66. Linear regression analysis shown that the CUHK test was the best to predict isokinetic eccentric hamstring performance at 30 degree/second, R(2)=0.81, P<.001). CONCLUSIONS: CUHK hamstring strength test is a reliable and valid tool to examine athletes' hamstring muscle performance. Clinician and sports coaches may adopt this test for screening and monitoring athletes or patients during rehabilitation or preseason period. Individualized rehabilitation or strength training recommendation could be made based on the test result.

Lee-Flynn, Sharon C.; Pomaki, Georgia; Delongis, Anita; Biesanz, Jeremy C.; Puterman, Eli (2011):

Daily cognitive appraisals, daily affect, and long-term depressive symptoms: The role of self-esteem and self-concept clarity in the stress process.

In: *Pers Soc Psychol Bull* 37 (2), S. 255–268.

Abstract:

The current study investigated how self-esteem and self-concept clarity are implicated in the stress process both in the short and long term. Initial and 2-year follow-up interviews were completed by 178 participants from stepfamily unions. In twice-daily structured diaries over 7 days, participants reported their main family stressor, cognitive appraisals (perceived stressor threat and stressor controllability), and negative affect. Results of multilevel modeling indicated that high self-esteem ameliorated the effect of daily negative cognitive appraisals on daily negative affect. Self-concept clarity also buffered the effect of low self-self-esteem on depressive symptoms 2 years later. Our findings point to the vulnerability of those having low self-esteem or low self-concept clarity in terms of both short- and long-term adaptation to stress. They indicate the need for the consideration of such individual differences in designing stress management interventions.

Lehman, Barbara J.; Cane, Arianna C.; Tallon, Shannon J.; Smith, Stephanie F. (2014):

Physiological and Emotional Responses to Subjective Social Evaluative Threat in Daily Life.

In: *Anxiety Stress Coping*, S. 1–31. DOI: 10.1080/10615806.2014.968563.

Abstract:

Background and Objectives. This study examined concurrent and delayed emotional and cardiovascular correlates of naturally occurring experiences with subjective social evaluative threat (SSET), and tested whether individual differences in social interaction anxiety moderated those associations. Methods. Sixty-eight participants wore ambulatory blood pressure monitors for three days. Following each blood pressure reading participants reported on SSET and negative emotions, yielding 1,770 momentary measures. Results. Multilevel modeling suggested that reports of greater SSET uniquely predicted elevations in anxiety and embarrassment, with elevations in anxiety, embarrassment, and shame extending to the hour following SSET. Reports of concurrent and previous-hour SSET also predicted cardiovascular elevations. Linkages between SSET and anxiety and shame, but not cardiovascular measures, were moderated by social interaction anxiety. Those higher in social interaction anxiety showed especially strong associations between SSET and both concurrent and delayed anxiety and greater delayed shame. Conclusions. This research suggests an important role for anxiety, embarrassment, and shame as emotional consequences of naturally occurring evaluative threat, especially for those who are more socially anxious. Further, this work replicates other naturalistic studies that have documented increased blood pressure at times of SSET, and extends that work by documenting cardiovascular responses into the following hour.

Lehmiller, Justin J.; Ioerger, Michael (2014):

Social networking smartphone applications and sexual health outcomes among men who have sex with men.

In: *PLoS One* 9 (1), S. e86603. DOI: 10.1371/journal.pone.0086603.

Abstract:

Several smartphone applications (apps) designed to help men who have sex with men (MSM) find casual sexual partners have appeared on the market recently. Apps of this nature have the potential to impact sexual health and behavior by providing constant access to a large supply of available partners. In this study, the sexual health history, behavior, and personality of MSM who use these apps was compared to MSM who meet partners in other ways. A sample of 110 adult MSM was recruited online to complete a cross-sectional survey. All participants were either single or involved in a non-exclusive romantic relationship. There were no statistically significant differences between app users and non-users in frequency of insertive or receptive anal sex without a condom. However, app users reported significantly more sexual partners and had a higher prevalence of ever being diagnosed with an STI than did non-users. App users did not differ from non-users on any demographic or personality variables (including erotophilia, sensation seeking, and self-control); however, when adjusting lifetime total sex partners for those met specifically through apps, app users still had significantly more partners. This pattern of results suggests that app users may be more sexually active in general. More work is needed to fully understand the association between this emerging technology and potential sexual health risks.

Leoncini, Giovanna; Ratto, Elena; Viazzi, Francesca; Vaccaro, Valentina; Parodi, Angelica; Falqui, Valeria et al. (2006):

Increased ambulatory arterial stiffness index is associated with target organ damage in primary hypertension.

In: *Hypertension* 48 (3), S. 397–403. DOI: 10.1161/01.HYP.0000236599.91051.1e.

Abstract:

Increased arterial stiffness has been shown to predict cardiovascular mortality in patients with primary hypertension. Asymptomatic organ damage is known to precede cardiovascular events. We investigated the relationship between a recently proposed index of stiffness derived from ambulatory blood pressure (BP) and target organ damage in 188 untreated patients with primary hypertension. Ambulatory arterial stiffness index was defined as 1 minus the regression slope of diastolic over systolic BP readings obtained from 24-hour recordings. Albuminuria was measured as the albumin:creatinine ratio, left ventricular mass index was assessed by echocardiography, and carotid abnormalities were evaluated by ultrasonography. The prevalence of microalbuminuria, left ventricular hypertrophy (LVH), and carotid abnormalities was 12%, 38%, and 19%, respectively. Ambulatory arterial stiffness index was positively related to age, triglycerides, office and 24-hour systolic BP, 24-hour pulse pressure, urinary albumin excretion, and carotid intima-media thickness. Patients with microalbuminuria, carotid abnormalities, or LVH showed higher ambulatory arterial stiffness index as compared with those without it. After adjusting for confounding factors, each SD increase in ambulatory arterial stiffness index entails an &2 times higher risk of microalbuminuria, carotid abnormalities, and LVH and doubles the risk of the occurrence of >or=1 sign of organ damage. Ambulatory arterial stiffness index is associated with organ damage in patients with primary hypertension. These data strengthen the role of this index as a marker of risk and help to explain the high cardiovascular mortality reported in patients with high ambulatory arterial stiffness index.

The effect of exercise absence on affect and body dissatisfaction as moderated by obligatory exercise beliefs and eating disordered beliefs and behaviors.

In: *Psychology of Sport and Exercise* 13 (4), S. 500–508. DOI: 10.1037/t01067-000;

Abstract:

Aim: Research suggests that exercise absence is frequently associated with greater guilt and negative affect, particularly when obligatory exercise beliefs and eating disordered psychopathology are considered. Two separate studies used ecological momentary assessment (EMA) to examine differences in mood on exercise and non-exercise days and the moderating impact of obligatory exercise beliefs and eating disordered beliefs and behaviors. Method: Both studies recruited female university students who endorsed frequent exercise behavior and study two also recruited based on level of eating disordered psychopathology. Participants completed the Obligatory Exercise Questionnaire at baseline and EMA measures of affect and exercise behavior for approximately one week. Study two participants also completed measures of body dissatisfaction and cognitions. Results: Results of study one suggest that obligation to exercise appears to have a greater impact on general level of affect than does exercise absence or the interaction of these two. In addition, in study two, eating disorder symptomatology was significantly associated with affect and cognition while exercise absence and obligatory exercise beliefs were not. Conclusions: The present studies suggest that the absence of exercise is not associated with significant changes in affect or cognitions. However, obligation to exercise and eating disorder symptomatology do impact affect and cognitions. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Lewandowski, Lawrence; Rieger, Brian; Smyth, Joshua; Perry, Lorraine; Gathje, Rebecca (2009):

Measuring post-concussion symptoms in adolescents: feasibility of ecological momentary assessment.

In: *Archives of clinical neuropsychology : the official journal of the National Academy of Neuropsychologists* 24 (8), S. 791–796. DOI: 10.1093/arclin/acp087.

Abstract:

Although there is a large literature examining head trauma in general, several areas remain understudied. Notably, little is known about symptom expression over the course of a day for adolescents recovering from concussion. Furthermore, intra-individual symptom variability has not been well characterized. This pilot study examined the feasibility of a momentary data-gathering method, as well as the sensitivity of the assessment to the subtle and dynamic changes in symptoms of concussion. Six adolescents, three of whom suffered a concussion and three non-injured controls, provided symptom ratings five times per day for 5 days. This ecological momentary assessment (EMA) was conducted on a personal digital assistant to capture variability in symptom reports while in the natural environment. Preliminary results indicated that the EMA method showed great promise as a research tool in natural settings (e.g., school and home). Adolescents were able to comply with all tasks with little interference in their daily activities. Students with concussion showed generally higher symptom ratings across physical, cognitive, and affective domains, and temporal and diurnal patterns for symptoms emerged. Implications for future research and patient care are discussed.

A three-level mixed-effects location scale model with an application to ecological momentary assessment data.

In: *Stat.Med.* (0277-6715 (Linking)). DOI: 10.1002/sim.5393.

Abstract:

In studies using ecological momentary assessment (EMA), or other intensive longitudinal data collection methods, interest frequently centers on changes in the variances, both within-subjects and between-subjects. For this, Hedeker et al. (Biometrics 2008; 64: 627-634) developed an extended two-level mixed-effects model that treats observations as being nested within subjects and allows covariates to influence both the within-subjects and between-subjects variance, beyond their influence on means. However, in EMA studies, subjects often provide many responses within and across days. To account for the possible systematic day-to-day variation, we developed a more flexible three-level mixed-effects location scale model that treats observations within days within subjects, and allows covariates to influence the variance at the subject, day, and observation level (over and above their usual effects on means) using a log-linear representation throughout. We provide details of a maximum likelihood solution and demonstrate how SAS PROC NLMIXED can be used to achieve maximum likelihood estimates

in an alternative parameterization of our proposed three-level model. The accuracy of this approach using NLMIXED was verified by a series of simulation studies. Data from an adolescent mood study using EMA were analyzed to demonstrate this approach. The analyses clearly show the benefit of the proposed three-level model over the existing two-level approach. The proposed model has useful applications in many studies with three-level structures where interest centers on the joint modeling of the mean and variance structure. Hierarchical functional data with mixed continuous and binary measurements.

In: *Biometrics. DOI:* 10.1111/biom.12211.

Abstract:

Motivated by objective measurements of physical activity, we take a functional data approach to longitudinal data with simultaneous measurement of a continuous and a binary outcomes. The regression structures are specified as smooth curves measured at various time-points with random effects that have a hierarchical correlation structure. The random effect curves for each variable are summarized using a few important principal components, and the association of the two longitudinal variables is modeled through the association of the principal component scores. We use penalized splines to model the mean curves and the principal component curves, and cast the proposed model into a mixed effects model framework for model fitting, prediction and inference. Via a quasilikelihood type approximation for the binary component, we develop an algorithm to fit the model. Data-based transformation of the continuous variable and selection of the number of principal components are incorporated into the algorithm. The method is applied to the motivating physical activity data and is evaluated empirically by a simulation study. Extensions for different types of outcomes are also discussed.

Li, Y.; Thijs, L.; Hansen, T. W.; Kikuya, M.; Boggia, J.; Richart, T. et al. (2010):

International database on ambulatory blood pressure monitoring in relation to cardiovascular outcomes investigators prognostic value of the morning blood pressure surge in 5645 subjects from 8 populations.

In: *Hypertension* 55 (4), S. 1040–1048.

Abstract:

Previous studies on the prognostic significance of the morning blood pressure surge (MS) produced inconsistent results. Using the International Database on Ambulatory Blood Pressure in Relation to Cardiovascular Outcome, we analyzed 5645 subjects (mean age: 53.0 years; 54.0% women) randomly recruited in 8 countries. The sleep-through and the preawakening MS were the differences in the morning blood pressure with the lowest nighttime blood pressure and the preawakening blood pressure, respectively. We computed multivariable-adjusted hazard ratios comparing the risk in ethnic- and sex-specific deciles of the MS relative to the average risk in the whole study population. During follow-up (median: 11.4 years), 785 deaths and 611 fatal and nonfatal cardiovascular events occurred. While accounting for covariables and the night:day ratio of systolic pressure, the hazard ratio of all-cause mortality was 1.32 (95% CI: 1.09 to 1.59; P=0.004) in the top decile of the systolic sleep-through MS (>or=37.0 mm Hg). For cardiovascular and noncardiovascular death, these hazard ratios were 1.18 (95% CI: 0.87 to 1.61; P=0.30) and 1.42 (95% CI: 1.11 to 1.80; P=0.005). For all cardiovascular, cardiac, coronary, and cerebrovascular events, the hazard ratios in the top decile of the systolic sleep-through MS were 1.30 (95% CI: 1.06 to 1.60; P=0.01), 1.52 (95% CI: 1.15 to 2.00; P=0.004), 1.45 (95% CI: 1.04 to 2.03; P=0.03), and 0.95 (95% CI: 0.68 to 1.32; P=0.74), respectively. Analysis of the preawakening systolic MS and the diastolic MS generated consistent results. In conclusion, a MS above the 90th percentile significantly and independently predicted cardiovascular outcome and might contribute to risk stratification by ambulatory blood pressure monitoring.

Li, Yan; Thijs, Lutgarde; Boggia, Jose; Asayama, Kei; Hansen, Tine W.; Kikuya, Masahiro et al. (2014):

Blood Pressure Load Does Not Add to Ambulatory Blood Pressure Level for Cardiovascular Risk Stratification.

In: *Hypertension. DOI:* 10.1161/HYPERTENSIONAHA.113.02780.

Abstract:

Experts proposed blood pressure (BP) load derived from 24-hour ambulatory BP recordings as a more accurate predictor of outcome than level, in particular in normotensive people. We analyzed 8711 subjects (mean age, 54.8 years; 47.0% women)

randomly recruited from 10 populations. We expressed BP load as percentage (%) of systolic/diastolic readings >/=135/>/=85 mm Hg and >/=120/>/=70 mm Hg during day and night, respectively, or as the area under the BP curve (mm Hgxh) using the same ceiling values. During a period of 10.7 years (median), 1284 participants died and 1109 experienced a fatal or nonfatal cardiovascular end point. In multivariable-adjusted models, the risk of cardiovascular complications gradually increased across deciles of BP level and load (P<0.001), but BP load did not substantially refine risk prediction based on 24-hour systolic or diastolic BP level (generalized R2 statistic </=0.294%; net reclassification improvement </=0.28%; integrated discrimination improvement </=0.001%). Systolic/diastolic BP load of 40.0/42.3% or 91.8/73.6 mm Hgxh conferred a 10-year risk of a composite cardiovascular end point similar to a 24-hour systolic/diastolic BP of 130/80 mm Hg. In analyses dichotomized according to these thresholds, increased BP load did not refine risk prediction in the whole study population (R2</=0.051) or in untreated participants with 24-hour ambulatory normotension (R2</=0.034). In conclusion, BP load does not improve risk stratification based on 24-hour BP level. This also applies to subjects with normal 24-hour BP for whom BP load was proposed to be particularly useful in risk stratification.

Understanding the Physical and Social Contexts of Children's Non-School Sedentary Behavior: An Ecological Momentary Assessment Study.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23493261.

Abstract:

BACKGROUND: Research on children's sedentary behavior has relied on recall-based self-report or accelerometer methods, which do not assess the context of such behavior. PURPOSE: This study used Ecological Momentary Assessment (EMA) to determine where and with whom children's sedentary behavior occurs during their non-school time. METHODS: Children (N = 120) ages 9-13 years (51% male, 33% Hispanic) wore mobile phones that prompted surveys (20 total) for four days. Surveys measured current activity (e.g., exercise, watching TV), physical location (e.g., home, outdoors), and social company (e.g., family, friends). RESULTS: Children engaged in a greater percentage of leisure-oriented (e.g., watching TV) than productive (e.g., reading, doing homework) sedentary behavior (70% vs. 30%, respectively). Most of children's sedentary activity occurred at home (85%). Children's sedentary activity took place most often with family members (58%). Differences in physical context of sedentary behavior were found for older vs. younger children (p < .05). Type of sedentary behavior differed by gender, racial/ethnic group, and social context (p's < .05). CONCLUSION: Children may prefer or have greater opportunities to be sedentary in some contexts than others. Research demonstrates the potential for using EMA to capture real-time information about children's sedentary behavior during their non-school time

Liao, Yue; Intille, Stephen S.; Dunton, Genevieve F. (2014):

Using Ecological Momentary Assessment to Understand Where and With Whom Adults' Physical and Sedentary Activity Occur.

In: *Int J Behav Med. DOI:* 10.1007/s12529-014-9400-z.

Abstract:

PURPOSE: This study used Ecological Momentary Assessment (EMA), a real-time self-report strategy, to describe the physical and social contexts of adults' physical activity and sedentary activity during their everyday lives and to determine whether these patterns and relationships differ for men and women. METHODS: Data from 114 adults were collected through mobile phones across 4 days. Eight electronic EMA surveys were randomly prompted each day asking about current activities (e.g., physical or sedentary activity), physical and social contexts, and perceived outdoor environmental features (e.g., greenness/vegetation, safety, and traffic). All participants also wore accelerometers during this period to objectively measure moderate-to-vigorous physical activity (MVPA) and sedentary activity. RESULTS: Home was the most common physical context for EMA-reported physical and sedentary activity. Most of these activities occurred when participants were alone. When alone, the most commonly EMA-reported physical activity and sedentary activity was walking and reading/using computer, respectively. When in outdoor home locations (e.g., yard and driveway) women demonstrated higher levels of MVPA, whereas men demonstrated higher levels of MVPA when in outdoor park settings (ps < .05). Men but not women demonstrated higher levels of MVPA in settings with a greater degree of perceived greenness and vegetation (p < .05). CONCLUSIONS: The current study shows how EMA via mobile phones and accelerometers can be combined to offer an innovative approach to assess the contexts of adults' daily physical and sedentary activity. Future studies could consider utilizing this method in more representative samples to gather context-specific information to inform the development of physical activity interventions.

Development and pilot testing of a mobile health solution for asthma self-management: asthma action plan smartphone application pilot study.

In: *Can.Respir.J* 20 (4), S. 301–306. Online verfügbar unter PM:23936890.

Abstract:

BACKGROUND: Collaborative self-management is a core recommendation of national asthma guidelines; the written action plan is the knowledge tool that supports this objective. Mobile health technologies have the potential to enhance the effectiveness of the action plan as a knowledge translation tool. OBJECTIVE: To design, develop and pilot a mobile health system to support asthma self-management. METHODS: The present study was a prospective, single-centre, nonrandomized, pilot preintervention-postintervention analysis. System design and development were guided by an expert steering committee. The network included an agnostic web browser-based asthma action plan smartphone application (SPA). Subjects securely transmitted symptoms and peak flow data daily, and received automated control assessment, treatment advice and environmental alerts. RESULTS: Twenty-two adult subjects (mean age 47 years, 82% women) completed the study. Biophysical data were received on 84% of subject days (subject day = 1 subject x 1 day). Subjects viewed their action plan current zone of control on 54% and current air quality on 61% of subject days, 86% followed self-management advice and 50% acted to reduce exposure risks. A large majority affirmed ease of use, clarity and timeliness, and 95% desired SPA use after the study. At baseline, 91% had at least one symptom criterion for uncontrolled asthma and 64% had >/=2, compared with 45% (P=0.006) and 27% (P=0.022) at study close. Mean Asthma Quality of Life Questionnaire score improved from 4.3 to 4.8 (P=0.047). CONCLUSIONS: A dynamic, real-time, interactive, mobile health system with an integrated asthma action plan SPA can support knowledge translation at the patient and provider levels

Ambulatory measurement of the ecg t-wave amplitude.

In: *Psychophysiology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-34204-001%26site%3dehost-live.

Abstract:

Abstract Ambulatory recording of the preejection period (PEP) can be used to measure changes in cardiac sympathetic nervous system (SNS) activity under naturalistic conditions. Here, we test the ECG T-wave amplitude (TWA) as an alternative measure, using 24-h ambulatory monitoring of PEP and TWA in a sample of 564 healthy adults. The TWA showed a decrease in response to mental stress and a monotonic decrease from nighttime sleep to daytime sitting and more physically active behaviors. Within-participant changes in TWA were correlated with changes in the PEP across the standardized stressors (r = .42) and the unstandardized naturalistic conditions (mean r = .35). Partialling out changes in heart rate and vagal effects attenuated these correlations, but they remained significant. Ambulatory TWA cannot replace PEP, but simultaneous recording of TWA and PEP provides a more comprehensive picture of changes in cardiac SNS activity in real-life settings. Development of wireless brain computer interface with embedded multitask scheduling and its application on real-time driver's drowsiness detection and warning.

In: *Biomedical Engineering, IEEE Transactions on* 55 (5), S. 1582–1591.

Abstract:

Biomedical signal monitoring systems have been rapidly advanced with electronic and information technologies in recent years. However, most of the existing physiological signal monitoring systems can only record the signals without the capability of automatic analysis. In this paper, we proposed a novel brain-computer interface (BCI) system that can acquire and analyze electroencephalogram (EEG) signals in real-time to monitor human physiological as well as cognitive states, and, in turn, provide warning signals to the users when needed. The BCI system consists of a four-channel biosignal acquisition/amplification module, a wireless transmission module, a dual-core signal processing unit, and a host system for display and storage. The embedded dual-core processing system with multitask scheduling capability was proposed to acquire and process the input EEG signals in real time. In addition, the wireless transmission module, which eliminates the inconvenience of wiring, can be switched between radio frequency (RF) and Bluetooth according to the transmission distance. Finally, the real-time EEG-based drowsiness monitoring and warning algorithms were implemented and integrated into the system to close the loop of the BCI system. The

practical online testing demonstrates the feasibility of using the proposed system with the ability of real-time processing, automatic analysis, and online warning feedback in real-world operation and living environments.

Changes in daily physical activity before and after total hip arthroplasty. A pilot study using accelerometry.

In: *Surgeon* (1479-666X (Linking)). DOI: 10.1016/j.surge.2012.04.006.

Abstract:

The present single-centre prospective follow-up study assessed the objective changes in physical activity undertaken before and after total hip arthroplasty (THA) using accelerometry. We enrolled 12 female patients who underwent home-based accelerometry assessment one month before and six months after the THA procedure. We assessed the daily amount of physical activity and energy expenditure related to physical activities. We also recorded the intensity of the physical activity, and pre- and post-operative clinical evaluation with the Harris Hip Score (HHS). At 6 months after surgery, we found a statistically significant increase of the total energy cost of physical activity (DA) (P=0.02), without significant increase of activity time (P>0.05). The energy cost of moderate/vigorous activity was statistically significant increased after surgery (P=0.008). Finally, HHS improved form 53.9+/-15.3 pre-operatively to 78.1+/-12.2 post-operatively (P=0.03). In our patients, the improvement was significant only for the total energy cost of daily activity. Thus, although patients did not exhibit a more active lifestyle, as shown by the slight increase of the activity time, they significantly increased the amount of moderate or vigorous activities performed after surgery

Linas, Beth S.; Latkin, Carl; Westergaard, Ryan P.; Chang, Larry W.; Bollinger, Robert C.; Genz, Andrew; Kirk, Gregory D. (2014):

Capturing illicit drug use where and when it happens: an ecological momentary assessment of the social, physical and activity environment of using versus craving illicit drugs.

In: *Addiction. DOI:* 10.1111/add.12768.

Abstract:

AIMS: To understand the environmental and contextual influences of illicit cocaine and heroin use and craving using mobile health (mHealth) methods. DESIGN: Interactive mHealth methods of ecological momentary assessment (EMA) were utilized in the Exposure Assessment in Current Time (EXACT) study to assess drug use and craving among urban drug users in real time. Participants were provided with mobile devices and asked to self-report every time they either craved (without using) or used heroin or cocaine for 30 days from November 2008 through May 2013. SETTING: Baltimore, MD, USA. PARTICIPANTS: A total of 109 participants from the AIDS Linked to the IntraVenous Experience (ALIVE) study. MEASUREMENTS: For each drug use or craving event, participants answered questions concerning their drug use, current mood and their social, physical and activity environments. Odds ratios (OR) of drug use versus craving were obtained from logistic regression models with generalized estimating equations of all reported events. FINDINGS: Participants were a median of 48.5 years old, 90% African American, 52% male and 59% HIV-infected. Participants were significantly more likely to report use rather than craving drugs if they were with someone who was using drugs [adjusted odds ratio (aOR) = 1.45, 95% confidence interval (CI) = 1.13, 1.86), in an abandoned space (aOR = 6.65, 95% CI = 1.78, 24.84) or walking/wandering (aOR = 1.68, 95% CI = 1.11, 2.54). Craving drugs was associated with being with a child (aOR = 0.26, 95% CI = 0.12, 0.59), eating (aOR = 0.54, 95% CI = 0.34, 0.85) or being at the doctor's office (aOR = 0.31, 95% CI = 0.12, 0.80). CONCLUSIONS: There are distinct drug using and craving environments among urban drug users, which may provide a framework for developing real-time context-sensitive interventions.

Lindamer, Laurie A.; McKibbin, Christine; Norman, Gregory J.; Jordan, Leslie; Harrison, Kelly; Abeyesinhe, Suranee; Patrick, Kevin (2008):

Assessment of physical activity in middle-aged and older adults with schizophrenia.

In: *Schizophrenia Research* 104 (1), S. 294–301.

Abstract:

BACKGROUND:

Regular physical activity (PA) decreases morbidity in the general population; yet, information about the amount and effects of PA in persons with schizophrenia is scant. To develop interventions to increase PA and to assess its potential benefits in this group, accurate measurement of PA is needed. The purpose of this study was to characterize PA and determine the test-retest reliability and concurrent validity of the Yale Physical Activity Scale (YPAS), a self-report measure, in persons with schizophrenia.

METHODS:

PA was assessed with the YPAS, a scale of motivational readiness for PA, and accelerometry in middle-aged and older persons with a diagnosis of schizophrenia (n=54) and in a comparison group with no known psychiatric diagnosis (n=27).

RESULTS:

On the YPAS measures, persons with schizophrenia reported on average 11 h per week of PA, whereas the non-psychiatric comparison group reported about 32 h per week. Only about 30% of schizophrenia subjects were classified as being regularly active relative to 62% of the comparison group on PA motivational stages of readiness. On the accelerometry measures, the schizophrenia group had lower levels of light activity than the comparison group, but there were no differences in moderate and vigorous activity or sedentary behavior. Only in the comparison group were there significant associations between YPAS and accelerometer variables. Several YPAS scores demonstrated high test-retest reliability in both groups, and concurrent validity was supported between the YPAS and PA motivational stages of readiness.

CONCLUSIONS:

We found that the YPAS is a reliable measure of PA in schizophrenia for some indices. Although the YPAS demonstrated concurrent validity with other self-report measures, it did not demonstrate concurrent validity when compared to PA measured by accelerometry in persons with schizophrenia. Use of multiple measures, both subjective and objective, is recommended when assessing PA in schizophrenia.

Lipton, Richard B.; Buse, Dawn C.; Hall, Charles B.; Tennen, Howard; Defreitas, Tiffani A.; Borkowski, Thomas M. et al. (2014):

Reduction in perceived stress as a migraine trigger: Testing the "let-down headache" hypothesis.

In: *Neurology. DOI:* 10.1212/WNL.0000000000000332.

Abstract:

OBJECTIVE: To test whether level of perceived stress and reductions in levels of perceived stress (i.e., "let-down") are associated with the onset of migraine attacks in persons with migraine. METHODS: Patients with migraine from a tertiary headache center were invited to participate in a 3-month electronic diary study. Participants entered data daily regarding migraine attack experience, subjective stress ratings, and other data. Stress was assessed using 2 measures: the Perceived Stress Scale and the Self-Reported Stress Scale. Logit-normal, random-effects models were used to estimate the odds ratio for migraine occurrence as a function of level of stress over several time frames. RESULTS: Of 22 enrolled participants, 17 (median age 43.8 years) completed >30 days of diaries, yielding 2,011 diary entries including 110 eligible migraine attacks (median 5 attacks per person). Level of stress was not generally associated with migraine occurrence. However, decline in stress from one evening diary to the next was associated with increased migraine onset over the subsequent 6, 12, and 18 hours, with odds ratios ranging from 1.5 to 1.9 (all p values < 0.05) for the Perceived Stress Scale. Decline in stress was associated with migraine onset after controlling for level of stress for all time points. Findings were similar using the Self-Reported Stress Scale. CONCLUSIONS: Reduction in stress from one day to the next is associated with migraine onset the next day. Decline in stress may be a marker for an impending migraine attack and may create opportunities for preemptive pharmacologic or behavioral interventions.

Lischetzke, Tanja; Angelova, Rozalina; Eid, Michael (2011):

Validating an indirect measure of clarity of feelings: Evidence from laboratory and naturalistic settings.

In: *Psychological Assessment* 23 (2), S. 447.

Abstract:

This study analyzed the reliability and validity of an indirect measure of clarity of feelings that is based on response latencies (RTs) of mood ratings. Fifty-two participants completed a laboratory session and an experience-sampling week with 6 measurement occasions per day. Shorter RT of mood ratings measured in the laboratory (but not self-reported dispositional clarity) predicted higher overall mood regulation success during the experience-sampling week. As a new indirect ambulatory measure of clarity, RTs of mood ratings were measured on handheld devices during the experience-sampling week. The new ambulatory RT measure of clarity demonstrated good psychometric properties. Within-occasions reliability (internal consistency)

was satisfactory, and between-occasions reliability (consistency of aggregated scores) was high. Ambulatory RT of mood ratings demonstrated moderate to high convergence with RT of mood ratings measured in the laboratory session. Both RT measures were unrelated to self-reported dispositional clarity of feelings. However, momentary RT converged with a self-report measure of momentary clarity on the within-persons level: Participants were faster to rate those mood items that they were more certain about. Evidence for the predictive validity of the new ambulatory RT measure was provided by the finding that on the within-persons level, shorter RT (but not self-reported momentary clarity) predicted higher mood regulation success and better mood at subsequent measurement occasions. The results suggest that RT of mood ratings can be used as a reliable and valid indicator of an individual's clarity of feelings in laboratory and experience-sampling studies.

Lischetzke, Tanja; Pfeifer, Henriette; Crayen, Claudia; Eid, Michael (2012):

Motivation to regulate mood as a mediator between state extraversion and pleasant-unpleasant mood.

In: *Journal of Research in Personality* 46 (4), S. 414–422. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-15637-002%26site%3dehost-live;lischetzke@uni-landau.de.

Abstract:

This experience sampling study investigated whether state extraversion (i.e., momentary extraverted behavior) is positively associated with pleasant affect within persons and whether mood regulation motivation mediates this relationship. Seven times per day for one week, 162 participants reported on their state extraversion, pleasant–unpleasant mood, and mood regulation intention. Higher state extraversion was related to more pleasant mood, and this within-persons relationship held for 89% of individuals. Analyses with lagged predictors revealed that state extraversion predicted an increase in pleasant mood from one occasion to the next. Dispositional extraversion did not moderate the within-persons relationship. Hedonic mood regulation intention mediated the relation between state extraversion and pleasant–unpleasant mood. The findings support a self-regulation explanation of the extraversion–pleasant affect link. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Litmanen, Topi; Lonka, Kirsti; Inkinen, Mikko; Lipponen, Lasse; Hakkarainen, Kai (2012):

Capturing teacher students' emotional experiences in context: Does inquiry-based learning make a difference?

In: *Instructional Science* 40 (6), S. 1083–1101. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-28705-011%26site%3dehost-live;topi.litmanen@helsinki.fi.

Abstract:

In the present study teacher students' contextual learning experiences were examined longitudinally in authentic study environments using the contextual activity sampling system, a means of mobile-supported experience sampling. The students' (n = 9) experiences were first recorded during a 2 week period in their first year of study. The same measurements were repeated again for a 2 week follow-up in the second year, accompanied by interviews before and after the follow-up. The first year of study consisted mostly of lectures and ordinary small-group work, whereas the second measurement period ran parallel to the completion of an intensive inquiry-based project, which was the focus of the present study. A multivariate analysis of variance revealed that studying during the inquiry-based period produced stronger experiences of being challenged as well as negative affects than the teacher-centered period. The participants' experiences of competence, commitment and positive affects did not differ during the two periods. However, interview data indicated that the participants enjoyed the inquiry-based period and that the work was intensive. Contextual data and interviews were also used to describe students' experiences during one particular study session during the inquiry-based project. The results suggest that negative affects may be an essential part of the process of gradually learning to take responsibility for both individual and collaborative learning processes. Possibilities for using experience-sampling methods to analyze collaborative learning are also discussed. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Altered cardiovascular rhythmicity in children with white coat and ambulatory hypertension.

In: *Pediatr Res* 67 (4), S. 419–423. DOI: 10.1203/PDR.0b013e3181d00b5b.

Abstract:

Adults with ambulatory hypertension or white coat hypertension (WCH) display abnormal cardiovascular rhythms. We studied cardiovascular rhythms by Fourier analysis of 24-h ambulatory blood pressure (BP) measurement profiles in 129 hypertensive children, 54 children with WCH, and 146 age-, height-, and gender-matched healthy subjects. The day/night mean arterial pressure ratio was lower in hypertensive and patients with WCH compared with controls (1.13 versus 1.16 versus 1.21, respectively; $p < 0.0001$). Eighty-five percent of controls were dippers compared with 74% of WCH (n.s.) and 64% of patients with ambulatory hypertension ($p < 0.0001$). The prevalence of 24-h rhythms was similar among the groups, but prevalence of 12-h BP rhythms was increased in hypertensive (67%) and WCH (72%) compared with controls (51%, $p < 0.0001$). The amplitudes of the 24-, 8-, and 6-h BP rhythms were reduced in hypertensive and WCH compared with controls ($p < 0.05$). Hypertensive and patients with WCH displayed delayed 24-, 12-, 8-, 6-h acrophases in comparison with controls ($p < 0.05$). In conclusion, hypertensive children exhibit abnormal cardiovascular rhythmicity compared with controls, especially a higher prevalence of nondipping compared with normotensive children. Abnormalities in patients with WCH are intermediate between healthy children and patients with ambulatory hypertension.

Novel approach to ambulatory assessment of human segmental orientation on a wearable sensor system.

In: *Journal of biomechanics* 42 (16), S. 2747–2752. DOI: 10.1016/j.jbiomech.2009.08.008.

Abstract:

A new method using a double-sensor difference based algorithm for analyzing human segment rotational angles in two directions for segmental orientation analysis in the three-dimensional (3D) space was presented. A wearable sensor system based only on triaxial accelerometers was developed to obtain the pitch and yaw angles of thigh segment with an accelerometer approximating translational acceleration of the hip joint and two accelerometers measuring the actual accelerations on the thigh. To evaluate the method, the system was first tested on a 2 degrees of freedom mechanical arm assembled out of rigid segments and encoders. Then, to estimate the human segmental orientation, the wearable sensor system was tested on the thighs of eight volunteer subjects, who walked in a straight forward line in the work space of an optical motion analysis system at three self-selected speeds: slow, normal and fast. In the experiment, the subject was assumed to walk in a straight forward way with very little trunk sway, skin artifacts and no significant internal/external rotation of the leg. The root mean square (RMS) errors of the thigh segment orientation measurement were between 2.4 degrees and 4.9 degrees during normal gait that had a 45 degrees flexion/extension range of motion. Measurement error was observed to increase with increasing walking speed probably because of the result of increased trunk sway, axial rotation and skin artifacts. The results show that, without integration and switching between different sensors, using only one kind of sensor, the wearable sensor system is suitable for ambulatory analysis of normal gait orientation of thigh and shank in two directions of the segment-fixed local coordinate system in 3D space. It can then be applied to assess spatio-temporal gait parameters and monitoring the gait function of patients in clinical settings.

Can Inner Peace be Improved by Mindfulness Training: A Randomized Controlled Trial.

In: *Stress.Health* (1532-3005 (Linking)). DOI: 10.1002/smi.2551.

Abstract:

This article reports a randomized controlled trial to investigate whether mindfulness training can successfully improve inner peace in participants with no known mental disorder. Fifty-seven participants were randomized to either mindfulness training (n = 29) or wait-list control (n = 28). The experience sampling method was used to measure the fleeting momentary experience of inner peace in participants. In addition, we used an experimental approach to assessing ability to focus attention: the Meditation Breath Attention Score, as well as the self-report Five-Facet Mindfulness Questionnaire (FFMQ). Compared with the wait-list control group, mindfulness training led to an increase in scores of inner peace, Meditation Breath Attention Score and FFMQ, using analysis of repeated measures analysis of variance. Change in inner peace was not, however, mediated by changes in self-rated mindfulness (FFMQ) nor by increased attentional focus. The findings provide first evidence suggesting that using mindfulness training improves the participants' inner peace. The focus here was on the immediate effects and future studies need to use follow-up. (c) 2013 The Authors. Stress and Health published by John Wiley & Sons Ltd

Liu, Weiying; Yue, Hongmei; Zhang, Jiabin; Pu, Jiayuan; Yu, Qin (2014):

Effects of plasma ghrelin, obestatin, and ghrelin/obestatin ratio on blood pressure circadian rhythms in patients with obstructive sleep apnea syndrome.

In: *Chin Med J (Engl)* 127 (5), S. 850–855.

Abstract:

BACKGROUND: Obstructive sleep apnea syndrome (OSAS) is strongly associated with obesity and with cardiovascular disease. Ghrelin and obestatin are two peptides from the same source but have opposite roles. Both of them can affect feeding and regulate vascular tune. The aim of this study was to investigate the relationship between plasma ghrelin, obestatin, the ratio of ghrelin and obestatin (G/O) and sleep parameters and blood pressure circadian rhythms in patients with OSAS. METHODS: This study enrolled 95 newly diagnosed over-weight OSAS patients (OSAS group), 30 body mass index (BMI)-match non-OSAS adults (over-weight group) and 30 non-OSAS normal weight adults (control group). Polysomnography (PSG) was performed in the OSAS group and over-weight group. Blood pressure of all subjects was monitored by means of 24-hour ambulatory blood pressure monitoring. The concentration of plasma ghrelin and obestatin was detected by enzyme-linked immunosorbent assay (ELISA). RESULTS: Plasma ghrelin levels in the OSAS group and over-weight group were significantly lower than that of the control group ($P < 0.05$). Plasma obestatin levels were lower in the over-weight group and OSAS group, but there was no significant difference among the three groups. The blood pressure in OSAS patients was higher, and there was a significant difference in all blood pressure parameters compared to the control group, and in the daytime average diastolic blood pressure (DBP), nocturnal average systolic blood pressure (SBP) and DBP, DBP variability values as compared to over-weight subjects. Furthermore, there were significantly more non-dipper patterns of blood pressure (including hypertension and normotension) in the OSAS group than in the other two groups ($P < 0.01$). Correlation analysis showed that ghrelin levels had a significant correlation with BMI and nocturnal average DBP but not with PSG parameters. In contrast, the G/O ratio had a negative correlation with apnea-hypopnea index (AHI) ($P < 0.05$), as well as a strong positive correlation with the blood pressure variability values ($P < 0.01$). In multivariate analyses, AHI ($P < 0.05$) and G/O ($P < 0.05$) were independently related to SBP variability changes, while AHI ($P < 0.05$), G/O ($P < 0.01$) and BMI ($P < 0.05$) were independently related to DBP variability changes. CONCLUSIONS: Our data show plasma ghrelin and obestatin levels were related to obesity in OSAS. Sleep apnea in OSAS patients could have led to an imbalance in G/O in the basis of obesity. Moreover, the imbalance may promote nighttime blood pressure elevation and affect blood pressure circadian disorder.

Liu, Y.; Zhu, S. H.; Wang, G. H.; Ye, F.; Li, P. Z. (2013):

Validity and reliability of multiparameter physiological measurements recorded by the equivital lifemonitor during activities of various intensities.

In: *J Occup.Environ.Hyg.* 10 (2), S. 78–85. DOI: 10.1080/15459624.2012.747404.

Abstract:

The Equivital LifeMonitor EQ02 is a multiparameter body-worn system capable of logging and transmitting physiological data describing a wearer's cardiorespiratory and thermal status. A number of vital signs can be acquired by the system, including electrocardiography, respiratory inductance plethysmography, posture/activity, multipoint skin temperature, and core temperature. The validity and reliability of the multiparameter physiological data recorded by the EQ02 were assessed. Participants performed resting, low-, and moderate intensity activities and wore the EQ02 and other calibrated laboratory physiological monitoring devices simultaneously. Heart rate, respiratory rate, multipoint skin temperature, and core temperature recorded by the EQ02 were compared with measurements recorded by standard devices. Results show that the validity error scores for HR and RR for all three activities were not significantly different from zero, and the CV, 95% LOA, and r were all clinically accepted. The validity error score for MT(SK) (0.59 degrees C) falls outside the limits of 0.5 degrees C, but the

differences were parallel, r remained high (0.96), and 95% LOA remained narrow (+/-0.88 degrees C). The validity error score for T(C) (-0.1 degrees C) was similar in direction and magnitude to other studies, and r (0.98) and 95% LOA (+/-0.22 degrees C) showed acceptable agreement between devices. The reliability error scores for HR, RR, MT(SK), and T(C) between trials were significantly different from zero. The 95% LOA, CV, and ICC for the EQ02 were similar to standard devices and were all clinically accepted. These findings demonstrate the validity and reliability of the EQ02 for ambulatory monitoring of multiple physiological parameters and suggest that the system could be used to provide a complete human physiological monitoring platform for the study of occupational health, environmental hygiene, and other application fields requiring ambulatory monitoring of multiparameter physiological status

Lo, Shih-Hsiang; Liau, Chiau-Suong; Hwang, Jing-Shiang; Wang, Jung-Der (2008):

Dynamic blood pressure changes and recovery under different work shifts in young women.

In: *Am J Hypertens* 21 (7), S. 759–764.

Abstract:

BACKGROUND:

Some studies have reported that shift work can affect blood pressure (BP), but few have studied recovery from BP changes occurring during different shifts.

METHODS:

We recruited 16 young female nurses working rotating shifts and six working the regular day shift. All received repeated ambulatory BP monitoring (ABPM) during their workdays and following day off.

RESULTS:

Our linear mixed-effect model showed that both systolic and diastolic BPs were significantly decreased during sleeping period and significantly increased while on working period, on a work day, but increased during sleeping period after a night shift or evening shift. BP measurements that changed after evening shift usually returned to baseline on consecutive off-duty day after day shift, but they did not completely return to baseline after a night shift ($P < 0.05$). We also found 69% of those working rotating shifts had at least changed once in dipper/nondipper status. The rates of change in dipper/nondipper status between work day and off-duty day were 33, 44, 50, and 38% for nurses worked in outpatient clinic, night shift, evening shift, and day shift, respectively.

CONCLUSION:

Shift work is significantly associated with BP and possibly dipper/nondipper status in young female nurses. Except for those working night shifts, BP levels returned to baseline the off-duty day after day shift. We recommend that potential influence of shift work be considered when evaluating a person's BP.

Lo, Shih-Hsiang; Lin, Lian-Yu; Hwang, Jing-Shiang; Chang, Yu-Yin; Liau, Chiau-Suong; Wang, Jung-Der (2010):

Working the night shift causes increased vascular stress and delayed recovery in young women.

In: *Chronobiology International* 27 (7), S. 1454–1468. DOI: 10.3109/07420528.2010.498067.

Abstract:

Shiftwork has been associated with elevated blood pressure (BP) and decreased heart-rate variability (HRV), factors that may increase the long-term risk of cardiovascular-related mortality and morbidity. This study explored the effect of shiftwork on dynamic changes in autonomic control of HRV (cardiac stress), systolic BP and diastolic BP, i.e., SBP and DBP (vascular stress), and recovery in the same subjects working different shifts. By studying the same subjects, the authors could reduce the effect of possible contribution of between-subject variation from genetic predisposition and environmental factors. The authors recruited 16 young female nurses working rotating shifts--day (08:00-16:00 h), evening (16:00-00:00 h), and night (00:00-08:00 h)--and 6 others working the regular day shift. Each nurse received simultaneous and repeated 48-h ambulatory electrocardiography and BP monitoring during their work day and the following off-duty day. Using a linear mixed-effect model to adjust for day shift, the results of the repeated-measurements and self-comparisons found significant shift differences in vascular stress. While working the night shift, the nurses showed significant increases in vascular stress, with increased SBP of 9.7 mm Hg. The changes of SBP and DBP seemed to peak during waking time at the same time on the day off as they did on the working day. Whereas HRV profiles usually returned to baseline level after each shift, the SBP and DBP of night-shift workers did not completely return to baseline levels the following off-duty day ($p < .001$). The authors concluded that although the nurses may recover from

cardiac stress the first day off following a night shift, they do not completely recover from increases in vascular stress on that day.

London, Bonita; Rosenthal, Lisa; Gonzalez, Angel (2011):

Assessing the role of gender rejection sensitivity, identity, and support on the academic engagement of women in nontraditional fields using experience sampling methods.

In: *Journal of Social Issues* 67 (3), S. 510–530. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-21044-006&site=ehost-live;bonita.london@stonybrook.edu.

Abstract:

Efforts to understand and alleviate the pervasive underrepresentation of women in science, technology, engineering, and mathematics (STEM) fields may benefit from the utilization of research methodologies that can model STEM engagement from multiple levels of analysis. We discuss the utility of experience sampling methodology (ESM) in capturing this broad range of factors that contribute to women's success and engagement in STEM fields—as well as other fields in which women have historically been underrepresented—with special focus on the importance of identity, social support, and gender-based rejection. We propose that the use of ESM may provide fine-grained details of women's STEM experiences, and thus model the challenges they face in STEM fields. The advantages of using ESM for capturing repeated measures of affect and behavior, the use of electronic methods of data collection, and the use of ESM to administer interventions are discussed. Long, Anna C.; Palermo, Tonya M.; Manees, Anne M. (2008):

Brief report: using actigraphy to compare physical activity levels in adolescents with chronic pain and healthy adolescents.

In: *Journal of Pediatric Psychology* 33 (6), S. 660–665.

Abstract:

OBJECTIVES:

This study compared activity levels of adolescents with chronic pain and healthy adolescents, and investigated relations between actigraphy and subjective measures of activity limitations and depression.

METHODS:

Forty adolescents (n = 20 with chronic pain, n = 20 otherwise healthy; 12-17 years; 72.5% females) participated. Adolescents completed questionnaires regarding pain, activity limitations, and depression. Activity levels were assessed for 7 days using the Actiwatch 64 device, yielding mean and peak activity levels, and time spent in moderate and sedentary activity.

RESULTS:

Physical activity was lower in adolescents with chronic pain than in healthy peers. Adolescents with chronic pain reported significantly higher levels of activity limitations and depression. Age and gender were related to activity. Higher activity was inversely correlated with pain frequency and depression. Peak activity was also significantly inversely related to self-reported pain intensity and activity limitations.

CONCLUSIONS:

Actigraphy may be useful for examining physical activity outcomes in adolescents with chronic pain.

Lopes, Vítor P.; Vasques, Catarina; Maia, José A. R.; Ferreira, J. C. V. (2007):

Habitual physical activity levels in childhood and adolescence assessed with accelerometry.

Abstract:

AIM:

The purposes of this study were: 1) to evaluate age and gender differences in physical activity (PA) of children and adolescents; 2) to find out if children and adolescents fulfill the PA recommendations of 60 min x day(-1) of moderate (MPA) to vigorous PA (VPA).

METHODS:

PA was assessed in 265 female and 238 male subjects, ranging from 6 to 18 years of age, grouped in 4 age groups, with MTI ActiGraph model 7164, during 7 consecutive days. The MTI actigraph data was reduced to bouts (30-, 20-, 10-, and 5-min) and minutes spent in MPA, VPA, and very VPA (VVPA).

RESULTS:

The oldest boys and girls revealed a lower number of PA bouts than the younger ones. Significant gender differences were found in daily VPA, $F(1, 492)=37.67$, $P<0.001$; and VVPA $F(1, 494)=24.11$, $P<0.001$. Boys were more active than girls. Significant age group differences were also found in MPA, $F(3, 494)=87.4$, $P<0.001$; VPA, $F(3, 492)=78.15$, $P<0.001$; and VVPA, $F(3, 454)=54.89$, $P<0.001$. In both genders MPA, VPA and VVPA decreased with age. Till the age of 14, children had means between 79.6+/-30.6 and 144.1+/-76.9 min*day(-1) of PA. After this age, there was a decrease to 44.1+/-19.9 min*day(-1) in girls and to 56.3+/-31.9 min*day(-1) in boys.

CONCLUSION:

Boys had more minutes a day of VPA and VVPA than girls. PA decreased with age. The subjects of this study, aged 6 to 15, fulfilled the recommendations of 60 min x day(-1) of MPA to VPA.

Lopez, Veronica; Ahumada, Luis; Galdames, Sergio; Madrid, Romina (2012):

School principals at their lonely work: Recording workday practices through ESM logs.

In: *Computers & Education* 58 (1), S. 413–422. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-27203-039&site=ehost-live;rominamadrid@gmail.com;sergiogaldames@gmail.com;lahumada@ucv.cl;veronica.lopez@ucv.cl.

Abstract:

This study used portable technology based on Experience Sampling Methodology (ESM log) to register workday practices of school principals and heads from Chilean schools who were implementing school improvement plans aimed at developing a culture of organizational learning. For a week, Smartphone devices which beeped seven times a day were given to School Principals and Heads of Technical-Pedagogical Units, who then answered closed questions about their current agenda. Six municipal schools in a district of the V Region of Chile participated in the study. The main results support the notion that, at the time of data collection, most school Principals and Heads of Technical-Pedagogical Units were working alone, and if they were interacting with other people, they were always in command. Following underlying assumed roles, most school principals reported performing administrative tasks, while Heads of Technical-Pedagogical Units mainly addressed instructional issues, fostering a rigid framework for the assignment of tasks. Follow-up semi-structured interviews confirmed that participants were not working as a team but rather alone on important issues and urgent matters. Participants regarded the use of the device as a very practical and useful tool to analyze their daily practices. Results are discussed focusing on the use of portable technology to address methodological issues faced when approaching research on educational leadership from a distributed leadership perspective. Lopez, Richard B.; Hofmann, Wilhelm; Wagner, Dylan D.; Kelley, William M.; Heatherton, Todd F. (2014):

Neural Predictors of Giving in to Temptation in Daily Life.

In: *Psychol Sci. DOI:* 10.1177/0956797614531492.

Abstract:

The ability to control desires, whether for food, sex, or drugs, enables people to function successfully within society. Yet, in tempting situations, strong impulses often result in self-control failure. Although many triggers of self-control failure have been identified, the question remains as to why some individuals are more likely than others to give in to temptation. In this study, we combined functional neuroimaging and experience sampling to determine if there are brain markers that predict whether people act on their food desires in daily life. We examined food-cue-related activity in the nucleus accumbens (NAcc), as well as activity associated with response inhibition in the inferior frontal gyrus (IFG). Greater NAcc activity was associated with greater likelihood of self-control failures, whereas IFG activity supported successful resistance to temptations. These findings demonstrate an important role for the neural mechanisms underlying desire and self-control in people's real-world experiences of temptations.

Loprinzi, Paul D.; Brosky, Joseph A. (2014):

Objectively-Measured Physical Activity and Balance Among U.S. Adults.

In: *J Strength Cond Res. DOI:* 10.1519/JSC.0000000000000402.

Abstract:

The purpose of this study was to examine the association between objectively-measured physical activity (PA) and balance in a nationally representative sample of U.S. adults 40 years of age and older. Data from the 2003-2004 NHANES were used. PA was measured over a 7-day period using accelerometry, and balance was assessed using the Romberg test. Participants completed a questionnaire regarding their subjective views on difficulty with falling in the past 12 months. For every 60-minute increase in light-intensity PA, participants were 10% (p = 0.04) more likely to have functional balance. Similarly, for every 1-minute increase in log-transformed MVPA, participants were 23% (p = 0.04) more likely to have functional balance. Regular PA, regardless of intensity, may have health benefits for older adults and is associated with functional balance.

Loprinzi, P. D.; Cardinal, B.; Crespo, C. J.; Brodowicz, G. R.; Andersen, R. E.; Smit, E. (2012):

Differences in Demographic, Behavioral, and Biological Variables Between those with Valid and Invalid Accelerometry Data: Implications for Generalizability.

In: *J.Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:22398390.

Abstract:

BACKGROUND: The exclusion of participants with invalid accelerometry data (IAD) may lead to biased results and/or lack of generalizability in large population studies. The purpose of this study was to investigate whether demographic, behavioral, and biological differences occur between those with IAD and valid accelerometry data (VAD) among adults using a representative sample of the civilian non-institutionalized U.S. population. METHODS: Ambulatory participants from NHANES (2003-2004) who were 20-85 years of age were included in the present study and wore an ActiGraph 7164 accelerometer for 7 days. A "valid person" was defined as those with 4 or more days of at least 10+ hrs of monitoring per day. Among adults (20-85 yrs), 3,088 participants provided VAD, and 987 providing IAD. Demographic, behavioral, and biological information was obtained from the household interview or from data obtained in a mobile examination center. RESULTS: Differences were observed in age, BMI, ethnicity, education, smoking status, marital status, use of street drugs, current health status, HDL-cholesterol, C-reactive protein, self-reported vigorous physical activity, and plasma glucose levels between those with VAD and IAD. CONCLUSIONS: Investigators should take into consideration the potential cut-off bias in interpreting results based on data that excludes IAD participants

Loprinzi, Paul D.; Lee, Hyo (2014):

Rationale for promoting physical activity among cancer survivors: literature review and epidemiologic examination.

In: *Oncol Nurs Forum* 41 (2), S. 117–125. DOI: 10.1188/14.ONF.117-125.

Abstract:

Purpose/Objectives: To review the extant literature on the link between physical activity and health outcomes among cancer survivors; identify evidence-based strategies to promote physical activity among this population; and conduct an epidemiologic study based on gaps from the literature review, examining the association between physical activity and various biologic markers.Data Sources: The authors used PubMed and Google Scholar up to July 2013, as well as data from the 2003-2006 National Health and Nutrition Examination Survey for the empirical study.Data Synthesis: Studies were examined through a systematic review process. In the epidemiologic study, 227 adult cancer survivors wore an accelerometer for four days or longer, with biologic markers (e.g., cholesterol) assessed from a blood sample.Conclusions: The review study demonstrated that cancer survivors are relatively inactive, but physical activity may help to reduce the risk of cancer recurrence and cancer-related mortality, increase cancer treatment rates, reduce pain and other side effects associated with cancer treatment, and improve physical and mental health. The epidemiologic study showed that physical activity was associated with several understudied biomarkers (e.g., neutrophils, white blood cells) that are linked with cancer recurrence, cancer-related mortality, and other chronic diseases.Implications for Nursing: Nurses are encouraged to promote physical activity in cancer survivors.

Loprinzi, Paul D.; Lee, Hyo; Cardinal, Bradley J. (2014):

Daily movement patterns and biological markers among adults in the United States.

In: *Prev Med* 60, S. 128–130. DOI: 10.1016/j.ypmed.2013.12.017.

Abstract:

OBJECTIVE: To examine the combined effects of sedentary (SED), light (LPA) and moderate-to-vigorous physical activity (MVPA) on biological markers among a nationally representative sample of U.S. adults. METHODS: Data from the 2003-2006 NHANES study was used, with 5580 adults (>/=20years) included in the study. Participants wore an ActiGraph 7164 accelerometer with accelerometry data used to create four movement pattern groups: >/=150min/week of MVPA and LPA>/=SED; >/=150min/week of MVPA and LPA<SED; <150min/week of MVPA but LPA>/=SED; and <150min/week of MVPA and LPA<SED. Blood samples were taken to assess various biological parameters (e.g., cholesterol). RESULTS: 47.2% (SE: 1.2) of Americans engaged in <150min/week of MVPA and had a negative LPA-SED balance. In general, participants who engaged in >/=150min/week of MVPA, regardless of LPA-SED balance, had more favorable biological levels; however, there was evidence showing that even if individuals engaged in <150min/week of MVPA, but if their LPA exceeded SED, they had more favorable levels of triglycerides and insulin. CONCLUSIONS: Programs are needed to increase American's engagement in MVPA, and also ensure that LPA exceeds SED behavior.

Loprinzi, Paul D.; Trost, Stewart G. (2010):

Parental influences on physical activity behavior in preschool children.

In: *Prev Med* 50 (3), S. 129–133.

Abstract:

OBJECTIVE:

To evaluate a conceptual model linking parent physical activity (PA) orientations, parental support for PA, and PA behavior in preschool children.

METHODS:

Participants were 156 parent-child dyads from 13 child care centers in Queensland, Australia. Parents completed a questionnaire measuring parental PA, parental enjoyment of PA, perceived importance of PA, parental support for PA, parents' perceptions of competence, and child PA at home. MVPA while attending child care was measured via accelerometry. Data were collected between May and August of 2003. The relationships between the study variables and child PA were tested using observed variable path analysis.

RESULTS:

Parental PA and parents' perceptions of competence were positively associated with parental support for PA (beta=0.23 and 0.18, respectively, $p<0.05$). Parental support, in turn, was positively associated with child PA at home (beta=0.16, $p<0.05$), but not at child care (beta=0.01, $p=0.94$). Parents' perceptions of competence was positively associated with both home-based and child care PA (beta=0.20 and 0.28, respectively, $p<0.05$).

CONCLUSIONS:

Family-based interventions targeting preschoolers should include strategies to increase parental support for PA. Parents who perceive their child to have low physical competence should be encouraged to provide adequate support for PA.

Reliability and concurrent validity of a peripheral pulse oximeter and health-app system for the quantification of heart rate in healthy adults.

In: *Health Informatics J. DOI:* 10.1177/1460458214540909.

Abstract:

There are downloadable applications (Apps) for cell phones that can measure heart rate in a simple and painless manner. The aim of this study was to assess the reliability of this type of App for a Smartphone using an Android system, compared to the radial pulse and a portable pulse oximeter. We performed a pilot observational study of diagnostic accuracy, randomized in 46 healthy volunteers. The patients' demographic data and cardiac pulse were collected. Radial pulse was measured by palpation of the radial artery with three fingers at the wrist over the radius; a low-cost portable, liquid crystal display finger pulse oximeter; and a Heart Rate Plus for Samsung Galaxy Note(R). This study demonstrated high reliability and consistency between systems

with respect to the heart rate parameter of healthy adults using three systems. For all parameters, ICC was > 0.93, indicating excellent reliability. Moreover, CVME values for all parameters were between 1.66-4.06 %. We found significant correlation coefficients and no systematic differences between radial pulse palpation and pulse oximeter and a high precision. Low-cost pulse oximeter and App systems can serve as valid instruments for the assessment of heart rate in healthy adults.

Louro, Maria J.; Pieters, Rik; Zeelenberg, Marcel (2007):

Dynamics of multiple-goal pursuit.

In: *Journal of Personality and Social Psychology* 93 (2), S. 174.

Abstract:

The authors propose and test a model of multiple-goal pursuit that specifies how individuals allocate effort among multiple goals over time. The model predicts that whether individuals decide to step up effort, coast, abandon the current goal, or switch to pursue another goal is determined jointly by the emotions that flow from prior goal progress and the proximity to future goal attainment, and proximally determined by changes in expectancies about goal attainment. Results from a longitudinal diary study and 2 experiments show that positive and negative goal-related emotions can have diametrically opposing effects on goal-directed behavior, depending on the individual's proximity to goal attainment. The findings resolve contrasting predictions about the influence of positive and negative emotions in volitional behavior, critically amend the goal gradient hypothesis, and provide new insights into the dynamics and determinants of multiple-goal pursuit. Luckmann, Roger; Vidal, Amin (2010):

Design of a handheld electronic pain, treatment and activity diary.

In: *J Biomed Inform* 43 (5), S. S32-S36.

Abstract:

Effective tools for recording and analyzing data on patients' pain experience, use of pain treatments, and physical function are needed to improve communication between providers and patients with noncancer chronic pain. A handheld electronic diary (HED) that can be used throughout the day may provide more useful and accurate information about pain, treatments, and function than available paper and on-line diaries that are designed to be used once daily, weekly or less often. Based on user-specified requirements we designed and built a prototype HED with 7 modules. Diary queries are followed by multiple choice responses customized to the patients' expected responses. Usability testing confirmed user comprehension and acceptability of the queries, response sets, and interface.

Luczak, Susan E.; Rosen, I. Gary (2014):

Estimating BrAC from transdermal alcohol concentration data using the BrAC estimator software program.

In: *Alcohol Clin Exp Res* 38 (8), S. 2243–2252. DOI: 10.1111/acer.12478.

Abstract:

BACKGROUND: Transdermal alcohol sensor (TAS) devices have the potential to allow researchers and clinicians to unobtrusively collect naturalistic drinking data for weeks at a time, but the transdermal alcohol concentration (TAC) data these devices produce do not consistently correspond with breath alcohol concentration (BrAC) data. We present and test the BrAC Estimator software, a program designed to produce individualized estimates of BrAC from TAC data by fitting mathematical models to a specific person wearing a specific TAS device. METHODS: Two TAS devices were worn simultaneously by 1 participant for 18 days. The trial began with a laboratory alcohol session to calibrate the model and was followed by a field trial with 10 drinking episodes. Model parameter estimates and fit indices were compared across drinking episodes to examine the calibration phase of the software. Software-generated estimates of peak BrAC, time of peak BrAC, and area under the BrAC curve were compared with breath analyzer data to examine the estimation phase of the software. RESULTS: In this single-subject design with breath analyzer peak BrAC scores ranging from 0.013 to 0.057, the software created consistent models for the 2 TAS devices, despite differences in raw TAC data, and was able to compensate for the attenuation of peak BrAC and latency of the time of peak BrAC that are typically observed in TAC data. CONCLUSIONS: This software program represents an important initial step for making it possible for non mathematician researchers and clinicians to obtain estimates of BrAC from TAC data in naturalistic drinking environments. Future research with more participants and greater variation in alcohol consumption levels and patterns, as well

as examination of gain scheduling calibration procedures and nonlinear models of diffusion, will help to determine how precise these software models can become.

Emotional and cardiovascular sensitization to daily stress following childhood parental loss.

In: *Developmental Psychology* 45 (1), S. 296–302. DOI: 10.1037/a0013888.

Abstract:

Adverse childhood events can influence the development of emotional and physiological self-regulatory abilities, with significant consequences for vulnerability to psychological and physical illness. This study evaluated stress sensitization and inoculation models of the impact of early parental death on stress exposure and reactivity in late adolescence/young adulthood. Ambulatory blood pressure (BP) and diary reports of minor stress were collected every 30 min during waking hours over a 24-hr period from 91 late adolescents/young adults (43 early bereaved, 48 nonbereaved). Across the sample, minor stressors were associated with elevated BP and negative affect. The bereaved group had lower BP than did the nonbereaved group. Within the bereaved group, higher perceived caring from the surviving parent was associated with fewer reports of minor stress and lower stress-related negative affect. Higher perceived parental caring during childhood was associated with lower BP across the sample and more frequent hassles in the nonbereaved group. Findings support both the stress inoculation and sensitization models, suggesting that childhood parental loss and parental caring exert important influences on children's development of stress sensitivity.

A standardized kudzu extract (NPI-031) reduces alcohol consumption in nontreatment-seeking male heavy drinkers.

In: *Psychopharmacology (Berl)* (0033-3158 (Linking)). DOI: 10.1007/s00213-012-2884-9.

Abstract:

OBJECTIVE: We previously demonstrated that short-term treatment with a standardized kudzu extract (NPI-031) reduced alcohol drinking by men and women in a natural setting. The present study was conducted in nontreatment-seeking heavy drinkers to assess the safety and efficacy of 4 weeks of kudzu extract in an outpatient setting. METHOD: This randomized between-subject, double-blind, placebo-controlled study involved 2 weeks of baseline, 4 weeks of treatment, and 2 weeks of follow-up. Seventeen men (21-33 years) who reported drinking 27.6 +/- 6.5 drinks/week with a diagnosis of alcohol abuse/dependence took either kudzu extract (250 mg isoflavones, t.i.d.) or matched placebo on a daily basis. They reported alcohol consumption and desire to use alcohol using a wrist actigraphy device; twice weekly laboratory visits were scheduled to monitor medication adherence and adverse events. RESULTS: Medication adherence was excellent and there were no adverse events and changes in vital signs, blood chemistry, and renal or liver function. There was no effect on alcohol craving, but kudzu extract significantly reduced the number of drinks consumed each week by 34-57 %, reduced the number of heavy drinking days, and significantly increased the percent of days abstinent and the number of consecutive days of abstinence. CONCLUSIONS: A standardized formulation of kudzu extract produced minimal side effects, was well-tolerated, and resulted in a modest reduction in alcohol consumption in young nontreatment-seeking heavy drinkers. Additional studies using treatment-seeking alcohol-dependent persons will be necessary to determine the usefulness of this herbal preparation in reducing alcohol use in other populations

Lukasiewicz, M.; Fareng, M.; Benyamina, A.; Blecha, L.; Reynaud, M.; Falissard, B. (2007):

Ecological momentary assessment in addiction.

Abstract:

Numerous symptoms in psychiatry are subjective (e.g., sadness, anxiety, craving or fatigue), fluctuate and are environment dependent. Accurate measurement of these phenomena requires repeated measures, and ideally needs to be performed in the patient's natural environment rather than in an artificial laboratory environment or a protected hospital environment. The usual paper and pencil questionnaires do not meet these two conditions for reasons of logistics. A recently developed method, ecological momentary assessment (EMA), made it possible to implement these field assessments via ingenious use of various devices (most frequently an electronic diary) coupling an auditory signal with computerized data capture. The subject carries the device with him/her at all times, and data is recorded in vivo in real time. The programming of repeated measures in the form of a Likert scale or pull-down menu is easily achieved. A recall alarm system can help increase compliance. Compared with classical

self-report, EMA improves the validity of the assessment of certain symptoms, which are the main evaluation criteria in clinical trials concerning certain pathologies (e.g., craving and treatment of addiction), where measurement was previously liable to bias. This article sets out to present this method, its advantages and disadvantages, and the interest it presents in psychiatry, in particular via three original applications developed by the authors including: measurement of reaction time without the knowledge of the subject in order to test certain cognitive models; use of a graphic solution for the data recorded for functional analysis of disorders; and the use of data collection via mobile phone and text messages, which also enables therapeutic interventions in real time by text messages, personalized on the basis of the situational data collected (e.g., in the case of craving, the associated mood, solitary or group consumption or concomitant occupations).

What leads to romantic attraction: similarity, reciprocity, security, or beauty? Evidence from a speed-dating study.

In: *J Personality* 77 (4), S. 933–964. DOI: 10.1111/j.1467-6494.2009.00570.x.

Abstract:

Years of attraction research have established several \"principles\" of attraction with robust evidence. However, a major limitation of previous attraction studies is that they have almost exclusively relied on well-controlled experiments, which are often criticized for lacking ecological validity. The current research was designed to examine initial attraction in a real-life setting-speed-dating. Social Relations Model analyses demonstrated that initial attraction was a function of the actor, the partner, and the unique dyadic relationship between these two. Meta-analyses showed intriguing sex differences and similarities. Self characteristics better predicted women's attraction than they did for men, whereas partner characteristics predicted men's attraction far better than they did for women. The strongest predictor of attraction for both sexes was partners' physical attractiveness. Finally, there was some support for the reciprocity principle but no evidence for the similarity principle.

Luque, Rafael; Casilari, Eduardo; Moron, Maria-Jose; Redondo, Gema (2014):

Comparison and characterization of Android-based fall detection systems.

In: *Sensors (Basel)* 14 (10), S. 18543–18574. DOI: 10.3390/s141018543.

Abstract:

Falls are a foremost source of injuries and hospitalization for seniors. The adoption of automatic fall detection mechanisms can noticeably reduce the response time of the medical staff or caregivers when a fall takes place. Smartphones are being increasingly proposed as wearable, cost-effective and not-intrusive systems for fall detection. The exploitation of smartphones' potential (and in particular, the Android Operating System) can benefit from the wide implantation, the growing computational capabilities and the diversity of communication interfaces and embedded sensors of these personal devices. After revising the state-of-the-art on this matter, this study develops an experimental testbed to assess the performance of different fall detection algorithms that ground their decisions on the analysis of the inertial data registered by the accelerometer of the smartphone. Results obtained in a real testbed with diverse individuals indicate that the accuracy of the accelerometry-based techniques to identify the falls depends strongly on the fall pattern. The performed tests also show the difficulty to set detection acceleration thresholds that allow achieving a good trade-off between false negatives (falls that remain unnoticed) and false positives (conventional movements that are erroneously classified as falls). In any case, the study of the evolution of the battery drain reveals that the extra power consumption introduced by the Android monitoring applications cannot be neglected when evaluating the autonomy and even the viability of fall detection systems.

Lurbe, Empar; Redon, Josep (2008):

Discrepancies in office and ambulatory blood pressure in adolescents: help or hindrance?

In: *Pediatr Nephrol* 23 (3), S. 341–345.

Abstract:

The goal of this commentary is to review the most relevant topics concerning the clinical utility of ambulatory blood pressure (BP) monitoring, such as the state of the art "reference BP values", the importance of the discrepant situations between office and ambulatory BP (white-coat and masked hypertension) and those of the recommended clinical indications to now. From a small number of studies, operational thresholds to define hypertension have been established. They are useful tools even though more studies are necessary to create strong reference values. Ambulatory BP measurement is increasingly recognized as

being indispensable to the diagnosis and management of hypertension, and it has contributed significantly to our understanding of hypertension by revealing or "unmasking" BP phenomena that were not readily apparent using traditional techniques of measurement in clinical practice. Ambulatory BP monitoring should be performed in adolescents with either office mild essential hypertension before starting antihypertensive drug treatment or a strong family history of hypertension or an early cardiovascular event. Obese children with normal office BP values will also benefit from ambulatory BP monitoring. Other indications are the assessment of refractory hypertension or drug-induced hypotension. Finally, additional BP information in chronic renal failure, diabetes, and autonomic neuropathy can be obtained by using ambulatory BP monitoring.

Behavioural activation versus mindfulness-based guided self-help treatment administered through a smartphone application: a randomised controlled trial.

In: *BMJ Open* 4 (1), S. e003440. DOI: 10.1136/bmjopen-2013-003440.

Abstract:

OBJECTIVES: Evaluating and comparing the effectiveness of two smartphone-delivered treatments: one based on behavioural activation (BA) and other on mindfulness. DESIGN: Parallel randomised controlled, open, trial. Participants were allocated using an online randomisation tool, handled by an independent person who was separate from the staff conducting the study. SETTING: General community, with recruitment nationally through mass media and advertisements. PARTICIPANTS: 40 participants diagnosed with major depressive disorder received a BA treatment, and 41 participants received a mindfulness treatment. 9 participants were lost at the post-treatment. INTERVENTION BA: An 8-week long behaviour programme administered via a smartphone application. Mindfulness: An 8-week long mindfulness programme, administered via a smartphone application. MAIN OUTCOME MEASURES: The Beck Depression Inventory-II (BDI-II) and the nine-item Patient Health Questionnaire Depression Scale (PHQ-9). RESULTS: 81 participants were randomised (mean age 36.0 years (SD=10.8)) and analysed. Results showed no significant interaction effects of group and time on any of the outcome measures either from pretreatment to post-treatment or from pretreatment to the 6-month follow-up. Subgroup analyses showed that the BA treatment was more effective than the mindfulness treatment among participants with higher initial severity of depression from pretreatment to the 6-month follow-up (PHQ-9: F (1, 362.1)=5.2, p<0.05). In contrast, the mindfulness treatment worked better than the BA treatment among participants with lower initial severity from pretreatment to the 6-month follow-up (PHQ-9: F (1, 69.3)=7.7, p<0.01); BDI-II: (F(1, 53.60)=6.25, p<0.05). CONCLUSIONS: The two interventions did not differ significantly from one another. For participants with higher severity of depression, the treatment based on BA was superior to the treatment based on mindfulness. For participants with lower initial severity, the treatment based on mindfulness worked significantly better than the treatment based on BA. TRIAL REGISTRATION: Clinical Trials NCT01463020.

Lyden, K.; Kozey Keadle, S. L.; Staudenmayer, J. W.; Freedson, P. S. (2012):

Validity of two wearable monitors to estimate breaks from sedentary time.

In: *Med.Sci.Sports Exerc.* 44 (11), S. 2243–2252. DOI: 10.1249/MSS.0b013e318260c477.

Abstract:

Investigations using wearable monitors have begun to examine how sedentary time behaviors influence health. PURPOSE: The objective of this study is to demonstrate the use of a measure of sedentary behavior and to validate the activPAL (PAL Technologies Ltd., Glasgow, Scotland) and ActiGraph GT3X (Actigraph, Pensacola, FL) for estimating measures of sedentary behavior: absolute number of breaks and break rate. METHODS: Thirteen participants completed two 10-h conditions. During the baseline condition, participants performed normal daily activity, and during the treatment condition, participants were asked to reduce and break up their sedentary time. In each condition, participants wore two ActiGraph GT3X monitors and one activPAL. The ActiGraph was tested using the low-frequency extension filter (AG-LFE) and the normal filter (AG-Norm). For both ActiGraph monitors, two count cut points to estimate sedentary time were examined: 100 and 150 counts per minute. Direct observation served as the criterion measure of total sedentary time, absolute number of breaks from sedentary time, and break rate (number of breaks per sedentary hour (brk.sed-h)). RESULTS: Break rate was the only metric sensitive to changes in behavior between baseline (5.1 [3.3-6.8] brk.sed-h) and treatment conditions (7.3 [4.7-9.8] brk.sed-h) (mean (95% confidence interval)). The activPAL produced valid estimates of all sedentary behavior measures and was sensitive to changes in break rate between conditions (baseline, 5.1 [2.8-7.1] brk.sed-h; treatment, 8.0 [5.8-10.2] brk.sed-h). In general, the AG-LFE and AG-Norm were not accurate in estimating break rate or the absolute number of breaks and were not sensitive to changes between conditions. CONCLUSION: This study demonstrates the use of expressing breaks from sedentary time as a rate per sedentary hour, a metric specifically relevant to free-living behavior, and provides further evidence that the activPAL is a valid tool to measure components of sedentary behavior in free-living environments

MacDonell, K.; Gibson-Scipio, W.; Lam, P.; Naar-King, S.; Chen, X. (2012):

Text Messaging to Measure Asthma Medication Use and Symptoms in Urban African American Emerging Adults: A Feasibility Study.

In: *J Asthma* (0277-0903 (Linking)). DOI: 10.3109/02770903.2012.733993.

Abstract:

Objective. Urban African American adolescents and young adults face disproportionate risk of asthma morbidity and mortality. This study was the first to assess the feasibility of Ecological Momentary Assessment via text messaging to measure asthma medication use and symptoms in African Americans aged 18-25 years. Methods. This study used automated text messaging with N = 16 participants for 14 consecutive days. Participants sent event-based messages whenever they experienced asthma symptoms or took asthma rescue or controller medications. They also received time-based messages daily that prompted for a response about asthma medications or symptoms. Results. Feasibility was assessed using response rates and participant feedback. Rates of event-based messages were relatively low (M = 0.85 messages sent per participant/day), but participants were very responsive to time-based messages (78.5%). All participants expressed positive feedback about the program, though 40.0% reported confusion with event-based messages and most preferred time-based messages. The assessment found low medication adherence rates and reasons for missing medication consistent with previous research with youth with asthma. Conclusion. Text messaging may be a useful method to measure medication use and symptoms in "real time," particularly using time-based prompts. Results could be used to provide personalized feedback on adherence as part of a tailored intervention

MacDonell, Karen E.; Naar-King, Sylvie; Murphy, Debra A.; Parsons, Jeffrey T.; Huszti, Heather (2011):

Situational temptation for HIV medication adherence in high-risk youth.

In: *AIDS patient care and STDs* 25 (1), S. 47–52.

Abstract:

Abstract This study explored the role of situational temptation, a component of self-efficacy, in adolescent and young adult (ages 16-24) HIV medication adherence by assessing participants' perceptions of their temptation to miss medications in various situations (e.g., when medication causes physical side effects, when there is fear of disclosure of HIV status). Youth (n = 186; 83% African American) were participants in a multisite clinical trial examining the efficacy of a motivational intervention. Data were collected using computer-assisted personal interviewing. Youth believed the most tempting reasons or situations that might lead them to miss their HIV medications to be symptoms (if the medicine caused you to have other physical symptoms) and sick (if the medicine made you sick to your stomach or made you throw up or if it tasted bad), but these were not significantly associated with nonadherence. This suggests disconnection between youths' expectations of temptation and actual tempting situations associated with nonadherence. Situational temptations associated with nonadherence included lack of social support, needing a break from medications, and not seeing a need for medications. Interventions to improve adherence should consider perceptions of HIV medications, particularly the benefits of taking medications and expectations of physical symptoms. Interventionists and clinicians should consider situations that may tempt youth to miss doses of medication and help youth gain insight into these temptations. Emerging methods, such as Ecological Momentary Assessment (e.g., daily diaries, cell phone text messaging), may be useful in gaining insight into the day-to-day experience of youth living with HIV.

MacE, C. J.; Maddison, R.; Olds, T.; Kerse, N. (2013):

Validation of a Computerised Use of Time Recall for Activity Measurement in Advanced Aged Adults.

In: *J Aging Phys.Act.* (1063-8652 (Linking)). Online verfügbar unter PM:23752221.

Abstract:

BACKGROUND: The Multimedia Activity Recall for Children and Adults (MARCA) is a computerised recall instrument recording use of time during 24-hours the previous day that has been developed to address limitations of current self-report physical activity measures for those in advanced age. METHODS: Test-retest reliability and convergent validity of the adult MARCA were assessed in a sample of 45 advanced aged adults (aged 84.9 SD+/-1.62 y) as a subsample of the Life and Living in Advanced Age Cohort Study New Zealand (LiLACS NZ). Test-retest methods required participants to recall the previous day's activity using the MARCA twice within the same day. Convergent validity was assessed against accelerometry. RESULTS: Test-retest reliability was high, with ICCs greater than 0.99 for moderate to vigorous physical activity (MVPA) and physical activity level (PAL). Compared to accelerometry, the MARCA demonstrated validity comparable to other self-report instruments with Spearman's coefficients of 0.34 and 0.59 for time spent in non-sedentary physical activity and PAL. CONCLUSION: The MARCA is a valid and reliable self-report tool for physical activity behaviours in advanced aged adults

MacFarlane, Duncan J.; Lee, Cherry C. Y.; Ho, Edmond Y. K.; Chan, K. L.; Chan, Dionise (2006):

Convergent validity of six methods to assess physical activity in daily life.

In: *Journal of applied physiology (Bethesda, Md. : 1985)* 101 (5), S. 1328–1334. DOI: 10.1152/japplphysiol.00336.2006.

Abstract:

The purpose was to examine the agreement (convergent validity) between six common measures of habitual physical activity to estimate durations of light, moderate, vigorous, and total activity in a range of free-living individuals. Over 7 consecutive days, 49 ethnic Chinese (30 men, 19 women), aged 15-55 yr, wore a Polar heart rate monitor, a uniaxial MTI, and triaxial Tritrac accelerometer, plus a Yamax pedometer for > or = 600 min/day. They also completed a daily physical activity log and on day 8 a Chinese version of the 7-day International Physical Activity Questionnaire. At each level of activity, there was good agreement between the two questionnaire-derived instruments and the two accelerometry-derived instruments, but wide variation across different instruments, with two- to fourfold differences in mean durations often seen. The heart rate monitor overestimated light activity and underestimated moderate activity compared with all other measures. Spearman correlation coefficients were low to moderate (0.2-0.5) across most measures of activity, with the pedometer showing correlations with total activity that were often superior to the other movement sensors. We conclude that, with the use of commonly accepted cut points for defining light, moderate, vigorous, and total activity, little convergent validity across the instruments was evident, suggesting these measures are sampling different levels of habitual physical activity and care is needed when comparing their results. To provide a more stable comparison of activity among different people, across studies, or against accepted physical activity promotion guidelines, further work is needed to fine tune the different cut points across a range of common activity monitors to provide more consistent results during free-living conditions.

MacHado-Rodrigues, A. M.; Figueiredo, A. J.; Mota, J.; Cumming, S. P.; Eisenmann, J. C.; Malina, R. M.; Coelho-E-Silva, M. J. (2012):

Concurrent validation of estimated activity energy expenditure using a 3-day diary and accelerometry in adolescents.

In: *Scandinavian Journal of Medicine & Science in Sports* 22 (2), S. 259–264. DOI: 10.1111/j.1600-0838.2010.01155.x.

Abstract:

Estimates of daily energy expenditure are important to studies of physical activity and energy balance. Objective measures are not always feasible and further research is needed to validate survey instruments and diaries. The study validates estimated activity energy expenditure (AEE) based on a 3-day diary protocol relative to AEE derived from uniaxial accelerometry in adolescents, 265 girls and 227 boys (12.5-16.4 years). Participants completed the diary and wore a GT1M Actigraph accelerometer on the same days. Height and weight were measured. Correlations between protocols were significant ($P<0.001$) but moderate, $r=0.65$ in males and $r=0.69$ in females. The highest correlation occurred among males on Friday, $r=0.74$ ($P<0.01$). Controlling for body mass, partial correlations between protocols decreased to 0.44 and 0.35 in males and females, respectively. About 97% of the cases fell within the limits of agreement in a Bland-Altman plot. The criterion of inclusion for the accelerometer excluded 18% of the initial sample. In summary, the 3-day diary was completed without any major problems and provided a reasonably valid alternative for assessing AEE. Concordance between methods was slightly lower for individuals with higher values of AEE.

MacKinnon, Sean P.; Battista, Susan R.; Sherry, Simon B.; Stewart, Sherry H. (2013):

Perfectionistic self-presentation predicts social anxiety using daily diary methods.

In: *Personality and Individual Differences*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-34177-001%26site%3dehost-live.

Abstract:

Perfectionistic self-presentation is thought to confer risk for social anxiety. Although this relationship is thought to occur dynamically from moment-to-moment, no research has yet tested this relationship using experience sampling methods. The present study stringently tested whether perfectionistic self-presentation predicted social anxiety beyond several important covariates using a 21-day experience sampling design. A sample of 165 undergraduates (75.6% women) completed a series of questionnaires each day for 21days using palm pilots. Generalizability theory and multilevel factor analyses suggested daily measures of perfectionistic self-presentation, social anxiety, perfectionism cognitions, and depressed mood evidence within-subjects and between-subjects variability, can be measured reliably, and represent distinct factors, allowing hypothesis testing. Multilevel regressions showed perfectionistic self-presentation predicted social anxiety at the between-subjects and within-subjects levels, even when controlling for socially prescribed perfectionism, perfectionism cognitions, and depressed mood.

Overall, perfectionistic self-presentation emerged as a robust predictor of daily social anxiety, clearly extending prior cross-sectional research on this topic. By understanding how perfectionism operates from day-to-day, we can better understand the processes that give rise to social anxiety, and ultimately how to devise more effective ways to help people suffering from social anxiety. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Caught in a Bad Romance: Perfectionism, Conflict, and Depression in Romantic Relationships.

In: *J.Fam.Psychol.* (0893-3200 (Linking)). DOI: 10.1037/a0027402.

Abstract:

According to the social disconnection model, perfectionistic concerns (i.e., harsh self-scrutiny, extreme concern over mistakes and others' evaluations, and excessive reactions to perceived failures) confer vulnerability to depressive symptoms indirectly through interpersonal problems. This study tested the social disconnection model in 226 heterosexual romantic dyads using a mixed longitudinal and experience sampling design. Perfectionistic concerns were measured using three partner-specific self-report questionnaires. Conflict was measured as a dyadic variable, incorporating reports from both partners. Depressive symptoms were measured using a self-report questionnaire. Perfectionistic concerns and depressive symptoms were measured at Day 1 and Day 28. Aggregated dyadic conflict was measured with daily online questionnaires from Days 2 to 15. Data were analyzed using structural equation modeling. There were four primary findings: (a) Dyadic conflict mediated the link between perfectionistic concerns and depressive symptoms, even when controlling for baseline depressive symptoms; (b) depressive symptoms were both an antecedent and a consequence of dyadic conflict; (c) perfectionistic concerns incrementally predicted dyadic conflict and depressive symptoms beyond neuroticism (i.e., a tendency to experience negative emotions) and other-oriented perfectionism (i.e., rigidly demanding perfection from one's partner); and (d) the relationships among variables did not differ based on gender. As the most rigorous test of the social disconnection model to date, this study provides strong support for this emerging model. Results also clarify the characterological and the interpersonal context within which depressive symptoms are likely to occur. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

MacReady, Anna L.; George, Trevor W.; Chong, Mary F.; Alimbetov, Dauren S.; Jin, Yannan; Vidal, Alberto et al. (2014):

Flavonoid-rich fruit and vegetables improve microvascular reactivity and inflammatory status in men at risk of cardiovascular disease--FLAVURS: a randomized controlled trial.

In: *Am J Clin Nutr* 99 (3), S. 479–489. DOI: 10.3945/ajcn.113.074237.

Abstract:

BACKGROUND: Observed associations between increased fruit and vegetable (F&V) consumption, particularly those F&Vs that are rich in flavonoids, and vascular health improvements require confirmation in adequately powered randomized controlled trials. OBJECTIVE: This study was designed to measure the dose-response relation between high-flavonoid (HF), low-flavonoid (LF), and habitual F&V intakes and vascular function and other cardiovascular disease (CVD) risk indicators. DESIGN: A single-blind, dose-dependent, parallel randomized controlled dietary intervention study was conducted. Male and female low-F&V consumers who had a >/= 1.5-fold increased risk of CVD (n = 174) were randomly assigned to receive an HF F&V, an LF F&V, or a habitual diet, with HF and LF F&V amounts sequentially increasing by 2, 4, and 6 (+2, +4, and +6) portions/d every 6 wk over habitual intakes. Microvascular reactivity (laser Doppler imaging with iontophoresis), arterial stiffness [pulse wave velocity, pulse wave analysis (PWA)], 24-h ambulatory blood pressure, and biomarkers of nitric oxide (NO), vascular function, and inflammation were determined at baseline and at 6, 12, and 18 wk. RESULTS: In men, the HF F&V diet increased endothelium-dependent microvascular reactivity (P = 0.017) with +2 portions/d (at 6 wk) and reduced C-reactive protein (P = 0.001), E-selectin (P = 0.0005), and vascular cell adhesion molecule (P = 0.0468) with +4 portions/d (at 12 wk). HF F&Vs increased plasma NO (P = 0.0243) with +4 portions/d (at 12 wk) in the group as a whole. An increase in F&Vs, regardless of flavonoid content in the groups as a whole, mitigated increases in vascular stiffness measured by PWA (P = 0.0065) and reductions in NO (P = 0.0299) in the control group. CONCLUSION: These data support recommendations to increase F&V intake to >/= 6 portions daily, with additional benefit from F&Vs that are rich in flavonoids, particularly in men with an increased risk of CVD. This trial was registered at www.controlled-trials.com as ISRCTN47748735.

Maddern-Leserer, Daniela (2012):

Stopping the downward spiral: Real-time monitoring of stress with cell phones as a self-help tool for relapse prevention.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (8-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99040-327&site=ehost-live.

Abstract:

This study investigated the relationship between awareness of stress-as a result of monitoring stress levels multiple times a day-and its impact on relapse to addiction. The sample included 17 participants enrolled in an outpatient drug rehabilitation clinic. Participants recorded their stress levels with their cell phones four times a day for a 3-week period. Three month post-participation relapse rates of individuals who voluntarily opted to participate in the study were compared to those who did not participate to determine whether participation in the study would confer differential success in the rehabilitation program. This study used a methodology similar to the Ecological Momentary Assessment (EMA). Results of this study showed that participants were twice as likely to remain in treatment compared to nonparticipants. Data analysis showed that participants' actual moment-to-moment stress remained fairly constant, however, participants reported a decrease in the perception of their stress. Furthermore, participants reported that they found it useful to participate and 100% of the participants reported that they would use this form of data collection again. The results of this study mirror the results of a study conducted by this researcher with a non-clinical sample. Reporting one's stress 4 times a day might help participants to become more mindful of their experience, thus becoming more tolerant of their affective states over time. Using cell phones to record stress levels multiple times a day may be a highly cost effective way to increase mindfulness, awareness, self-control as well as social support, and might increase the likelihood of program completion. These results are consistent with the literature on mindfulness training, suggesting that mindfulness may disrupt the spiral of stress precipitated by alcohol relapse, and thus, enhance clinical outcomes in substance-abusing populations. Magnan, R. E.; Koblitz, A. R.; McCaul, K. D.; Dillard, A. J. (2012):

Self-Monitoring Effects of Ecological Momentary Assessment on Smokers' Perceived Risk and Worry.

In: *Psychol.Assess.* (1040-3590 (Linking)). DOI: 10.1037/a0031232.

Abstract:

Using ecological momentary assessment (EMA), we sought to determine whether differences in reporting would exist for smokers who self-monitored their smoking-related negative thoughts five times daily in comparison to a non-EMA control group. One hundred seventeen smokers were randomly assigned to two conditions. Eighty-eight smokers carried personal digital assistants (PDAs) for 2 weeks and monitored negative thoughts each day, and 29 smokers did not self-monitor their negative thoughts. All smokers completed pretest and posttest assessments reporting their perceived risk and worry associated with smoking consequences. The data revealed evidence of self-monitoring effects, as smokers in the EMA condition reported less worry after 2 weeks of self-monitoring compared to smokers in the control condition. The two conditions did not differ in their reports of perceived risk of smoking consequences. These data suggest that EMA procedures asking respondents to self-monitor their thoughts about smoking may influence feelings about their smoking behavior. Maher, Carol; Crettenden, Angela; Evans, Kerry; Thiessen, Myra; Toohey, Monica; Dollman, Jim (2014):

A pedometer based physical activity self-management program for children and adolescents with physical disability - design and methods of the StepUp study.

In: *BMC Pediatr* 14, S. 31. DOI: 10.1186/1471-2431-14-31.

Abstract:

BACKGROUND: Physical activity affords a wide range of physiological and psychological benefits for children and adolescents, yet many children with physical disabilities are insufficiently active to achieve these benefits. The StepUp program is a newly developed 6-week pedometer-based self-management program for children and adolescents with physical disability. Participants use a pedometer to undertake a 6-week physical activity challenge, with personalised daily step count goals set in consultation with a physiotherapist. The study aims to evaluate the effectiveness of the StepUp program, using a randomised control trial design. METHODS/DESIGN: A target sample of 70 young people with physical disabilities (aged 8-17 years, ambulant with or without aid, residing in Adelaide) will be recruited. Participants will be randomly allocated to either

intervention or control following completion of baseline assessments. Assessments are repeated at 8 weeks (immediately post intervention) and 20 weeks (12 weeks post intervention). The primary outcome is objective physical activity determined from 7 day accelerometry, and the secondary outcomes are exercise intention, physical self-worth, quality of life and fatigue. Analyses will be undertaken on an intention-to-treat basis using random effects mixed modelling. DISCUSSION: This study will provide information about the potential of a low-touch and low-cost physical activity intervention for children and adolescents with cerebral palsy. TRIAL REGISTRATION: Australian New Zealand Clinical Trials Registry (ANZCTR): ACTRN12613000023752.

Reconsidering the sedentary behaviour paradigm.

In: *PLoS One* 9 (1), S. e86403. DOI: 10.1371/journal.pone.0086403.

Abstract:

AIMS: Recent literature has posed sedentary behaviour as an independent entity to physical inactivity. This study investigated whether associations between sedentary behaviour and cardio-metabolic biomarkers remain when analyses are adjusted for total physical activity. METHODS: Cross-sectional analyses were undertaken on 4,618 adults from the 2003/04 and 2005/06 U.S. National Health and Nutrition Examination Survey. Minutes of sedentary behaviour and moderate-to-vigorous physical activity (MVPA), and total physical activity (total daily accelerometer counts minus counts accrued during sedentary minutes) were determined from accelerometry. Associations between sedentary behaviour and cardio-metabolic biomarkers were examined using linear regression. RESULTS: Results showed that sedentary behaviour was detrimentally associated with 8/11 cardio-metabolic biomarkers when adjusted for MVPA. However, when adjusted for total physical activity, the associations effectively disappeared, except for C-reactive protein, which showed a very small, favourable association (beta = -0.06) and triglycerides, which showed a very small, detrimental association (beta = 0.04). Standardised betas suggested that total physical activity was consistently, favourably associated with cardio-metabolic biomarkers (9/11 biomarkers, standardized beta = 0.08-0.30) while sedentary behaviour was detrimentally associated with just 1 biomarker (standardized beta = 0.12). CONCLUSION: There is virtually no association between sedentary behaviour and cardio-metabolic biomarkers once analyses are adjusted for total physical activity. This suggests that sedentary behaviour may not have health effects independent of physical activity.

Mahlberg, Richard; Walther, S. (2007):

Actigraphy in agitated patients with dementia.

In: *Zeitschrift für Gerontologie und Geriatrie* 40 (3), S. 178–184.

Abstract:

Especially in pharmacotherapeutic research, a variety of methods to monitor behavioural and psychological symptoms of dementia (BPSD) are currently being discussed. To date, the most frequently used of these are clinical scales, which, however, are subjective and highly dependent on personnel resources. In our study, we tested the usefulness of actigraphy as a more direct and objective way to measure day-night rhythm disturbances and agitated behaviour. After a baseline assessment, 24 patients with probable dementia of the Alzheimer type (NINCDS-ADRDA) and agitated behaviour received either 3 mg melatonin (n=7), 2.5 mg dronabinol (n=7), or placebo (n=10) for two weeks. In addition, 10 young and 10 elderly healthy subjects were examined as a control group. Motor activity levels were assessed using an actigraph worn continuously on the wrist of the non-dominant hand. At the beginning and the end of the study, patients' Neuropsychiatric Inventory (NPI) scores were also assessed. In the verum group, actigraphic nocturnal activity (P=0.001), NPI total score (P=0.043), and NPI agitation subscale score (P=0.032) showed significant reductions compared to baseline. The treatment-baseline ratio of nocturnal activity (P=0.021) and treatment-baseline difference of the nocturnal portion of 24 h activity (P=0.012) were reduced. Patients' baseline activity levels were similar to those seen in healthy elderly subjects. Younger healthy subjects exhibited higher motor activity even at night. There was no correlation between actigraphy and NPI. Both actigraphic measures and the gold standard clinical scale were able to distinguish between the verum and placebo groups. However, because they did not correlate with each other, they clearly represent different aspects of BPSD, each of which reacts differently to therapy. As a result, actigraphy may well come to play an important role in monitoring treatment success in BPSD.

Mahler, Anja; Steiniger, Jochen; Endres, Matthias; Paul, Friedemann; Boschmann, Michael; Doss, Sarah (2014):

Increased Catabolic State in Spinocerebellar Ataxia Type 1 Patients.

In: *Cerebellum. DOI:* 10.1007/s12311-014-0555-6.

Abstract:

Autosomal dominant spinocerebellar ataxia type 1 (SCA1) is a genetic movement disorder with neuronal loss in the cerebellum, brainstem, and other cerebral regions. The course of SCA1 is accompanied with progressive weight loss and amyotrophia-the causes for that remain, however, unclear. We tested the hypothesis that an imbalance between energy intake and expenditure contributes to weight loss in SCA1 patients. Anthropometric measures, energy intake (food records), and resting (calorimetry) and free-living (accelerometry) energy expenditure were determined in 10 patients with genetically proven SCA1 and 10 healthy controls closely matched for age, sex, and body composition. At rest, energy expenditure per kilogram fat-free mass was 22 % and fat oxidation rate 28 % higher in patients vs. controls indicating an increased catabolic state. Under free-living conditions, total energy expenditure and daily step counts were significantly lower in patients vs. controls. However, most patients were able to maintain energy intake and expenditure in a balanced state. Resting energy expenditure, fat oxidation, and activity energy expenditure per step count are higher, whereas 24-h total energy expenditure is lower in SCA1 patients vs. healthy controls. An altered autonomic nervous system activity, gait ataxia, and a decreased physical activity might contribute to this outcome.

Job strain, effort-reward imbalance and ambulatory blood pressure: results of a cross-sectional study in call handler operators.

In: *International archives of occupational and environmental health* 84 (4), S. 383–391. DOI: 10.1007/s00420-010-0576-5.

Abstract:

OBJECTIVES\r\nTo examine the association between two job stress models-the job strain (JDC) and the effort-reward imbalance (ERI) model-and ambulatory blood pressure monitoring in call handler operators.\r\nMETHODS\r\nParticipants included 74 women (age, 34.9 ± 9.9 years) and 26 men (age 36.0 ± 10.8 years) who were monitored on 2 workdays for ambulatory blood pressure. Measures of both job stress models were related to blood pressure by the generalized estimating equations (GEE) method while adjusting for potential confounders (gender, age, cigarette smoking, alcohol consumption, educational level, marital status, time of day, and work schedule).\r\nRESULTS\r\nWorkshifts were associated with an increase of 3-4 and 14 mmHg in mean arterial pressure (MAP) compared with diurnal activities out of work and sleeping period, respectively ($P < 0.001$). Ambulatory blood pressure was also significantly related with work schedule preference: unpleasant work schedule was associated with an increase of 2 mmHg in MAP compared with pleasant work schedule ($P = 0.013$). In the ERI model, subjects scoring high in work stress have higher ambulatory blood pressure at work, at home, and during sleep. Work stress by time interaction was not longer significant when controlling for potential confounders: generalized estimating equations revealed that MAP was influenced by BMI (>25 vs. <25: 0.7 (0.2-1.1) mmHg), workshift preference (unpleasant vs. pleasant: 2 (0.4-3.6) mmHg), and time of day. Weak not significant relation was found between ABP and psychosocial factors evaluated by the JDC and ERI models.\r\nCONCLUSION\r\nThese results do not support work stress as a significant factor influencing ABP in a homogeneous group of call-handlers. Complementary information independently obtained from the two work stress models could provide more exhaustive explanations on the stress-related effects on blood pressure.

Assessing eating context and fruit and vegetable consumption in children: new methods using food diaries in the UK National Diet and Nutrition Survey Rolling Programme.

In: *Int.J Behav.Nutr.Phys.Act.* 9 (1479-5868 (Linking)), S. 126. DOI: 10.1186/1479-5868-9-126.

Abstract:

BACKGROUND: Eating context is the immediate environment of each eating occasion (EO). There is limited knowledge on the effects of the eating context on food consumption in children, due to the difficulty in measuring the multiple eating contexts children experience throughout the day. This study applied ecological momentary assessment using food diaries to explore the relationships between eating context and fruit and vegetable consumption in UK children. METHODS: Using 4 d unweighed food diaries, data were collected for 642 children aged 1.5-10y in two years of the UK National Diet and Nutrition Survey (2008-2010). Participants recorded all foods and drinks consumed at each EO, where and with whom the food was consumed, whether the TV was on and if eaten at a table. Mixed logistic regression and mixed multinomial logistic regression were used to calculate associations between eating contexts and fruit and vegetables (FV) consumed by quartiles. RESULTS: Of 16,840 EOs, 73% took place at home and 31% with parents only. Frequency of eating alone and with friends increased with age. Compared to eating at home, children aged 1.5-3y were more likely to consume fruit at care outside home (>10-50g OR:2.39; >50-100g OR:2.12); children aged 4-6y were more likely to consume fruit (>50-100g OR:3.53; >100g OR:1.88) and vegetables at school (>30-60g OR:3.56). Compared to eating with parents only, children aged 1.5-3y were more likely to consume fruit with friends (>10-50g OR:2.69; >50-100g OR:3.49), and with carer and other children/others (>10-50g OR:2.25); children aged 4-6y were more likely to consume fruit (>50-100g OR:1.96) and vegetables with friends (>30-60g OR:3.56). Children of all ages were more likely to eat

vegetables when the TV was off than on and at a table than not at table. CONCLUSIONS: The use of food diaries to capture multiple eating contexts and detailed fruit and vegetable consumption data was demonstrated at a population level. Higher odds of FV consumption were seen from structured settings such as school and care outside home than at home, as well as when eating at a table and the TV off. This study highlights eating contexts where provision of fruit and vegetables could be improved, especially at home. Future research should take eating context into consideration when planning interventions to target children's food consumption and eating behaviour

Malik, Aiysha; Goodwin, Guy M.; Holmes, Emily A. (2012):

Contemporary approaches to frequent mood monitoring in bipolar disorder.

In: *Journal of Experimental Psychopathology* 3 (4), S. 572–581. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-27687-005%26site%3dehost-live;emily.holmes@psych.ox.ac.uk.

Abstract:

Mood fluctuations are problematic in bipolar disorder. Current approaches to frequent monitoring of mood in bipolar disorder are paper diaries and electronic handheld devices. These approaches are limited in several ways, notably in the reliability of the data being collected which is often retrospectively reported. The experience sampling method offers a research paradigm which could be modified for use in clinical settings, to real time frequent mood monitoring. Mobile phone technology has also recently been developed to monitor weekly mood in a bipolar sample, demonstrating successful compliance rates. We propose the use of mobile phone technology as a novel method for frequently monitoring mood in bipolar disorder. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Maloney, Ann E.; Bethea, T. Carter; Kelsey, Kristine S.; Marks, Julie T.; Paez, Sadye; Rosenberg, Angela M. et al. (2008):

A pilot of a video game (DDR) to promote physical activity and decrease sedentary screen time.

In: *Obesity* 16 (9), S. 2074–2080.

Abstract:

OBJECTIVE:

We examined the feasibility of Dance Dance Revolution (DDR), a dance video game, in participants' homes, to increase physical activity (PA) and to decrease sedentary screen time (SST).

METHODS AND PROCEDURES:

Sixty children (7.5 +/- 0.5 years) were randomized in a 2:1 ratio to DDR or to wait-list control (10-week delay). DDR use was logged, PA was measured objectively by accelerometry. SST was self-reported at weeks 0 and 10. At week 28, after both groups had access to DDR, accelerometry and SST were repeated.

RESULTS:

Mean use of DDR was 89 +/- 82 (range 0-660 min) min per week (mpw). The DDR group showed increased vigorous PA and a reduction in light PA; the control group showed no increase in moderate and/or vigorous PA (MVPA) although they also had a reduction in light PA. Differences between the groups were not observed. The DDR group also reported a decrease in SST of -1.2 +/- 3.7 h per week (hpw) ($P < 0.05$), whereas the controls reported an increase of +3.0 +/- 7.7 hpw (nonsignificant). The difference in SST between the groups was significant, with less SST in the DDR group. Between weeks 10 and 28, numeric reductions in SST were reported in both groups. In the DDR group, SST at week 28 (8.8 +/- 6.0 hpw) was lower than baseline (10.5 +/- 5.5 hpw; $P < 0.03$).

DISCUSSION:

This pilot study suggests that DDR reduces SST and may facilitate slight increases in vigorous PA. Further study is needed to better characterize children and contexts in which DDR may promote a healthy lifestyle.

Long-Term Prognostic Value of Blood Pressure Variability in the General Population Results of the Pressioni Arteriose Monitorate e Loro Associazioni Study.

In: *Hypertension* 49 (6), S. 1265–1270.

Abstract:

The hypothesis has been advanced that cardiovascular prognosis is related not only to 24-hour mean blood pressure but also to blood pressure variability. Data, however, are inconsistent, and no long-term prognostic study is available. In 2012 individuals randomly selected from the population of Monza (Milan), 24-hour ambulatory blood pressure (Spacelabs 90207) was measured via readings spaced by 20 minutes. Systolic and diastolic blood pressure variability was obtained by calculating the following: (1) the SD of 24-hour, day, and night mean values; (2) the day-night blood pressure difference; and (3) the residual or erratic blood pressure variability (Fourier spectral analysis). Fatal cardiovascular and noncardiovascular events were registered for 148 months. When adjusted for age, sex, 24-hour mean blood pressure, and other risk factors, there was no relationship between the risk of death and 24-hour, day, and night blood pressure SDs. In contrast, the adjusted risk of cardiovascular death was inversely related to day-night diastolic BP difference (beta coefficient=-0.040; P<0.02) and showed a significant positive relationship with residual diastolic blood pressure variability (beta coefficient=0.175; P<0.002). Twenty-four-hour mean blood pressure attenuation of nocturnal hypotension and erratic diastolic blood pressure variability all independently predicted the mortality risk, with the erratic variability being the most important factor. Our data show that the relationship of blood pressure to prognosis is complex and that phenomena other than 24-hour mean values are involved. They also provide the first evidence that short-term erratic components of blood pressure variability play a prognostic role, with their increase being accompanied by an increased cardiovascular risk.

Mancia, Giuseppe; Facchetti, Rita; Bombelli, Michele; Grassi, Guido; Sega, Roberto (2006):

Long-term risk of mortality associated with selective and combined elevation in office, home, and ambulatory blood pressure.

In: *Hypertension* 47 (5), S. 846–853. DOI: 10.1161/01.HYP.0000215363.69793.bb.

Abstract:

In the Pressioni Arteriose Monitorate e Loro Associazioni (PAMELA) study, office, home, and ambulatory blood pressure (BP) values were measured contemporaneously between 1990 and 1993 in a large population sample (n=2051). Cardiovascular (CV) and non-CV death certificates were collected over the next 148 months, which allowed us to assess the prognostic value of selective and combined elevation in these 3 BPs over a long follow-up. There were 69 CV and 233 all-cause deaths. Compared with subjects with normal office and 24-hour BP, the hazard ratio for CV death showed a progressive increase in those with a selective office BP elevation (white-coat hypertension), a selective 24-hour BP elevation (masked hypertension), and elevation in both office and 24-hour BP. This was the case also when the above conditions were identified by office versus home BP values. Selective elevation in home versus ambulatory BP or vice versa also carried an increased risk. There was indeed a progressive increase in both CV and all-cause mortality risk from subjects in whom office, home, and ambulatory BP were all normal to those in whom 1, 2, or all 3 BPs were elevated, regardless of which BP was considered. The trends remained significant after adjustment for age and gender, as well as, in most instances, after further adjustment for other cardiovascular risk factors. Thus, white-coat hypertension and masked hypertension, both when identified by office and ambulatory or by office and home BPs, are not prognostically innocent. Indeed, each BP elevation (office, home, or ambulatory) carries an increase in risk mortality that adds to that of the other BP elevations.

Mancini, M.; Zampieri, C.; Carlson-Kuhta, P.; Chiari, L.; Horak, F. B. (2009):

Anticipatory postural adjustments prior to step initiation are hypometric in untreated Parkinson's disease: an accelerometer-based approach.

In: *European journal of neurology : the official journal of the European Federation of Neurological Societies* 16 (9), S. 1028–1034. DOI: 10.1111/j.1468-1331.2009.02641.x.

Abstract:

BACKGROUND AND PURPOSE\r\nAnticipatory postural adjustments (APAs), prior to step initiation, are bradykinetic in advanced Parkinson's disease (PD) and may be one of the factors associated with 'start hesitation'. However, little is known about APAs in the early stage of PD. In this study, we determined whether body-worn accelerometers could be used to characterize step initiation deficits in subjects with early-to-moderate, untreated PD.\r\nMETHODS\r\nEleven PD and 12 healthy control subjects

were asked to take two steps. Postural adjustments were compared from center of pressure (COP) and from acceleration of the trunk at the center of mass level (L5).\r\nRESULTS\r\nOur findings show that APAs measured from the peak COP displacement toward the swing leg and the peak trunk acceleration toward the stance leg were smaller in untreated PD compared with control subjects. The magnitude of APAs measured from peak COP displacements and accelerations were correlated.\r\nCONCLUSION\r\nThese results suggest that quantitative analysis of step initiation from one accelerometer on the trunk could provide useful information for the characterization of patients in early stages of PD, when clinical evidence of start hesitation may not be detectable. Ambulatory monitoring of step initiation is also promising for monitoring patient progression in the home environment, and eventually providing feedback for preventing freezing of gait episodes.

Development of two electronic bladder diaries: A patient and healthcare professionals pilot study.

In: *Neurourol.Urodyn.* (0733-2467 (Linking)). DOI: 10.1002/nau.22469.

Abstract:

AIMS: Assess patients' preferences in a pilot crossover study of two different electronic voiding diaries against a standard paper diary. Assess urological health professional (HP) opinions on the electronic bladder diary reporting system. METHODS: Two different electronic diaries were developed: (1) electronically read diary-a card with predefined slots read by a card reader and (2) e-diary-a handheld touch screen device. Data uploaded from either electronic diary produced an electronic report. We recruited 22 patients split into two cohorts for each electronic diary, 11 completed each type of electronic diary for 3 days either preceded or followed by a standard paper diary for 3 days. Both diaries were completed on the 7th day. Patients' perceptions of both diaries were recorded using a standardized questionnaire. A HP study recruited 22 urologists who were given the paper diary and the electronic reports. Time taken for analysis was recorded along with accuracy and HP preferences. RESULTS: The majority of patients (82%) preferred the e-diary and only 1/11 found it difficult to use. Patients had the same preference for the electronically read diary as the paper diary. The paper diary took 66% longer to analyze than the electronic report ($P < 0.001$) and was analyzed with an accuracy of 58% compared to 100%. Slightly more HP (9%) preferred the electronic report to the paper diary. CONCLUSIONS: This proposed e-diary with its intuitive interface has overcome previous deficiencies in electronic diaries with most patients finding the format user-friendly. Electronic reports make analysis and interpretation by HP quicker and more accurate. Neurourol. Urodynam. (c) 2013 Wiley Periodicals, Inc

Manikonda, J. P.; Störk, S.; Tögel, S.; Lobmüller, A.; Grünberg, I.; Bedel, S. et al. (2008):

Contemplative meditation reduces ambulatory blood pressure and stress-induced hypertension: a randomized pilot trial.

In: *J Hum Hypertens* 22 (2), S. 138–140.

Abstract:

A total of 52 pharmacologically untreated subjects with essential hypertension were randomly allocated to either 8 weeks of contemplative meditation combined with breathing techniques (CMBT) or no intervention in this observer-blind controlled pilot trial. CMBT induced clinically relevant and consistent decreases in heart rate, systolic and diastolic blood pressure if measured during office readings, 24-h ambulatory monitoring and mental stress test. Longer-term studies should evaluate CMBT as an antihypertensive strategy.

Manios, Efstathios D.; Koroboki, Eleni A.; Tsivgoulis, Georgios K.; Spengos, Konstantinos M.; Spiliopoulou, Ioanna K.; Brodie, Fiona G. et al. (2008):

Factors influencing white-coat effect.

In: *Am J Hypertens* 21 (2), S. 153–158.

Abstract:

BACKGROUND:

The transient blood pressure (BP) rise during clinical visits is usually referred to as white-coat effect (WCE). The aim of the present study was to investigate factors that may influence the WCE.

METHODS:

A total of 2004 subjects underwent office BP measurements and 24-h ambulatory BP monitoring (ABPM) on the same day. The WCE was estimated as the difference between office and average daytime ambulatory BP (ABP). According to the office and daytime BP values, the study population was divided into normotensives (NTs), white-coat hypertensives (WCHs), masked hypertensives (MHTs), and sustained hypertensives (SHTs). Statistical analyses were performed using one-way analysis of variance and multiple linear regression models.

RESULTS:

The mean systolic and diastolic WCE was 9 +/- 16 and 7 +/- 12 mm Hg, respectively. In the entire group of patients, multiple linear regression models revealed independent determinants of systolic WCE in the following rank order: office systolic BP (SBP) (beta = 0.727; P < 0.001), female gender (beta = 0.166; P < 0.001), daytime SBP variability (beta = 0.128; P < 0.001), age (beta = 0.039, P = 0.020), and smoking (beta = 0.031, P = 0.048). A 1.0 mm Hg increase in daytime SBP variability correlated with an increment of 0.589 mm Hg (95% confidence intervals, 0.437-0.741) in the systolic WCE. The regression analyses for diastolic WCE revealed the same factors as independent determinants. A 1.0 mm Hg increase in daytime diastolic BP (DBP) variability was independently associated with an increment of 0.418 mm Hg (95% confidence intervals, 0.121-0.715) in the diastolic WCE.

CONCLUSIONS:

Factors such as gender, age, smoking, office BPV and daytime BPV may exert an important influence on the magnitude of the WCE.

Mann, Eleanor; Hunter, Myra S. (2011):

Concordance between self-reported and sternal skin conductance measures of hot flushes in symptomatic perimenopausal and postmenopausal women: a systematic review.

In: *Menopause* 18 (6), S. 709–722.

Abstract:

OBJECTIVE:

Sternal skin conductance is considered the gold standard in hot flush and night sweat measurement, but results sometimes differ from women's own self-reports. To date, there has been no systematic review of concordance between sternal skin conductance and self-report measures. An exploratory meta-analysis was conducted to quantify concordance between these measures and to explore the reasons for discordance between them.

METHODS:

A search of Medline, EMBASE, Web of Science, and PsychInfo from inception to December 2009 was conducted. Studies that measured self-reported hot flushes and/or night sweats and sternal skin conductance concurrently in symptomatic perimenopausal and postmenopausal women were retained for data extraction. Studies were included if data on concordance between the two measures were available.

RESULTS:

Concordance rates overall were 29%, but variability between studies was too broad to identify a single typical concordance rate. However, concordance rates for ambulatory monitoring were more homogeneous and also had a 29% concordance rate. Nonambulatory studies tended to result in more concordant hot flushes (54%) than ambulatory studies did, and night sweats tended to be under-reported more often than over-reported (46% and 22%, respectively).

CONCLUSIONS:

Concordance rates were typically lower than early reports of sternal skin conductance measures but were highly variable between studies. Possible measurement error and study conditions might partly explain the discordance and variation in study findings, but further exploration of the effects of symptom perception is warranted. Use of both measures concurrently is likely to achieve more reliable and valid measurement of hot flushes and night sweats than either measure alone.

Marcano Belisario, J. S.; Huckvale, K.; Greenfield, G.; Car, J.; Gunn, L. H. (2013):

Smartphone and tablet self management apps for asthma.

In: *Cochrane.Database.Syst.Rev.* 11 (1361-6137 (Linking)), S. CD010013. DOI: 10.1002/14651858.CD010013.pub2.

Abstract:

BACKGROUND: Asthma is one of the most common long-term conditions worldwide, which places considerable pressure on patients, communities and health systems. The major international clinical guidelines now recommend the inclusion of self management programmes in the routine management of patients with asthma. These programmes have been associated with improved outcomes in patients with asthma. However, the implementation of self management programmes in clinical practice, and their uptake by patients, is still poor. Recent developments in mobile technology, such as smartphone and tablet computer apps, could help develop a platform for the delivery of self management interventions that are highly customisable, low-cost and easily accessible. OBJECTIVES: To assess the effectiveness, cost-effectiveness and feasibility of using smartphone and tablet apps to facilitate the self management of individuals with asthma. SEARCH METHODS: We searched the Cochrane Airways Group Register (CAGR), the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, EMBASE, PsycINFO, CINAHL, Global Health Library, Compendex/Inspec/Referex, IEEEXplore, ACM Digital Library, CiteSeer(x) and CAB abstracts via Web of Knowledge. We also searched registers of current and ongoing trials and the grey literature. We checked the reference lists of all primary studies and review articles for additional references. We searched for studies published from 2000 onwards. The latest search was run in June 2013. SELECTION CRITERIA: We included parallel randomised controlled trials (RCTs) that compared self management interventions for patients with clinician-diagnosed asthma delivered via smartphone apps to self management interventions delivered via traditional methods (e.g. paper-based asthma diaries). DATA COLLECTION AND ANALYSIS: We used standard methods expected by the Cochrane Collaboration. Our primary outcomes were symptom scores; frequency of healthcare visits due to asthma exacerbations or complications and health-related quality of life. MAIN RESULTS: We included two RCTs with a total of 408 participants. We found no cluster RCTs, controlled before and after studies or interrupted time series studies that met the inclusion criteria for this systematic review. Both RCTs evaluated the effect of a mobile phone-based asthma self management intervention on asthma control by comparing it to traditional, paper-based asthma self management. One study allowed participants to keep daily entries of their asthma symptoms, asthma medication usage, peak flow readings and peak flow variability on their mobile phone, from which their level of asthma control was calculated remotely and displayed together with the corresponding asthma self management recommendations. In the other study, participants recorded the same readings twice daily, and they received immediate self management feedback in the form of a three-colour traffic light display on their phones. Participants falling into the amber zone of their action plan twice, or into the red zone once, received a phone call from an asthma nurse who enquired about the reasons for their uncontrolled asthma.We did not conduct a meta-analysis of the data extracted due to the considerable degree of heterogeneity between these studies. Instead we adopted a narrative synthesis approach. Overall, the results were inconclusive and we judged the evidence to have a GRADE rating of low quality because further evidence is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate. In addition, there was not enough information in one of the included studies to assess the risk of bias for the majority of the domains. Although the other included study was methodologically rigorous, it was not possible to blind participants or personnel in the study. Moreover, there are concerns in both studies in relation to attrition bias and other sources of bias.One study showed that the use of a smartphone app for the delivery of an asthma self management programme had no statistically significant effect on asthma symptom scores (mean difference (MD) 0.01, 95% confidence interval (CI) -0.23 to 0.25), asthma-related quality of life (MD of mean scores 0.02, 95% CI -0.35 to 0.39), unscheduled visits to the emergency department (OR 7.20, 95% CI 0.37 to 140.76) or frequency of hospital admissions (odds ratio (OR) 3.07, 95% CI 0.32 to 29.83). The other included study found that the use of a smartphone app resulted in higher asthma-related quality of life scores at six-month follow-up (MD 5.50, 95% CI 1.48 to 9.52 for the physical component score of the SF-12 questionnaire; MD 6.00, 95% CI 2.51 to 9.49 for the mental component score of the SF-12 questionnaire), improved lung function (PEFR) at four (MD 27.80, 95% CI 4.51 to 51.09), five (MD 31.40, 95% CI 8.51 to 54.29) and six months (MD 39.20, 95% CI 16.58 to 61.82), and reduced visits to the emergency department due to asthma-related complications (OR 0.20, 95% CI 0.04 to 0.99). Both studies failed to find any statistical differences in terms of adherence to the intervention and occurrence of other asthma-related complications. AUTHORS' CONCLUSIONS: The current evidence base is not sufficient to advise clinical practitioners, policy-makers and the general public with regards to the use of smartphone and tablet computer apps for the delivery of asthma self management programmes. In order to understand the efficacy of apps as standalone interventions, future research should attempt to minimise the differential clinical management of patients between control and intervention groups. Those studies evaluating apps as part of complex, multicomponent interventions, should attempt to tease out the relative contribution of each intervention component. Consideration of the theoretical constructs used to inform the development of the intervention would help to achieve this goal. Finally, researchers should also take into account: the role of ancillary components in moderating the observed effects, the seasonal nature of asthma and long-term adherence to self management practices

Marceau, Lisa D.; Link, Carol; Jamison, Robert N.; Carolan, Sarah (2007):

Electronic diaries as a tool to improve pain management: is there any evidence?

In: *Pain Medicine* 8 (s3), S. S101-S109.

Abstract:

OBJECTIVE:

Chronic pain is a common and costly syndrome which affects approximately one in three US adults. Factors such as shortened length of the medical visit, increased availability of technological approaches to care, and a more informed patient all suggest

that a new paradigm is required for chronic pain management. Although much has been written about the use of electronic diaries in clinical trials, little has been presented about the use of these diaries in clinic practice and their potential for changing pain behavior. The intent of this preliminary study is to measure accessibility and usability of a software program designed for use on a personal digital assistant and to discuss how the software program may impact clinic practice and patient behavior.

METHODS:

We present the results of a preliminary, randomized, comparison, crossover trial of 36 chronic pain patients who were asked to monitor their pain, mood, activity interference, medication use, and pain location on either a paper or electronic diary for 2 weeks. Patients in the electronic diary condition were able to observe changes in their ratings over time and view them on a secure web site.

RESULTS:

No differences were found between paper and electronic tracking on pain descriptors, pain interference, mood, or helpfulness of medication. Similar to past findings, patients found the electronic diary easier to use ($P < 0.0001$) and would continue using it ($P < 0.05$) over paper if given the choice. Importantly, patients using the electronic diary reported more frequently that a provider suggested medication change ($P < 0.05$) based on feedback from the electronic diary. One trend requiring further investigation is that electronic diary users reported that the diary enabled them and their doctor to make care adjustments according to changes in pain status.

CONCLUSION:

This study goes beyond previous research on preference and data quality to investigate how the information provided may affect patient and physician perspectives toward pain management. Although not the initial intent of this study, findings indicate that electronic tracking may provide information which can affect management decisions. A follow-up study is ongoing to investigate these initial results. If found to be true, electronic monitoring may have broad implications for health care, policy, and improvement in quality of care for chronic pain sufferers in the future.

Marceau, Lisa D.; Link, Carol L.; Smith, Lauren D.; Carolan, Sarah J.; Jamison, Robert N. (2010):

In-clinic use of electronic pain diaries: barriers of implementation among pain physicians.

In: *Journal of pain and symptom management* 40 (3), S. 391–404. DOI: 10.1016/j.jpainsymman.2009.12.021.

Abstract:

OBJECTIVES\r\nThe aim of this study was to examine barriers to the use of electronic diaries within the clinic setting and determine outcome differences between patients who used electronic diaries to monitor their progress with summary data feedback and patients who monitored their progress with paper diaries without summary data feedback.\r\nMETHODS\r\nOne hundred thirty-four (n=134) chronic pain patients were asked to monitor their pain, mood, activity interference, medication use, and pain location on either a paper or electronic diary immediately before each monthly clinic visit for 10 months. Patients and their treating physicians in the electronic diary group (n=67) were able to observe changes in their ratings whereas patients using the paper diaries (n=67) had no feedback about their data entry.\r\nRESULTS\r\nMost participants believed that completing pain diaries was beneficial; yet, only 23% of patients in the experimental condition felt that the data from the electronic diaries improved their care and less than 15% believed that their doctor made a change in their treatment based on the summary diary information.\r\nCONCLUSION\r\nIn general, treating physicians were positive about the use of electronic diaries, although they admitted that they did not regularly incorporate the summary data in their treatment decision making because either they forgot or they were too busy. Future studies in understanding barriers to physicians' and patients' use of diary data to impact treatment outcome are needed to improve care for persons with chronic pain.

Marhe, R.; Waters, A. J.; van de Wetering, B. J.; Franken, I. H. (2012):

Implicit and Explicit Drug-Related Cognitions During Detoxification Treatment Are Associated With Drug Relapse: An Ecological Momentary Assessment Study.

In: *J Consult Clin.Psychol.* (0022-006X (Linking)). DOI: 10.1037/a0030754.

Abstract:

Objective: Relapse is a major problem in drug addiction treatment. Both drug craving and drug-related cognitions (e.g., attentional bias and implicit attitudes to drugs) may contribute to relapse. Using ecological momentary assessments, we examined whether craving and cognitions assessed during drug detoxification treatment were associated with relapse. Method: Participants were 68 heroin-dependent inpatients undergoing clinical detoxification at an addiction treatment center. Participants carried around a personal digital assistant for 1 week. Participants completed up to 4 random assessments (RAs) per day. They also completed an assessment when they experienced a temptation to use drugs (TA). At each assessment,

participants reported their craving and attitudes to drugs. Implicit cognitions were assessed with a drug Stroop task (attentional bias) and an Implicit Association Test (implicit attitudes). Results: Individuals who relapsed during the study week exhibited a larger attentional bias and more positive implicit attitudes to drugs than did nonrelapsers at TAs (but not RAs). In addition, compared to nonrelapsers, relapsers reported higher levels of craving and more positive explicit attitudes to drugs at TAs than at RAs. Additional within-subject analyses revealed that attentional bias for drugs at TAs increased before relapse. Conclusions: Drug-related cognitive processes assessed with ecological momentary assessments were associated with relapse during drug detoxification. Real-time assessment of craving and cognitions may help to identify which individuals are at risk of relapse and when they are at risk of relapse. Psycho-Informatics: Big Data shaping modern psychometrics.

In: *Med Hypotheses* 82 (4), S. 405–411. DOI: 10.1016/j.mehy.2013.11.030.

Abstract:

For the first time in history, it is possible to study human behavior on great scale and in fine detail simultaneously. Online services and ubiquitous computational devices, such as smartphones and modern cars, record our everyday activity. The resulting Big Data offers unprecedented opportunities for tracking and analyzing behavior. This paper hypothesizes the applicability and impact of Big Data technologies in the context of psychometrics both for research and clinical applications. It first outlines the state of the art, including the severe shortcomings with respect to quality and quantity of the resulting data. It then presents a technological vision, comprised of (i) numerous data sources such as mobile devices and sensors, (ii) a central data store, and (iii) an analytical platform, employing techniques from data mining and machine learning. To further illustrate the dramatic benefits of the proposed methodologies, the paper then outlines two current projects, logging and analyzing smartphone usage. One such study attempts to thereby quantify severity of major depression dynamically; the other investigates (mobile) Internet Addiction. Finally, the paper addresses some of the ethical issues inherent to Big Data technologies. In summary, the proposed approach is about to induce the single biggest methodological shift since the beginning of psychology or psychiatry. The resulting range of applications will dramatically shape the daily routines of researches and medical practitioners alike. Indeed, transferring techniques from computer science to psychiatry and psychology is about to establish Psycho-Informatics, an entire research direction of its own.

Marsden, Paul A.; Smith, Jaclyn A.; Kelsall, Angela A.; Owen, Emily; Naylor, Jonathan R.; Webster, Deborah et al. (2008):

A comparison of objective and subjective measures of cough in asthma.

In: *The Journal of allergy and clinical immunology* 122 (5), S. 903–907. DOI: 10.1016/j.jaci.2008.08.029.

Abstract:

BACKGROUND\r\nCough is widely recognized as a key symptom in the diagnosis and the monitoring of asthma, but little is known about how best to assess cough in asthma.\r\nOBJECTIVE\r\nTo determine how objective cough rates correlate with subjective measures of cough in asthma.\r\nMETHODS\r\nWe studied 56 subjects, median age 42.0 years (range, 28.5-71), 34 (60.7%) female, with asthma. Subjects performed cough reflex sensitivity testing (concentration of citric acid causing 2 and 5 coughs [C2 and C5]), 24-hour fully ambulatory cough recordings, subjectively scored the severity of their cough (visual analog scales and 0-5 score) and completed a cough-related quality of life questionnaire (Leicester Cough Questionnaire). Ambulatory cough recordings were manually counted and reported in cough seconds per hour (cs/h).\r\nRESULTS\r\nThe median time spent coughing was 2.6 cs/h (range, 0.0-14.2), with subjects spending more time coughing by day (median, 3.9 cs/h [0.0-18.5]) than by night (median, 0.3 cs/h [0.0-8.7]; P < .001). A weak inverse relationship was seen between day cough rates and log(10)C2 (r = -0.39; P = .03) but not log(10)C5 (r = -0.08; P = .65). Objective time spent coughing was also weak-moderately associated with subjective cough scores and visual analog scales, and most strongly correlated with cough-related quality of life (r = -0.54; P < .001).\r\nCONCLUSION\r\nSubjective measures of cough and cough reflex sensitivity are poor surrogates for objective cough frequency in asthma. When designing studies to assess interventions for cough in asthma, we advocate a combination of both objective measures of cough and cough-related quality of life.

Using ecological momentary assessment to evaluate current physical activity.

In: *Biomed Res Int* 2014, S. 915172. DOI: 10.1155/2014/915172.

Abstract:

OBJECTIVE: The purpose of this study was to assess the value of ecological momentary assessment in evaluating physical activity among children, adolescents, and adults. It also determines whether ecological momentary assessment fulfills the criteria of validity, reliability, objectivity, norms, and standardization applied to the tools used for the evaluation of physical activity. METHODS: The EBSCO-CINHAL, Medline, PsycINFO, PubMed, and SPORTDiscuss databases were reviewed in December 2012 for articles associated with EMA. RESULTS: Of the 20 articles examined, half (10) used electronic methods for data collection, although various methods were used, ranging from pen and paper to smartphone applications. Ten studies used objective monitoring equipment. Nineteen studies were performed over 4 days. While the validity of the EMA method was discussed in 18 studies, only four found it to be objective. In all cases, the EMA procedures were precisely documented and confirmed to be feasible. CONCLUSIONS: Ecological momentary assessment is a valid, reliable, and feasible approach to evaluate activity and sedentary behavior. Researchers should be aware that while ecological momentary assessment offers many benefits, it simultaneously imposes many limitations which should be considered when studying physical activity.

Martikainen, Silja; Pesonen, Anu-Katriina; Lahti, Jari; Heinonen, Kati; Pyhala, Riikka; Tammelin, Tuija et al. (2014):

Physical activity and hypothalamic-pituitary-adrenocortical axis function in adolescents.

In: *Psychoneuroendocrinology* 49, S. 96–105. DOI: 10.1016/j.psyneuen.2014.06.023.

Abstract:

Little is known about the associations between physical activity (PA) and hypothalamic-pituitary-adrenocortical axis (HPAA) activity in adolescents. This knowledge could offer insight into the links between PA and well-being in youth. We studied whether objectively-measured PA is associated with diurnal salivary cortisol responses and morning salivary cortisol responses after a low-dose overnight dexamethasone suppression test (DST) in adolescent girls and boys. We conducted a cross-sectional birth cohort study in Helsinki, Finland. At a mean age of 12.4 (SD=0.5) years, 150 girls and 133 boys wore wrist-worn accelerometers over at least 4 days to measure PA. Their salivary cortisol was measured across 1 day and upon awakening after a low-dose overnight DST (3mug/kg of weight). Girls with higher overall PA and vigorous PA (VPA), and less sedentary time had lower salivary cortisol upon awakening and/or after (decreases between |0.17| and |0.25| SDs per SD increase in overall PA, VPA and decrease in sedentary time; P-values<0.039). Boys with higher overall PA, and less sedentary time had greater suppression of salivary cortisol following overnight DST (suppression between |0.24| and |0.27| SDs per SD increase in overall PA and decrease in sedentary time; P-values<0.012). Overall PA, VPA and sedentary time did not associate with DST suppression in girls or with diurnal salivary cortisol in boys. These results show that PA is associated with altered HPAA function in early adolescents, and that the associations are sex specific.

Martin, C. K.; Nicklas, T.; Gunturk, B.; Correa, J. B.; Allen, H. R.; Champagne, C. (2013):

Measuring food intake with digital photography.

In: *J Hum.Nutr.Diet.* (0952-3871 (Linking)). DOI: 10.1111/jhn.12014.

Abstract:

The Digital Photography of Foods Method accurately estimates the food intake of adults and children in cafeterias. When using this method, images of food selection and leftovers are quickly captured in the cafeteria. These images are later compared with images of 'standard' portions of food using computer software. The amount of food selected and discarded is estimated based upon this comparison, and the application automatically calculates energy and nutrient intake. In the present review, we describe this method, as well as a related method called the Remote Food Photography Method (RFPM), which relies on smartphones to estimate food intake in near real-time in free-living conditions. When using the RFPM, participants capture images of food selection and leftovers using a smartphone and these images are wirelessly transmitted in near real-time to a server for analysis. Because data are transferred and analysed in near real-time, the RFPM provides a platform for participants to quickly receive feedback about their food intake behaviour and to receive dietary recommendations for achieving weight loss and health promotion goals. The reliability and validity of measuring food intake with the RFPM in adults and children is also reviewed. In sum, the body of research reviewed demonstrates that digital imaging accurately estimates food intake in many environments and it has many advantages over other methods, including reduced participant burden, elimination of the need for participants to estimate portion size, and the incorporation of computer automation to improve the accuracy, efficiency and cost-effectiveness of the method

Martinez, Sylvia; Guzman, Stephanie (2013):

Gender and racial/ethnic differences in self-reported levels of engagement in high school math and science courses.

In: *Hispanic Journal of Behavioral Sciences* 35 (3), S. 407–427. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-26122-007%26site%3dehost-live;symartin@indiana.edu.

Abstract:

While gender and racial/ethnic performance gaps in math and science have been well documented, we know little about how students feel while they are in these courses. Using a sample of 793 high school students who participated in the Experience Sampling Method of the Study of Youth and Social Development, this study examines the gender and racial/ethnic differences in self-reported levels of challenge, a measure of student engagement, while students are in math and science courses. Results from multivariate regression analyses indicate that boys report similar levels of engagement while in math and science classes, but girls do not. While Black female students report lower levels of challenge in math classes, Latina girls report lower levels of challenge while in science class in comparison to other racial/ethnic groups. Martin-Martinez, D.; Casaseca-De-La-Higuera, P.; Alberola-Lopez, S.; Andres-De-Llano, J.; Lopez-Villalobos, J. A.; Ardura-Fernandez, J.; Alberola-Lopez, C. (2012):

Nonlinear analysis of actigraphic signals for the assessment of the attention-deficit/hyperactivity disorder (ADHD).

In: *Med.Eng Phys.* (1350-4533 (Linking)). DOI: 10.1016/j.medengphy.2011.12.023.

Abstract:

Attention-deficit/hyperactivity disorder (ADHD) is the most common neurobehavioral disorder in children and adolescents; however, its etiology is still unknown, which hinders the existence of reliable, fast and inexpensive standard diagnostic methods. In this paper, we propose a novel methodology for automatic diagnosis of the combined type of ADHD based on nonlinear signal processing of 24h-long actigraphic registries. Since it relies on actigraphy measurements, it constitutes an inexpensive and non-invasive objective diagnostic method. Our results on real data reach 96.77% sensitivity and 84.38% specificity by means of multidimensional classifiers driven by combined features from different time intervals. Our analysis also reveals that, if features from a single time interval are used, the whole 24-h interval is the only one that yields classification figures with practical diagnostic capabilities. Overall, our figures overcome those obtained by actigraphy-based methods reported and are comparable with others based on more expensive (and not so convenient) adquisition methods

Martino, S. C.; Scharf, D. M.; Setodji, C. M.; Shadel, W. G. (2011):

Measuring Exposure to Protobacco Marketing and Media: A Field Study Using Ecological Momentary Assessment.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntr223.

Abstract:

INTRODUCTION: The aims of this study were to validate ecological momentary assessment (EMA) as a method for measuring exposure to tobacco-related marketing and media and to use this method to provide detailed descriptive data on college students' exposure to protobacco marketing and media. METHODS: College students (n = 134; ages 18-24 years) recorded their exposures to protobacco marketing and media on handheld devices for 21 consecutive days. Participants also recalled exposures to various types of protobacco marketing and media at the end of the study period. RESULTS: Retrospectively recalled and EMA-based estimates of protobacco marketing exposure captured different information. The correlation between retrospectively recalled and EMA-logged exposures to tobacco marketing and media was moderate (r = .37, p < .001), and EMA-logged exposures were marginally associated with the intention to smoke at the end of the study, whereas retrospective recall of exposure was not. EMA data showed that college students were exposed to protobacco marketing through multiple channels in a relatively short period: Exposures (M = 8.24, SD = 7.85) occurred primarily in the afternoon (42%), on weekends (35%), and at point-of-purchase locations (68%) or in movies/TV (20%), and exposures to Marlboro, Newport, and Camel represented 56% of all exposures combined and 70% of branded exposures.Conclusions:Findings support the validity of EMA as a method for capturing detailed information about youth exposure to protobacco marketing and media that are not captured through other

existing methods. Such data have the potential to highlight areas for policy change and prevention in order to reduce the impact of tobacco marketing on youth

Martire, L. M.; Keefe, F. J.; Schulz, R.; Parris Stephens, M. A.; Mogle, J. A. (2013):

The impact of daily arthritis pain on spouse sleep.

In: *Pain* 154 (9), S. 1725–1731. DOI: 10.1016/j.pain.2013.05.020.

Abstract:

Although chronic pain has been linked to poorer psychosocial well-being in the spouse, the extent to which patient pain affects spouse sleep is unknown. The aim of the present study was to test the hypothesis that greater daily knee pain would be associated with poorer sleep for the spouse that evening. We also tested the hypothesis that this pain contagion is exacerbated in couples who have a close relationship. A total of 138 knee osteoarthritis (OA) patients and their spouses completed baseline interviews and a 22-day diary assessment. Multilevel lagged models indicated that greater knee OA pain at the end of the day was associated with spouses' poorer overall sleep quality that night and feeling less refreshed after sleep. In contrast, there was no evidence that spouse sleep was related to greater patient pain the next day. The effects of patient pain on spouse sleep were not due to disturbances in patient sleep and were also independent of spouse sex, depressive symptoms, and physical comorbidities; both partners' negative affect; and the quality of marital interactions throughout the day. As predicted, we also found that patient pain was more strongly related to less refreshing sleep for spouses who were in a close relationship. Findings illustrate that chronic pain may place the spouse's health at risk and suggest an important target for couple-oriented interventions

Martire, Lynn M.; Stephens, Mary Ann Parris; Mogle, Jacqueline; Schulz, Richard; Brach, Jennifer; Keefe, Francis J. (2013):

Daily spousal influence on physical activity in knee osteoarthritis.

In: *Annals of Behavioral Medicine* 45 (2), S. 213–223. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-09593-011%26site%3dehost-live;lmm51@psu.edu.

Abstract:

Background: Physical activity is critical for the management of knee osteoarthritis, and the spouse may play a role in encouraging or discouraging physical activity. Purpose: The purpose of this study was to examine four types of spousal influence—spouses' daily activity, autonomy support, pressure, and persuasion—on the daily physical activity of adults living with knee osteoarthritis. Methods: A total of 141 couples reported their daily experiences for 22 days using a handheld computer and wore an accelerometer to measure moderate activity and steps. Results: Spouses' autonomy support for patient physical activity, as well as their own level of activity, was concurrently associated with patients' greater daily moderate activity and steps. In addition, on days when male patients perceived that spouses exerted more pressure to be active, they spent less time in moderate activity. Conclusions: Couple-oriented interventions for knee osteoarthritis should target physical activity in both partners and spousal strategies for helping patients stay active. Maselli, M.; Giantin, V.; Franchin, A.; Zanatta, F.; Sarti, S.; Corradin, M. L. et al. (2014):

Detection of blood pressure increments in active elderly individuals: The role of ambulatory blood pressure monitoring.

In: *Nutr Metab Cardiovasc Dis. DOI:* 10.1016/j.numecd.2014.01.003.

Abstract:

BACKGROUND AND AIMS: Physiological aging can lead to an increase in blood pressure (BP) over time even in regularly exercising elders. Office BP measurements (OBPM) might be unable to detect these BP variations. The aim of this study was to analyze BP changes over 3.5 years in active elders using ABPM. METHODS AND RESULTS: The study involved 80 active subjects >/=65 years old who exercised regularly. At baseline and again 3.5 years later, all subjects had lab tests, weight, body mass index (BMI), body composition, resting energy expenditure (REE) recorded; they underwent OBPM, ABPM and physical activity assessment. Over 3.5 years, our sample's mean weight, BMI, body composition, REE, albumin, and physical activity levels, did not change significantly. The prevalence of hypertension detected by OBPM dropped from 68.8% to 61.3%. ABPM revealed an increase in mean 24-h BP (Deltasystolic: 5.3 +/- 13.6 mmHg; p = 0.001; Deltadiastolic: 1.8 +/- 6.7 mmHg; p = 0.018) and mean

daytime BP (Deltasystolic: 5.8 +/- 13.5 mmHg; p = 0.001; Deltadiastolic: 1.9 +/- 7.1 mmHg; p = 0.022); the prevalence of hypertension detected by ABPM increased from 50% to 65%, also due to an increase (from 8.8% to 16.3%) in masked hypertension. There was no correlation between BP changes and changes in body composition and REE. CONCLUSION: BP tends to increase over time in active elders, regardless of changes in body composition or level of physical activity. ABPM is an appropriate method for detecting these BP variations in active elders and to reveal cases of masked hypertension that might otherwise escape detection by OBPM.

Mastrototaro, John; Shin, John; Marcus, Alan; Sulur, Giri (2008):

The accuracy and efficacy of real-time continuous glucose monitoring sensor in patients with type 1 diabetes.

In: *Diabetes technology & therapeutics* 10 (5), S. 385–390. DOI: 10.1089/dia.2007.0291.

Abstract:

BACKGROUND\r\nThe accuracy and efficacy of the Medtronic Diabetes (Northridge, CA) Real-Time (RT)-Continuous Glucose Monitoring (CGM) sensor were analyzed in 72 subjects with type 1 diabetes.\r\nMETHODS\r\nThis was a retrospective analysis of 60,050 temporally paired data points (sensor and glucose meter values) obtained during the course of an outpatient ambulatory study evaluating the efficacy of a sensor-augmented pump system in adults and adolescents. Subjects uploaded sensor values and self-monitoring blood glucose data to the CareLink Clinical Application (Medtronic Diabetes) via the Internet, every 2 weeks during the course of the study.\r\nRESULTS\r\nThe overall percentage of sensor readings within +/-20% or +/-30% agreement of reference glucose readings was 75.6% and 86.8%, respectively. The highest rate of agreement occurred in the 240-400 mg/dL range, where 79.9% of sensor readings were within +/-20% of meter values and 91.5% of sensor readings were within 30% of meter values. The mean absolute relative difference for all subjects was 15.8%, and the median absolute relative difference was 10.9%. The bias was -2.13 mg/dL. Paired glucose measurements from the RT-CGM and meter demonstrated that 95.9% of paired points in the overall subject population fell in zones A and B of the Clarke Error Grid. Consensus Error Grid Analysis established that 99.2% of paired data points were in zones A and B.\r\nCONCLUSIONS\r\nThis study reports the accuracy of a continuous glucose sensor with a large number of paired data points (60,050). RT-CGM is safe and well tolerated and provides readings that are in close agreement with glucose meter values.

Mathers, Megan; Canterford, Louise; Olds, Tim; Hesketh, Kylie; Ridley, Kate; Wake, Melissa (2009):

Electronic media use and adolescent health and well-being: cross-sectional community study.

In: *Academic pediatrics* 9 (5), S. 307–314. DOI: 10.1016/j.acap.2009.04.003.

Abstract:

OBJECTIVE\r\nTo describe time adolescents spend using electronic media (television, computer, video games, and telephone); and to examine associations between self-reported health/well-being and daily time spent using electronic media overall and each type of electronic media.\r\nMETHODS\r\nDesign-Cross-sectional data from the third (2005) wave of the Health of Young Victorians Study, an Australian school-based population study. Outcome Measures-Global health, health-related quality of life (HRQoL; KIDSCREEN), health status (Pediatric Quality of Life Inventory 4.0; PedsQL), depression/anxiety (Kessler-10), and behavior problems (Strengths and Difficulties Questionnaire). Exposure Measures-Duration of electronic media use averaged over 1 to 4 days recalled with the Multimedia Activity Recall for Children and Adolescents (MARCA) computerized time-use diary. Analysis-Linear and logistic regression; adjusted for demographic variables and body mass index z score.\r\nRESULTS\r\nA total of 925 adolescents (mean +/- standard deviation age, 16.1+/-1.2 years) spent, on average, 3 hours 16 minutes per day using electronic media (television, 128 minutes per day; video games, 35; computers, 19; telephone, 13). High overall electronic media use was associated with poorer behavior, health status, and HRQoL. Associations with duration of specific media exposures were mixed; there was a favorable association between computer use (typing/Internet) and psychological distress, whereas high video game use was associated with poorer health status, HRQoL, global health, and depression/anxiety. Television and telephone durations were not associated with any outcome measure.\r\nCONCLUSIONS\r\nDespite television's associations with obesity, time spent in other forms of media use appear more strongly related to adolescent health and well-being. This study supports efforts to reduce high video game use and further exploration of the role of computers in health enhancement.

Matias, Gabriela P.; Nicolson, Nancy A.; Freire, Teresa (2011):

Solitude and cortisol: Associations with state and trait affect in daily life.

In: *Biol Psychol* 86 (3), S. 314–319.

Abstract:

The social context can impact psychological and physiological functioning. Being alone, in particular, is experienced as more negative on average than being with others, in both normative and pathological populations. This study investigates whether daily solitude is associated with changes in cortisol and, if so, whether momentary and trait affect can explain this relationship. Forty-four female college students used the Experience Sampling Method during a week, completing questionnaires and collecting saliva 8 times daily. Effects of current solitude, affect, and trait affectivity on cortisol were tested with multilevel regression. Cortisol levels were significantly higher when individuals were alone. Although momentary affective states changed during solitude and were also associated with cortisol, they did not fully explain the effects of solitude on cortisol. Trait affectivity moderated the association between solitude and cortisol. Findings may help clarify how daily experience may heighten risk of depression or other negative health outcomes in vulnerable individuals.

Matic, Aleksandar; Osmani, Venet; Mayora, Oscar (Hg.) (2012):

Speech activity detection using accelerometer.

Engineering in Medicine and Biology Society (EMBC), 2012 Annual International Conference of the IEEE: IEEE.

Abstract:

The level of social activity is linked to the overall wellbeing and to various disorders, including stress. In this regard, a myriad of automatic solutions for monitoring social interactions have been proposed, usually including audio data analysis. Such approaches often face legal and ethical issues and they may also raise privacy concerns in monitored subjects thus affecting their natural behaviour. In this paper we present an accelerometer-based speech detection which does not require capturing sensitive data while being an easily applicable and a cost-effective solution.

An automated system for 24-h monitoring of cough frequency: the leicester cough monitor.

In: *Biomedical Engineering, IEEE Transactions on* 54 (8), S. 1472–1479.

Abstract:

The objective monitoring of cough for extended periods of time has long been recognized as an important step towards a better understanding of this symptom, and a better management of chronic cough patients. In this paper, we present a system for the automatic analysis of 24-h, continuous, ambulatory recordings of cough. The system uses audio recordings from a miniature microphone and the detection algorithm is based on statistical models of the time-spectral characteristics of cough sounds. We validated the system against manual counts obtained by a trained observer on 40 ambulatory recordings and our results show a median sensitivity value of 85.7%, median positive predictive value of 94.7% and median false positive rate of 0.8 events/h. An analysis application was developed, with a graphical user interface, allowing the use of the system in clinical settings by technical or medical staff. The result of the analysis of a recording session is presented as a concise, graphical-based report. The modular nature of the system interface facilitates its enhancement with the integration of further modules.

Matsumura, Kenta; Rolfe, Peter; Lee, Jihyoung; Yamakoshi, Takehiro (2014):

iPhone 4s Photoplethysmography: Which Light Color Yields the Most Accurate Heart Rate and Normalized Pulse Volume Using the iPhysioMeter Application in the Presence of Motion Artifact?

In: *PLoS One* 9 (3), S. e91205. DOI: 10.1371/journal.pone.0091205.

Abstract:

Recent progress in information and communication technologies has made it possible to measure heart rate (HR) and normalized pulse volume (NPV), which are important physiological indices, using only a smartphone. This has been achieved with reflection mode photoplethysmography (PPG), by using a smartphone's embedded flash as a light source and the camera as a light sensor. Despite its widespread use, the method of PPG is susceptible to motion artifacts as physical displacements influence photon propagation phenomena and, thereby, the effective optical path length. Further, it is known that the wavelength of light used for PPG influences the photon penetration depth and we therefore hypothesized that influences of motion artifact could be wavelength-dependant. To test this hypothesis, we made measurements in 12 healthy volunteers of HR and NPV derived from reflection mode plethysmograms recorded simultaneously at three different spectral regions (red, green and blue) at the same physical location with a smartphone. We then assessed the accuracy of the HR and NPV measurements under the influence of motion artifacts. The analyses revealed that the accuracy of HR was acceptably high with all three wavelengths (all rs > 0.996, fixed biases: -0.12 to 0.10 beats per minute, proportional biases: r = -0.29 to 0.03), but that of NPV was the best with green light (r = 0.791, fixed biases: -0.01 arbitrary units, proportional bias: r = 0.11). Moreover, the signal-to-noise ratio obtained with green and blue light PPG was higher than that of red light PPG. These findings suggest that green is the most suitable color for measuring HR and NPV from the reflection mode photoplethysmogram under motion artifact conditions. We conclude that the use of green light PPG could be of particular benefit in ambulatory monitoring where motion artifacts are a significant issue.

Matt, Alissa Anne Haedt (2013):

Ecological Momentary Assessment of Purging Disorder.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 74 (2-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99161-020%26site%3dehost-live.

Abstract:

Purging Disorder (PD) is characterized by purging after normal or small amounts of food among individuals who are not underweight. Several studies indicate that PD is associated with distress and impairment, underscoring the need for intervention. However, little is known about factors that trigger and maintain purging in PD. This study examined antecedents and consequences of purging using Ecological Momentary Assessment (EMA), a design that involved repeated assessments of current psychological states in participants' natural environments. Women with PD (N = 24) were recruited from the community to make multiple daily ratings of affect, shape/weight concerns, violation of dietary rules, and stomach discomfort using random-, interval-, and event-contingent recordings over a two-week period. Multilevel model analyses were used to examine between-day differences (purge versus non-purge day) and within-day changes in psychological variables relative to purging behavior. Results supported study hypotheses that negative affect and shape/weight concerns would be higher and positive affect would be lower on days when participants purged compared to days they did not purge. In addition, antecedent analyses supported within-day increases in negative affect, shape/weight concerns, and stomach discomfort prior to purging; however, only changes in positive affect and shape/weight concerns on purge days differed from naturally-occurring changes observed on non-purge days. For consequence analyses, negative affect, shape/weight concerns, and stomach discomfort decreased following purging on purge days, and trajectories of change were significantly different from non-purge days. Finally, exploratory analyses suggested that lower levels of impulsivity enhanced associations between antecedent affect and purging. These data are crucial to understand why women with PD purge after consuming normal or small amounts of food and may point to specific targets for the development of effective interventions. Mattocks, Calum; Leary, S. A. M.; Ness, Andy; Deere, Kevin; Saunders, Joanne; Kirkby, Joanne et al. (2007):

Intraindividual variation of objectively measured physical activity in children.

In: *Med Sci Sports Exerc* 39 (4), S. 622–629.

Abstract:

PURPOSE:

This study examined the seasonal and intraindividual variation in objectively measured physical activity in 11- to 12-yr-olds.

METHODS:

Children were asked to wear a uniaxial accelerometer for 7 d four times throughout the course of about a year. A random-intercepts model was used to separate the inter- and intraindividual components of physical activity. Gender, age, body mass index (BMI), height, and month of measurement were fitted to the model as potential confounders.

RESULTS:

A total of 315 children had valid data for at least two measurement occasions, and 244 had data for all four measurement occasions. The unadjusted intraclass correlation coefficient (ICC) for total activity (counts per minute) was 0.54; 0.49 after adjusting for gender, age, and BMI; and 0.53 after adjusting for gender, age, BMI, and month. Further adjustment for pubertal status at baseline had no effect on the ICC. Restricting the analysis to only those with data for all four measurement occasions (N=244), or to measurements taken on school days only, had no effect on the ICC. The fully adjusted ICC was 0.51 for weekdays only and 0.39 for weekend days only. For minutes of moderate to vigorous physical activity, minutes of vigorous activity, minutes of sedentary behavior, and number of 30-min blocks of sedentary behavior, the fully adjusted ICC were 0.45, 0.37, 0.59, and 0.39, respectively. The analysis was repeated for boys and girls separately, but the differences in ICC were small.

CONCLUSION:

There was substantial intraindividual variation in the objectively measured physical activity of these children. Studies using single a measurement occasion where physical activity is the exposure should take this into account to adjust for regression dilution.

Matzek, Brett A.; Fivecoat, Phillip T.; Ritz, Reis B. (2014):

Novel approach to the diagnosis of fractures in an austere environment using a stethoscope and a cellular phone.

In: *Wilderness Environ Med* 25 (1), S. 99–102. DOI: 10.1016/j.wem.2013.09.011.

Abstract:

BACKGROUND: Fracture diagnosis in the austere environment where radiographic tests are not available can be a challenge. In the past, a diagnostic technique has been described using a tuning fork and stethoscope to assess decreased sound conduction in the fractured extremity. In this study, we evaluate the use of a cellular phone's vibrate function and a stethoscope to limit equipment carried by expeditionary practitioners. OBJECTIVE: The purpose of this study was to evaluate the accuracy of fracture diagnosis using a cellular phone and stethoscope. METHODS: This is a pilot study to assess the usefulness of the above technique before clinical implementation. In 3 cadavers, we created fractures of the humerus and femur. Twenty-seven emergency medicine residents and an attending physician performed the diagnostic technique. RESULTS: Overall, the use of the cellular phone and stethoscope resulted in a sensitivity of 73% (95% confidence interval [CI]: 0.64 to 0.81) and a specificity of 83% (95% CI: 0.77 to 0.88), with a positive predicted value of 68% (95% CI: 0.59 to 0.77) and a negative predicted value of 86% (95% CI: 0.81 to 0.90). Positive likelihood ratio was 4.3, and negative likelihood ratio was 0.32. CONCLUSIONS: The use of a cellular phone and stethoscope may be a useful tool for the diagnosis of fractures in the austere environment. However, further study is needed to validate these findings in the clinical environment.

Mazze, Roger; Strock, Ellie; Morgan, Blaine; Wesley, David; Bergenstal, Richard; Cuddihy, Robert (2009):

Diurnal glucose patterns of exenatide once weekly: a 1-year study using continuous glucose monitoring with ambulatory glucose profile analysis.

In: *Endocrine practice : official journal of the American College of Endocrinology and the American Association of Clinical Endocrinologists* 15 (4), S. 326–334. DOI: 10.4158/EP09046.ORR.

Abstract:

OBJECTIVE\r\nTo use continuous glucose monitoring (CGM) to characterize diurnal glucose patterns produced by a novel formulation of exenatide consisting of biodegradable polymeric microspheres that entrap exenatide and provide extended release enabling once-weekly administration.\r\nMETHODS\r\nWe performed a subgroup analysis of patients with type 2 diabetes who participated in a multicenter trial (DURATION-1: Effects of Exenatide Long-Acting Release on Glucose Control and Safety in Subjects With Type 2 Diabetes Mellitus) comparing once-weekly with twice-daily formulations of exenatide. We are the only center to use CGM with ambulatory glucose profile (AGP) analysis to characterize glucose exposure, variability, and stability in participants assigned to exenatide once weekly.\r\nRESULTS\r\nSeven of the 303 patients in the larger study population were included in the subgroup analysis. Mean age (57.6 +/- 7 years), weight (102 +/- 17 kg), body mass index (34 +/- 3 kg/m2), and duration of diabetes (5 +/- 2 years) were comparable to characteristics of the larger study population. At 30 weeks and 52 weeks, participants treated with exenatide once weekly had a mean reduction in hemoglobin A1c level of 1.3 +/- 0.3% and 1.0 +/- 0.3%, respectively (P<.05). CGM analysis revealed a significant (P<.01) decrease in diurnal glucose exposure for 4 participants during nocturnal and daytime periods. Excess glucose exposure (compared with reference values) decreased in 6 of 7 participants, as did glucose variability. Glucose stability improved in 5 participants. The percentage of glucose values less than 70 mg/dL initially increased during the first half of the study then decreased to baseline levels by study end.\r\nCONCLUSIONS\r\nIndividual glucose profiles revealed that changes in hemoglobin A1c did not consistently parallel

alterations in glucose exposure, variability, and stability. AGPs provided a visual representation of improved glucose responses to exenatide once weekly.

McAuliff, Bradley D.; Kovera, Margaret Bull; Nunez, Gabriel (2009):

Can jurors recognize missing control groups, confounds, and experimenter bias in psychological science?

In: *Law and human behavior* 33 (3), S. 247–257. DOI: 10.1007/s10979-008-9133-0.

Abstract:

This study examined the ability of jury-eligible community members (N = 248) to detect internal validity threats in psychological science presented during a trial. Participants read a case summary in which an expert testified about a study that varied in internal validity (valid, missing control group, confound, and experimenter bias) and ecological validity (high, low). Ratings of expert evidence quality and expert credibility were higher for the valid versus missing control group versions only. Internal validity did not influence verdict or ratings of plaintiff credibility and no differences emerged as a function of ecological validity. Expert evidence quality, expert credibility, and plaintiff credibility were positively correlated with verdict. Implications for the scientific reasoning literature and for trials containing psychological science are discussed.

McCabe, K. O.; Fleeson, W. (2012):

What is extraversion for? Integrating trait and motivational perspectives and identifying the purpose of extraversion.

In: *Psychol.Sci.* 23 (12), S. 1498–1505. DOI: 10.1177/0956797612444904.

Abstract:

The purpose of this study was to determine whether the manifestation of extraversion (i.e., acting and being extraverted) in everyday behavior can be explained by intentional (functional) constructs, namely, goals. By using a model in which personality states serve as an outcome of specific, momentary goal pursuit, we were able to identify the function of extraversion states in everyday behavior. Using experience-sampling methodology, we asked participants to describe their state extraversion, goal pursuit, and state affect over 10 days. Results show that 18 selected goals predicted 74% of the variance in state extraversion; both within-person and between-person fluctuations in state extraversion were strongly associated with changes in momentary goal pursuit. We extended findings relating state extraversion and state positive affect, showing that the relationship between goals and positive affect was partially mediated by state extraversion

McCabe, Kira O.; MacK, Lori; Fleeson, William (2012):

A guide for data cleaning in experience sampling studies. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 321–338. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-018%26site%3dehost-live.

Abstract:

(from the chapter) The purpose of this chapter is to recommend strategies for preventing and identifying problems in personal digital assistant (PDA) data. We provide a guide for data cleaning procedures, which may promote and facilitate PDA usage in studies that employ experience sampling methodology (ESM). The literature lacks a clear discussion and standardization of how to detect errors in PDA data and how to prepare the data for analysis. It is important to clean PDA data properly for at least three reasons. First, careful cleaning ensures that PDA studies adhere to the rigorous standardization that is fundamental to psychological research. Second, proper data cleaning enhances the reliability, validity, and power of the data. Third, data cleaning prevents data errors from being compounded and exacerbated when conducting analyses, particularly analyses of individual differences in within-person effects. We are assuming that readers are familiar with ESM and other daily measures. However, for completeness, by ESM we denote a method that allows for repeated measurement of behavior states within the context of individuals' everyday lives. The cleaning step is sometimes the most difficult step in the whole process of conducting an ESM study, but researchers should not allow complexity of the data to prevent them from upholding rigorous scientific standards. In this chapter, we present several problems we have found when cleaning our own data, along with our

recommendations for identifying and solving these problems. Our approach in this chapter presumes use of certain kinds of technology; specifically, we use Palm Z22 PDAs with the Experience Sampling Program (ESP; Barrett & Feldman Barrett, 2000), which interfaces with the Palm OS platform. However, the techniques are generalizable across technologies, with adaptation. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

McCance, Andrea Silke (2012):

Emotional labor in intercultural service encounters: An experience sampling study.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (7-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99020-432&site=ehost-live.

Abstract:

The body of literature surrounding emotional labor, defined as service employees' effort to manage their emotions to meet organizational goals (Hochschild, 1983; Morris & Feldman, 1996), exhibits a severe lack of studies examining intercultural service encounters (i.e., service episodes in which a provider from culture A delivers a service to a customer from culture B; Stauss & Mang, 1999). This dissertation posits an intrapersonal model of emotional labor in intercultural service encounters. Central to this model is the construct of cultural competence (Earley & Ang, 2003), which is defined as the ability to adapt effectively and flexibly in culturally diverse settings. Using experience sampling methodology with a hospitality industry sample, I found that cultural competence was associated with deep acting and performance. Openness to experience predicted cultural competence through active seeking of multicultural experience (i.e., multicultural personality). Implications for the selection (based on openness) and training (for deep acting and cultural competence) of service providers in an increasingly globalized service industry are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

McCarthy, Danielle E.; Piasecki, Thomas M.; Fiore, Michael C.; Baker, Timothy B. (2006):

Life before and after quitting smoking: an electronic diary study.

In: *Journal of Abnormal Psychology* 115 (3), S. 454–466. DOI: 10.1037/0021-843X.115.3.454.

Abstract:

This article describes a multidimensional, multivariate, and multilevel approach to the assessment of nicotine withdrawal. In this prospective study, 70 adult smokers assigned to an active or placebo nicotine patch condition completed multiple daily assessments using an electronic diary. Average and individual growth curves were estimated for affective and nonaffective withdrawal symptoms. All symptoms but hunger increased significantly on the quit day and remained elevated for three weeks. Variability in symptom experiences across individuals increased from pre- to post-quit. Relations between symptom reports (e.g., negative affect or craving) and episodic events (e.g., stressful events or seeing someone smoke) changed from pre-quit to post-quit. Pre-quit increases in negative affect and quit-day increases in craving were inversely related to abstinence three months after the quit day, suggesting that anticipatory and immediate reactions to quitting influence success.

McCarthy, Danielle E.; Piasecki, Thomas M.; Lawrence, Daniel L.; Jorenby, Douglas E.; Shiffman, Saul; Baker, Timothy B. (2008):

Psychological mediators of bupropion sustained-release treatment for smoking cessation.

In: *Addiction* 103 (9), S. 1521–1533.

Abstract:

AIM:

The study aimed to test simultaneously our understanding of the effects of bupropion sustained-release (SR) treatment on putative mediators and our understanding of determinants of post-quit abstinence, including withdrawal distress, cigarette craving, positive affect and subjective reactions to cigarettes smoked during a lapse. The specificity of bupropion SR effects was also tested in exploratory analyses.

DESIGN:

Data from a randomized, placebo-controlled clinical trial of bupropion SR were submitted to mediation analyses.

SETTING:

Center for Tobacco Research and Intervention, Madison, WI, USA.

PARTICIPANTS:

A total of 403 adult, daily smokers without contraindications to bupropion SR use.

INTERVENTION:

Participants were assigned randomly to receive a 9-week course of bupropion SR or placebo pill and to receive eight brief individual counseling sessions or no counseling.

MEASUREMENTS:

Ecological momentary assessment ratings of smoking behavior and putative mediators were collected pre- and post-quit.

FINDINGS:

Results of structural equation and hierarchical linear models did not support the hypothesis that bupropion SR treatment improves short-term abstinence by reducing withdrawal distress or affecting the subjective effects of a lapse cigarette, but provided partial support for mediation by cigarette craving reduction and enhanced positive affect. Bupropion SR effects on point-prevalence abstinence at 1 month post-quit were also mediated partially by enhanced motivation to quit and self-efficacy.

CONCLUSIONS:

Results provided some support for models of bupropion SR treatment and relapse and suggested that motivational processes may partially account for bupropion SR efficacy.

McClain, James J.; Sisson, Susan B.; Washington, Tracy L.; Craig, Cora L.; Tudor-Locke, Catrine (2007):

Comparison of Kenz Lifecorder EX and ActiGraph accelerometers in 10-yr-old children.

In: *Med Sci Sports Exerc* 39 (4), S. 630.

Abstract:

A new accelerometer, the Kenz Lifecorder EX (LC; Suzuken Co. Ltd, Nagoya, Japan), offers promise as a feasible monitor alternative to the commonly used Actigraph (AG: Actigraph LLC, Fort Walton Beach, FL).

PURPOSE:

This study compared the LC and AG accelerometers and the Yamax SW-200 pedometer (DW) under free-living conditions with regard to children's steps taken and time in light-intensity physical activity (PA) and moderate to vigorous PA (MVPA).

METHODS:

Participants (N=31, age=10.2 +/- 0.4 yr) wore LC, AG, and DW monitors from arrival at school (7:45 a.m.) until they went to bed. Time in light and MVPA intensities were calculated using two separate intensity classifications for the LC (LC_4 and LC_5) and four classifications for the AG (AG_Treuth, AG_Puyau, AG_Trost, and AG_Freedson). Both accelerometers provided steps as outputs. DW steps were self-recorded. Repeated-measures ANOVA was used to assess overlapping monitor outputs.

RESULTS:

There was no difference between DW and LC steps (Delta=200 steps), but a nonsignificant trend was observed in the pairwise comparison between DW and AG steps (Delta=1001 steps, P=0.058). AG detected significantly greater steps than the LC (Delta=801 steps, P=0.001). Estimates of light-intensity activity minutes ranged from a low of 75.6 +/- 18.4 min (LC_4) to a high of 309 +/- 69.2 min (AG_Treuth). Estimates of MVPA minutes ranged from a low of 25.9 +/- 9.4 min (LC_5) to a high of 112.2 +/- 34.5 min (AG_Freedson). No significant differences in MVPA were seen between LC_5 and AG_Treuth (Delta=4.9 min) or AG_Puyau (Delta=1.7 min).

CONCLUSION:

The LC detected a comparable number of steps as the DW but significantly fewer steps than the AG in children. Current results indicate that the LC_5 and either AG_Treuth or AG_Puyau intensity derivations provide similar mean estimates of time in MVPA during-free living activity in 10-yr-old children.

Deconstructing alcohol use on a night out in england: Promotions, preloading and consumption.

In: *Drug and Alcohol Review*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-19277-001%26site%3dehost-live.

Abstract:

Abstract Introduction and Aims To examine alcohol consumed during a drinking event (a single drinking occasion) by those attending public house/on-trade establishments on nights with standard pricing and nights with promotional prices. Design and Methods Data (n = 425) were collected in an ecological momentary assessment over eight nights in two locations (Midlands and London) on both promotional and standard (Saturday) nights. Multiple regression was used to predict event alcohol consumption by sex, age, type of night, alcohol preloading behaviour, marital and employment status, education, Alcohol Use Disorders Identification Test alcohol consumption questions separately or total AUDIT-C and social group size. Results Mean (UK) units consumed were 11.8 (London) and 14.4 (Midlands). In London, consumption was similar on promotional and standard nights, but in the Midlands, standard night consumption was three units higher. Preloading was reported by 30%; more common on standard nights. Regression analyses revealed being male, preloading and past-year total AUDIT-C were associated with higher event consumption. However, when AUDIT-C questions were added separately, being a standard night was associated with increased event consumption and different AUDIT-C questions were significantly associated with event consumption in each location. Discussion and Conclusions Event consumption reflected heavy episodic drinking and was influenced by price. Promotional night consumption either matched standard Saturday night consumption or was slightly lower. In London, there was a significant preference for drinking at least one promotional beverage on promotional nights. On standard nights, consumption was over a wider range of venues, and preloading with off-trade alcohol was more likely. [McClatchley K, Shorter GW, Chalmers J. Deconstructing alcohol use on a night out in England: Promotions, preloading and consumption. Drug Alcohol Rev 2014] (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

I Am Your Smartphone and I Know You Are About to Smoke: The Application of Mobile Sensing and Computing Approaches to Smoking Research and Treatment.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt054.

Abstract:

Much is known about the immediate and predictive antecedents of smoking lapse, which include situations (e.g., presence of other smokers), activities (e.g., alcohol consumption), and contexts (e.g., outside). This commentary suggests smartphone-based systems could be used to infer these predictive antecedents in real time and provide the smoker with just-in-time intervention. The smartphone of today is equipped with an array of sensors, including GPS, cameras, light sensors, barometers, accelerometers, and so forth, that provide information regarding physical location, human movement, ambient sounds, and visual imagery. We propose that libraries of algorithms to infer these antecedents can be developed and then incorporated into diverse mobile research and personalized treatment applications. While a number of challenges to the development and implementation of such applications are recognized, our field benefits from a database of known antecedents to a problem behavior, and further research and development in this exciting area are warranted

McClung, Holly L.; Sigrist, Lori D.; Smith, Tracey J.; Karl, J. Philip; Rood, Jennifer C.; Young, Andrew J.; Bathalon, Gaston P. (2009):

Monitoring energy intake: a hand-held personal digital assistant provides accuracy comparable to written records.

In: *Journal of the American Dietetic Association* 109 (7), S. 1241–1245. DOI: 10.1016/j.jada.2009.04.015.

Abstract:

New approaches to assess energy intake (EI) may have advantages over traditional written methods, but validity of these emerging methodologies must be demonstrated. This exploratory study compared EI obtained using a hand-held personal digital assistant (PDA) and traditional written records with total energy expenditure measured by doubly labeled water (TEE(DLW)). Twenty-six volunteers (aged 23+/-4 years, body mass index [calculated as kg/m(2)] 24+/-2) participated in a randomized (either PDA or written record group) and matched (for sex, age, and body mass index) study for 7 consecutive days between June 2005 and April 2006 to record EI. Group comparisons were made with t and Mann-Whitney U tests. Bland-Altman

plots were used to compare limits of agreement between methods. Volunteers remained weight stable during the study period (0.2+/-0.8 kg; P>0.05). Reported EI by written record and PDA were similar to TEE(DLW); 105% vs 92% of TEE(DLW), respectively (P>0.05). There was a significant relationship between reported EI by PDA and TEE(DLW) (r=0.60, P<0.05), but not for written record (r=0.45, P>0.05). Limits of agreement indicated both written record and PDA had large variability (range 1,394 to -1,472 kcal/day). Findings suggest the bias in using a PDA is similar to that observed when using a written record for estimation of EI in weight-stable volunteers.

The Remote Monitoring of Smoking in Adolescents.

In: *Adolesc Psychiatry (Hilversum)* 3 (2), S. 156–162. DOI: 10.2174/2210676611303020006.

Abstract:

BACKGROUND/OBJECTIVES: Cigarette smoking remains the leading cause of preventable death in the United States with the vast majority of adult smokers starting prior to the age of 18. Despite the public health relevance and implications of studying smoking in adolescents, little is known about the initiation of quit attempts, the process of relapse, and the most efficacious treatment interventions in this high-risk and underserved population. Issues such as retention in research studies and accuracy of self-reports have prompted investigators to explore innovative technology-based systems to integrate into treatment studies and services delivery. METHODS: This paper will review the remote monitoring of smoking through means of ecological momentary assessment, biochemical verification of smoking verified through video capture, physiological monitoring, and mobile-delivered interventions using self-reported smoking outcomes in adolescents, when applicable. RESULTS: Use of remote monitoring methods in adolescent smokers has been limited thus far, though monitoring technology in adults has shown promise for understanding relapse and delivering treatment interventions. CONCLUSIONS: Comprehensive technology-based systems that do not rely primarily on self-report to monitor smoking would be a highly fruitful and innovative avenue to explore with adolescent smokers. Technology integration holds great promise to improve health-related research, treatment delivery, cost-effectiveness, and just-in-time interventions, but its novelty comes with unique problems and concerns to be carefully considered.

McCormick, Bryan P.; Frey, Georgia; Lee, Chien-Tsung; Chun, Sanghee; Sibthorp, Jim; Gajic, Tomislav et al. (2008):

Predicting transitory mood from physical activity level among people with severe mental illness in two cultures.

In: *The International journal of social psychiatry* 54 (6), S. 527–538. DOI: 10.1177/0020764008091423.

Abstract:

BACKGROUND\r\nPrevious studies have indicated that physical activity (PA) is positively related to health-related quality of life and well-being among people with severe mental illness (SMI). Physical activity is broadly defined in this research as any skeletal muscle movement resulting in energy expenditure, including common daily activities such as housework and gardening, as well as walking for transportation and formal exercise. Although the physical health benefits of PA are well documented, evidence suggests that PA provides psychological benefits as well.\r\nAIMS\r\nThe purpose of this study was to identify if PA level was associated with transitory mood in the everyday lives of people with SMI across two cultures.\r\nMETHODS\r\nSubjects were drawn through mental health centres in Serbia (n = 12) and the USA (n = 11). Data were collected using both experience sampling methodology and accelerometry. Data were analyzed using hierarchical linear modelling.\r\nRESULTS\r\nSubjects demonstrated low levels of PA, which did not differ significantly between groups. Hierarchical analysis indicated that PA remained significantly positively associated with mood after accounting for individual variation, and this was consistent across groups.\r\nCONCLUSIONS\r\nThis study reinforces previous findings that people with SMI demonstrate low PA levels generally. It also supports the consideration of physical activity interventions as a regular part of psychiatric rehabilitation. It appears that increased PA may have the potential to affect both physical health and mood among people with SMI.

McCormick, B. P.; Frey, G. C.; Lee, C-T; Gajic, T.; Stamatovic-Gajic, B.; Maksimovic, M. (2009):

A pilot examination of social context and everyday physical activity among adults receiving Community Mental Health Services.

In: *Acta Psychiatrica Scandinavica* 119 (3), S. 243–247. DOI: 10.1111/j.1600-0447.2008.01331.x.

Abstract:

OBJECTIVE\r\nCommunity mental health center (CMHC) clients include a variety of people with moderate to severe mental illnesses who also report a number of physical health problems. Physical activity (PA) has been identified as one intervention to improve health among this population; however, little is known about the role of social context in PA. The purpose of this study was to examine the role of social context in everyday PA among CMHC clients.\r\nMETHOD\r\nData were collected from CMHC clients in two cultures using accelerometery and experience sampling methods. Data were analyzed using hierarchical linear modeling.\r\nRESULTS\r\nIndependence in housing nor culture was significantly associated with levels of PA. Being alone was significantly negatively related to PA level.\r\nCONCLUSION\r\nSocial isolation appears to be negatively related to PA at the level of everyday life. Physical activity interventions with this population should consider including social components as a part of PA.

McCrae, C. S.; Vatthauer, K. E.; Dzierzewski, J. M.; Marsiske, M. (2012):

Habitual Sleep, Reasoning, and Processing Speed in Older Adults with Sleep Complaints.

In: *Cognit.Ther.Res* 36 (2), S. 156–164. DOI: 10.1007/s10608-011-9425-4.

Abstract:

The relationship between habitual sleep and cognition in older adults with sleep complaints is poorly understood, because research has focused on younger adults, used experimental or retrospective quasi-experimental designs, and generally produced equivocal results. Prospective studies using sleep diaries are rare, but may provide important insights into this relationship as they offer greater ecological validity and allow for examination of the impact of night-to-night variability in sleep (an often overlooked aspect of sleep) on cognitive performance. Seventy-two older adults (M(age) = 70.18 years, SD(age) = 7.09 years) completed fourteen consecutive days of sleep diaries and paper/pencil self-administered cognitive tasks, including measures of processing speed (Symbol Digit) and reasoning (Letter Series). Regression analyses revealed increased average total wake time (TWT) during the night was associated with higher Symbol Digit scores, beta = 0.45, P < 0.05. Night-to-night variability in either total sleep time (TST) or TWT was not associated with either cognitive measure. Implications and potential explanations for these initially counterintuitive findings are discussed

McCrorie, Paul Rw; Fenton, Candida; Ellaway, Anne (2014):

Combining GPS, GIS, and accelerometry to explore the physical activity and environment relationship in children and young people - a review.

In: *Int J Behav Nutr Phys Act* 11 (1), S. 93. DOI: 10.1186/s12966-014-0093-0.

Abstract:

The environment has long been associated with physical activity engagement, and recent developments in technology have resulted in the ability to objectively quantify activity behaviours and activity context. This paper reviews studies that have combined Global Positioning Systems (GPS), Geographic Information Systems (GIS) and accelerometry to investigate the PA-environment relationship in children and young people (5-18 years old). Literature searches of the following bibliographic databases were undertaken: Sportdiscus, Medline, Embase, CINAHL, Psychinfo and Applied Social Sciences Index and Abstracts (ASSIA). Fourteen studies met the inclusion criteria, and covered topics including greenspace use, general land use, active travel, and the built environment. Studies were largely cross-sectional and took place across developed countries (UK, USA, Canada, New Zealand, and Australia). Findings suggest that roads and streets, school grounds, and the home location are important locations for total PA, and moderate to vigorous PA (MVPA). The relationship between greenspace was positive, however, multiple definitions and outcome measures add complexity to the results. MVPA was more likely in those exposed to higher levels of greenspace compared to sedentary individuals. Total MVPA time in greenspace is low, but when framed as a proportion of the total can be quite high. Domestic gardens may be an important area for higher intensity activity.Researchers are encouraged to show transparency in their methods. As a relatively new area of research, with ever-evolving technology, future work is best placed in developing novel, but robust, methods to investigate the PA and environment relationship. Further descriptive work is encouraged to build on a small but increasing knowledge base; however, longitudinal studies incorporating seasonal/weather variation would also be extremely beneficial to elicit some of the nuances associated with land use. A greater understanding of geographic variation (i.e. within and between countries), as well as urban/suburban and rural dwelling is welcomed, and future work should also include the investigation of psycho-social health as an outcome, as well as differences in socio-economic status, sex and adiposity.

McDermott, Mary M.; Ades, Philip A.; Dyer, Alan; Guralnik, Jack M.; Kibbe, Melina; Criqui, Michael H. (2008):

Corridor-based functional performance measures correlate better with physical activity during daily life than treadmill measures in persons with peripheral arterial disease.

In: *Journal of vascular surgery* 48 (5), S. 1231-7, 1237.e1. DOI: 10.1016/j.jvs.2008.06.050.

Abstract:

OBJECTIVE\r\nTo compare associations of physical activity during daily life with treadmill walking performance and corridor-based functional performance measures in persons with lower extremity peripheral arterial disease (PAD).\r\nSTUDY DESIGN\r\nCross-sectional.\r\nSUBJECTS\r\nOne hundred fifty-six men and women with PAD who completed baseline measurements and were randomized into the study to improve leg circulation (SILC) exercise clinical trial.\r\nMAIN OUTCOME MEASURES\r\nParticipants completed a Gardner-Skinner treadmill protocol. Corridor-based functional performance measures were the 6-minute walk, walking velocity over four meters at usual and fastest pace, and the short physical performance battery (SPPB) (0-12 scale, 12 = best). Physical activity during daily life was measured continuously over 7 days with a Caltrac (Muscle Dynamics Fitness Network, Inc, Torrence, Calif) accelerometer.\r\nRESULTS\r\nAdjusting for age, gender, and race, higher levels of physical activity during daily life were associated with greater distance achieved in the 6-minute walk (P trend = .001), faster fast-paced four-meter walking velocity (P trend < .001), faster usual-paced four-meter walking speed (P trend = .027) and a higher SPPB (P trend = .005). The association of physical activity level with maximum treadmill walking distance did not reach statistical significance (P trend = .083). There were no associations of physical activity with treadmill distance to onset of leg symptoms (P trend = .795).\r\nCONCLUSION\r\nFunctional performance measures are more strongly associated with physical activity levels during daily life than treadmill walking measures.

McDoniel, Scott O.; Wolskee, Patricia; Shen, Jeff (2010):

Treating obesity with a novel hand-held device, computer software program, and Internet technology in primary care: the SMART motivational trial.

In: *Patient education and counseling* 79 (2), S. 185–191. DOI: 10.1016/j.pec.2009.07.034.

Abstract:

OBJECTIVE\r\nThe purpose of this study was to evaluate the short-term motivational effect of a technology-based weight reduction program for obese adults.\r\nMETHODS\r\nOne hundred and eleven obese (37.0+/-5.8 kg/m(2)) middle aged (45.5+/-10.8 years) adults (62% female) were randomly assigned to a usual care or experimental (SMART: self-monitoring and resting metabolic rate technology) group. The usual care group received a standard nutritional program in accordance to national guidelines. All participants received a comprehensive weight management program consisting of motivational interviewing (MI) sessions and automated e-mail behavioral newsletters. Bodyweight, arterial blood pressure, and psychobehavioral constructs were assessed over 12 weeks.\r\nRESULTS\r\nCompleter analysis (n=80) indicated a significant improvement in bodyweight (-3.9%), systolic arterial pressure (-4 mmHg), and all motivational constructs following the 12-week study (p<or=.05). However, there were no significant differences between groups at any time period.\r\nCONCLUSION\r\nBased on these data, a 12-week comprehensive weight reduction program consisting of MI and automated e-mail behavioral newsletters with or without SMART is efficacious in treating obese adults.\r\nPRACTICE IMPLICATIONS\r\nAlthough both treatment programs were equally effective, clinicians should consider a treatment program that meets the need of the patient. This study was registered at ClinicalTrails.gov NCT00750022.

Ambulatory impedance cardiography in hypertension: a validation study.

In: *Eur J Cardiovasc Nurs* 7 (3), S. 204–213.

Abstract:

The management of hypertension is improved by knowledge of the hemodynamics underlying blood pressure. Impedance Cardiography (ICG) provides data on a range of hemodynamic variables that affect blood pressure. However, ICG captures only fixed descriptions of hemodynamic characteristics. Improvements in ambulatory technology have led to the development of the Ambulatory Impedance Monitor (AIM) which records hemodynamic data during the activities of daily living. The purpose of this study was to evaluate the sensitivity of the AIM to detect hemodynamic changes associated with postural shift in persons with hypertension. Using a repeated measures cross-over design, sitting and standing hemodynamic measures were taken in seventeen persons with hypertension while wearing the AIM-BpTRU system designed for standard office use and the AIM-Spacelabs system designed for ambulatory monitoring. Both AIM-blood pressure monitoring systems detected significant changes from sitting to standing posture in heart rate (p=0.03), stroke volume (p=0.002), left ventricular ejection time (p<0.001),

systemic vascular resistance (p=0.03) and diastolic blood pressure (p<0.001). Additionally, both systems generated measures of cardiac function that were positively correlated (p<0.001) and not significantly different (p>0.05). Our findings support previous work and demonstrate that the AIM provides valid and reliable estimates of cardiac function in persons with hypertension.

McGarty, Arlene M.; Penpraze, Victoria; Melville, Craig A. (2014):

Accelerometer use during field-based physical activity research in children and adolescents with intellectual disabilities: A systematic review.

In: *Res Dev Disabil* 35 (5), S. 973–981. DOI: 10.1016/j.ridd.2014.02.009.

Abstract:

Many methodological questions and issues surround the use of accelerometers as a measure of physical activity during field-based research. To ensure overall research quality and the accuracy of results, methodological decisions should be based on study research questions. This paper aims to systematically review accelerometer use during field-based research in children and adolescents with intellectual disabilities. Medline, Embase, Cochrane Library, Web of Knowledge, PsycINFO, PubMed, and a thesis database (up to May 2013) were searched to identify relevant articles. Articles which used accelerometry-based monitors, quantified activity levels, and included ambulatory children and adolescents (</=18 years) with intellectual disabilities were included. Based on best practice guidelines, a form was developed to extract data based on 17 research components of accelerometer use. The search identified 429 articles. Ten full-text articles met the criteria and were included in the review. Many shortcomings in accelerometer use were identified, with the percentage of review criteria met ranging from 12% to 47%. Various methods of accelerometer use were reported, with most use decisions not based on population-specific research. However, a lack of measurement research, e.g., calibration/validation, for children and adolescents with intellectual disabilities is limiting the ability of field-based researchers to make to the most appropriate accelerometer use decisions. The methods of accelerometer use employed can have significant effects on the quality and validity of results produced, which researchers should be more aware of. To allow informed use decisions, there should be a greater focus on measurement research related to children and adolescents with intellectual disabilities.

McGillicuddy, J. W.; Gregoski, M. J.; Weiland, A. K.; Rock, R. A.; Brunner-Jackson, B. M.; Patel, S. K. et al. (2013):

Mobile Health Medication Adherence and Blood Pressure Control in Renal Transplant Recipients: A Proof-of-Concept Randomized Controlled Trial.

In: *JMIR.Res Protoc.* 2 (2), S. e32. DOI: 10.2196/resprot.2633.

Abstract:

BACKGROUND: Mobile phone based programs for kidney transplant recipients are promising tools for improving long-term graft outcomes and better managing comorbidities (eg, hypertension, diabetes). These tools provide an easy to use self-management framework allowing optimal medication adherence that is guided by the patients' physiological data. This technology is also relatively inexpensive, has an intuitive interface, and provides the capability for real-time personalized feedback to help motivate patient self-efficacy. Automated summary reports of patients' adherence and blood pressure can easily be uploaded to providers' networks helping reduce clinical inertia by reducing regimen alteration time. OBJECTIVE: The aim of this study was to assess the feasibility, acceptability, and preliminary outcomes of a prototype mobile health (mHealth) medication and blood pressure (BP) self-management system for kidney transplant patients with uncontrolled hypertension. METHODS: A smartphone enabled medication adherence and BP self-management system was developed using a patient and provider centered design. The development framework utilized self-determination theory with iterative stages that were guided and refined based on patient/provider feedback. A 3-month proof-of-concept randomized controlled trial was conducted in 20 hypertensive kidney transplant patients identified as non-adherent to their current medication regimen based on a month long screening using an electronic medication tray. Participants randomized to the mHealth intervention had the reminder functions of their electronic medication tray enabled and received a bluetooth capable BP monitor and a smartphone that received and transmitted encrypted physiological data and delivered reminders to measure BP using text messaging. Controls received standard of care and their adherence continued to be monitored with the medication tray reminders turned off. Providers received weekly summary reports of patient medication adherence and BP readings. RESULTS: Participation and retention rates were 41/55 (75%) and 31/34 (91%), respectively. The prototype system appears to be safe, highly acceptable, and useful to patients and providers. Compared to the standard care control group (SC), the mHealth intervention group exhibited significant improvements in medication adherence and significant reductions in clinic-measured systolic blood pressures across the monthly evaluations. Physicians made more anti-hypertensive medication adjustments in the mHealth group versus the standard care group (7 adjustments in 5 patients versus 3 adjustments in 3 patients) during the 3-month trial based on the information provided in the weekly reports. CONCLUSIONS: These data support the acceptability and feasibility of the prototype mHealth system. Further trials with larger sample sizes and additional biomarkers (eg, whole blood medication levels) are needed to

examine efficacy and effectiveness of the system for improving medication adherence and blood pressure control after kidney transplantation over longer time periods. McGowan, Neil J.; Gough, Kathleen; Padfield, Paul L. (2009):

Nocturnal dipping is reproducible in the long term.

In: *Blood Press Monit* 14 (5), S. 185–189. DOI: 10.1097/MBP.0b013e32832ff4e1.

Abstract:

OBJECTIVE\r\nTo examine the long-term reproducibility of nocturnal dipping as a dichotomous and continuous variable.\r\nMETHODS\r\nRetrospective review of an ambulatory blood pressure monitor (ABPM) database of approximately 15 000 patients. Reproducibility of ABPM was assessed by repeatability coefficient. Kappa (kappa) statistic and intraclass correlation coefficient were used to quantify dipping as a dichotomous and continuous variable, respectively.\r\nRESULTS\r\nThere were 512 never-treated patients with two ABPM assessments, a mean of 29 (+/-19) months apart. Blood pressure was 2/0 mmHg (awake) and 2/1 mmHg (asleep) higher on the second ABPM. The repeatability coefficient for awake systolic and awake diastolic pressure was 5.9 and 6.2%, respectively. When the dipper/non-dipper (dichotomous) classification was applied to both ABPMs, dipping status was unchanged in 76% of patients, kappa = 0.29. When nocturnal dip was expressed as a continuous variable, the mean nocturnal dip was 14% and the median absolute change between assessments was 3.8%, intraclass correlation coefficient = 0.60. The time interval between assessments was subdivided into (i) within 6 months, (ii) 6 months to 1 year, (iii) 1-2 years, (iv) 2-3 years and (v) more than 3 years. There was remarkable consistency independent of time interval for dipping expressed as a continuous variable but not as dipper/non-dipper.\r\nCONCLUSION\r\nThese findings show that in the long term, nocturnal dip is more stable when expressed as a continuous variable. As recent evidence show cardiovascular risk to be inversely related to nocturnal blood pressure in a continuous manner, surely it makes more sense to express nocturnal dip in a similar way to aid stratification of overall cardiovascular risk.

McGregor, Stephen J.; Busa, Michael A.; Skufca, Joseph; Yaggie, James A.; Bollt, Erik M. (2009):

Control entropy identifies differential changes in complexity of walking and running gait patterns with increasing speed in highly trained runners.

In: *Chaos (Woodbury, N.Y.)* 19 (2), S. 26109. DOI: 10.1063/1.3147423.

Abstract:

Regularity statistics have been previously applied to walking gait measures in the hope of gaining insight into the complexity of gait under different conditions and in different populations. Traditional regularity statistics are subject to the requirement of stationarity, a limitation for examining changes in complexity under dynamic conditions such as exhaustive exercise. Using a novel measure, control entropy (CE), applied to triaxial continuous accelerometry, we report changes in complexity of walking and running during increasing speeds up to exhaustion in highly trained runners. We further apply Karhunen-Loeve analysis in a new and novel way to the patterns of CE responses in each of the three axes to identify dominant modes of CE responses in the vertical, mediolateral, and anterior/posterior planes. The differential CE responses observed between the different axes in this select population provide insight into the constraints of walking and running in those who may have optimized locomotion. Future comparisons between athletes, healthy untrained, and clinical populations using this approach may help elucidate differences between optimized and diseased locomotor control.

McKee, Heather C.; Ntoumanis, Nikos; Taylor, Ian M. (2014):

An Ecological Momentary Assessment of Lapse Occurrences in Dieters.

In: *Ann Behav Med. DOI:* 10.1007/s12160-014-9594-y.

Abstract:

PURPOSE: The aim of this study is to investigate the factors related to dietary lapse occurrence in a community sample of dieters. METHODS: An ecological momentary assessment (EMA) methodology, via mobile phone-based diaries, was employed to record dietary lapse occurrences in a group of dieters (N = 80; M age = 41.21 +/- 15.60 years; M BMI = 30.78 +/- 7.26) over 7 days. RESULTS: Analyses indicated that lapses were positively associated with the strength of dietary temptation, presence of others, coping responses, and the environment (exposure to food cues) in which the dieters were in; lapses were more likely to occur in the evening and were negatively associated with the use of coping mechanisms. Additionally, lapse occurrence was

found to mediate the relationships among the above predictors of lapse and the self-efficacy to resist future dietary temptations. CONCLUSIONS: Results provide an insight into the occurrence of lapses in dieters and have implications for interventions focusing on weight loss maintenance and relapse prevention.

McKee, Stephanie; Smith, Heather J.; Koch, Aubrey; Balzarini, Rhonda; Georges, Marissa; Callahan, Matthew Paolucci (2013):

Looking up and seeing green: Women's everyday experiences with physical appearance comparisons.

In: *Psychology of Women Quarterly* 37 (3), S. 351–365. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-27656-006%26site%3dehost-live;heather.smith@sonoma.edu.

Abstract:

Psychological research documents the extent to which physical appearance comparisons are associated with negative emotional experiences, but researchers typically study physical appearance comparisons isolated from other comparison experiences. As part of a signal-contingent experience sampling design, 87 female undergraduate students recorded whether they had made any comparison about any topic after they received a text message at three randomly chosen times a day for 7 days. In contrast to other comparisons, physical appearance comparisons were more likely to be upward contrasts to dissimilar targets associated with increased envy, less inspiration, less pride, and less anxiety. Women who reported more demographically similar close friends reported more envy following physical appearance comparisons in contrast to women who reported more demographically diverse close friends. Women who associated their body with a better quality of life reported more inspiration and less envy following physical appearance comparisons. More demographically diverse close friends and a more positive body image may protect women from the negative emotional consequences associated with physical appearance comparisons. These data indicate that the positive benefits for interpersonal judgments associated with close cross-group friends extend to intrapersonal reactions to physical appearance comparisons. McKibbin, Christine L.; Patterson, Thomas L.; Norman, Gregory; Patrick, Kevin; Jin, Hua; Roesch, Scott et al. (2006):

A lifestyle intervention for older schizophrenia patients with diabetes mellitus: a randomized controlled trial.

In: *Schizophrenia Research* 86 (1), S. 36–44.

Abstract:

PURPOSE:

We tested the feasibility and preliminary efficacy of a lifestyle intervention for middle-aged and older patients with schizophrenia and type-2 diabetes mellitus, using a randomized pre-test, post-test control group design.

METHOD:

Individuals with a diagnosis of schizophrenia or schizoaffective disorder over the age of 40 were randomly assigned to 24-week Diabetes Awareness and Rehabilitation Training (DART; n=32) groups or Usual Care plus Information (UCI; n=32) comparison groups. Participants were recruited from board-and-care facilities and day treatment programs. Fifty-seven patients completed baseline and 6-month assessments consisting of an interview, measures of body mass index, blood pressure, fasting blood chemistry, and accelerometry. A mixed-model analysis of variance was used to analyze the data.

RESULTS:

A significant group x time interaction was found for body weight, with patients in the DART group losing a mean of 5 lb and those in the UCI gaining a mean 6 lb. Significant group x time interactions were also found for triglycerides, diabetes knowledge, diabetes self-efficacy, and self-reported physical activity, but not for fasting plasma glucose or glycosylated hemoglobin.

CONCLUSIONS:

Group-based lifestyle interventions are feasible and produce positive health changes in middle-aged and older patients with schizophrenia and diabetes mellitus.

McKinstry, B.; Hanley, J.; Wild, S.; Pagliari, C.; Paterson, M.; Lewis, S. et al. (2013):

Telemonitoring based service redesign for the management of uncontrolled hypertension: multicentre randomised controlled trial.

In: *BMJ* 346 (0959-535X (Linking)), S. f3030. Online verfügbar unter PM:23709583.

Abstract:

OBJECTIVE: To determine if an intervention consisting of telemonitoring and supervision by usual primary care clinicians of home self measured blood pressure and optional patient decision support leads to clinically important reductions in daytime systolic and diastolic ambulatory blood pressure in patients with uncontrolled blood pressure. DESIGN: Multicentre randomised controlled trial. SETTING: 20 primary care practices in south east Scotland. PARTICIPANTS: 401 people aged 29-95 years with uncontrolled blood pressure (mean daytime ambulatory measurement >/=135/85 mm Hg but </=210/135 mm Hg). INTERVENTION: Self measurement and transmission of blood pressure readings to a secure website for review by the attending nurse or doctor and participant, with optional automated patient decision support by text or email for six months. MAIN OUTCOME MEASURES: Blinded assessment of mean daytime systolic ambulatory blood pressure six months after randomisation. RESULTS: 200 participants were randomised to the intervention and 201 to usual care; primary outcome data were available for 90% of participants (182 and 177, respectively). The mean difference in daytime systolic ambulatory blood pressure adjusted for baseline and minimisation factors between intervention and usual care was 4.3 mm Hg (95% confidence interval 2.0 to 6.5; P=0.0002) and for daytime diastolic ambulatory blood pressure was 2.3 mm Hg (0.9 to 3.6; P=0.001), with higher values in the usual care group. The intervention was associated with a mean increase of one general practitioner (95% confidence interval 0.5 to 1.6; P=0.0002) and 0.6 (0.1 to 1.0; P=0.01) practice nurse consultations during the course of the study. CONCLUSIONS: Supported self monitoring by telemonitoring is an effective method for achieving clinically important reductions in blood pressure in patients with uncontrolled hypertension in primary care settings. However, it was associated with increase in use of National Health Service resources. Further research is required to determine if the reduction in blood pressure is maintained in the longer term and if the intervention is cost effective. TRIAL REGISTRATION: Current Controlled Trials ISRCTN72614272

McLellan, C. P.; Lovell, D. I. (2012):

Neuromuscular responses to impact and collision during elite rugby league match play.

In: *J Strength.Cond.Res* 26 (5), S. 1431–1440. DOI: 10.1519/JSC.0b013e318231a627.

Abstract:

The purpose of this study was to investigate the relationship between the prematch and short-term postmatch neuromuscular responses to the intensity, number, and distribution of impacts associated with collisions during elite Rugby League match play. Twenty-two elite male Rugby League players were monitored during 8 regular season competition matches using portable global positioning system (GPS) technology. The intensity, number, and distribution of impact forces experienced by players during match play were recorded using integrated accelerometry. Peak rate of force development (PRFD), peak power (PP), and peak force (PF) were measured during a countermovement jump on a force plate 24 hours prematch, 30 minutes prematch, 30 minutes postmatch and then at 24-hour intervals for a period of 5 days postmatch. The change in the dependent variables at each sample collection time was compared with that at 24 hours prematch and 30-minute prematch measures. There were significant ($p < 0.05$) decreases in PRFD and PP up to 24 hours postmatch with PF significantly ($p < 0.05$) being decreased 30 minutes postmatch. Significant ($p < 0.05$) correlations were found between the total number of impacts and PRFD and PP 30 minutes postmatch. Impact zones 4 (7.1-8.0 G), 5 (>8.1-10.0 G), and 6 (>10.1 G) were significantly ($p < 0.05$) correlated to PRFD and PP 30 minutes postmatch with the number of zone 5 and 6 impacts significantly ($p < 0.05$) correlated to PRFD and PP 24 hours postmatch. Elite Rugby League match play resulted in significant neuromuscular fatigue and was highly dependent on the number of heavy collisions >7.1G. Results demonstrate that neuromuscular function is compromised for up to 48 hours postmatch indicating that at least 2 days of modified activity is required to achieve full neuromuscular recovery after elite Rugby League match play. Position-specific demands on energy systems and the influence of repeated blunt force trauma during collisions during elite Rugby League match play should be considered when planning postmatch recovery protocols and training activities to optimize subsequent performance

McLure, S. A.; Summerbell, C. D.; Reilly, J. J. (2009):

Objectively measured habitual physical activity in a highly obesogenic environment.

In: *Child: care, health and development* 35 (3), S. 369–375. DOI: 10.1111/j.1365-2214.2009.00946.x.

Abstract:

BACKGROUND\r\nWhile the prevalence of overweight and obesity among children continues to grow nationally, prevalence in the North-East of England is among the highest in the UK. The objective of this study was to investigate the habitual physical activity levels in a particularly obesogenic environment in the North-East of England.\r\nMETHODS\r\nEight primary schools were selected using a stratified random sampling frame ranking average deprivation levels. Participating children (n = 246, mean age 10 years) wore an accelerometer (Actigraph, GT-256) over five consecutive days (weekend plus three weekdays). Total daily moderate-to-vigorous intensity physical activity was calculated using thresholds by Puyau and colleagues.\r\nRESULTS\r\nOnly 7% (17/246) of children were sufficiently active. Boys were more physically active than girls (766 +/- 268 vs. 641 +/- 202 counts/min, 95% CI for the difference 63-186 cpm.). Total physical activity was not influenced significantly by deprivation levels or weight status, and there were no significant differences in physical activity between school or weekend days.\r\nCONCLUSIONS\r\nThe North-East of England is a recognized 'hot spot' for paediatric obesity and the present study shows that low levels of habitual physical activity are typical. Choice of accelerometry threshold affects both the apparent amount of physical activity and the ability to detect groups with particularly low levels of physical activity.

McMahon, E. J.; Bauer, J. D.; Hawley, C. M.; Isbel, N. M.; Stowasser, M.; Johnson, D. W. et al. (2012):

The effect of lowering salt intake on ambulatory blood pressure to reduce cardiovascular risk in chronic kidney disease (LowSALT CKD study): protocol of a randomized trial.

In: *BMC Nephrol* 13 (1471-2369 (Linking)), S. 137. DOI: 10.1186/1471-2369-13-137.

Abstract:

ABSTRACT: BACKGROUND: Despite evidence implicating dietary sodium in the pathogenesis of cardiovascular disease (CVD) in chronic kidney disease (CKD), quality intervention trials in CKD patients are lacking. This study aims to investigate the effect of reducing sodium intake on blood pressure, risk factors for progression of CKD and other cardiovascular risk factors in CKD. METHODS/DESIGN: The LowSALT CKD study is a six week randomized-crossover trial assessing the effect of a moderate (180 mmol/day) compared with a low (60 mmol/day) sodium intake on cardiovascular risk factors and risk factors for kidney function decline in mild-moderate CKD (stage III-IV). The primary outcome of interest is 24-hour ambulatory blood pressure, with secondary outcomes including arterial stiffness (pulse wave velocity), proteinuria and fluid status. The randomized crossover trial (Phase 1) is supported by an ancillary trial (Phase 2) of longitudinal-observational design to assess the longer term effectiveness of sodium restriction. Phase 2 will continue measurement of outcomes as per Phase 1, with the addition of patient-centered outcomes, such as dietary adherence to sodium restriction (degree of adherence and barriers/enablers), quality of life and taste assessment. DISCUSSION: The LowSALT CKD study is an investigator-initiated study specifically designed to assess the proof-of-concept and efficacy of sodium restriction in patients with established CKD. Phase 2 will assess the longer term effectiveness of sodium restriction in the same participants, enhancing the translation of Phase 1 results into practice. This trial will provide much-needed insight into sodium restriction as a treatment option to reduce risk of CVD and CKD progression in CKD patients. TRIAL REGISTRATION: Universal Trial Number: U1111-1125-2149. Australian New Zealand Clinical Trials Registry Number: ACTRN12611001097932

McManus, D. D.; Lee, J.; Maitas, O.; Esa, N.; Pidikiti, R.; Carlucci, A. et al. (2012):

A novel application for the detection of an irregular pulse using an iPhone 4S in patients with atrial fibrillation.

In: *Heart Rhythm* (1547-5271 (Linking)). DOI: 10.1016/j.hrthm.2012.12.001.

Abstract:

BACKGROUND: Atrial fibrillation (AF) is common and associated with adverse health outcomes. Timely detection of AF can be challenging using traditional diagnostic tools. Smartphone use is increasing and may provide an inexpensive and user-friendly means to diagnose AF. OBJECTIVE: To test the hypothesis that a smartphone-based application could detect an irregular pulse from AF. METHODS: Seventy-six adults with persistent AF were consented for participation in our study. We obtained pulsatile time series recordings before and after cardioversion using an iPhone 4S camera. A novel smartphone application conducted real-time pulse analysis using 2 statistical methods: root mean square of successive RR difference (RMSSD/mean) and Shannon entropy (ShE). We examined the sensitivity, specificity, and predictive accuracy of both algorithms using the 12-lead electrocardiogram as the gold standard. RESULTS: RMSDD/mean and ShE were higher in participants in AF than in those with sinus rhythm. The 2 methods were inversely related to AF in regression models adjusting for key factors including heart rate and blood pressure (beta coefficients per SD increment in RMSDD/mean and ShE were-0.20 and-0.35; P<.001). An algorithm combining the 2 statistical methods demonstrated excellent sensitivity (0.962), specificity (0.975), and accuracy (0.968) for beat-to-beat discrimination of an irregular pulse during AF from sinus rhythm. CONCLUSIONS: In a prospectively recruited cohort of 76 participants undergoing cardioversion for AF, we found that a novel algorithm analyzing signals recorded using an iPhone 4S

accurately distinguished pulse recordings during AF from sinus rhythm. Data are needed to explore the performance and acceptability of smartphone-based applications for AF detection

McMinn, David; Oreskovic, Nicolas M.; Aitkenhead, Matt J.; Johnston, Derek W.; Murtagh, Shemane; Rowe, David A. (2014):

The physical environment and health-enhancing activity during the school commute: global positioning system, geographical information systems and accelerometry.

In: *Geospat Health* 8 (2), S. 569–572.

Abstract:

Active school travel is in decline. An understanding of the potential determinants of health-enhancing physical activity during the school commute may help to inform interventions aimed at reversing these trends. The purpose of this study was to identify the physical environmental factors associated with health-enhancing physical activity during the school commute. Data were collected in 2009 on 166 children commuting home from school in Scotland. Data on location and physical activity were measured using global positioning systems (GPS) and accelerometers, and mapped using geographical information systems (GIS). Multi-level logistic regression models accounting for repeated observations within participants were used to test for associations between each land-use category (road/track/path, other man-made, greenspace, other natural) and moderate-to-vigorous physical activity (MVPA). Thirty-nine children provided 2,782 matched data points. Over one third (37.1%) of children's school commute time was spent in MVPA. Children commuted approximately equal amounts of time via natural and man-made land-uses (50.2% and 49.8% respectively). Commuting via road/track/path was associated with increased likelihood of MVPA (Exp(B)=1.23, P <0.05), but this association was not seen for commuting via other manmade land-uses. No association was noted between greenspace use and MVPA, but travelling via other natural land-uses was associated with lower odds of MVPA (Exp(B)=0.32, P <0.05). Children spend equal amounts of time commuting to school via man-made and natural land-uses, yet man-made transportation route infrastructure appears to provide greater opportunities for achieving health-enhancing physical activity levels.

McMurdo, M. E.; Argo, I.; Crombie, I. K.; Feng, Z.; Sniehotta, F. F.; Vadiveloo, T. et al. (2012):

Social, environmental and psychological factors associated with objective physical activity levels in the over 65s.

In: *PLoS One* 7 (2), S. e31878. DOI: 10.1371/journal.pone.0031878.

Abstract:

OBJECTIVE: To assess physical activity levels objectively using accelerometers in community dwelling over 65 s and to examine associations with health, social, environmental and psychological factors. DESIGN: Cross sectional survey. SETTING: 17 general practices in Scotland, United Kingdom. PARTICIPANTS: Random sampling of over 65 s registered with the practices in four strata young-old (65-80 years), old-old (over 80 years), more affluent and less affluent groups. MAIN OUTCOME MEASURES: Accelerometry counts of activity per day. Associations between activity and Theory of Planned Behaviour variables, the physical environment, health, wellbeing and demographic variables were examined with multiple regression analysis and multilevel modelling. RESULTS: 547 older people (mean (SD) age 79(8) years, 54% female) were analysed representing 94% of those surveyed. Accelerometry counts were highest in the affluent younger group, followed by the deprived younger group, with lowest levels in the deprived over 80 s group. Multiple regression analysis showed that lower age, higher perceived behavioural control, the physical function subscale of SF-36, and having someone nearby to turn to were all independently associated with higher physical activity levels (R(2) = 0.32). In addition, hours of sunshine were independently significantly associated with greater physical activity in a multilevel model. CONCLUSIONS: Other than age and hours of sunlight, the variables identified are modifiable, and provide a strong basis for the future development of novel multidimensional interventions aimed at increasing activity participation in later life

McMurdo, Marion E. T.; Sugden, Jacqui; Argo, Ishbel; Boyle, Paul; Johnston, Derek W.; Sniehotta, Falko F.; Donnan, Peter T. (2010):

Do pedometers increase physical activity in sedentary older women? A randomized controlled trial.

In: *J Am Geriatr Soc* 58 (11), S. 2099–2106.

Abstract:

OBJECTIVES:

To determine the effectiveness of a behavior change intervention (BCI) with or without a pedometer in increasing physical activity in sedentary older women.

DESIGN:

Prospective randomized controlled trial.

SETTING:

Primary care, City of Dundee, Scotland.

PARTICIPANTS:

Two hundred four sedentary women aged 70 and older.

INTERVENTIONS:

Six months of BCI, BCI plus pedometer (pedometer plus), or usual care.

MEASUREMENTS:

PRIMARY OUTCOME:

change in daily activity counts measured by accelerometry.

SECONDARY OUTCOMES:

Short Physical Performance Battery, health-related quality of life, depression and anxiety, falls, and National Health Service resource use.

RESULTS:

One hundred seventy-nine of 204 (88%) women completed the 6-month trial. Withdrawals were highest from the BCI group (15/68) followed by the pedometer plus group (8/68) and then the control group (2/64). After adjustment for baseline differences, accelerometry counts increased significantly more in the BCI group at 3 months than in the control group (P = .002) and the pedometer plus group (P = .04). By 6 months, accelerometry counts in both intervention groups had fallen to levels that were no longer statistically significantly different from baseline. There were no significant changes in the secondary outcomes.

CONCLUSION:

The BCI was effective in objectively increasing physical activity in sedentary older women. Provision of a pedometer yielded no additional benefit in physical activity, but may have motivated participants to remain in the trial.

McMurray, Robert G.; Ward, Dianne S.; Elder, John P.; Lytle, Leslie A.; Strikmiller, Patricia K.; Baggett, Christopher D.; Young, Deborah R. (2008):

Do overweight girls overreport physical activity?

In: *American Journal of Health Behavior* 32 (5), S. 538.

Abstract:

OBJECTIVE:

To determine if overweight adolescent girls are more likely to overreport physical activity compared to normal-weight girls.

METHODS:

Participation in physical activities and perceived intensity of activities were assessed from the previous day physical activity recall (PDPAR) in 1021 girls aged 11-14 years old (37% overweight). Daily minutes of moderate to vigorous physical activity (MVPA) were measured using accelerometry.

RESULTS:

Girls in the "at-risk for overweight" and "overweight" categories had 17.7% and 19.4% fewer minutes of MVPA per block reported on the PDPAR compared to normal-weight girls ($P<0.05$).

CONCLUSIONS:

Overweight adolescent girls tend to overreport their total amount of physical activity.

McParlin, Catherine; Robson, Stephen C.; Tennant, Peter W. G.; Besson, Hervé; Rankin, Judith; Adamson, Ashley J. et al. (2010):

Objectively measured physical activity during pregnancy: a study in obese and overweight women.

In: *BMC pregnancy and childbirth* 10 (1), S. 76.

Abstract:

BACKGROUND:

Obese and overweight women may benefit from increased physical activity (PA) during pregnancy. There is limited published data describing objectively measured PA in such women.

METHODS:

A longitudinal observational study of PA intensity, type and duration using objective and subjective measurement methods. Fifty five pregnant women with booking body mass index (BMI) ≥ 25 kg/m2 were recruited from a hospital ultrasound clinic in North East England. 26 (47%) were nulliparous and 22 (40%) were obese (BMI ≥ 30 kg/m2). PA was measured by accelerometry and self report questionnaire at 13 weeks, 26 weeks and/or 36 weeks gestation. Outcome measures were daily duration of light, moderate or vigorous activity assessed by accelerometry; calculated overall PA energy expenditure, (PAEE), and PAEE within four domains of activity based on self report.

RESULTS:

At median 13 weeks gestation, women recorded a median 125 mins/day light activity and 35 mins/day moderate or vigorous activity (MVPA). 65% achieved the minimum recommended 30 mins/day MVPA. This proportion was maintained at 26 weeks (62%) and 36 weeks (71%). Women achieving more than 30 mins/day MVPA in the first trimester showed a significant reduction in duration of MVPA by the third trimester (11 mins/day, p = 0.003). Walking, swimming and floor exercises were the most commonly reported recreational activities but their contribution to estimated energy expenditure was small.

CONCLUSION:

Overweight and obese pregnant women can achieve and maintain recommended levels of PA throughout pregnancy. Interventions to promote PA should target changes in habitual activities at work and at home, and in particular walking.

McTavish, Fiona M.; Chih, Ming Yuan; Shah, Dhavan; Gustafson, David H. (2012):

How patients recovering from alcoholism use a smartphone intervention.

In: *Journal of Dual Diagnosis* 8 (4), S. 294–304. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31918-006%26site%3dehost-live;fmctavish@chess.wisc.edu.

Abstract:

Objective: Mobile technology has the potential to radically improve addiction treatment and continuing care by offering emotional and instrumental support anywhere and just in time. This is particularly important in addiction because timing is critical to preventing relapse. Although most experts consider alcoholism to be a chronic disease, providers do not typically offer ongoing support for relapse prevention after patients complete treatment, even though a central characteristic of alcoholism and other addictive behaviors is their chronically relapsing nature. A-CHESS is a smartphone-based system for preventing relapse to heavy drinking among people leaving active alcohol dependence treatment. A-CHESS is designed to improve competence, social relatedness, and motivation, the three tenets of self-determination theory. This paper reports on the relative impact and use of A-CHESS 4 months after patients entered the study and discusses implications of the results on treating addiction and chronic diseases generally. Methods: A total of 349 individuals with alcohol dependence leaving residential treatment were randomly assigned to either receive A-CHESS + Treatment as usual or treatment as usual (standard aftercare). Patients came from two treatment agencies, one in the Midwest and one in the Northeast. Patients assigned to A-CHESS received a smartphone for 8 months and were followed for 12. The authors analyzed use patterns during the first 4 months of use by those receiving A-CHESS. Results: Participants used A-CHESS heavily and sustained their use over time. Ninety-four percent of A-CHESS participants used the application during the first week after residential treatment. At week 16, almost 80% continued to access A-CHESS. Participants with alcohol and drug dependence showed higher levels of system use than those with alcohol dependence only. Participants with a mental health diagnosis had slightly lower levels of use at the end of the intervention period (week 16), although more than 70% still accessed the system. Conclusions: These findings illustrate that patients with alcohol dependence, alcohol and drug dependence, and mental health issues will use smartphone applications such as A-CHESS for ongoing support, resources, and information, thus extending patient care if given the opportunity. Further analysis is needed to determine whether sustained A-CHESS use improves outcomes. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Meegan, Sean P.; Goedereis, Eric A. (2006):

Life task appraisals, spouse involvement in strategies, and daily affect among short- and long-term married couples.

In: *Journal of Family Psychology* 20 (2), S. 319–327. DOI: 10.1037/0893-3200.20.2.319.

Abstract:

The purpose of this study was to examine predictors and consequences of spouses' involvement in each others' strategies for pursuing important personal goals called life tasks. Husbands and wives within 39 short- and long-term marriages described five life tasks and provided appraisals of whether each was shared with their spouse. Participants later completed 14 consecutive diary entries recording daily life task pursuit strategies, the extent of spouse involvement in each, and measures of positive and negative affect. Results indicated that interdependence in life task appraisals prospectively predicted greater spouse involvement, and greater spouse involvement was associated with more positive affect for that day. Life task appraisals may provide avenues for understanding couples' strategies for dealing with goals or stressors and how those strategies affect mood.

Meeus, Mira; van Eupen, Inge; Willems, Joke; Kos, Daphne; Nijs, Jo (2011):

Is the International Physical Activity Questionnaire-Short Form (IPAQ-SF) valid for assessing physical activity in chronic fatigue syndrome?

In: *Disability and rehabilitation* 33 (1), S. 9–16.

Abstract:

PURPOSE:

To evaluate the criterion validity and internal consistency of the International Physical Activity Questionnaire-short form (IPAQ-sf) in Chronic Fatigue Syndrome (CFS) patients.

METHOD:

Fifty-six CFS patients completed the IPAQ-sf after they wore a tri-axial accelerometer and filled out activity diaries during 1 week. Spearman rank correlation coefficients and Cronbach's Alpha were calculated.

RESULTS:

The IPAQ-sf correlated significantly with the energy expenditure and Metabolic Equivalents (METs) minutes spent moderately to vigorously active following the activity diary and accelerometer. These correlation coefficients were however low (r varying between 0.282 and 0.426) and rather irrelevant, since CFS patients hardly reach moderate or vigorous activity levels. Internal consistency between the three subitems used for the total score of the IPAQ-sf was 0.337.

CONCLUSION:

The observed associations between the IPAQ-sf data and the data obtained from the accelerometer (gold standard) and the diaries were too low to be in support of the use of the IPAQ-sf in patients with CFS. The IPAQ-sf does not seem an appropriate tool to assess physical activity in CFS patients. Further study is required to seek for a valid, practical and affordable tool.

Mehl, Matthias R.; Conner, Tamlin S. (2012):

Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-000%26site%3dehost-live.

Abstract:

(from the jacket) Laboratory-based experimental methods historically have been the strength and pride of psychology and related disciplines. Yet a comprehensive science of behavior also requires the study of humans in real life. Bringing together leading investigators, this book reviews the breadth of current approaches for studying how people think, feel, and behave in everyday environments. The Handbook is organized in four parts. Part I covers the theoretical and methodological foundations of conducting daily life research. Part II provides guidance for designing a high-quality study and selecting and implementing appropriate methods. The chapters describe experience sampling methods, diary methods, ambulatory physiological measures, and other tools—including recording technologies and computerized approaches—that allow repeated, real-time measurement in natural settings. Part III focuses on techniques for analyzing intensive data from daily life, featuring practical discussions of

power analysis, psychometrics, data cleaning, multilevel modeling, time series analysis, and other topics. Part IV reviews how methods for studying daily life have been employed in different subfields and research areas, such as the study of emotion, close relationships, personality, health, development, psychopathology, and mental health treatment. Specific advantages and challenges inherent to using the methods in each area are discussed. Timely and authoritative, this handbook meets a key need for research psychologists and for graduate students in social/personality, health, developmental, industrial/organizational, and clinical psychology. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (jacket)

Mehl, Matthias R.; Gosling, Samuel D.; Pennebaker, James W. (2006):

Personality in its natural habitat: manifestations and implicit folk theories of personality in daily life.

In: *Journal of Personality and Social Psychology* 90 (5), S. 862–877. DOI: 10.1037/0022-3514.90.5.862.

Abstract:

To examine the expression of personality in its natural habitat, the authors tracked 96 participants over 2 days using the Electronically Activated Recorder (EAR), which samples snippets of ambient sounds in participants' immediate environments. Participants' Big Five scores were correlated with EAR-derived information on their daily social interactions, locations, activities, moods, and language use; these quotidian manifestations were generally consistent with the trait definitions and (except for Openness) often gender specific. To identify implicit folk theories about daily manifestations of personality, the authors correlated the EAR-derived information with impressions of participants based on their EAR sounds; judges' implicit folk theories were generally accurate (especially for Extraversion) and also partially gender specific. The findings point to the importance of naturalistic observation studies on how personality is expressed and perceived in the natural stream of everyday behavior.

Mehl, Matthias R.; Robbins, Megan L. (2012):

Naturalistic observation sampling: The Electronically Activated Recorder (EAR). In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 176–192. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-010%26site%3dehost-live.

Abstract:

(from the chapter) The Electronically Activated Recorder (EAR) is a portable audio recorder that is set to record periodically brief snippets of ambient sounds. Participants attach it to their belts or carry it in a purse-like bag while going about their daily lives. In tracking moment-to-moment ambient sounds around the participants, the EAR yields acoustic logs of their days as they naturally unfold. In sampling only a fraction of the time, instead of recording continuously, it makes large-scale naturalistic observation studies feasible. Our purpose in this chapter is to provide a review and discussion of this still relatively young naturalistic observational sampling method. Within the research methods for studying daily life, the EAR clearly occupies a methodological niche; it is not for everyone and everything. It is highly labor-intensive and thus requires careful deliberation as to when it should be used instead of more economic methods (e.g., experience sampling, daily diaries). However, in providing ecological behavioral measures that are independent of self-report and often beyond what self-report can capture, it can yield valuable findings that are difficult to obtain otherwise and support the field in the mission gradually to "put a bit more behavior back into the science of behavior" (Baumeister, Vohs, & Funder, 2007). (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Meininger, Janet C.; Gallagher, Martina R.; Eissa, Mona A.; Nguyen, Thong Q.; Chan, Wenyaw (2014):

Sleep Duration and Its Association With Ambulatory Blood Pressure in a School-Based, Diverse Sample of Adolescents.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpt297.

Abstract:

BACKGROUND: Evidence is accumulating that sleep duration is related to blood pressure (BP) and hypertensive status, but the strength of the association varies by age, and findings are inconsistent for adolescents. This cross-sectional study tested the hypothesis that sleep duration, both during the night and during naps, would be negatively associated with ambulatory systolic BP (SBP) and diastolic BP (DBP) measured over 24 hours in adolescents. METHODS: In this ethnically diverse (37% non-Hispanic black, 31% Hispanic, 29% non-Hispanic white, 3% other), school-based sample of 366 adolescents aged 11-16 years, ambulatory BP was measured every 30 minutes for 24 hours on a school day; actigraphy was used to measure sleep duration. Covariables included demographic factors, anthropometric indices, physical activity, and position and location at the time of each BP measurement. Mixed models were used to test day and night sleep duration as predictors of 24-hour SBP and DBP, controlling for covariables. RESULTS: The mean sleep duration was 6.83 (SD = 1.36) hours at night, and 7.23 (SD = 1.67) hours over 24 hours. Controlling for duration of sleep during the day and covariables, each additional hour of nighttime sleep was associated with lower SBP (-0.57; P < 0.0001); controlling for nighttime sleep duration and covariables, each additional hour of daytime sleep was associated with lower SBP (-0.73; P < 0.001) and lower DBP (-0.50; P < 0.001). CONCLUSIONS: Longer sleep duration was significantly associated with lower ambulatory SBP and DBP in adolescents. The findings have potential implications for cardiovascular health in this age group.

Smartphone-based solutions for fall detection and prevention: the FARSEEING approach.

In: *Z.Gerontol.Geriatr.* 45 (8), S. 722–727. DOI: 10.1007/s00391-012-0404-5.

Abstract:

Falls are not an inevitable consequence of aging. The risk and rate of falls can be reduced. Recent improvements in smartphone technology enable implementation of a wide variety of services and applications, thus making the smartphone more of a digital companion than simply a communication tool. This paper presents the results obtained by the FARSEEING project where smartphones are one example of intervention in a population-based scenario. The applications developed take advantage of the smartphone-embedded inertial sensors and require that subjects wear the smartphone by means of a waist belt. The uFall Android application has been developed for monitoring the user's motor activities at home. The application does not require any direct interaction with the user and it is also capable of running a real-time fall-detection algorithm. uTUG is a stand-alone application for instrumenting the Timed Up and Go test, which is a test often included in fall risk assessment protocols. The application acts like a pocket-sized motion laboratory, since it is capable not only of recording the trial but also of processing the data and immediately displaying the results. uTUG is designed to be self-administrable at home

Melton, Bridget F.; Bigham, Lauren E.; Bland, Helen W. (2013):

The feasibility of using video journaling to collect ecological momentary assessment data: Application to health behavior change interventions.

In: *Journal of Computing in Higher Education*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-02888-001%26site%3dehost-live;bmelton@georgiasouthern.edu.

Abstract:

The purpose of this research was to evaluate the feasibility of an ecological momentary assessment (EMA) technique in a health behavior change intervention offered within university general health courses. A six-week health behavior change project was used with two groups: video journaling and traditional (pencil and paper) group. Research methodology employed was a quantitative, quasi-experimental, control and experimental group posttest comparison design. Stage of change data and program satisfaction surveys were collected from participants at a midsized southeastern university (n = 72; 36 video and 36 traditional). Participants were selected through non-probability, purposive sampling. Upon completion of the behavior change intervention 88.9 % (N = 32) of video journaling participants reported being in either the action or maintenance stage of change compared to 63.9 % (N = 23) of the traditional group. Significant difference was found between the video journaling and traditional groups in levels of satisfaction with the program (M = 3.96, SE = 0.79; M = 3.53, SE = .53 respectively; t = −2.74, p < 0.05). EMA techniques using video journaling to aid behavior change interventions among late adolescence showed promise with further research needed to focus on long-term effects of such interventions.

Memari, A. H.; Ghaheri, B.; Ziaee, V.; Kordi, R.; Hafizi, S.; Moshayedi, P. (2012):

Physical activity in children and adolescents with autism assessed by triaxial accelerometry.

In: *Pediatr.Obes.* (2047-6302 (Linking)). DOI: 10.1111/j.2047-6310.2012.00101.x.

Abstract:

What is already known about this subject Individuals with disabilities are more likely to be sedentary compared to the general population. Individuals with ASD show several impairments in motor and physical functioning. Lack of opportunity is the primary factor that brings minimal physical activity to children with ASD. What this study adds There was a substantial reduction in level of PA across the adolescent years in ASD. A decline in PA level and opportunities at school can contribute to a reduction in individual's total PA in ASD. Household structure, sedentary activities, comorbidities and obesity are associated with PA level in children and adolescents with ASD. OBJECTIVE: This study aimed to examine physical activity (PA) patterns in children with autism spectrum disorder (ASD) as well as to address PA determinant factors by employing triaxial accelerometry. METHODS: In a school-based cross-sectional study of 80 children and adolescents with ASD (mean = 9.6, standard deviation = 1.8), we investigated demographics, children's behavioural and clinical profile, and their PA data as objectively measured using an Actigraph GT3X on the right hip for seven consecutive days. All activity measures were expressed as counts per minute (c.p.m.). RESULTS: There was a substantial reduction in activity across the adolescent years in ASD. Girls were significantly less active than boys with ASD. Participants were remarkably less active in school compared to after-school, and there was a PA decline during weekdays compared to weekends, which was not significant. Household structure, sedentary pursuits, comorbidities and obesity were identified as other determinants of PA in children with ASD. CONCLUSIONS: Given the limited objective assessment of PA in children with ASD, our findings stressed the need for improving PA programmes, particularly for girls and older children with ASD. This study also provided important information for counselling clinicians, families and school policy-makers about health issues in ASD

Mena, L. J.; Maestre, G. E.; Hansen, T. W.; Thijs, L.; Liu, Y.; Boggia, J. et al. (2013):

How Many Measurements Are Needed to Estimate Blood Pressure Variability Without Loss of Prognostic Information?

In: *Am J Hypertens* (0895-7061 (Linking)). DOI: 10.1093/ajh/hpt142.

Abstract:

BACKGROUND: Average real variability (ARV) is a recently proposed index for short-term blood pressure (BP) variability. We aimed to determine the minimum number of BP readings required to compute ARV without loss of prognostic information. METHODS: ARV was calculated from a discovery dataset that included 24-hour ambulatory BP measurements for 1,254 residents (mean age = 56.6 years; 43.5% women) of Copenhagen, Denmark. Concordance between ARV from full (>/=80 BP readings) and randomly reduced 24-hour BP recordings was examined, as was prognostic accuracy. A test dataset that included 5,353 subjects (mean age = 54.0 years; 45.6% women) with at least 48 BP measurements from 11 randomly recruited population cohorts was used to validate the results. RESULTS: In the discovery dataset, a minimum of 48 BP readings allowed an accurate assessment of the association between cardiovascular risk and ARV. In the test dataset, over 10.2 years (median), 806 participants died (335 cardiovascular deaths, 206 cardiac deaths) and 696 experienced a major fatal or nonfatal cardiovascular event. Standardized multivariable-adjusted hazard ratios (HRs) were computed for associations between outcome and BP variability. Higher diastolic ARV in 24-hour ambulatory BP recordings predicted ($P < 0.01$) total (HR = 1.12), cardiovascular (HR = 1.19), and cardiac (HR = 1.19) mortality and fatal combined with nonfatal cerebrovascular events (HR = 1.16). Higher systolic ARV in 24-hour ambulatory BP recordings predicted ($P < 0.01$) total (HR = 1.12), cardiovascular (HR = 1.17), and cardiac (HR = 1.24) mortality. CONCLUSIONS: Forty-eight BP readings over 24 hours were observed to be adequate to compute ARV without meaningful loss of prognostic information

Mendoza, J. A.; McLeod, J.; Chen, T. A.; Nicklas, T. A.; Baranowski, T. (2012):

Convergent Validity of Preschool Children's Television Viewing Measures among Low-Income Latino Families: A Cross-Sectional Study.

In: *Child Obes* (2153-2168 (Linking)). DOI: 10.1089/chi.2012.0116.

Abstract:

Abstract Background: Television viewing is an important modifiable risk factor for childhood obesity. However, valid methods for measuring children's TV viewing are sparse and few studies have included Latinos, a population disproportionately affected by

obesity. The goal of this study was to test the reliability and convergent validity of four TV viewing measures among low-income Latino preschool children in the United States. Methods: Latino children (n=96) ages 3-5 years old were recruited from four Head Start centers in Houston, Texas (January, 2009, to June, 2010). TV viewing was measured concurrently over 7 days by four methods: (1) TV diaries (parent reported), (2) sedentary time (accelerometry), (3) TV Allowance (an electronic TV power meter), and (4) Ecological Momentary Assessment (EMA) on personal digital assistants (parent reported). This 7-day procedure was repeated 3-4 weeks later. Test-retest reliability was determined by intraclass correlations (ICC). Spearman correlations (due to nonnormal distributions) were used to determine convergent validity compared to the TV diary. Results: The TV diary had the highest test-retest reliability (ICC=0.82, p<0.001), followed by the TV Allowance (ICC=0.69, p<0.001), EMA (ICC=0.46, p<0.001), and accelerometry (ICC=0.36-0.38, p<0.01). The TV Allowance (r=0.45-0.55, p<0.001) and EMA (r=0.47-0.51, p<0.001) methods were significantly correlated with TV diaries. Accelerometer-determined sedentary minutes were not correlated with TV diaries. The TV Allowance and EMA methods were significantly correlated with each other (r=0.48-0.53, p<0.001). Conclusions: The TV diary is feasible and is the most reliable method for measuring US Latino preschool children's TV viewing

Mendozzi, Laura; Tronci, Federica; Garegnani, Massimo; Pugnetti, Luigi (2010):

Sleep disturbance and fatigue in mild relapsing remitting multiple sclerosis patients on chronic immunomodulant therapy: an actigraphic study.

In: *Multiple sclerosis (Houndmills, Basingstoke, England)* 16 (2), S. 238–247. DOI: 10.1177/1352458509354551.

Abstract:

BACKGROUND\r\nPoor sleep is common in MS and it contributes to fatigue. The beta interferons produce systemic effects which may not adapt and may induce fatigue.\r\nOBJECTIVE\r\nTo verify whether subjective poor sleep and fatigue during chronic therapy correspond to reduced sleep efficiency obtained by actigraphy at home.\r\nMETHODS\r\n42 ambulatory relapsing remitting MS patients with mild disability were monitored for at least 7 nights. Habitual sleep quality and fatigue were assessed with the MOS sleep measure and the Fatigue Severity Scale. Sleep logs provided daily sleep quality assessments during actigraphy at home. Patients were grouped according to their current treatment: no therapy, glatiramer acetate, IFNbeta 3 times a week, and IFNbeta once a week.\r\nRESULTS AND CONCLUSION\r\nSleep efficiency was reduced by an average of 5% in 2/3 of the nights following IFNbeta injections compared to the other nights, and daily sleep ratings correlated with actigraphy. Patients on glatiramer acetate also showed a lower sleep efficiency than patients without therapy. Actigraphy data were only modestly correlated with MOSsm scores, not with fatigue. Long term adaptation of sleep effects of immunomodulant agents is incomplete and needs to be considered in treatment planning and assessment of sleep in MS.

A mobile-phone-based breath carbon monoxide meter to detect cigarette smoking.

In: *Nicotine Tob Res. DOI:* 10.1093/ntr/ntt275.

Abstract:

INTRODUCTION: Mobile phones hold considerable promise for delivering evidence-based smoking cessation interventions that require frequent and objective assessment of smoking status via breath carbon monoxide (Breath CO) measurement. However, there are currently no commercially available mobile-phone-based Breath CO meters. We developed a mobile-phone-based Breath CO meter prototype that attaches to and communicates with a smartphone through an audio port. The purpose of the current study was to evaluate the reliability and validity of Breath CO measures collected with the mobile meter prototype and assess the usability and acceptability of the meter. METHODS: Participants included 20 regular smokers (>/=10 cigarettes/day), 20 light smokers (<10 cigarettes/day), and 20 nonsmokers. Expired air samples were collected 4 times from each participant: twice with the mobile meter and twice with a commercially available Breath CO meter. RESULTS: Measures calculated by the mobile meter correlated strongly with measures calculated by the commercial meter (r = .96, p < .001). In addition, the mobile meter accurately distinguished between smokers and nonsmokers. The area under the receiver-operating characteristic curve for the mobile meter was 94.7%, and the meter had a combined sensitivity and specificity of 1.86 at an abstinence threshold of </=6 ppm. Responses on an acceptability survey indicated that smokers liked the meter and would be interested in using it during a quit attempt. CONCLUSIONS: The results of the current study suggest that a mobile-phone-based Breath CO meter is a reliable, valid, and acceptable device for distinguishing between smokers and nonsmokers.

Mermelstein, Robin; Hedeker, Donald; Weinstein, Sally (2010):

Ecological momentary assessment of mood-smoking relationships in adolescent smokers.

Abstract:

Experimentation with cigarette smoking remains a common phenomenon among adolescents, with 46.2% of high school seniors having tried smoking in 2007 (Johnston, O'Malley, Bachman, & Schulenberg, 2008). Not all adolescents who try cigarette smoking continue to smoke, however. In 2007, 12.3% of high school seniors smoked daily (Johnston et al., 2008). Although these prevalence rates represent a noticeable decline from peak lifetime prevalence rates of greater than 75% in the mid-1970s and 28.8% for daily smoking in 1977, they are still a cause of concern, considering both the enormous health consequences of smoking (U.S. Department of Health and Human Services, 1994) and the difficulty most adolescents have in stopping smoking once they escalate to more frequent levels (Mermelstein, 2003). A critical step in reducing the toll from smoking is preventing or interrupting the progression from those first cigarettes to continued use. Unfortunately, we know relatively little about the trajectories from first cigarette to more established smoking or about the factors that may influence this progression. Factors that influence progression may be quite distinct from those that influence first trials with cigarettes (Flay, Hu, & Richardson, 1998; Turner, Mermelstein, & Flay, 2004). For example, whereas social influence processes are well established predictors of initial experimentation, mood or emotional factors may play more of a role in progression beyond initial trials with smoking (Eissenberg & Balster, 2000; Turner et al., 2004). The goal of this chapter is to provide a more in-depth examination of the relationship between mood and smoking among adolescents who have initiated smoking. Toward this end, we highlight some essential methodological issues in understanding the mood-smoking relationship among adolescents, with a focus on the unique opportunities available to examine these relationships using ecological momentary assessment (EMA). Do event-contingent diaries about marital conflict change marital interactions?

In: *Behav Res Ther* 46 (2), S. 253–262.

Abstract:

Recent increase in the use of diary measures has prompted questions about the effect completing diaries has on participants. After extensive training, married couples completed event-contingent diaries about their couple disagreements for 15 days, focusing on emotional and behavioral aspects of marital conflict. Serving as a control for placebo effects of participation, the diary group (n=110) and a non-randomized control group (n=57) also completed brief daily checklists, with minimal training, over the reporting period. Before and after the reporting period, couples engaged in videotaped conflict-resolution tasks that were coded for conflict behaviors and emotions expressed. ANOVAs comparing groups indicated that completing event-contingent diaries for 15 days had no apparent effects on observed husbands' and wives' expressed emotions and behaviors during marital interactions. Parental reports on the brief daily diaries indicated minimal differences between the groups in global measures of marital functioning. At the same time, husbands' self-reports in the home indicated decreasing perceptions of marital quality over the recording period. Thus, although no differences in conflict tactics emerged based on observed marital interactions in the laboratory, certain self-reports of responding suggested potential reactivity effects.

Metcalf, Brad; Henley, William; Wilkin, Terence (2012):

Effectiveness of intervention on physical activity of children: Systematic review and meta-analysis of controlled trials with objectively measured outcomes (EarlyBird 54).

In: *BMJ: British Medical Journal* 345 (7876), S. 1–11. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-27786-001%26site%3dehost-live;brad.metcalf@nhs.net.

Abstract:

Objective: To determine whether, and to what extent, physical activity interventions affect the overall activity levels of children. Design: Systematic review and meta-analysis. Data sources: Electronic databases (Embase, Medline, PsycINFO, SPORTDiscus) and reference lists of included studies and of relevant review articles. Study selection: Design: randomised controlled trials or controlled clinical trials (cluster and individual) published in peer reviewed journals. Intervention: incorporated a component designed to increase the physical activity of children/adolescents and was at least four weeks in duration. Outcomes: measured whole day physical activity objectively with accelerometers either before or immediately after the end of the intervention period. Data analysis: Intervention effects (standardised mean differences) were calculated for total physical activity, time spent in

moderate or vigorous physical activity, or both for each study and pooled using a weighted random effects model. Meta-regression explored the heterogeneity of intervention effects in relation to study participants, design, intervention type, and methodological quality. Results: Thirty studies (involving 14 326 participants; 6153 with accelerometer measured physical activity) met the inclusion criteria and all were eligible for meta-analysis/meta-regression. The pooled intervention effect across all studies was small to negligible for total physical activity (standardised mean difference 0.12, 95% confidence interval 0.04 to 0.20; P < 0.01) and small for moderate or vigorous activity (0.16, 0.08 to 0.24; P < 0.001). Meta-regression indicated that the pooled intervention effect did not differ significantly between any of the subgroups (for example, for total physical activity, standardised mean differences were 0.07 for age < 10 years and 0.16 for ≥10 years, P = 0.19; 0.07 for body mass index across the entire range and 0.22 for exclusively overweight/obese children, P = 0.07; 0.12 for study duration ≤ 6 months and 0.09 for > 6 months, P = 0.71; 0.15 for home/family based intervention and 0.10 for school based intervention, P = 0.53; and 0.09 for higher quality studies and 0.14 for lower quality studies, P = 0.52). Conclusions: This review provides strong evidence that physical activity interventions have had only a small effect (approximately 4 minutes more walking or running per day) on children's overall activity levels. This finding may explain, in part, why such interventions have had limited success in reducing the body mass index or body fat of children. Meuret, Alicia E.; Rosenfield, David; Wilhelm, Frank H.; Zhou, Enlu; Conrad, Ansgar; Ritz, Thomas; Roth, Walton T. (2011):

Do unexpected panic attacks occur spontaneously?

In: *Biological Psychiatry* 70 (10), S. 985–991. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24621-016&site=ehost-live;ameuret@smu.edu.

Abstract:

Background: Spontaneous or unexpected panic attacks, per definition, occur "out of the blue," in the absence of cues or triggers. Accordingly, physiological arousal or instability should occur at the onset of, or during, the attack, but not preceding it. To test this hypothesis, we examined if points of significant autonomic changes preceded the onset of spontaneous panic attacks. Methods: Forty-three panic disorder patients underwent repeated 24-hour ambulatory monitoring. Thirteen natural panic attacks were recorded during 1960 hours of monitoring. Minute-by-minute epochs beginning 60 minutes before and continuing to 10 minutes after the onset of individual attacks were examined for respiration, heart rate, and skin conductance level. Measures were controlled for physical activity and vocalization and compared with time matched control periods within the same person. Results: Significant patterns of instability across a number of autonomic and respiratory variables were detected as early as 47 minutes before panic onset. The final minutes before onset were dominated by respiratory changes, with significant decreases in tidal volume followed by abrupt carbon dioxide partial pressure increases. Panic attack onset was characterized by heart rate and tidal volume increases and a drop in carbon dioxide partial pressure. Symptom report was consistent with these changes. Skin conductance levels were generally elevated in the hour before, and during, the attacks. Changes in the matched control periods were largely absent. Conclusions: Significant autonomic irregularities preceded the onset of attacks that were reported as abrupt and unexpected. The findings invite reconsideration of the current diagnostic distinction between uncued and cued panic attacks. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Meyer, Ursina; Schindler, Christian; Zahner, Lukas; Ernst, Dominique; Hebestreit, Helge; van Mechelen, Willem et al. (2014):

Long-term effect of a school-based physical activity program (KISS) on fitness and adiposity in children: a cluster-randomized controlled trial.

In: *PLoS One* 9 (2), S. e87929. DOI: 10.1371/journal.pone.0087929.

Abstract:

BACKGROUND: School-based intervention studies promoting a healthy lifestyle have shown favorable immediate health effects. However, there is a striking paucity on long-term follow-ups. The aim of this study was therefore to assess the 3 yr-follow-up of a cluster-randomized controlled school-based physical activity program over nine month with beneficial immediate effects on body fat, aerobic fitness and physical activity. METHODS AND FINDINGS: Initially, 28 classes from 15 elementary schools in Switzerland were grouped into an intervention (16 classes from 9 schools, n = 297 children) and a control arm (12 classes from 6 schools, n = 205 children) after stratification for grade (1st and 5th graders). Three years after the end of the multi-component physical activity program of nine months including daily physical education (i.e. two additional lessons per week on top of three regular lessons), short physical activity breaks during academic lessons, and daily physical activity homework, 289 (58%) participated in the follow-up. Primary outcome measures included body fat (sum of four skinfolds), aerobic fitness (shuttle run test), physical activity (accelerometry), and quality of life (questionnaires). After adjustment for grade, gender, baseline value and clustering within classes, children in the intervention arm compared with controls had a significantly higher average level of aerobic fitness at follow-up (0.373 z-score units [95%-CI: 0.157 to 0.59, p = 0.001] corresponding to a shift from the 50th to the 65th percentile between baseline and follow-up), while the immediate beneficial effects on the other primary outcomes were not

sustained. CONCLUSIONS: Apart from aerobic fitness, beneficial effects seen after one year were not maintained when the intervention was stopped. A continuous intervention seems necessary to maintain overall beneficial health effects as reached at the end of the intervention. TRIAL REGISTRATION: ControlledTrials.com ISRCTN15360785.

Meyer, Jotie; Tallir, Isabel B.; Soenens, Bart; Vansteenkiste, Maarten; Aelterman, Nathalie; van Den Berghe, Lynn et al. (2013):

Does Observed Controlling Teaching Behavior Relate to Students' Motivation in Physical Education?

In: *Journal of Educational Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-34345-001%26site%3dehost-live.

Abstract:

Self-determination theory (SDT) has served as a theoretical framework for considerable research on teaching behavior and student motivation. The majority of studies have focused on need-supportive teaching behavior at the expense of need-thwarting teaching behavior (i.e., the "dark side" of teaching). The goal of the present study was to examine motivational dynamics involved in controlling teaching behavior in the context of physical education (PE). The majority of studies on observed teaching behavior were conducted in the laboratory. To augment the ecological validity in the present study, the behavior of PE teachers was videotaped to rate their controlling teaching behavior in a real-life setting. In a sample of 56 teachers and 702 secondary school students, controlling teaching behavior during a specific PE class, as observed by external raters, was related positively to students' perceived controlling teaching behavior and, through these perceptions, to controlled motivation and amotivation. These associations were obtained in spite of the low incidence of controlling teaching behaviors, suggesting that students may be quite sensitive to controlling teaching behaviors. No associations were found between observed controlling behavior and student autonomous motivation and students' perceptions of autonomy-supportive teaching. Practical implications and recommendations for PE teachers' professional development training are included. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Mezick, Elizabeth J.; Matthews, Karen A.; Hall, Martica; Kamarck, Thomas W.; Strollo, Patrick J.; Buysse, Daniel J. et al. (2010):

Low life purpose and high hostility are related to an attenuated decline in nocturnal blood pressure.

In: *Health Psychol* 29 (2), S. 196.

Abstract:

OBJECTIVE:

An attenuation of the nighttime decline in blood pressure (BP) predicts cardiovascular disease and cardiovascular-related mortality, beyond daytime BP levels. We investigated whether positive and negative psychological attributes were associated with sleep-wake BP ratios and examined sleep parameters as potential mediators of these relationships.

DESIGN:

Two hundred twenty-four participants (50% men; 43% Black; mean age = 60 years) underwent ambulatory BP monitoring for 2 days and nights. Self-reports of positive and negative psychological attributes were collected. In-home polysomnography was conducted for 2 nights, and a wrist actigraph was worn for 9 nights.

MAIN OUTCOME MEASURES:

Sleep-wake mean arterial pressure (MAP) ratios.

RESULTS:

After adjustment for demographics, body mass index, and hypertensive status, low life purpose and high hostility were associated with high sleep-wake MAP ratios. Depression, anxiety, and optimism were not related to MAP ratios. Sleep latency, fragmentation, architecture, and the apnea-hypopnea index were examined as potential mediators between psychological attributes and MAP ratios; only long sleep latency mediated the relationship between hostility and MAP ratios.

CONCLUSION:

Low life purpose and high hostility are associated with high sleep-wake BP ratios in Black and White adults, and these relationships are largely independent of sleep.

Michel, Gisela (2006):

A multi-level decomposition of variance in somatic symptom reporting in families with adolescent children.

In: *British Journal of Health Psychology* 11 (Pt 2), S. 345–355. DOI: 10.1348/135910705X53506.

Abstract:

OBJECTIVES\r\nThis paper examines four different levels of possible variation in symptom reporting: occasion, day, person and family.\r\nDESIGN\r\nIn order to rule out effects of retrospection, concurrent symptom reporting was assessed prospectively using a computer-assisted self-report method.\r\nMETHODS\r\nA decomposition of variance in symptom reporting was conducted using diary data from families with adolescent children. We used palmtop computers to assess concurrent somatic complaints from parents and children six times a day for seven consecutive days. In two separate studies, 314 and 254 participants from 96 and 77 families, respectively, participated. A generalized multilevel linear models approach was used to analyze the data. Symptom reports were modelled using a logistic response function, and random effects were allowed at the family, person and day level, with extra-binomial variation allowed for on the occasion level.\r\nRESULTS\r\nSubstantial variability was observed at the person, day and occasion level but not at the family level.\r\nCONCLUSIONS\r\nTo explain symptom reporting in normally healthy individuals, situational as well as person characteristics should be taken into account. Family characteristics, however, would not help to clarify symptom reporting in all family members.

Michielsen, M. E.; Selles, R. W.; Stam, H. J.; Ribbers, G. M.; Bussmann, J. B. (2012):

Quantifying Nonuse in Chronic Stroke Patients: A Study Into Paretic, Nonparetic, and Bimanual Upper-Limb Use in Daily Life.

In: *Arch.Phys.Med.Rehabil.* (0003-9993 (Linking)). DOI: 10.1016/j.apmr.2012.03.016.

Abstract:

Michielsen ME, Selles RW, Stam HJ, Ribbers GM, Bussmann JB. Quantifying nonuse in chronic stroke patients: a study into paretic, nonparetic, and bimanual upper-limb use in daily life. OBJECTIVE: To quantify uni- and bimanual upper-limb use in patients with chronic stroke in daily life compared with healthy controls. DESIGN: Cross-sectional observational study. SETTING: Outpatient rehabilitation center. PARTICIPANTS: Patients with chronic stroke (n=38) and healthy controls (n=18). INTERVENTION: Not applicable. MAIN OUTCOME MEASURES: Upper-limb use in daily life was measured with an accelerometry-based upper-limb activity monitor, an accelerometer based measurement device. Unimanual use of the paretic and the nonparetic side and bimanual upper-limb use were measured for a period of 24 hours. Outcomes were expressed in terms of both duration and intensity. RESULTS: Patients used their unaffected limb much more than their affected limb (5.3h vs 2.4h), while controls used both limbs a more equal amount of time (5.4h vs 5.1h). Patients used their paretic side less than controls used their nondominant side and their nonparetic side more than controls their dominant side. The intensity with which patients used their paretic side was lower than that with which controls used their nondominant side, while that of the nonparetic side was higher than that of the dominant side of controls. Finally, patients used their paretic side almost exclusively in bimanual activities. During bimanual activities, the intensity with which they used their affected side was much lower than that of the nonaffected side. CONCLUSION: Our data show considerable nonuse of the paretic side, both in duration and in intensity, and both during unimanual and bimanual activities in patients with chronic stroke. Patients do compensate for this with increased use of the nonparetic side

Middelweerd, Anouk; Mollee, Julia S.; van der Wal, C.; Brug, Johannes; Te Velde, Saskia J. (2014):

Apps to promote physical activity among adults: a review and content analysis.

In: *Int J Behav Nutr Phys Act* 11 (1), S. 97. DOI: 10.1186/s12966-014-0097-9.

Abstract:

BackgroundIn May 2013, the iTunes and Google Play stores contained 23,490 and 17,756 smartphone applications (apps) categorized as Health and Fitness, respectively. The quality of these apps, in terms of applying established health behavior change techniques, remains unclear.MethodsThe study sample was identified through systematic searches in iTunes and Google Play. Search terms were based on Boolean logic and included AND combinations for physical activity, healthy lifestyle, exercise, fitness, coach, assistant, motivation, and support. Sixty-four apps were downloaded, reviewed, and rated based on the taxonomy of behavior change techniques used in the interventions. Mean and ranges were calculated for the number of observed behavior change techniques. Using nonparametric tests, we compared the number of techniques observed in free and paid apps and in iTunes and Google Play.ResultsOn average, the reviewed apps included 5 behavior change techniques (range 2 inverted question mark8). Techniques such as self-monitoring, providing feedback on performance, and goal-setting were used most

frequently, whereas some techniques such as motivational interviewing, stress management, relapse prevention, self-talk, role models, and prompted barrier identification were not. No differences in the number of behavior change techniques between free and paid apps, or between the app stores were found.ConclusionsThe present study demonstrated that apps promoting physical activity applied an average of 5 out of 23 possible behavior change techniques. This number was not different for paid and free apps or between app stores. The most frequently used behavior change techniques in apps were similar to those most frequently used in other types of physical activity promotion interventions.

Miller, G. D.; Jakicic, J. M.; Rejeski, W. J.; Whit-Glover, M. C.; Lang, W.; Walkup, M. P.; Hodges, M. L. (2012):

Effect of Varying Accelerometry Criteria on Physical Activity: The Look AHEAD Study.

In: *Obesity (Silver.Spring)* (1930-7381 (Linking)). DOI: 10.1038/oby.2012.118.

Abstract:

The importance of physical activity in weight management is widely documented. Although accelerometers offer an objective measure of activity that provide a valuable tool for intervention research, considerations for processing these data need further development. This study tests the effects of using different criteria for accelerometry data reduction. Data were obtained from 2,240 overweight and obese individuals with type 2 diabetes mellitus (T2DM) from the Look AHEAD study, with 2,177 baseline accelerometer files used for analysis. Number, duration, and intensity of moderate (>/=3 metabolic equivalents (METS)) and vigorous (>/=6 METS) activity bouts were compared using various data reduction criteria. Daily wear time was identified as 1,440 min/day minus non-wear time. Comparisons of physical activity patterns for non-wear time (using either 20, 30, or 60 min of continuous zeros), minimal daily wear time (8, 10, and 12 h), number of days with available data (4, 5, and 6 days), weekdays vs. weekends, and 1- or 2-min time interruptions in an activity bout were performed. In this mostly obese population with T2DM (BMI = 36.4 kg/m(2); mean age = 59.0 years), there were minimal differences in physical activity patterns using the different methods of data reduction. Altering criteria led to differences in the number of available data (sample size) meeting specific criteria. Although our results are likely directly applicable only to obese individuals with T2DM, an understudied population with regards to physical activity, the systematic analysis for data reduction employed can be more generalizable and provide guidance in this area in the absence of standard procedures

Miller, Megan A.; Rothenberger, Scott D.; Hasler, Brant P.; Donofry, Shannon D.; Wong, Patricia M.; Manuck, Stephen B. et al. (2014):

Chronotype predicts positive affect rhythms measured by ecological momentary assessment.

In: *Chronobiol Int*, S. 1–9. DOI: 10.3109/07420528.2014.983602.

Abstract:

Evening chronotype, a correlate of delayed circadian rhythms, is associated with depression. Altered positive affect (PA) rhythms may mediate the association between evening chronotype and depression severity. Consequently, a better understanding of the relationship between chronotype and PA may aid in understanding the etiology of depression. Recent studies have found that individuals with evening chronotype show delayed and blunted PA rhythms, although these studies are relatively limited in sample size, representativeness and number of daily affect measures. Further, published studies have not included how sleep timing changes on workday and non-workdays, or social jet lag (SJL) may contribute to the chronotype-PA rhythm link. Healthy non-depressed adults (n = 408) completed self-report affect and chronotype questionnaires. Subsequently, positive and negative affects were measured hourly while awake for at least two workdays and one non-workday by ecological momentary assessment (EMA). Sleep variables were collected via actigraphy and compared across chronotype groups. A cosinor variant of multilevel modeling was used to model individual and chronotype group rhythms and to calculate two variables: (1) amplitude of PA, or the absolute amount of daily variation from peak to trough during one period of the rhythm and (2) acrophase, or the time at which the peak amplitude of affect rhythms occurred. On workdays, individuals with evening chronotype had significantly lower PA amplitudes and later workday acrophase times than their morning type counterparts. In contrast to predictions, SJL was not found to be a mediator in the relationship between chronotype and PA rhythms. The association of chronotype and PA rhythms in healthy adults may suggest the importance of daily measurement of PA in depressed individuals and would be consistent with the hypothesis that evening chronotype may create vulnerability to depression via delayed and blunted PA rhythms.

Neuroticism, Negative Affect, and Negative Affect Instability: Establishing Convergent and Discriminant Validity Using Ecological Momentary Assessment.

In: *Personality and Individual Differences* 47 (8), S. 873–877. DOI: 10.1016/j.paid.2009.07.007.

Abstract:

Few investigations have examined the role of affective instability within a broad model of general personality functioning. The present study employed self-report and ecological momentary assessments (EMA) to examine the relations between self-reported Five-Factor Model Neuroticism, EMA average negative affect, and EMA negative affect instability. Results suggest that Neuroticism and negative affect instability are related yet distinct constructs, and that Neuroticism better represents average negative affect across time. Results also suggest that negative affect instability is related to low Agreeableness and specific externalizing facets of Neuroticism, such as Angry Hostility and Impulsiveness. The implications of these findings and potential areas for future research are discussed.

Mills, Jacqueline; Fuller-Tyszkiewicz, Matthew; Holmes, Millicent (2014):

State body dissatisfaction and social interactions: An experience sampling study.

In: *Psychology of Women Quarterly* 38 (4), S. 551–562. DOI: 10.1037/t06423-000;

Abstract:

To date, there has been limited empirical scrutiny of the correlates and consequences of day-to-day state body dissatisfaction fluctuations within naturalistic contexts. We used ecological momentary assessment (a form of naturalistic observation) to evaluate whether state body dissatisfaction was concurrently and/or prospectively associated with occurrence and quality of social interactions. Women (N = 121), aged 18 to 40, completed a brief trait-based survey and then nominated a 7-day period within which to receive seven text messages daily, at random intervals, prompting them to complete measures of body dissatisfaction at that moment. If they were currently or had recently engaged in social interactions, they were also asked to fill out questions rating the quality of these interactions (operationalized in terms of enjoyment of, and control in, the interaction). Findings suggest that the relationship between state body dissatisfaction and aspects of social interactions is complex and may vary over time. Cross-sectionally, state body dissatisfaction and social interaction quality were negatively associated. Prospectively, however, body dissatisfaction predicted subsequent avoidance of social interactions. Interestingly, when women chose to avoid social interactions, their body dissatisfaction worsened, yet when they did engage in social interactions, they reported improved body satisfaction. Importantly, the links between state body dissatisfaction and social interactions may be moderated by body mass index and trait body satisfaction levels. Potential mechanisms underlying the association between state body dissatisfaction and quality and quantity of social interactions are discussed, and future research avenues are proposed to further understand their inter-relation. Potential of a smartphone as a stress-free sensor of daily human behaviour.

In: *Behav Brain Res. DOI:* 10.1016/j.bbr.2014.06.007.

Abstract:

Behaviour is one of the most powerful objective signals that connotes psychological functions regulated by neuronal network systems. This study searched for simple behaviours using smartphone sensors with three axes for measuring acceleration, angular speed and direction. We used quantitative analytic methodology of pattern recognition for work contexts, individual workers and seasonal effects in our own longitudinally recorded data. Our 13 laboratory members were involved in the care of common marmosets and domestic chicks, which lived in separate rooms. They attached a smartphone to their front waist-belts during feeding and cleaning in five care tasks. Behavioural characteristics such as speed, acceleration and azimuth, pitch, and roll angles were monitored. Afterwards, participants noted subjective scores of warmth sensation and work efficiency. The multivariate time series data were characterized by the subjective scores and environmental factors such as room temperature, season, and humidity, using the linear mixed model. In contrast to high-precision but stress-inducing sensors, the mobile sensors measuring daily behaviours allowed us to quantify the effects of the psychological states and environmental factors on the behavioural traits.

Daily collection of self-reporting sleep disturbance data via a smartphone app in breast cancer patients receiving chemotherapy: a feasibility study.

In: *J Med Internet Res* 16 (5), S. e135. DOI: 10.2196/jmir.3421.

Abstract:

BACKGROUND: Improvements in mobile telecommunication technologies have enabled clinicians to collect patient-reported outcome (PRO) data more frequently, but there is as yet limited evidence regarding the frequency with which PRO data can be collected via smartphone applications (apps) in breast cancer patients receiving chemotherapy. OBJECTIVE: The primary objective of this study was to determine the feasibility of an app for sleep disturbance-related data collection from breast cancer patients receiving chemotherapy. A secondary objective was to identify the variables associated with better compliance in order to identify the optimal subgroups to include in future studies of smartphone-based interventions. METHODS: Between March 2013 and July 2013, patients who planned to receive neoadjuvant chemotherapy for breast cancer at Asan Medical Center who had access to a smartphone app were enrolled just before the start of their chemotherapy and asked to self-report their sleep patterns, anxiety severity, and mood status via a smartphone app on a daily basis during the 90-day study period. Push notifications were sent to participants daily at 9 am and 7 pm. Data regarding the patients' demographics, interval from enrollment to first self-report, baseline Beck's Depression Inventory (BDI) score, and health-related quality of life score (as assessed using the EuroQol Five Dimensional [EQ5D-3L] questionnaire) were collected to ascertain the factors associated with compliance with the self-reporting process. RESULTS: A total of 30 participants (mean age 45 years, SD 6; range 35-65 years) were analyzed in this study. In total, 2700 daily push notifications were sent to these 30 participants over the 90-day study period via their smartphones, resulting in the collection of 1215 self-reporting sleep-disturbance data items (overall compliance rate=45.0%, 1215/2700). The median value of individual patient-level reporting rates was 41.1% (range 6.7-95.6%). The longitudinal day-level compliance curve fell to 50.0% at day 34 and reached a nadir of 13.3% at day 90. The cumulative longitudinal compliance curve exhibited a steady decrease by about 50% at day 70 and continued to fall to 45% on day 90. Women without any form of employment exhibited the higher compliance rate. There was no association between any of the other patient characteristics (ie, demographics, and BDI and EQ5D-3L scores) and compliance. The mean individual patient-level reporting rate was higher for the subgroup with a 1-day lag time, defined as starting to self-report on the day immediately after enrollment, than for those with a lag of 2 or more days (51.6%, SD 24.0 and 29.6%, SD 25.3, respectively; P=.03). CONCLUSIONS: The 90-day longitudinal collection of daily self-reporting sleep-disturbance data via a smartphone app was found to be feasible. Further research should focus on how to sustain compliance with this self-reporting for a longer time and select subpopulations with higher rates of compliance for mobile health care.

Minami, Haruka (2013):

Relations among affect, abstinence motivation and confidence, and daily lapse risk among smokers trying to quit.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 74 (5-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99220-543%26site%3dehost-live.

Abstract:

Aims: This study prospectively tested the hypothesis that changes in momentary affect, abstinence motivation, and confidence would predict lapse risk over the next 12-48 hours using Ecological Momentary Assessment (EMA) data from smokers attempting to quit smoking. The moderating effects of high-risk contexts on relations between cognitions (motivation and confidence) and lapse risk were also tested. Method: 79 adult, daily smokers recorded their momentary affect, motivation to quit, abstinence confidence, and smoking behaviors in near real time with multiple EMA reports using electronic diaries post-quit. Results: Multilevel models indicated that increases in negative affect predicted greater lapse risk up to 12 hours, but not 24 hours later. Neither positive nor negative affect had significant effects on subsequent cognitions. High levels of motivation appeared to reduce increases in lapse risk that occur over hours. Momentary increases in confidence predicted greater lapse risk over 12 hours in high-risk situations, but not in the absence of potent smoking triggers. Conclusion: Momentary changes in negative affect, motivation, and confidence, during a quit attempt all had short-term effects on smoking lapse. Negative affect had short-lived effects on lapse risk, whereas high levels of motivation protected against the risk of lapsing that accumulates over hours. Contrary to expectations, an acute increase in confidence may increase vulnerability to lapse in the context of potent smoking triggers. Relations observed among affect, cognitions, and lapse seem to depend critically on the timing of assessments and the contexts in which the assessments occur. Using Ecological Measures of Smoking Trigger Exposure to Predict Smoking Cessation Milestones.

In: *Psychol Addict Behav. DOI:* 10.1037/adb0000017.

Abstract:

This study used ecological momentary assessment data from adult daily smokers attempting to quit smoking to assess relations between exposure to contextual risk factors and cessation failure, latency to a first smoking lapse, or progression from lapse to relapse (smoking 7 days in a row). Participants were adult, daily smokers enrolled in a randomized controlled clinical trial of bupropion SR and individual counseling who were followed to 1 year postquit. Participants reported exposure to high-risk contexts and behaviors, including being where cigarettes were available or smoking was permitted, being around others smoking in prospective, real-time assessment for 2 weeks pre- and 4 weeks postquit. Results showed that greater exposure to contextual risk factors during the prequit did not predict cessation failure. However, Cox regression survival analyses revealed that spending a greater proportion of time where cigarettes were easily available following at least 1 day of abstinence predicted shorter latency to a first lapse, even after controlling for baseline risk factors such as gender, nicotine dependence, depressive symptoms, and living with a smoker. Greater cigarette availability following a lapse was not associated with progression from lapse to relapse with or without baseline risk factors in the model. This suggests that postquit environmental risk factors, such as cigarette availability, increase lapse risk, and stable risk factors, such as living with smokers and higher baseline carbon monoxide level or depressive symptoms, remain potent predictors of progression to relapse. Real-time contextual risk assessments postquit predict lapse above and beyond stable, baseline risk factors. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Minami, Haruka; Yeh, Vivian M.; Bold, Krysten W.; Chapman, Gretchen B.; McCarthy, Danielle E. (2014):

Relations among affect, abstinence motivation and confidence, and daily smoking lapse risk.

In: *Psychol Addict Behav* 28 (2), S. 376–388. DOI: 10.1037/a0034445.

Abstract:

This study tested the hypothesis that changes in momentary affect, abstinence motivation, and confidence would predict lapse risk over the next 12-24 hr using Ecological Momentary Assessment (EMA) data from smokers attempting to quit smoking. One hundred and three adult, daily, treatment-seeking smokers recorded their momentary affect, motivation to quit, abstinence confidence, and smoking behaviors in near real time with multiple EMA reports per day using electronic diaries postquit. Multilevel models indicated that initial levels of negative affect were associated with smoking, even after controlling for earlier smoking status, and that short-term increases in negative affect predicted lapses up to 12, but not 24, hr later. Positive affect had significant effects on subsequent abstinence confidence, but not motivation to quit. High levels of motivation appeared to reduce increases in lapse risk that occur over hours although momentary changes in confidence did not predict lapse risk over 12 hr. Negative affect had short-lived effects on lapse risk, whereas higher levels of motivation protected against the risk of lapsing that accumulates over hours. An increase in positive affect was associated with greater confidence to quit, but such changes in confidence did not reduce short-term lapse risk, contrary to expectations. Relations observed among affect, cognitions, and lapse seem to depend critically on the timing of assessments. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Minassian, Arpi; Henry, Brook L.; Geyer, Mark A.; Paulus, Martin P.; Young, Jared W.; Perry, William (2010):

The quantitative assessment of motor activity in mania and schizophrenia.

In: *J Affect Disord* 120 (1-3), S. 200–206. DOI: 10.1016/j.jad.2009.04.018.

Abstract:

BACKGROUND\r\nIncreased motor activity is a cardinal feature of the mania of Bipolar Disorder (BD), and is thought to reflect dopaminergic dysregulation. Motor activity in BD has been studied almost exclusively with self-report and observer-rated scales, limiting the ability to objectively quantify this behavior. We used an ambulatory monitoring device to quantify motor activity in BD and schizophrenia (SCZ) patients in a novel exploratory paradigm, the human Behavioral Pattern Monitor (BPM).\r\nMETHOD\r\n28 patients in the manic phase of BD, 17 SCZ patients, and 21 nonpatient (NC) subjects were tested in the BPM, an unfamiliar room containing novel objects. Motor activity was measured with a wearable ambulatory monitoring device (LifeShirt).\r\nRESULTS\r\nManic BD patients exhibited higher levels of motor activity when exploring the novel environment than SCZ and NC groups. Motor activity showed some modest relationships with symptom ratings of mania and

psychosis and was not related to smoking or body mass index.\r\nLIMITATIONS\r\nAlthough motor activity did not appear to be impacted significantly by antipsychotic or mood-stabilizing medications, this was a naturalistic study and medications were not controlled, thus limiting conclusions about potential medication effects on motor activity.\r\nCONCLUSION\r\nManic BD patients exhibit a unique signature of motoric overactivity in a novel exploratory environment. The use of an objective method to quantify exploration and motor activity may help characterize the unique aspects of BD and, because it is amenable to translational research, may further the study of the biological and genetic bases of the disease.

State mood, task performance, and behavior at work: A within-persons approach.

In: *Organizational Behavior and Human Decision Processes* 112 (1), S. 43–57.

Abstract:

We examine the intra-individual relationships between state mood and the primary components of the individual-level criterion space (task performance, organizational citizenship behavior, and work withdrawal) as they vary within the stream of work. Using experience-sampling methods, 67 individuals in a call center responded to surveys on palmtop computers at random intervals 4–5 times each day for 3 weeks (total N = 2329). These data were matched to objective task performance obtained from organizational call records (total N = 1191). Within-persons, periods of positive mood were associated with periods of improved task performance (as evidenced by shorter call time) and engaging in work withdrawal. Trait meta-mood moderated these relationships. Specifically, individuals who attended to their moods had a stronger relationship between mood and speed of task performance (call time) and individuals able to repair their mood cognitively evidenced a weaker relationship between mood and withdrawal. Implications and the use of within-persons designs are discussed.

Minutolo, Roberto; Borrelli, Silvio; Scigliano, Raffaele; Bellizzi, Vincenzo; Chiodini, Paolo; Cianciaruso, Bruno et al. (2007):

Prevalence and clinical correlates of white coat hypertension in chronic kidney disease.

In: *Nephrol Dial Transplant* 22 (8), S. 2217–2223.

Abstract:

BACKGROUND:

The role of white coat hypertension (WCH) in the poor control of blood pressure (BP) in chronic kidney disease (CKD) is ill defined.

METHODS:

We measured systolic clinical (CBP) and ambulatory blood pressure (ABP) in 290 consecutive patients with non-dialysis CKD [glomerular filtration rate (GFR) <60 ml/min/1.73 m(2)]. We defined normotension (NOR) if CBP and daytime ABP <130 mmHg, sustained hypertension (SH) when both BP >or=130 mmHg, WCH if only daytime ABP <130 mmHg, and masked hypertension (MH) when only CBP <130 mmHg.

RESULTS:

NOR patients were 15.5%, WCH 31.7%, SH 46.9% and MH 5.9%. Due to the high prevalence of WCH, achievement of BP target (<130 mmHg) was more than doubled by daytime ABP than CBP (47.2 vs 21.4%). WCH was characterized by prevalence of diabetes (31.5%), left ventricular hypertrophy (LVH; 50.0%) and CBP values (146 +/- 12 mmHg) lower than in SH (41.9%, 71.3% and 158 +/- 18 mmHg) but greater than in NOR (17.8%, 37.8% and 118 +/- 7 mmHg). Among patients with CBP >or=130 mmHg, the independent risk of having SH rather than WCH increased in the presence of higher CBP [Odds ration (OR) 1.61, 95% confidence intervals (CI) 1.29-2.02], LVH (OR 1.94, 95% CI 1.03-3.63) and proteinuria (OR 3.12, 95% CI 1.31-7.43). In the WCH group, 24 h, daytime and nighttime ABP were 118 +/- 7/68 +/- 8, 120 +/- 7/71 +/- 8 and 112 +/- 12/63 +/- 9 mmHg, respectively.

CONCLUSIONS:

In CKD, WCH is highly prevalent and can be predicted in the absence of higher CBP, LVH and proteinuria. In these patients, pursuing a low BP target may not be safe because of the risk of cardio-renal hypoperfusion especially at nighttime.

Biobehavioral mechanisms of topiramate's effects on alcohol use: an investigation pairing laboratory and ecological momentary assessments.

In: *Addict Biol. DOI:* 10.1111/adb.12192.

Abstract:

Topiramate reduces drinking, but little is known about the mechanisms that precipitate this effect. This double-blind randomized placebo-controlled study assessed the putative mechanisms by which topiramate reduces alcohol use among 96 adult non-treatment-seeking heavy drinkers in a laboratory-based alcohol cue reactivity assessment and in the natural environment using ecological momentary assessment methods. Topiramate reduced the quantity of alcohol heavy drinkers consumed on drinking days and reduced craving while participants were drinking but did not affect craving outside of drinking episodes in either the laboratory or in the natural environment. Topiramate did not alter the stimulant or sedative effects of alcohol ingestion during the ascending limb of the blood alcohol curve. A direct test of putative mechanisms of action using multilevel structural equation mediation models showed that topiramate reduced drinking indirectly by blunting alcohol-induced craving. These findings provide the first real-time prospective evidence that topiramate reduces drinking by reducing alcohol's priming effects on craving and highlight the importance of craving as an important treatment target of pharmacotherapy for alcoholism.

Miranda, Robert; Monti, Peter M.; Ray, Lara; Treloar, Hayley R.; Reynolds, Elizabeth K.; Ramirez, Jason et al. (2014):

Characterizing subjective responses to alcohol among adolescent problem drinkers.

In: *J Abnorm Psychol* 123 (1), S. 117–129. DOI: 10.1037/a0035328.

Abstract:

Theoretical models of alcoholism emphasize the acute reinforcing properties of alcohol as chief determinants of drinking, and animal research suggests adolescents are uniquely sensitive to these effects. Human studies of these phenomena, however, are virtually nonexistent. We used ecological momentary assessment methods to capture adolescents' subjective responses to alcohol in real time in their natural environments. Adolescent participants were 22 problem drinkers, ages 15 to 19 years (M = 18.3, SD = 0.09; 55% female; 55% alcohol dependent). Participants consumed alcohol on 38% of days during a 1-week monitoring period, with an average of 5 drinks per occasion. Momentary data revealed that adolescents experience decreased stimulation and increased sedation and "high" across the ascending limb of the blood alcohol curve. Notably, greater craving predicted higher volumes of subsequent alcohol consumption during the episode, whereas greater "high" attenuated use. To test for developmental differences in these effects, we pooled these data with data from a similarly ascertained sample of 36 adult heavy drinkers, ages 24 to 64 years (M = 38.1, SD = 11.8; 50% female; 61% alcohol dependent). Adolescents were more sensitive to the stimulant effects of alcohol than adults. This study provides novel data on how adolescent problem drinkers experience alcohol in their natural contexts and illustrates how these effects, which appear to differ from adult problem drinkers, confer liability for future drinking. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Miranda, R.; Ray, L.; Blanchard, A.; Reynolds, E. K.; Monti, P. M.; Chun, T. et al. (2013):

Effects of naltrexone on adolescent alcohol cue reactivity and sensitivity: an initial randomized trial.

In: *Addict.Biol.* (1355-6215 (Linking)). DOI: 10.1111/adb.12050.

Abstract:

Adolescent alcohol use is associated with myriad adverse consequences and contributes to the leading causes of mortality among youth. Despite the magnitude of this public health problem, evidenced-based treatment initiatives for alcohol use disorders in youth remain inadequate. Identifying promising pharmacological approaches may improve treatment options. Naltrexone is an opiate receptor antagonist that is efficacious for reducing drinking in adults by attenuating craving and the rewarding effects of alcohol. Implications of these findings for adolescents are unclear; however, given that randomized trials of naltrexone with youth are non-existent. We conducted a randomized, double-blinded, placebo-controlled cross-over study, comparing naltrexone (50 mg/daily) and placebo in 22 adolescent problem drinkers aged 15-19 years (M = 18.36, standard deviation = 0.95; 12 women). The primary outcome measures were alcohol use, subjective responses to alcohol consumption, and alcohol-cue-elicited craving assessed in the natural environment using ecological momentary assessment methods, and craving and physiological reactivity assessed using standard alcohol cue reactivity procedures. Results showed that naltrexone reduced the likelihood of drinking and heavy drinking (P's </= 0.03), blunted craving in the laboratory and in the natural environment (P's </= 0.04), and altered subjective responses to alcohol consumption (P's </= 0.01). Naltrexone was generally well tolerated by participants. This study provides the first experimentally controlled evidence that naltrexone reduces drinking

and craving, and alters subjective responses to alcohol in a sample of adolescent problem drinkers, and suggests larger clinical trials with long-term follow-ups are warranted

Inter-day glycemic variability assessed by continuous glucose monitoring in insulin-treated type 2 diabetes patients on hemodialysis.

In: *Diabetes technology & therapeutics* 12 (10), S. 749–753.

Abstract:

BACKGROUND:

Type 2 diabetes patients on chronic hemodialysis have a high prevalence of cardiovascular complications and often show a poor glycemic control. Single-spot glycemic measurements are not always meaningful, and the hemoglobin A1c (HbA1c) value does not reflect short-term variations in glucose metabolism in this patient category. Therefore, to better understand their metabolic balance, we studied a group of diabetes patients on hemodialysis by a continuous glucose monitoring (CGM) system.

METHODS:

Twelve insulin-treated type 2 diabetes patients on hemodialysis were studied by a microdialysis-based subcutaneous glucose sensor over a period of 2 days, including the dialysis day (HD) and the following inter-dialytic period ("free" day [FD]).

RESULTS:

The mean 24-h glycemic value, the mean amplitude of glucose excursions, and the SD of mean glucose were significantly higher in the HD than the FD (186 ± 50 vs. 154 ± 25 mg/dL, $P<0.05$; 75 ± 22 vs. 56 ± 15 mg/dL, $P<0.05$; and 57 ± 6 vs. 35 ± 11 mg/dL, $P<0.05$, respectively). Considering the 48-h recording, there was a direct correlation between the mean glucose concentration and the HbA1c ($r=0.47$, $P<0.05$), whereas no association was observed between the measures of glucose variability and HbA1c.

CONCLUSIONS:

Insulin-treated diabetes patients on hemodialysis showed different glucose profiles between the HD and the FD. In particular, in the HD they have had an increased glycemic variability, which may represent an adjunctive risk factor for cardiovascular complications. Therefore the use of a CGM system, as a means of assessing the measures of glycemic variability, could improve the management of insulin therapy in these patients.

Mitchell, John T.; Dennis, Michelle F.; English, Joseph S.; Dennis, Paul A.; Brightwood, Amy; Beckham, Jean C.; Kollins, Scott H. (2014):

Ecological Momentary Assessment of Antecedents and Consequences of Smoking in Adults with Attention-Deficit/Hyperactivity Disorder.

In: *Subst Use Misuse. DOI:* 10.3109/10826084.2014.912229.

Abstract:

The current study assessed antecedents and consequences of ad lib cigarette smoking in smokers diagnosed with attention-deficit/hyperactivity disorder (ADHD) using ecological momentary assessment (EMA). Adult smokers with ADHD (n = 17) completed 870 smoking and 622 nonsmoking electronic diary entries over a 7-day observation period of their naturalistic smoking behavior. Data collection occurred from 2011 to 2012. Generalized estimating equations indicated that ADHD smokers were more likely to smoke when urge to smoke, negative affect, boredom, stress, worry, and restlessness were elevated. In addition, participants were more likely to smoke in situations that elicited higher levels of nervousness and frustration. ADHD symptoms, in general, did not differ between smoking and nonsmoking contexts, though hyperactive-impulsive ADHD symptoms were elevated prior to smoking in frustrating situations. Additional situational antecedent variables were associated with smoking, including being in the presence of others smoking, being in a bar or restaurant, while outside, and while consuming caffeinated or alcoholic beverages. Participants also reported a significant improvement in urge to smoke, negative affect, stress, hunger, and ADHD symptoms after smoking a cigarette. Findings suggest certain contextual factors that may maintain ad lib cigarette smoking in smokers with ADHD and identify potential treatment targets in smoking cessation interventions for this at-risk group. Clinical implications and future research directions are discussed. Funding for this study was provided by the National Institute on Drug Abuse.

Reliability and validity of goniometric iPhone applications for the assessment of active shoulder external rotation.

In: *Physiother Theory Pract. DOI:* 10.3109/09593985.2014.900593.

Abstract:

ABSTRACT Purpose/hypothesis: The purpose of this study was to determine the reliability and validity of two smartphone applications: (1) GetMyROM - inclinometery-based and (2) DrGoniometry - photo-based in the measurement of active shoulder external rotation (ER) as compared to standard goniometry (SG). Participants: Ninety-four Texas Woman's University Doctor of Physical Therapy students from the School of Physical Therapy - Houston campus, were recruited to participate in this study. Materials/methods: Two iPhone applications were compared to SG using both novice and experienced raters. Active shoulder ER range of motion was measured over two time periods in random order by blinded novice and experienced raters. Results: Intra-rater reliability using novice raters for the two applications ranged from an intraclass correlation coefficient (ICC) of 0.79 to 0.81 with SG at 0.82. Inter-rater reliability (novice/expert) for the two applications ranged from an ICC of 0.92 to 0.94 with SG at 0.91. Concurrent validity (when compared to SG) ranged from 0.93 to 0.94. There were no significant differences between the novice and experienced raters. Conclusion: Both applications were found to be reliable and comparable to SG. A photo-based application potentially offers a superior method of measurement as visualizing the landmarks may be simplified in this format and it provides a record of measurement. Clinical relevance: Further study using patient populations may find the two studied applications are useful as an adjunct for clinical practice.

Classification of sporting activities using smartphone accelerometers.

In: *Sensors.(Basel)* 13 (4), S. 5317–5337. DOI: 10.3390/s130405317.

Abstract:

In this paper we present a framework that allows for the automatic identification of sporting activities using commonly available smartphones. We extract discriminative informational features from smartphone accelerometers using the Discrete Wavelet Transform (DWT). Despite the poor quality of their accelerometers, smartphones were used as capture devices due to their prevalence in today's society. Successful classification on this basis potentially makes the technology accessible to both elite and non-elite athletes. Extracted features are used to train different categories of classifiers. No one classifier family has a reportable direct advantage in activity classification problems to date; thus we examine classifiers from each of the most widely used classifier families. We investigate three classification approaches; a commonly used SVM-based approach, an optimized classification model and a fusion of classifiers. We also investigate the effect of changing several of the DWT input parameters, including mother wavelets, window lengths and DWT decomposition levels. During the course of this work we created a challenging sports activity analysis dataset, comprised of soccer and field-hockey activities. The average maximum F-measure accuracy of 87% was achieved using a fusion of classifiers, which was 6% better than a single classifier model and 23% better than a standard SVM approach

Mitoma, Hiroshi; Yoneyama, Mitsuru; Orimo, Satoshi (2010):

24-hour recording of parkinsonian gait using a portable gait rhythmogram.

In: *Internal Medicine* 49 (22), S. 2401–2408.

Abstract:

OBJECTIVE:

In the advanced stage of Parkinson's disease (PD), motor fluctuation is a frequent and a disabling problem. Despite its importance, motor fluctuation has received little scientific analysis probably due to limitation in objective assessment. Here, we focused on gait disorders to estimate motor fluctuation in daily activities.

PATIENTS AND METHODS:

Using a new device, the portable gait rhythmogram, we recorded gait rhythm continuously over 24 hours in 22 patients with PD and in 11 normal controls, for quantitative evaluation of motor fluctuation. The duration of one gait cycle was measured.

RESULTS:

Continuous 24-hour recording identified changes in gait rhythm, which correlated with fluctuation of PD symptoms. Different motor fluctuations were observed; a shift to a faster gait cycle was noted in patients with short-step walking, festination or freezing of gait, whereas a shift to a slower gait cycle was observed in patients with bradykinesia or instability.

CONCLUSION:

Characterization of motor fluctuation using this device could help in the selection of appropriate anti-PD medications.

Pedometer accuracy for children: can we recommend them for our obese population?

In: *Pediatrics* 123 (1), S. e127-31. DOI: 10.1542/peds.2008-1908.

Abstract:

OBJECTIVE\r\nIn this study, we investigated the accuracy of measuring walking steps with commercially available pedometers and an accelerometer-based step-counter in normal and overweight children. Our primary hypothesis was that commercially available pedometers are not an accurate measure of walking steps in normal and overweight children while walking. Our secondary hypothesis was that the accelerometer-based step-counter provides an accurate measure of walking steps in normal and overweight children.\r\nMETHODS\r\nThirteen boys (11 +/- 1 years) and 14 girls (11 +/- 1 years) who ranged in BMI from 15 to 27 kg/m(2) (16 normal and 11 overweight or obese) were recruited. Each child wore 4 pedometers at the waist and 1 accelerometer-based step-counter on each ankle. Steps were manually counted and energy expenditure was measured while the child walked on the treadmill at 0.5, 1.0, 1.5, and 2.0 mph, each for 5 minutes. The step-counting devices were also validated while children walked on level ground at a self-selected pace.\r\nRESULTS\r\nFor the commercially available pedometers at the lowest speed of 0.5 mph, the percentage error approximated 100% for both of the pedometers. At the fastest speed of 2.0 mph, the percentage error approximated 60%. Conversely the accelerometer-based step-counter showed a percentage error of 24% +/- 22% (mean +/- SD) at 0.5 mph; however, as walking speed increased, the error declined to 5% +/- 8% at 1.0 mph, 4% +/- 5% at 1.5 mph, and 2% +/- 2% at 2.0 mph. The relationship between steps counted and walking energy expenditure showed good linear correlation.\r\nCONCLUSIONS\r\nCommercially available pedometers are less accurate for measuring walking and require discretion in their use for children. The accuracy of the accelerometer-based step-counter enables it to be used as a tool to assess and potentially promote physical activity in normal and overweight children.

Mizuike, Chihiro; Ohgi, Shohei; Morita, Satoru (2009):

Analysis of stroke patient walking dynamics using a tri-axial accelerometer.

In: *Gait Posture* 30 (1), S. 60–64. DOI: 10.1016/j.gaitpost.2009.02.017.

Abstract:

The purpose of this study was to describe the characteristics of stroke patient gait using the acceleration signals which were obtained during walking. Sixty-three stroke hemiplegic patients and 21 age-matched healthy elderly individuals took part in this study. A wireless tri-axial accelerometer, fixed to a belt at the level of the L3 spinous process, was used to measure trunk acceleration. Subjects were instructed to walk at a self-selected, comfortable walking speed. The acceleration signal was sampled at the rate of 200 Hz. Gait parameters and functional recovery tests were also evaluated. We analyzed the correlation between the gait parameters, functional recovery and acceleration. Acceleration was utilized as the root mean square (RMS), normalized RMS by velocity and average step length, as a measure of gait smoothness, and autocorrelation (AC) as a measure of stride similarity and regularity. The raw RMS and AC values of the stroke were significantly lower than the matched healthy elderly ($p<0.01$) in all axes. In contrast, the stroke patients' normalized RMS values were higher than the controls ($p<0.05$) in all axes. These results suggest that accelerometry gait parameters can discriminate between the stroke patients and the control group. The values of normalized RMS correlated with the smoothness or dynamics of the walking pattern, which reflects motor recovery and gait abilities. This study suggests that normalized RMS of accelerometer recordings from the trunk is valid in objectively measuring walking movements as an index of treatment outcome for patients in rehabilitation.

Ambulatory bruxism recording system with sleep-stage analyzing function.

In: *Journal of prosthodontic research* 53 (3), S. 150–154. DOI: 10.1016/j.jpor.2009.01.001.

Abstract:

PURPOSE\r\nThe aim of this study was to develop an ambulatory bruxism recording system capable of sleep-stage analysis.\r\nMETHODS\r\nA portable EMG system was used to record masseter muscle activity. An EMG sensor was attached onto the masseter muscle belly at either side. EMG data were stored on a notebook type personal computer. A sound level meter was used to assess the sound level of bruxism. Sound level (dB) readings were taken every second and recorded on the same computer. A prototype of sleep sensor, a wristwatch-style biological signal sensor-recorder device, recorded and stored pulse wave, acceleration and temperature on a memory card. All stored data were transferred to a personal computer and analyzed.\r\nRESULTS\r\nThe whole system was transportable within a protective case and weighed approximately 5kg. Raw EMG signals were processed to derive integrated EMG data. TOSHIBA Sleep Analysis Program classified sleep-stages as awake, shallow sleep, deep sleep and REM based on the activity of the autonomic nervous system that was estimated from the fluctuations of pulse intervals. An EMG, sound level and sleep-stage analysis program was developed to analyze all data simultaneously. Using this program, the masseter muscle activity, sound level and sleep-stage could be quantified and correlated.\r\nCONCLUSION\r\nWe developed an ambulatory bruxism recording system that analyzes sleep-stage. We expect that this system will enable us to measure sleep bruxism activity in each sleep-stage on an electromyographical and auditory basis at the subject's home.

Modesti, P. A. (2013):

Season, temperature and blood pressure: A complex interaction.

In: *Eur.J Intern.Med* 24 (7), S. 604–607. DOI: 10.1016/j.ejim.2013.08.002.

Abstract:

An increase in blood pressure values measured during winter either in the office, at home, or at ambulatory blood pressure monitoring was consistently observed. Besides potentially contributing to increase the risk for cardiovascular events during the cold season, long term blood pressure variations can influence results of clinical trials, epidemiological surveys, and require personalized management of antihypertensive medications in the single patient. Those variations are often considered as an effect of climate, due to the close correlation observed in various countries and in different settings between temperature and blood pressure among children, adults, and specially the elderly. However, obtaining true measurements of exposition is a main problem when investigating the effects of climate on human health especially when the aim is to disentangle the effects of climate from those of seasonality. The aim of the present note is not to provide a complete review of the literature demonstrating the implications of seasonal blood pressure changes in the clinical and experimental setting; rather it is to consider methodological aspects useful to investigate the interaction between seasonality and temperature on blood pressure and to make health care providers aware of the implications of environmental factors on blood pressure in clinical and research settings

Unit-specific calibration of Actigraph accelerometers in a mechanical setup–Is it worth the effort? The effect on random output variation caused by technical inter-instrument variability in the laboratory and in the field.

In: *BMC medical research methodology* 8 (1), S. 19.

Abstract:

Background

Potentially, unit-specific in-vitro calibration of accelerometers could increase field data quality and study power. However, reduced inter-unit variability would only be important if random instrument variability contributes considerably to the total variation in field data. Therefore, the primary aim of this study was to calculate and apply unit-specific calibration factors in multiple accelerometers in order to examine the impact on random output variation caused by inter-instrument variability.

Methods

Instrument-specific calibration factors were estimated in 25 MTI- and 53 CSA accelerometers in a mechanical setup using four different settings varying in frequencies and/or amplitudes. Calibration effect was analysed by comparing raw and calibrated data after applying unit-specific calibration factors to data obtained during quality checks in a mechanical setup and to data collected during free living conditions.

Results

Calibration reduced inter-instrument variability considerably in the mechanical setup, both in the MTI instruments (raw SDbetween units = 195 counts*min-1 vs. calibrated SDbetween units = 65 counts*min-1) and in the CSA instruments (raw SDbetween units = 343 counts*min-1 vs. calibrated SDbetween units = 67 counts*min-1). However, the effect of applying the derived calibration to children's and adolescents' free living physical activity data did not alter the coefficient of variation (CV) (children: CVraw = 30.2% vs. CVcalibrated = 30.4%, adolescents: CVraw = 36.3% vs. CVcalibrated = 35.7%). High correlations (r = 0.99 & r = 0.98, respectively) were observed between raw and calibrated field data, and the proportion of the total variation caused by the MTI- and CSA monitor was estimated to be only 1.1% and 4.2%, respectively. Compared to the CSA instruments, a significantly increased (9.95%) mean acceleration response was observed post hoc in the batch of MTI instruments, in which a significantly reduced inter-instrumental reliability was observed over time.

Conclusion

The application of unit-specific calibration factors to data collected during free living conditions had no apparent effect on inter-instrument variability. In all probability, the effect of technical calibration was primarily attenuated in the field by other more dominant sources of variation. However, routine technical assessments are still very important for determining the acceleration responses in the batch of instruments being used and, if performed after every field use, for preventing decidedly broken instruments from being returned into the field repeatedly.

Moe-Nilssen, Rolf; Aaslund, Mona Kristin; Hodt-Billington, Caroline; Helbostad, Jorunn L. (2010):

Gait variability measures may represent different constructs.

In: *Gait Posture* 32 (1), S. 98–101. DOI: 10.1016/j.gaitpost.2010.03.019.

Abstract:

Many measures of gait variability have been reported, but the degree to which such measures are associated and thus represent a common construct is inconclusive. The purpose of this paper is to establish construct validity of commonly used spatio-temporal footfall variability and trunk variability measures taking into account the effect of measurement error. Twenty-three older individuals, aged 80+/-5 years performed four repeated walks at preferred speed, 0.97+/-0.16m/s. Gait data were obtained by an electronic walkway and by trunk accelerometry. Of initially 13 variability measures, five satisfied a reliability criterion of ICC> or =0.80 and were included in a subsequent construct validity analysis. Of these, step length variability and step time variability did not correlate significantly, while step length variability correlated closely with anteroposterior interstep trunk variability, and step time variability with vertical interstep trunk variability. Mediolateral interstep trunk variability did not correlate significantly with any of the other measures. This finding supports the notion that this measure may represent still a different aspect of variability. Different gait variability measures representing different constructs should be included in gait analysis to enhance our understanding of variability in gait.

Mogle, Jacqueline (2012):

Development of a daily diary method for the assessment of everyday cognitive failures.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (7-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99020-471&site=ehost-live.

Abstract:

Assessing how well an individual can meet real world cognitive demands is an important clinical outcome, particularly for older adults. Research examining real world cognitive functioning has used both lab-based tasks as well as questionnaires. However, these assessments were limited for a number of reasons. Lab-based tasks lack personal relevance which may affect the strategies and amount of effort individuals apply, reducing their ecological validity. Questionnaires are considered more ecologically valid but require individuals to recall cognitive failures over weeks and months depending on an individual's fallible cognitive ability to remember their mistakes over long periods of time. More recent research has attempted to develop methods for the daily reporting of cognitive failures but focus primarily on memory failures and ignore more general types of cognitive failures. These daily diary studies also failed to assess the impact of cognitive failures on daily functioning. The current study built on this previous research and introduced a set of assessment tools designed to capture missed activities, memory failures, and difficulties with attention and concentration that individuals experience on a daily basis as well as the impact of these events on daily functioning. One hundred thirty-one participants, 20 to 80 years old completed these assessments once each day for a period of seven days as well as a series of lab-based cognitive tasks. These data revealed that participants reported missing the most activities due to overload (e.g., running out of time) but found missing activities due to somatic complaints as the most bothersome. With regard to daily memory failures, participants reported equal numbers of retrospective and prospective memory failures but reported expecting more future consequences from prospective memory failures. Older participants reported experiencing more missed activities and memory failures but rated these events as less bothersome, less interfering, and as less likely to bring about future consequences compared with younger adults. Daily failures of attention and

concentration were captured using a Likert-style scale that assesses cognitive interference. This questionnaire exhibited adequate reliability and factor structure both between- and within-persons and tapped a construct separable from negative affect. Finally, there was evidence of weak relationships among self-reported cognitive failures and objective cognitive performance. Findings are discussed relative to previous research on self-reported cognitive failures, the importance of assessing other daily processes and their effects on daily cognitive failures, and the continued lack of relationship between self-reported cognitive failures and objective cognitive performance. Mohr, Cynthia; Armeli, Stephen; Tennen, Howard; Todd, Michael (2010):

The complexities of modeling mood-drinking relationships: Lessons learned from daily process research.

Abstract:

Motivational models of alcohol consumption posit that adults drink to enhance positive experiences and to reduce the effects of negative experiences (Cooper, Frone, Russell, & Mudar, 1995; Cox & Klinger, 1988). The latter, referred to as drinking to cope (DTC) or tension-reduction drinking, is associated with alcohol-related problems (Cooper et al., 1995). Identifying and understanding DTC patterns is an important step in assessing and then preventing alcohol abuse. Although numerous cross-sectional or multiwave longitudinal studies have examined DTC, most have examined between-person associations of negative affect and drinking or have relied on individuals' recall of their motivations, the reliability of which is questionable (e.g., Ptacek, Smith, Espe, & Raffety, 1994; Todd, Armeli, Tennen, Carney, & Affleck, 2003). Yet implicit in DTC theory is a dynamic process whereby negative events and emotions rapidly unfold and yield bidirectional influences with alcohol consumption, such that negative experiences increase alcohol consumption, which in turn increases negative experiences. Daily process designs in which events, emotions, and consumption are assessed close to the time they occur are uniquely suited to capturing these processes. Specifically, such studies address the question, Do individuals drink relatively more (or less) when they experience increases in stress and negative moods? Daily process studies have documented within-person negative mood-drinking associations in adult and college student populations, although results are often contradictory across studies. In this chapter, we briefly review daily process methodology and research findings from these studies related to tension-reduction drinking. We further explore the complexities of mood-drinking relationships by probing alternative analytical approaches, along with a consideration of within- and between-person moderators that may explicate when and for whom negative moods enhance alcohol consumption. We conclude with a discussion of the benefits and limitations of daily process methodology in assessing negative mood-related drinking (NMRD). Mojza, Eva J.; Lorenz, Christian; Sonnentag, Sabine; Binnewies, Carmen (2010):

Daily recovery experiences: the role of volunteer work during leisure time.

In: *Journal of Occupational Health Psychology* 15 (1), S. 60–74. DOI: 10.1037/a0017983.

Abstract:

This study focused on the role of volunteer work for daily recovery from work. In a 1-week diary study with 166 employees, we assessed the amount of time spent on volunteer work during leisure time, and the recovery facets of psychological detachment from work (i.e., mentally switching off from work), mastery experiences (i.e., pursuing challenging activities), and community experiences (i.e., cultivating relationships) every day before participants went to bed. Results from hierarchical linear modeling (n = 529 days) showed volunteer work during leisure time to be positively related to mastery experiences and community experiences suggesting volunteer work to contribute to successful recovery by creating new resources.

Moliner-Urdiales, D.; Ruiz, J. R.; Ortega, F. B.; Rey-Lopez, J. P.; Vicente-Rodriguez, G.; España-Romero, V. et al. (2009):

Association of objectively assessed physical activity with total and central body fat in Spanish adolescents; the HELENA Study.

In: *International journal of obesity (2005)* 33 (10), S. 1126–1135. DOI: 10.1038/ijo.2009.139.

Abstract:

OBJECTIVES\r\nTo examine the association of objectively assessed physical activity (PA) with markers of total and central body fat in adolescents, and to determine whether meeting the current PA recommendations (> or = 60 min day(-1) of at least moderate intensity PA) is associated with reduced levels of total and central body fat.\r\nSUBJECTS/METHODS\r\nA total of 365 Spanish adolescents aged 12.5-17.5 years participated in this cross-sectional study. PA was assessed by accelerometry and

expressed as average PA (counts per minute), and min day(-1) of light, moderate, moderate to vigorous (MVPA) and vigorous PA. MVPA was dichotomized into < 60 min day(-1) and > or = 60. Total body fat was measured by DXA, BodPod and the sum of six skinfolds. Central body fat was measured by DXA at three regions (R1, R2 and R3), and waist circumference.\r\nRESULTS\r\nAll markers of central body fat were negatively associated with vigorous PA (P < 0.01) after controlling for sex, age and pubertal status. Abdominal adiposity measured at R1, R2 and R3 was also negatively associated with MVPA (P < or = 0.001), and with average PA (P < 0.01). All markers of total body fat were negatively associated with vigorous PA (P < 0.01), MVPA (P < 0.01) and average PA (P < 0.05). Adolescents engaged on at least 60 min day(-1) MVPA presented lower levels of total (P < 0.05) and central body fat (P < or = 0.01).\r\nCONCLUSIONS\r\nThe results suggest that vigorous PA may have a greater effect on preventing obesity in adolescents than does PA of lower intensity, whereas both average PA and at least moderate PA may have an impact on total and central body fat in youth.

Mondorf, W.; Siegmund, B.; Mahnel, R.; Richter, H.; Westfeld, M.; Galler, A.; Pollmann, H. (2009):

Haemoassist--a hand-held electronic patient diary for haemophilia home care.

In: *Haemophilia* 15 (2), S. 464–472. DOI: 10.1111/j.1365-2516.2008.01941.x.

Abstract:

On-demand or prophylactic home-treatment is currently the treatment of choice for haemophilia patients. To allow physicians to monitor the amount of factor concentrates administered, the patients document each factor injection in a paper-diary. Nevertheless, because of the fact that most patients visit their physicians only two to four times a year, there could be considerable delay in detecting medication problems. The aim of this pilot study was to assess whether an electronic documentation tool could successfully replace traditional paper-diaries for haemophilia A patients and enable the physician to have a timely overview of the patient's treatment. An electronic, hand-held documentation tool, Haemoassist, was developed. In this study, patients using prophylaxis and on-demand therapies documented their factor consumption both electronically and on paper-diaries. Documentations were compared and descriptively evaluated. Patients also completed a survey to evaluate the feasibility and gather their opinions on the Haemoassist system. Ten patients from two haemophilia treatment centres in Germany submitted a total of 548 records via hand-held device during the observation period, from March 2006 to February 2007. Comparison of electronic and paper-based records showed differing responses among patients with some patients entering more electronic and some others more paper-based documentations. In the questionnaires on feasibility and usefulness of Haemoassist, three patients preferred the electronic tool, two patients wanted to continue using paper-based diaries, and one had no preference. The study shows that an electronic documentation system is feasible for haemophilia patients and provides the physician with the opportunity to more closely monitor patients. However, not all patients seem to be qualified for using an electronic tool, and the tool has to run reliably without major errors for ensuring reliability and acceptability. In the future, Haemoassist might support quality assurance in haemophilia treatment and improve guidance in the home-care setting.

Monk, Rebecca L.; Heim, Derek (2014):

A real-time examination of context effects on alcohol cognitions.

In: *Alcohol Clin Exp Res* 38 (9), S. 2454–2459. DOI: 10.1111/acer.12504.

Abstract:

BACKGROUND: This research used context aware experiential sampling to investigate the effect of contexts on in vivo alcohol-related outcome expectancies. METHODS: A time-stratified random sampling strategy was adopted to assess 72 students and young professionals at 5 daily intervals over the course of a week using a specifically designed smartphone application. This application recorded respondents' present situational and social contexts, alcohol consumption, and alcohol-related cognitions in real-time. RESULTS: In vivo social and environmental contexts and current alcohol consumption accounted for a significant proportion of variance in outcome expectancies. For instance, prompts which occurred while participants were situated in a pub, bar, or club and in a social group of friends were associated with heightened outcome expectancies in comparison with other settings. CONCLUSIONS: Alcohol-related expectancies do not appear to be static but instead demonstrate variation across social and environmental contexts. Modern technology can be usefully employed to provide a more ecologically valid means of measuring such beliefs.

Mönkemüller, K.; Neumann, H.; Fry, L. C.; Kolfenbach, S.; Malfertheiner, P. (2009):

Katheterfreie pH-Metrie mittels Bravo-Kapsel versus Standard-pH-Metrie bei Patienten mit nicht erosiver Refluxkrankheit (NERD).

In: *Zeitschrift für Gastroenterologie* 47 (4), S. 351–356. DOI: 10.1055/s-2008-1027945.

Abstract:

BACKGROUND\r\npH-monitoring is considered the gold standard for the detection of acid reflux in patients with non-erosive reflux disease (NERD). Preliminary pH studies performed over periods longer than 24 hours have shown that in up to one-third of subjects abnormal pH exposure is detected only on the second day of monitoring. Therefore, pH-monitoring during 48 hours may yield more information about pathological acid reflux in patients being investigated for NERD.\r\nAIM\r\nThe aim of this study was to compare conventional 24-hour pH-monitoring with the new wireless 48-hour Bravo pH-monitoring in patients with NERD.\r\nPATIENTS AND METHODS\r\nPatients with typical reflux symptoms, a positive reflux disease questionnaire and negative endoscopy (NERD) and without any form of acid suppressive therapy were included in this prospective study. The patients were divided into two groups: group A for conventional 24-hour pH-monitoring and group B for wireless 48-h Bravo pH-monitoring.\r\nRESULTS\r\n76 patients with a diagnosis of NERD based on a positive RDQ questionnaire and negative endoscopy were included. (47 woman, 29 men, median age: 49 years). 54 underwent conventional pH-monitoring and 22 underwent 48-h pH-monitoring with the new wireless BRAVO system. The overall incidence of acid reflux was 55 % in patients with NERD. Acid reflux was detected less frequently when using Bravo as compared to conventional pH-monitoring. In addition, the Bravo pH-metry showed a large day-to-day variability.\r\nCONCLUSIONS\r\nProlonged pH-monitoring over a period longer than 24 hours did not improve the detection of acid reflux in patients with NERD. Thus, it appears that the Bravo pH-metry does not offer an advantage over standard pH-metry in the daily clinical practice.

Moody, William E.; Tomlinson, Laurie A.; Ferro, Charles J.; Steeds, Richard P.; Mark, Patrick B.; Zehnder, Daniel et al. (2014):

Effect of A Reduction in glomerular filtration rate after NEphrectomy on arterial STiffness and central hemodynamics: rationale and design of the EARNEST study.

In: *Am Heart J* 167 (2), S. 141-149.e2. DOI: 10.1016/j.ahj.2013.10.024.

Abstract:

BACKGROUND: There is strong evidence of an association between chronic kidney disease (CKD) and cardiovascular disease. To date, however, proof that a reduction in glomerular filtration rate (GFR) is a causative factor in cardiovascular disease is lacking. Kidney donors comprise a highly screened population without risk factors such as diabetes and inflammation, which invariably confound the association between CKD and cardiovascular disease. There is strong evidence that increased arterial stiffness and left ventricular hypertrophy and fibrosis, rather than atherosclerotic disease, mediate the adverse cardiovascular effects of CKD. The expanding practice of live kidney donation provides a unique opportunity to study the cardiovascular effects of an isolated reduction in GFR in a prospective fashion. At the same time, the proposed study will address ongoing safety concerns that persist because most longitudinal outcome studies have been undertaken at single centers and compared donor cohorts with an inappropriately selected control group. HYPOTHESES: The reduction in GFR accompanying uninephrectomy causes (1) a pressure-independent increase in aortic stiffness (aortic pulse wave velocity) and (2) an increase in peripheral and central blood pressure. METHODS: This is a prospective, multicenter, longitudinal, parallel group study of 440 living kidney donors and 440 healthy controls. All controls will be eligible for living kidney donation using current UK transplant criteria. Investigations will be performed at baseline and repeated at 12 months in the first instance. These include measurement of arterial stiffness using applanation tonometry to determine pulse wave velocity and pulse wave analysis, office blood pressure, 24-hour ambulatory blood pressure monitoring, and a series of biomarkers for cardiovascular and bone mineral disease. CONCLUSIONS: These data will prove valuable by characterizing the direction of causality between cardiovascular and renal disease. This should help inform whether targeting reduced GFR alongside more traditional cardiovascular risk factors is warranted. In addition, this study will contribute important safety data on living kidney donors by providing a longitudinal assessment of well-validated surrogate markers of cardiovascular disease, namely, blood pressure and arterial stiffness. If any adverse effects are detected, these may be potentially reversed with the early introduction of targeted therapy. This should ensure that kidney donors do not come to long-term harm and thereby preserve the ongoing expansion of the living donor transplant program (NCT01769924).

Association between video display terminal use and dry eye disease in school children.

In: *J Pediatr Ophthalmol Strabismus* 51 (2), S. 87–92. DOI: 10.3928/01913913-20140128-01.

Abstract:

PURPOSE: To evaluate the risk factors of dry eye disease in school children associated with video display terminal use. METHODS: Two-hundred eighty-eight children were classified in either a dry eye disease group or control group according to the diagnostic criteria of dry eye disease. The results of ocular examinations, including best-corrected visual acuity, slit-lamp examination, and tear break-up time, were compared between groups. The results of questionnaires concerning video display terminal use and ocular symptoms were also compared. RESULTS: Twenty-eight children were included in the dry eye disease group and 260 children were included in the control group. Gender and best-corrected visual acuity were not significantly different between the two groups. Smartphone use was more common in the dry eye disease group (71%) than the control group (50%) (P = .036). The daily duration of smartphone use and total daily duration of video display terminal use were associated with increased risk of dry eye disease (P = .027 and .001, respectively), but the daily duration of computer and television use did not increase the risk of dry eye disease (P = .677 and .052, respectively). CONCLUSIONS: The results showed that smartphone use is an important dry eye disease risk factor in children. Close observation and caution regarding video display terminal use, especially smartphones, are needed for children. [J Pediatr Ophthalmol Strabismus 2014;51(2):87-92.].

Moore, Helen J.; Ells, Louisa J.; McLure, Sally A.; Crooks, Sean; Cumbor, David; Summerbell, Carolyn D.; Batterham, Alan M. (2008):

The development and evaluation of a novel computer program to assess previous-day dietary and physical activity behaviours in school children: The Synchronised Nutrition and Activity Program TM (SNAP TM).

In: *British Journal of Nutrition* 99 (06), S. 1266–1274.

Abstract:

Self-report recall questionnaires used to measure physical activity and dietary intake in children can be labour intensive and monotonous and tend to focus on either dietary intake or physical activity. The web-based software, Synchronised Nutrition and Activity ProgramTM (SNAPTM), was developed to produce a novel, simple, quick and engaging method of assessing energy balance-related behaviours at a population level, combining principles from new and existing 24 h recall methodologies, set within a user-friendly interface. Dietary intake was measured using counts for twenty-one food groups and physical activity levels were measured in min of moderate to vigorous physical activity (MVPA). A combination of the mean difference between methods, type II regression and non-parametric limits of agreement techniques were used to examine the accuracy and precision of SNAPTM. Method comparison analyses demonstrated a good agreement for both dietary intake and physical activity behaviours. For dietary variables, accuracy of SNAPTM (mean difference) was within ± 1 count for the majority of food groups. The proportion of the sample with between-method agreement within ± 1 count ranged from 0·40 to 0·99. For min of MVPA, there was no substantial fixed or proportional bias, and a mean difference between methods (SNAPTM – accelerometry) of − 9 min. SNAPTM provides a quick, accurate, low-burden, cost-effective and engaging method of assessing energy balance behaviours at a population level. Tools such as SNAPTM, which exploit the popularity, privacy and engagement of the computer interface, and linkages with other datasets, could make a substantial contribution to future public health monitoring and research.

Moore, Steven T.; MacDougall, Hamish G.; Ondo, William G. (2008):

Ambulatory monitoring of freezing of gait in Parkinson's disease.

In: *J Neurosci Methods* 167 (2), S. 340–348.

Abstract:

Freezing of gait (FOG) is common in advanced Parkinson's disease (PD), is resistant to treatment and negatively impacts quality of life. In this study an ambulatory FOG monitor was validated in 11 PD patients. The vertical linear acceleration of the left shank was acquired using an ankle-mounted sensor array that transmitted data wirelessly to a pocket PC at a rate of 100 Hz. Power analysis showed high-frequency components of leg movement during FOG in the 3-8 Hz band that were not apparent during volitional standing, and power in this 'freeze' band was higher (p=0.00003) during FOG preceded by walking (turning or obstacles) than FOG preceded by rest (gait initiation). A freeze index (FI) was defined as the power in the 'freeze' band divided by the power in the 'locomotor' band (0.5-3 Hz) and a threshold chosen such that FI values above this limit were designated as FOG. A global threshold detected 78% of FOG events and 20% of stand events were incorrectly labeled as FOG. Individual calibration of the freeze threshold improved accuracy and sensitivity of the device to 89% for detection of FOG with 10% false positives. Ambulatory monitoring may significantly improve clinical management of FOG.

Ecological Momentary Assessment of the Effects of Craving and Affect on Risk for Relapse During Substance Abuse Treatment.

In: *Psychology of Addictive Behaviors*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-36063-001%26site%3dehost-live.

Abstract:

The primary goals of this study were to use ecological momentary assessment (EMA) to examine the extent to which proximal factors (cravings and affect) were temporally associated with relapse, and to assess the role of distal factors (e.g., coping styles) in moderating these associations. We also examined whether using EMA procedures impacted relapse rates. A sample of 100 male (n = 66) and female (n = 34) patients entering outpatient treatment for substance abuse completed a baseline assessment of substance dependence, stress, social support, coping styles, family history of substance abuse, and self-efficacy. Half of the participants were randomly assigned to receive training in using a handheld computer to respond to 3 random prompts each day for 4 months regarding cravings, affect, and substance use. All participants completed 2- and 4-month follow-up assessments of substance use. Results showed that using EMA procedures did not influence relapse rates. Hierarchical linear modeling showed that individuals who reported an increase in cravings on a given prompt were 14 times more likely to report relapse on the subsequent prompt than individuals who did not experience an increase in cravings. In addition, women, older individuals, and individuals who use distraction and disengagement as coping styles were at increased risk for relapse when experiencing an increase in cravings. Individuals who use acceptance as a coping style were at decreased risk for relapse when experiencing an increase in cravings. The study highlights the importance of tailoring treatments to address the needs of particular individuals and risk factors. Within-person variations in self-focused attention and negative affect in depression and anxiety: A diary study.

In: *Cognition and Emotion* 24 (1), S. 48–62.

Abstract:

This study examined within-person co-occurrence of self-focus, negative affect, and stress in a community sample of adolescents with or without emotional disorders. As part of a larger study, 278 adolescents were interviewed about emotional disorders. Later, they completed diary measures over three days, six times a day, reporting their current thoughts, affect, and levels of stress. Negative affect was independently related to both concurrent stress and self-focus. Importantly, the association between negative affect and self-focus was stronger among participants with a recent unipolar mood disorder, compared to those with an anxiety disorder, comorbid anxiety and depression, or those without an emotional disorder. The implications of these findings to theories of self-focus and its role in emotional disorders are discussed.

Moran, Andrew; Palmas, Walter; Pickering, Thomas G.; Schwartz, Joseph E.; Field, Lesley; Weinstock, Ruth S.; Shea, Steven (2006):

Office and ambulatory blood pressure are independently associated with albuminuria in older subjects with type 2 diabetes.

In: *Hypertension* 47 (5), S. 955–961. DOI: 10.1161/01.HYP.0000216634.73504.7d.

Abstract:

Blood pressure strongly predicts microalbuminuria and later progression to renal failure in people with diabetes. Ambulatory blood pressure monitoring seems to be superior to office blood pressure in predicting progression to microalbuminuria in type 1 diabetes. The associations of ambulatory blood pressure with office blood pressure and microalbuminuria in type 2 diabetes remain unclear. We studied the association of office blood pressure taken with an automated device and ambulatory blood pressure with spot urine albumin:creatinine ratio in 1180 older people with type 2 diabetes participating in the Informatics for Diabetes Education and Telemedicine Study. Office and awake systolic blood pressure were independently associated with albuminuria ($P<0.001$ for both) in a multivariate linear regression analysis that adjusted for age, gender, duration of diabetes, hemoglobin A1c, number of antihypertensive medications, and use of an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker. Twelve percent of participants had well-controlled office blood pressure but not ambulatory blood pressure, whereas 14% had well-controlled ambulatory but not office blood pressure. The prevalence of microalbuminuria and macroalbuminuria in these subgroups was intermediate between those with well-controlled or uncontrolled blood pressure by

both methods. We found, in a multiethnic group of older subjects with type 2 diabetes, that office systolic blood pressure and awake systolic ambulatory blood pressure exhibited independent associations with degree of albuminuria.

Physical training does not increase allergic inflammation in asthmatic children.

In: *European respiratory journal* 32 (6), S. 1570–1575.

Abstract:

The effects of a 3-month physical training programme on airway inflammation and clinical outcomes were studied in school-aged children with asthma. Subjects with persistent allergic asthma (aged 12.7+/-3.4 yrs; n = 34) were randomly allocated into training and control groups. Exercise consisted of twice-weekly 50-min sessions for 12 weeks. Inflammation was assessed by levels of exhaled nitric oxide, blood eosinophils, eosinophil cationic protein, C-reactive protein, and total and mite-specific immunoglobulin (Ig)E. Lung volumes and bronchial responsiveness to methacholine were determined. The Paediatric Asthma Quality of Life Questionnaire and Paediatric Asthma Caregiver's Quality of Life Questionnaire were used to evaluate activity restrictions, symptoms and emotional stress. The efficacy of the training was assessed by accelerometry. Following the programme, the exercise group spent twice as much time as the controls undertaking moderate-to-vigorous activities. No differences in changes were seen between groups for asthma outcomes. However, total IgE decreased more in the exercise group, as did mite-specific IgE. Training did not increase inflammation in children with persistent asthma, and may have decreased both total and allergen-specific immunoglobulin E levels. It is concluded that there is no reason to discourage asthmatic children with controlled disease to exercise.

Depression and internet use among older adolescents: An experience sampling approach.

In: *Psychology* 3 (9A), S. 743–748. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-13996-001%26site%3dehost-live;mamoreno@pediatrics.wisc.edu.

Abstract:

Background: Depression is common and consequential among adolescents. Previous work has found varied relationships between depression and internet use. The purpose of this study was to examine internet use and depression by applying a rigorous assessment tool: experience sampling method (ESM). Methods: Older adolescents between the ages of 18 and 23 years were recruited from a large state university. Participants received 6 text message surveys randomly each day during a 7-day ESM campaign. Survey questions assessed whether they were currently online and for how long. Participants also completed the PHQ-9 depression survey. Calculation of internet use time included multilevel modeling and probability modeling. Analysis of covariance (ANCOVA) assessed the association between internet use and depression. Results: Among our 189 participants, the mean age was 18.9 (SD=.9), 58.8% were female and most were Caucasian (90.5%). Total daily internet use time was calculated as 66 minutes by ESM summary, 55 minutes by ESM modeling and 65 minutes by probability modeling. We found a difference in PHQ-9 scores when comparing low daily internet use (<30 minutes), regular use (30 minutes to 3 hours) and high use (>3 hours) (p=.01) with a significant U-shaped association (p=.004). The high use group had a mean PHQ-9 score of 7.3 (SD=5.1) compared to the regular use group score of 4.9 (SD=3.9) (p=.02). Conclusions: Results suggest a U shaped association between internet use and depression. These findings may present statistical differences that lack clinical significance. Internet use and multitasking among older adolescents: An experience sampling approach.

In: *Computers in Human Behavior*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-04501-001&site=ehost-live.

Abstract:

Internet use is challenging for individuals to quantify and describe. Previous internet use studies have relied on self-report measures, which may be subject to recall bias. This studied aimed to assess college student internet use using a real-time methodology, experience sampling method (ESM). Undergraduate students participated in a 7-day ESM campaign using text message surveys sent at 6 random times each day. Survey questions evaluated current internet use time and activities. Analyses included hierarchical clustering analysis, multilevel and probability modeling. Among the 189 participants, mean age was 18.9 (SD=0.9), 58.8% were female and most were Caucasian (90.5%). The modeled average total amount of daily internet time was 56min, 95% CI [51, 62]. The correlation between self-reported internet use time and ESM data was 0.31 ($p<0.001$). Over half of the time participants were on the internet they reported multitasking (56.5%, 95% CI [52.7%, 60.4%]). Study findings suggest that multitasking is frequent among college students, which may explain over-reported internet use. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Moron, Maria Jose; Luque, Rafael; Casilari, Eduardo (2014):

On the capability of smartphones to perform as communication gateways in medical wireless personal area networks.

In: *Sensors (Basel)* 14 (1), S. 575–594. DOI: 10.3390/s140100575.

Abstract:

This paper evaluates and characterizes the technical performance of medical wireless personal area networks (WPANs) that are based on smartphones. For this purpose,a prototype of a health telemonitoring system is presented. The prototype incorporates a commercial Android smartphone, which acts as a relay point, or "gateway", between a set of wireless medical sensors and a data server. Additionally, the paper investigates if the conventional capabilities of current commercial smartphones can be affected by their use as gateways or "Holters" in health monitoring applications. Specifically, the profiling has focused on the CPU and power consumption of the mobile devices. These metrics have been measured under several test conditions modifying the smartphone model, the type of sensors connected to the WPAN, the employed Bluetooth profile (SPP (serial port profile) orHDP (health device profile)), the use of other peripherals, such as a GPS receiver, the impact of the use of the Wi-Fi interface or the employed method to encode and forward the data that are collected from the sensors.

Cigarette smoking and cardiovascular risk in young women with polycystic ovary syndrome.

In: *Int J Fertil Steril* 7 (4), S. 301–312.

Abstract:

BACKGROUND: To verify if in lean polycystic ovary syndrome (PCOS) patients, the smok- ing habitude might increase the risk of cardiovascular (CV) disease. MATERIALS AND METHODS: In this prospective observational study, eighty-one women were divided into the following three groups: group I with 27 non-smokers, group II with 26 light-smokers (1-10 cigarettes/day), and group III with 28 heavy smokers (>10 cigarettes/ day). They were submitted to fasting blood sampling; blood measurement of nitrites/ni- trates (NO_2-/ NO_3), biochemical and hormonal parameters; ovarian ultrasonographic (US) analysis; doppler evaluation of uterine and ophthalmic arteries; brachial artery flow-medi- ated vasodilatation; 24-hour ambulatory blood pressure monitoring; and oral glucose toler- ance test (OGTT). RESULTS: Doppler analysis revealed higher uterine and ophthalmic arteries pulsatility in- dex (PI) and ophthalmic artery back pressure in group III compared with group I. The brachial artery diameter and PI, at baseline, was similar among all groups. After the re- active hyperemia, a more intense vasodilatation was observed in group I in comparison with group III. The 24-hour blood pressure demonstrated that, in group III patients, the 24-hour, day- and night-time diastolic blood pressure (DBP), was higher in comparison with non-smokers. The atherogenic index of plasma (AIP) was higher in heavy smokers than in non-smokers. The leukocytes and homocysteine (HCY) values were increased in group III. The NO_2-/ NO_3- plasma levels were reduced in heavy smokers in compari- son with non-smokers. The insulin, glucose and C-peptide plasma values were higher in group III than in other groups. In heavy smokers, the estimates of insulin sensitivity (ISI) and pancreatic beta-cell function (HOMA-B) were higher compared to the other groups. CONCLUSION: Smoking habitude in lean PCOS patients may increase the soft markers of CV risk.

Compliance with momentary pain measurement using electronic diaries: a systematic review.

In: *Eur J Pain* 13 (4), S. 354–365.

Abstract:

Electronic diaries are increasingly used to assess daily pain in many different forms and populations. This systematic review aims to survey the characteristics of studies using electronic pain diaries and to examine how these characteristics affect compliance. A literature search of 11 electronic databases was conducted. Studies were evaluated on the basis of predetermined inclusion criteria by two independent reviewers. Study characteristics were grouped into four categories: general, population, electronic diary, and sampling procedure (i.e., response, attrition, and compliance rates) including strategies to enhance compliance. The 62 included publications reported from 43 different datasets. Papers were usually written in English and published as from 2000. Samples mostly consisted of female chronic pain patients aged 19–65 years from western countries. Most diaries held less than 20 items and were completed up to 6 times daily at fixed or prompted times for 1 month at most. Less than 25% of the studies reported both response and attrition rates; however, a majority reported compliance. Compliance was generally high, and positively associated with shorter diaries, age, having a user's manual, financial compensation and using an alarm. It is important that the various study characteristics are catalogued carefully, especially response and attrition rates, because they can affect compliance. Measures of momentary pain are often developed for the purpose of a certain study; standardisation and validation of these measures is recommended. Finally, authors should mention whether they report on data that has also been used in previous studies.

A comparison of clinical and objective measures of freezing of gait in Parkinson's disease.

In: *Parkinsonism Relat Disord* (1353-8020 (Linking)). DOI: 10.1016/j.parkreldis.2012.03.001.

Abstract:

Freezing of gait, a paroxysmal motor block, is common in the latter stages of Parkinson's disease. The current 'gold standard' of assessing the severity of freezing is based on clinical identification (by up to 3 raters) of the number of episodes from video. The aims of this study were to systematically assess this 'gold standard' across multiple Parkinson's disease centers, and to compare these clinical ratings with objective measures derived from lower limb acceleration data. Video recordings were acquired during a timed up-and-go task from 10 Parkinson's disease patients (with a clinical history of freezing) in the 'off' state. Patients were instrumented with accelerometers on the lateral aspect of each shank. Ten experienced clinicians were recruited from four

Parkinson's disease centers to independently assess the videos for number and duration of freezing events. The reliability of clinical video assessment for number of freezing events was moderate (intraclass correlation coefficient 0.63). Percent time frozen (cumulative duration of freezing episodes/total duration of the walking task) demonstrated stronger agreement between raters (0.73). Agreement of accelerometry-derived measures of freezing severity with mean clinician ratings was strong for number of episodes (0.78) and very strong for percent time frozen (0.93). The results demonstrate the viability of objective measures of freezing, and that percent time frozen is a more reliable metric of severity than number of freezing events for both clinical and objective measures. The large variability between clinicians suggests that caution should be used when comparing subjective ratings across centers

Morris, Margaret E.; Kathawala, Qusai; Leen, Todd K.; Gorenstein, Ethan E.; Guilak, Farzin; Labhard, Michael; Deleeuw, William (2010):

Mobile therapy: Case study evaluations of a cell phone application for emotional self-awareness.

In: *J Med Internet Res* 12 (2), S. 33–50. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-05856-003&site=ehost-live;margaret.morris@intel.com.

Abstract:

Background: Emotional awareness and self-regulation are important skills for improving mental health and reducing the risk of cardiovascular disease. Cognitive behavioral therapy can teach these skills but is not widely available. Objective: This exploratory study examined the potential of mobile phone technologies to broaden access to cognitive behavioral therapy techniques and to provide in-the-moment support. Methods: We developed a mobile phone application with touch screen scales for mood reporting and therapeutic exercises for cognitive reappraisal (ie, examination of maladaptive interpretations) and physical relaxation. The application was deployed in a one-month field study with eight individuals who had reported significant stress during an employee health assessment. Participants were prompted via their mobile phones to report their moods several times a day on a Mood Map-a translation of the circumplex model of emotion-and a series of single-dimension mood scales. Using the prototype, participants could also activate mobile therapies as needed. During weekly open-ended interviews, participants discussed their use of the device and responded to longitudinal views of their data. Analyses included a thematic review of interview narratives, assessment of mood changes over the course of the study and the diurnal cycle, and interrogation of this mobile data based on stressful incidents reported in interviews. Results: Five case studies illustrate participants' use of the mobile phone application to increase self-awareness and to cope with stress. One example is a participant who had been coping with longstanding marital conflict. After reflecting on his mood data, particularly a drop in energy each evening, the participant began practicing relaxation therapies on the phone before entering his house, applying cognitive reappraisal techniques to cope with stressful family interactions, and talking more openly with his wife. His mean anger, anxiety and sadness ratings all were lower in the second half of the field study than in the first (P ? .01 for all three scales). Similar changes were observed among other participants as they used the application to negotiate bureaucratic frustrations, work tensions and personal relationships. Participants appeared to understand the mood scales developed for this experience sampling application and responded to them in a way that was generally consistent with self-reflection in weekly interviews. Interview accounts of mood changes, associated with diurnal cycles, personal improvement over the course of the study, and stressful episodes, could be seen in the experience sampling data. Discrepancies between interview and experience-sampling data highlighted the ways that individuals responded to the two forms of inquiry and how they calibrated mood ratings over the course of the study. Conclusions: Participants quickly grasped the Mood Mapping and therapeutic concepts, and applied them creatively in order to help themselves and empathize with others. Applications developed for mobile phones hold promise for delivering state-of-the-art psychotherapies in a nonstigmatizing fashion to many people who otherwise would not have access to therapy. Morrison, Leanne G.; Hargood, Charlie; Lin, Sharon Xiaowen; Dennison, Laura; Joseph, Judith; Hughes, Stephanie et al. (2014):

Understanding usage of a hybrid website and smartphone app for weight management: a mixed-methods study.

In: *J Med Internet Res* 16 (10), S. e201. DOI: 10.2196/jmir.3579.

Abstract:

BACKGROUND: Advancements in mobile phone technology offer huge potential for enhancing the timely delivery of health behavior change interventions. The development of smartphone-based health interventions (apps) is a rapidly growing field of research, yet there have been few longitudinal examinations of how people experience and use these apps within their day-to-day routines, particularly within the context of a hybrid Web- and app-based intervention. OBJECTIVE: This study used an in-

depth mixed-methods design to examine individual variation in (1) impact on self-reported goal engagement (ie, motivation, self-efficacy, awareness, effort, achievement) of access to a weight management app (POWeR Tracker) when provided alongside a Web-based weight management intervention (POWeR) and (2) usage and views of POWeR Tracker. METHODS: Thirteen adults were provided access to POWeR and were monitored over a 4-week period. Access to POWeR Tracker was provided in 2 alternate weeks (ie, weeks 1 and 3 or weeks 2 and 4). Participants' goal engagement was measured daily via self-report. Mixed effects models were used to examine change in goal engagement between the weeks when POWeR Tracker was and was not available and whether the extent of change in goal engagement varied between individual participants. Usage of POWeR and POWeR Tracker was automatically recorded for each participant. Telephone interviews were conducted and analyzed using inductive thematic analysis to further explore participants' experiences using POWeR and POWeR Tracker. RESULTS: Access to POWeR Tracker was associated with a significant increase in participants' awareness of their eating (beta1=0.31, P=.04) and physical activity goals (beta1=0.28, P=.03). The level of increase varied between individual participants. Usage data showed that participants used the POWeR website for similar amounts of time during the weeks when POWeR Tracker was (mean 29 minutes, SD 31 minutes) and was not available (mean 27 minutes, SD 33 minutes). POWeR Tracker was mostly accessed in short bursts (mean 3 minutes, SD 2 minutes) during convenient moments or moments when participants deemed the intervention content most relevant. The qualitative data indicated that nearly all participants agreed that it was more convenient to access information on-the-go via their mobiles compared to a computer. However, participants varied in their views and usage of the Web- versus app-based components and the informational versus tracking tools provided by POWeR Tracker. CONCLUSIONS: This study provides evidence that smartphones have the potential to improve individuals' engagement with their health-related goals when used as a supplement to an existing online intervention. The perceived convenience of mobile access to information does not appear to deter use of Web-based interventions or strengthen the impact of app access on goal engagement. A mixed-methods design enabled exploration of individual variation in daily usage of the app-based tools.

Morrison, Ryan; Penpraze, Victoria; Greening, Ruth; Underwood, Tom; Reilly, John J.; Yam, Philippa S. (2014):

Correlates of objectively measured physical activity in dogs.

In: *Vet J* 199 (2), S. 263–267. DOI: 10.1016/j.tvjl.2013.11.023.

Abstract:

To increase physical activity (PA) levels in dogs and to better evaluate their energy requirements, there is a need to understand which factors or correlates are associated with PA and/or sedentary behaviour. Improving our understanding of these correlates also has implications for prescribed energy requirements in dogs. PA was measured using accelerometry in 62 dogs from two common breeds (Labrador retrievers and Cocker spaniels). Five potential correlates (age, sex, breed, neuter status, body condition score) were tested for associations with total volume of PA, light-moderate intensity PA, vigorous intensity PA and sedentary behaviour. Age and breed were associated with total volume of PA, light-moderate intensity PA and sedentary behaviour in the final models. Age was associated with vigorous intensity PA. The final models explained 60%, 40%, 63% and 44% of variance in total volume of PA, light-moderate intensity PA, vigorous intensity PA and sedentary behaviour, respectively. These results should improve understanding of the variation in energy requirements of dogs, as well as the development of age and breed-specific diets and the prevention and treatment of canine obesity.

Moses Passini, Christina; Pihet, Sandrine; Favez, Nicolas (2014):

Assessing specific discipline techniques: A mixed-methods approach.

In: *Journal of Child and Family Studies* 23 (8), S. 1389–1402. DOI: 10.1037/t00815-000.

Abstract:

This study explored, in a community sample of mothers of toddlers, parenting beliefs and values, to gain insight into the parent–child relationship. Acceptance of specific discipline techniques (DTs), and their actual use in daily life were examined. A mixed-methods approach comprising three different methods was used: (1) parenting beliefs and values were explored with Q-methodology; (2) acceptance of the DTs was assessed with the questionnaire Dimensions of Discipline Inventory; and (3) actual use of those DTs in daily-life incidents of discipline was documented using ecological momentary assessment for ten consecutive days. The results showed the mothers' parenting beliefs and values reflected a warm parent–child relationship. The mothers rated explaining rules, timeout, removal of privileges, and social reinforcement as moderately to highly acceptable. However, planned ignoring received a low acceptance rating. Mothers' high acceptability ratings of the DTs contrasted with moderate use when they were faced with their misbehaving child, with the exception of explaining rules, which was always manifested. Yelling and spanking received the lowest acceptance ratings. Nonetheless, in daily life, yelling was employed as often as timeout. These findings suggest the need for more attention to be paid to both acceptance and daily use of specific DTs in order to highlight DTs which parents may have difficulty implementing. Assessment of Parental Discipline in Daily Life.

In: *J Fam.Psychol.* (0893-3200 (Linking)). DOI: 10.1037/a0031504.

Abstract:

The use of ecological momentary assessment (EMA) for studying parenting has been rare. We examined the psychometric properties and structural validity of an EMA Parenting Scale based on 32 mothers' reports of their parenting over a period of 10 consecutive days, and explored the acceptance of the scale and compliance with the procedure. The results suggested that the EMA Parenting Scale was well accepted for the assessment of daily parenting, and that it consistently captured the overreactive and lax dimensions of parenting across different episodes of child misbehavior. Moreover, multilevel analyses suggested that the scale was sensitive to change across different parenting episodes, and that it reliably assessed the dimensions at both the personal and situational levels. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

Moskowitz, D. S.; Russell, Jennifer J.; Sadikaj, Gentiana; Sutton, Rachel (2009):

Measuring people intensively.

In: *Canadian Psychology/Psychologie Canadienne* 50 (3), S. 131.

Abstract:

An overview is provided of measures that are administered repeatedly in daily life. Variations of this methodology have been referred to as ecological momentary assessment, diary methods, daily process measures, and most broadly as intensive repeated measures in naturalistic settings (IRM-NS). Contrasts are drawn between IRM-NS methods on the basis of different sampling strategies, such as time-contingent recording, signal-contingent recording, and event-contingent recording. Common threats to the internal validity, construct validity, and external validity of IRM-NS measures are reviewed, along with ways to reduce these threats. The statistical analysis of IRM-NS data is considered, with a particular focus on the investigation of intraindividual variability. An extended example is provided of an IRM-NS measure, an event-contingent recording method for the assessment of interpersonal behaviour. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

Motl, Robert W.; Learmonth, Yvonne C.; Pilutti, Lara A.; Dlugonski, Deirdre; Klaren, Rachel (2014):

Validity of minimal clinically important difference values for the multiple sclerosis walking scale-12?

In: *Eur Neurol* 71 (3-4), S. 196–202. DOI: 10.1159/000356116.

Abstract:

Background and Objective: Minimal clinically important difference (MCID) values of 4 and 6 points have been proposed for interpreting meaningful change in Multiple Sclerosis Walking Scale-12 (MSWS-12) scores. This study examined the validity of those MCID values based on capturing corresponding changes in other walking outcomes in persons with multiple sclerosis (MS). Methods: On 2 occasions separated by 6 months, 82 persons with MS completed the MSWS-12, timed 25-ft walk (T25FW), 6-min walk (6MW), and gait analysis, and then wore an accelerometer over a 7-day period. We generated change scores for the MSWS-12 and formed groups of stable, worsened, and improved perceived walking based on both 4- and 6-point changes. The groups were compared for corresponding changes in other walking measures over time using mixed-model ANOVAs. Results: The mixed-model ANOVAs did not identify statistically significant group-by-time interactions on the T25FW ($p = 0.98$ and $p = 0.67$), the 6MW ($p = 0.89$ and $p = 0.72$), gait ($p = 0.54$ and $p = 0.21$), or accelerometry ($p = 0.40$ and $p = 0.68$) for MCID values of 4- or 6-point changes in MSWS-12 scores. Conclusions: We did not confirm that MCID values of 4 and 6 points for the MSWS-12 correspond with changes in performance, gait, and free-living assessments of walking in MS. (c) 2014 S. Karger AG, Basel.

Reactivity in baseline accelerometer data from a physical activity behavioral intervention.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24250-001&site=ehost-live.

Abstract:

Objective: This brief report describes the possibility of reactivity in the baseline assessment of physical activity using accelerometry from two separate randomized controlled trials of a behavior intervention for increasing physical activity in persons with multiple sclerosis (MS). Method: The samples included 18 persons with multiple sclerosis (MS) from Study 1 and 20 from Study 2 who were randomized into treatment arms of the intervention. The participants initially wore an accelerometer over a 7-day period for collection of baseline data, and one week later wore a pedometer over a 7-day period for collection of data for self-monitoring and goal setting in week 1 of the 12-week intervention. The accelerometer and pedometer data were both expressed in average steps per day over a 7-day period. Results: There was a moderate (d = .56), statistically significant (p = .03) difference of 1,822 steps per day between baseline and week 1 of the intervention in Study 1. There was a large (d = 1.36), statistically significant (p = .0001) difference of 2,338 steps per day in Study 2. Conclusion: We are unaware of other research describing a significant change in physical activity between baseline and the first week of a behavioral intervention and believe that this change reflects reactivity in the baseline assessment using accelerometry. Motl, R. W.; Pilutti, L.; Sandroff, B. M.; Dlugonski, D.; Sosnoff, J. J.; Pula, J. H. (2012):

Accelerometry as a measure of walking behavior in multiple sclerosis.

In: *Acta Neurol.Scand.* (0001-6314 (Linking)). DOI: 10.1111/ane.12036.

Abstract:

OBJECTIVE: Accelerometry has been identified as a possible ecologically valid and objective approach for measuring community ambulation in multiple sclerosis (MS). This study provides a validation of accelerometer output based on associations with Expanded Disability Status Scale (EDSS), Patient Determined Disease Steps (PDDS) Scale, and Multiple Sclerosis Walking Scale-12 (MSWS-12) scores, timed 25-foot walk (T25FW) and 6-min walk (6MW) performance, oxygen cost (O(2) cost) of walking, and spatial and temporal parameters of gait. MATERIALS AND METHODS: 256 persons with MS completed the PDDS and MSWS-12, underwent an examination for the generation of an EDSS score, undertook two T25FW tests and a 6MW while wearing a portable metabolic unit for measuring the O(2) cost of walking, completed two trials of comfortable walking on a GAITRite electronic walkway for measuring spatial and temporal parameters of gait, and then wore an Actigraph accelerometer during the waking hours of a 7-day period. RESULTS: The accelerometer output was significantly correlated with EDSS (rho = -0.522), PDDS (rho = -0.551), and MSWS-12 (rho = -0.617) scores, T25FW (rho = -0.595) and 6MW (rho = 0.630) performance, and O(2) cost of walking (rho = -0.457). Regarding gait parameters, the accelerometer output was significantly correlated with velocity (rho = 0.420), cadence (rho = 0.349), step time (rho = -0.353), step length (rho = 0.395), double support (rho = -0.424), and single support (rho = 0.400). CONCLUSION: We provide comprehensive evidence from a large sample of persons with MS that further supports accelerometry as a measure of walking behavior

Commercially available accelerometry as an ecologically valid measure of ambulation in individuals with multiple sclerosis.

In: *Expert.Rev.Neurother.* 12 (9), S. 1079–1088. DOI: 10.1586/ern.12.74.

Abstract:

Ambulatory impairment is a prevalent consequence of multiple sclerosis (MS) that is often measured in controlled contexts using performance tests that lack ecological validity. This underscores the importance of considering alternative, ecologically valid approaches, such as commercially available accelerometers, for measuring community ambulation in individuals with MS. This consideration is warranted based on problems with existing measures of ambulation in MS (e.g., poor responsiveness and patient-clinician discordance); conceptual associations among MS pathology, impairment and gait function with relevance for the signal detected by accelerometers; assumptions that are empirically supported for the application of commercially available accelerometers as a measure of community ambulation; and evidence supporting the output of commercially available accelerometers as a measure of ambulation. Collectively, the authors believe the time is ripe for the application of commercially available accelerometers as an outcome measure of community ambulation in MS. Such an application has the potential to maximize the understanding of ambulatory impairments in real-world conditions for clinical research and practice involving individuals with MS

Energy cost of walking and its association with gait parameters, daily activity, and fatigue in persons with mild multiple sclerosis.

In: *Neurorehabilitation and Neural Repair* 26 (8), S. 1015–1021. DOI: 10.1037/t12541-000;

Abstract:

Background: Energy cost of walking (Cw) is elevated in persons with multiple sclerosis (MS), perhaps because of gait impairment, and may impact daily activity and fatigue. Objective: The authors examined for associations between C[sub]w[/sub], spatiotemporal gait parameters, daily activity, and perceived fatigue in persons with mild MS. Methods: Forty-four participants completed 4 trials of walking on a GAITRite mat and one 6-minute trial of walking on a treadmill at a constant, controlled speed of 54 m min−1 while expired gases were analyzed for oxygen consumption. Participants also completed the Fatigue Severity Scale (FSS) and wore a waist-mounted accelerometer for 7 days. Results. C[sub]w[/sub] was significantly and inversely associated with gait speed (r = −.25) and stride length (r = −.32) and positively associated with double limb support (r = .27). C[sub]w[/sub] was significantly and inversely associated with daily accelerometer activity counts (r = −.35) and positively associated with FSS scores (ρ = .31). Conclusion: The results support the development and application of rehabilitation strategies to address impaired gait parameters as an approach to improve C[sub]w[/sub], daily activities, and fatigue. Motl, Robert W.; Snook, Erin M.; Agiovlasitis, Stamatis (2011):

Does an accelerometer accurately measure steps taken under controlled conditions in adults with mild multiple sclerosis?

In: *Disabil Health J* 4 (1), S. 52–57.

Abstract:

BACKGROUND:

Accurate measurement is required by researchers and clinicians who are interested in the physical activity behavior of individuals with multiple sclerosis (MS). Advances in technology have resulted in an increased number of motion sensors such as pedometers and accelerometers that are worn on the body and that measure bodily movement. Accelerometers are becoming less expensive and more user-friendly, but there is limited evidence regarding the accuracy of measurement in persons with MS.

OBJECTIVE:

The present study examined the accuracy of an ActiGraph accelerometer for measuring steps taken during controlled conditions in persons with MS compared with a sample of individuals without MS.

METHODS:

The participants were 24 adults with mild MS and 24 adults without MS who undertook three 6-minute periods of walking at 54, 80, and 107 m·min(-1) on a motor-driven treadmill. We measured steps taken through observation and an ActiGraph model 7164 accelerometer worn around the waist above the right hip.

RESULTS:

The accelerometer accurately measured steps during moderate (80 m·min(-1)) and fast (107 m·min(-1)) walking in both persons with MS and control subjects. There was a small degree of underestimation of step counts (≈4% error) for the accelerometer during slower walking (54 m·min(-1)) in both persons with MS and control subjects.

CONCLUSIONS:

Such findings support the accuracy of a waist worn ActiGraph accelerometer for the measurement of steps in persons with MS and control subjects.

A very short visual analog form of the Center for Epidemiologic Studies Depression Scale (CES-D) for the idiographic measurement of depression.

In: *J Affect Disord* 128 (3), S. 220–234.

Abstract:

BACKGROUND:

The experience sampling method, also referred to as ecological momentary assessment (ESM-EMA) has recently gained popularity in the study of depression. However, no psychometrically sound multidimensional depression questionnaires specifically designed for the ESM-EMA context are currently available.

AIMS:

The main objective of the present study was to develop and validate a very short visual analog scale of the Center for Epidemiologic Studies Depression Scales (CES-D-VAS-VS) specifically designed for the ESM-EMA context. To this end, the full French version of the CES-D was adapted for the ESM-EMA context. From this full-length adapted version a very short version was then extracted from this longer instrument and validated.

STUDY DESIGN:

A sample comprising 163 patients with a major depressive episode (MDE) and 306 participants without mental disorders was involved in this study.

RESULTS:

The obtained results provided support for the factor validity, strong measurement invariance (invariance of the loadings and intercepts of the measurement model) across sex and clinical status groups, reliability and convergent validity of the CES-D-VAS-VS. This instrument comprises 4 items measuring positive affect, depressive affect, somatic complaints and disturbed interpersonal relationships.

CONCLUSION:

The present results provide preliminary evidence regarding the construct validity of the CES-D-VAS-VS among patients and community adults sample but also underline the need to rely on latent variables methods in the use of this instrument to account for the differential levels of measurement errors (uniquenessess) that were observed across groups.

Wegoto: A Smartphone-based approach to assess and improve accessibility for wheelchair users.

In: *Conf.Proc.IEEE Eng Med.Biol.Soc.* 2013 (1557-170X (Linking)), S. 1194–1197. DOI: 10.1109/EMBC.2013.6609720.

Abstract:

This paper proposes a description of a Smartphone-based approach to assess and improve accessibility for wheelchair users. The developed system employs a dedicated Smartphone application that records various complementary sensor measurements (acceleration, deceleration, inclination, orientation, speed, GPS position) and permits obstacle denunciation. Then, accessibility information are reported on maps in a Geographic Information System which can calculate the most accessible route for wheelchair users taking into account their profiles and capabilities. A case study involving a wheelchair-dependent paraplegic was performed to preliminary assess the feasibility of our Smartphone-based approach to provide an accessibility index for wheelchair users. Although preliminary, our results do suggest that the Wegoto system could be used as an innovative assistive navigation system for wheelchair users and ultimately could help to improve their autonomy and quality of life

Emotional states preceding and following acts of non-suicidal self-injury in bulimia nervosa patients.

In: *Behav Res Ther* 47 (1), S. 83–87.

Abstract:

Bulimia nervosa and non-suicidal self-injury (NSSI) co-occur at high rates, and both have been conceptualized as maladaptive emotion regulation strategies. Treatments focusing on emotion regulation have been designed for both problem behaviors, yet, there exists very little research examining the temporal emotional states surrounding acts of NSSI. Using ecological momentary assessment (EMA) methodology, the current study examined the temporal association between positive and negative emotional states prior to and consequent to acts of NSSI within a subset of bulimia nervosa patients. Results indicate significant increases in negative affect, and decreases in positive affect, prior to an NSSI act. Post-NSSI, positive affect significantly increased while negative affect remained unchanged. The findings offer partial support for an emotion regulation paradigm to understanding NSSI within bulimic populations and implications for treatment are discussed.

Metabolic syndrome in subjects with white-coat hypertension: impact on left ventricular structure and function.

In: *J Hum Hypertens* 21 (11), S. 854–860.

Abstract:

Some reports have suggested that white-coat hypertension (WCH) is associated with some features of the metabolic syndrome (MetS). These metabolic disturbances, instead of WCH per se, may potentially explain the greater extent of end-organ damage sometimes observed in WCH subjects (WCHs) when compared to normotensive individuals (NTs). The aim of the present cross-sectional study was to compare left ventricular (LV) structure and function in three groups of subjects: WCHs with MetS, WCHs without MetS and NTs. A total of 145 WCHs, 35% of whom had MetS, were enrolled. As controls, 35 NTs were also studied. In all subjects, routine blood chemistry, echocardiographic examination and 24-h ambulatory blood pressure monitoring were performed. When compared with WCHs without MetS, those with MetS showed higher LV mass indexed by height elevated by a power of 2.7 (LVMH(2.7)) (49.6+/-14.8 vs 38.9+/-9.8 g/m(2.7); P<0.0001). The same parameter was greater in WCHs without MetS than in NTs (32+/-8 g/m(2.7); P=0.004). Moreover, the E-wave deceleration time was longer in WCHs with MetS than in those without it (236.2+/-66.4 vs 200.5+/-30.8 ms; P<0.0001). The relationship of MetS with LVMH(2.7) was confirmed in multivariate regression models. Our results seem to suggest that MetS may have a deleterious influence on LV structure and function in WCH. However, WCH, being associated with an increased LV mass, also in subjects without MetS, may not be considered as an innocuous phenomenon.

Muller, A.; Mitchell, J. E.; Crosby, R. D.; Cao, L.; Johnson, J.; Claes, L.; De, Zwaan M. (2012):

Mood states preceding and following compulsive buying episodes: an ecological momentary assessment study.

In: *Psychiatry Res* (0165-1781 (Linking)). DOI: 10.1016/j.psychres.2012.04.015.

Abstract:

This study examined the extent to which patterns of mood and daily stress experienced by individuals with compulsive buying (CB) are associated with CB episodes by using Ecological Momentary Assessment. The comparison of mood and the impact of daily stress on days on which CB occurred to those days on which CB episodes did not occur did not reveal any significant differences. Within-day analysis indicated that negative affect increased significantly and positive affect decreased significantly prior to a CB episode. There was also evidence of a significant decrease in negative affect following a CB episode. Positive affect did not change significantly after a CB episode. The findings suggest that CB episodes hold negative reinforcing properties for individuals with CB. Treatment of patients with CB should focus on functional assessment of the affective antecedents and consequences of CB episodes and the identification of alternative, more functional behaviors to deal with these affective states

Effects of an Exercise Intervention on Bone Mass in Pediatric Bone Tumor Patients.

In: *Int J Sports Med. DOI:* 10.1055/s-0033-1358475.

Abstract:

The aim was to evaluate the effects of additional exercises during inpatient stays on bone mass in pediatric bone tumor patients. 21 patients were non-randomly allocated either to the exercise group (n=10) or the control group (n=11). DXA of the lumbar spine, the non-affected femur and both calcanei was performed after completion of neoadjuvant chemotherapy (baseline), as well as 6 and 12 months after baseline. Bone mineral content (BMC), bone mineral density (BMD) and height-corrected lumbar spine Z-scores were determined. Group changes after 6 and 12 months were compared by covariance analyses. Additionally, daily physical activities (PA) were assessed by means of accelerometry. After adjusting for initial age, height and weight, mean reductions in lumbar spine and femoral BMC were lower in the exercise group (not significant). Effect sizes during the observational period for lumbar spine and femur BMC were generally small (partial eta(2)=0.03). The exercise group demonstrated substantially higher PA levels in terms of gait cycles per day, per hour and moderate PA (activities above 40 gait cycles per minute). Additional exercises for bone tumor patients are feasible during hospitalization. Though the intervention did not influence BMC, it appeared beneficial regarding PA promotion with respect to volume and intensity.

Mullins, Morell E.; Devendorf, Shelba A. (2007):

Assessing goal-directed attention as an indicator of self-regulation: A comparison of two approaches.

In: *North American Journal of Psychology* 9 (2), S. 229.

Abstract:

Research on self-regulation has continually expanded our understanding of psychological processes in a variety of contexts. A number of theories of self-regulation exist, many of which include goals and goal-directed attention as critical components. One under-researched aspect of the topic, however, is its measurement (Zeidner, Boekaerts, & Pintrich, 2000). We suggest that Likert-type scales may be inadequate to assess the goal-focused aspect of self-regulation, and that a diary assessment may be superior. A model centered around self-regulation in a laboratory training context is presented and tested using both a Likert-type scale and a diary measure of the construct. Regression analyses indicate that the diary performed more consistently with research-based expectations for self-regulation. Implications and future research directions are discussed.

Assessing adolescent asthma symptoms and adherence using mobile phones.

In: *J Med Internet Res* 15 (7), S. e141. DOI: 10.2196/jmir.2413.

Abstract:

BACKGROUND: Self-report is the most common method of measuring medication adherence but is influenced by recall error and response bias, and it typically does not provide insight into the causes of poor adherence. Ecological momentary assessment (EMA) of health behaviors using mobile phones offers a promising alternative to assessing adherence and collecting related data that can be clinically useful for adherence problem solving. OBJECTIVE: To determine the feasibility of using EMA via mobile phones to assess adolescent asthma medication adherence and identify contextual characteristics of adherence decision making. METHODS: We utilized a descriptive and correlational study design to explore a mobile method of symptom and

adherence assessment using an interactive voice response system. Adolescents aged 12-18 years with a diagnosis of asthma and prescribed inhalers were recruited from an academic medical center. A survey including barriers to mobile phone use, the Illness Management Survey, and the Pediatric Asthma Quality of Life Questionnaire were administered at baseline. Quantitative and qualitative assessment of asthma symptoms and adherence were conducted with daily calls to mobile phones for 1 month. The Asthma Control Test (ACT) was administered at 2 study time points: baseline and 1 month after baseline. RESULTS: The sample consisted of 53 adolescents who were primarily African American (34/53, 64%) and female (31/53, 58%) with incomes US$40K/year or lower (29/53, 55%). The majority of adolescents (37/53, 70%) reported that they carried their phones with them everywhere, but only 47% (25/53) were able to use their mobile phone at school. Adolescents responded to an average of 20.1 (SD 8.1) of the 30 daily calls received (67%). Response frequency declined during the last week of the month (b=-0.29, P<.001) and was related to EMA-reported levels of rescue inhaler adherence (r= 0.33, P=.035). Using EMA, adolescents reported an average of 0.63 (SD 1.2) asthma symptoms per day and used a rescue inhaler an average of 70% of the time (SD 35%) when they experienced symptoms. About half (26/49, 53%) of the instances of nonadherence took place in the presence of friends. The EMA-measured adherence to rescue inhaler use correlated appropriately with asthma control as measured by the ACT (r=-0.33, P=.034). CONCLUSIONS: Mobile phones provided a feasible method to assess asthma symptoms and adherence in adolescents. The EMA method was consistent with the ACT, a widely established measure of asthma control, and results provided valuable insights regarding the context of adherence decision making that could be used clinically for problem solving or as feedback to adolescents in a mobile or Web-based support system

Mulvaney, S. A.; Rothman, R. L.; Dietrich, M. S.; Wallston, K. A.; Grove, E.; Elasy, T. A.; Johnson, K. B. (2011):

Using mobile phones to measure adolescent diabetes adherence.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0025543.

Abstract:

Objectives: 1) describe and determine the feasibility of using cell-phone-based ecological momentary assessment (EMA) to measure blood glucose monitoring and insulin administration in adolescent Type 1 diabetes, 2) relate EMA to traditional self-report and glycemic control, and 3) identify patterns of adherence by time of day and over time using EMA. Method: Adolescents with Type 1 diabetes (n = 96) completed baseline measures of cell phone use and adherence. Glycemic control (measured by levels of HbA1c) was obtained from medical records. A subgroup of adolescents (n = 50) completed 10 days of EMA to assess blood glucose monitoring frequency, timing of glucose monitoring, insulin administration, and insulin dosing. One third of adolescents were not allowed to use their cell phones for diabetes at school. Parental restrictions on cell phone use at home were not prevalent. Results: The EMA response rate (59%) remained stable over the 10-day calling period. Morning time was associated with worse monitoring and insulin administration, accounting for 59-74% of missed self-care tasks. EMA-reported missed glucose checks and missed insulin doses were correlated to traditional self-report data, but not to HbA1c levels. Trajectory analyses identified two subgroups: one with consistently adequate adherence, and one with more variable, and worse, adherence. The latter adherence style showed worse glycemic control. Conclusion: Mobile phones provide a feasible method to measure glucose monitoring and insulin administration in adolescents, given a limited assessment duration. The method provided novel insights regarding patterns of adherence and should be explored in clinical settings for targeting or tailoring interventions.

Munsch, S.; Meyer, A. H.; Quartier, V.; Wilhelm, F. H. (2012):

Binge eating in binge eating disorder: a breakdown of emotion regulatory process?

In: *Psychiatry Res* 195 (3), S. 118–124. DOI: 10.1016/j.psychres.2011.07.016.

Abstract:

Current explanatory models for binge eating in binge eating disorder (BED) mostly rely on models for bulimia nervosa (BN), although research indicates different antecedents for binge eating in BED. This study investigates antecedents and maintaining factors in terms of positive mood, negative mood and tension in a sample of 22 women with BED using ecological momentary assessment over a 1-week. Values for negative mood were higher and those for positive mood lower during binge days compared with non-binge days. During binge days, negative mood and tension both strongly and significantly increased and positive mood strongly and significantly decreased at the first binge episode, followed by a slight though significant, and longer lasting decrease (negative mood, tension) or increase (positive mood) during a 4-h observation period following binge eating. Binge eating in BED seems to be triggered by an immediate breakdown of emotion regulation. There are no indications of an accumulation of negative mood triggering binge eating followed by immediate reinforcing mechanisms in terms of substantial and stable improvement of mood as observed in BN. These differences implicate a further specification of etiological models and could serve as a basis for developing new treatment approaches for BED

The Q223R polymorphism in the leptin receptor associates with objectively measured light physical activity in free-living Japanese.

In: *Physiol Behav* 129C, S. 199–204. DOI: 10.1016/j.physbeh.2014.02.053.

Abstract:

Physical activity (PA) is associated with reductions in the risk of all-cause mortality and in the prevalence of cardiovascular disease and stroke. Nevertheless, a large proportion of the general population may not be sufficiently active. PA level has been reported to be influenced by genetic factors, and we investigated whether Q223R polymorphism in the leptin receptor (LEPR) gene was associated with PA level. A total of 556 Japanese adults aged 24-65years old participated in this cross-sectional study. The duration and intensity of PA were objectively evaluated by triaxial accelerometry. Q223R polymorphism was determined by the TaqMan method. The distribution of Q223R polymorphism was: QQ 0.7%, QR 22.6%, and RR 76.6%. The relation between the LEPR genotype and PA level was analyzed by ANCOVA with age and sex as covariates in the Q dominant genetic model. There were significant differences between LEPR genotypes and the time spent in light PA or inactive time. The subjects with RR genotype showed significantly shorter time spent in light PA (RR genotype: 559.4+/-102.9min/day, QQ/QR genotype: 579.9+/-103.1min/day) and longer inactive time (RR genotype: 815.5+/-107.5min/day, QQ/QR genotype: 792.3+/-107.7min/day) than the subjects with QQ/QR genotype (P<0.05). There were no such differences in the time spent in moderate or vigorous PA. These results suggest that the variety of PA level, especially spontaneous PA in humans, is partly caused by diversity in the LEPR gene.

Modeling of EEG electrode artifacts and thermal ripples in human radiofrequency exposure studies.

In: *Bioelectromagnetics* 35 (4), S. 273–283. DOI: 10.1002/bem.21837.

Abstract:

The effects of radiofrequency (RF) exposure on wake and sleep electroencephalogram (EEG) have been in focus since mobile phone usage became pervasive. It has been hypothesized that effects may be explained by (1) enhanced induced fields due to RF coupling with the electrode assembly, (2) the subsequent temperature increase around the electrodes, or (3) RF induced thermal pulsing caused by localized exposure in the head. We evaluated these three hypotheses by means of both numerical and experimental assessments made with appropriate phantoms and anatomical human models. Typical and worst-case electrode placements were examined at 900 and 2140 MHz. Our results indicate that hypothesis 1 can be rejected, as the induced fields cause <20% increase in the 10 g-averaged specific absorption rate (SAR). Simulations with an anatomical model indicate that hypothesis 2 is also not supported, as the realistic worst-case electrode placement results in a maximum skin temperature increase of 0.31 degrees C while brain temperature elevations remained <0.1 degrees C. These local short-term temperature elevations are unlikely to change brain physiology during the time period from minutes to several hours after exposure. The maximum observed temperature ripple due to RF pulses is <0.001 degrees C for GSM-like signals and <0.004 degrees C for 20-fold higher pulse energy, and offers no support for hypothesis 3. Thus, the mechanism of interaction between RF and changes in the EEG power spectrum remains unknown. Bioelectromagnetics. 35:273-283, 2014. (c) 2014 Wiley Periodicals, Inc.

Murphy, S. L.; Kratz, A. L.; Williams, D. A.; Geisser, M. E. (2012):

The Association between Symptoms, Pain Coping Strategies, and Physical Activity Among People with Symptomatic Knee and Hip Osteoarthritis.

In: *Front Psychol* 3 (1664-1078 (Electronic)), S. 326. DOI: 10.3389/fpsyg.2012.00326.

Abstract:

Effective use of coping strategies by people with chronic pain conditions is associated with better functioning and adjustment to chronic disease. Although the effects of coping on pain have been well studied, less is known about how specific coping strategies relate to actual physical activity patterns in daily life. The purpose of this study was to evaluate how different coping strategies relate to symptoms and physical activity patterns in a sample of adults with knee and hip osteoarthritis (OA; N = 44). Physical activity was assessed by wrist-worn accelerometry; coping strategy use was assessed by the Chronic Pain Coping Inventory. We hypothesized that the use of coping strategies that reflect approach behaviors (e.g., Task Persistence), would be associated with higher average levels of physical activity, whereas avoidance coping behaviors (e.g., Resting, Asking for

Assistance, Guarding) and Pacing would be associated with lower average levels of physical activity. We also evaluated whether coping strategies moderated the association between momentary symptoms (pain and fatigue) and activity. We hypothesized that higher levels of approach coping would be associated with a weaker association between symptoms and activity compared to lower levels of this type of coping. Multilevel modeling was used to analyze the momentary association between coping and physical activity. We found that higher body mass index, fatigue, and the use of Guarding were significantly related to lower activity levels, whereas Asking for Assistance was significantly related to higher activity levels. Only Resting moderated the association between pain and activity. Guarding, Resting, Task Persistence, and Pacing moderated the association between fatigue and activity. This study provides an initial understanding of how people with OA cope with symptoms as they engage in daily life activities using ecological momentary assessment and objective physical activity measurement

Murphy, Susan L.; Smith, Dylan M. (2010):

Ecological measurement of fatigue and fatigability in older adults with osteoarthritis.

In: *The journals of gerontology. Series A, Biological sciences and medical sciences* 65 (2), S. 184–189. DOI: 10.1093/gerona/glp137.

Abstract:

BACKGROUND\r\nFatigue is associated with loss of independence in older adults; however, little is known about optimal treatment or how fatigue manifests in daily life activities. \"Fatigability\" was recently proposed to clarify the fatigue-activity relationship. The purpose of this study was to present a new measurement method of fatigability and begin to test its validity.\r\nMETHODS\r\nOur sample included 40 adults with knee or hip osteoarthritis (OA) and 20 healthy controls. Fatigue was measured by ecological momentary assessment several times a day along with continuous measurement of physical activity using a wrist-worn accelerometer. Fatigability was measured as the fatigue increase after a period of high activity.\r\nRESULTS\r\nCompared with controls, participants with OA were approximately four times more likely to have an increase in fatigue after a high activity interval (37.0% vs 9.8%). Among people with OA, average fatigue and fatigability were not highly related (r = .13). Fatigue was most strongly associated with reported physical function, pain, and vitality, whereas fatigability was most strongly associated with body mass index, OA severity, and knee strength.\r\nCONCLUSIONS\r\nAlthough fatigue among people with OA was more associated with subjective reports of physical function and symptoms, pairing fatigue reports with physical activity tapped objective factors that may be related to the biomechanical demands of daily life activities. Thus, fatigability measurement may help discern how symptoms relate to daily life function and help to refine treatment approaches in OA.

Murphy, Susan L.; Smith, Dylan M.; Clauw, Daniel J.; Alexander, Neil B. (2008):

The impact of momentary pain and fatigue on physical activity in women with osteoarthritis.

In: *Arthritis Care & Research* 59 (6), S. 849–856.

Abstract:

OBJECTIVE:

To examine the daily life patterns of both pain and fatigue symptoms and objective physical activity (using ambulatory monitoring) in women with symptomatic lower extremity osteoarthritis (OA), and to evaluate how momentary symptoms impact physical activity levels.

METHODS:

Sixty women age >or=55 years (40 with knee or hip OA and 20 matched controls) participated in an observational study involving 2 laboratory visits and a 5-day home data collection period. During the home period physical activity levels were assessed continuously, and symptoms were inputted 6 times a day into an enhanced accelerometer at prespecified time points.

RESULTS:

In the OA group as compared with the control group over the 5-day period, average physical activity was significantly lower (P = 0.02) and peak physical activity tended to be lower (P = 0.06). Although pain and fatigue overall were of moderate severity in this cohort, fatigue escalated throughout each day. In a hierarchical linear model, fatigue was most strongly associated with physical activity (beta = -30.1, P < 0.0001). Pain was more weakly associated with physical activity and in the direction opposite to what was hypothesized (beta = 16.9, P = 0.04).

CONCLUSION:

Momentary reports of fatigue negatively predicted physical activity levels and were much more strongly related to physical activity than momentary pain. In order to help women with knee or hip OA manage symptoms and become more physically active, it may be important to emphasize fatigue management.

Murphy, Susan L.; Strasburg, Debra M.; Lyden, Angela K.; Smith, Dylan M.; Koliba, Jessica F.; Dadabhoy, Dina P.; Wallis, Susan M. (2008):

Effects of activity strategy training on pain and physical activity in older adults with knee or hip osteoarthritis: a pilot study.

In: *Arthritis Care & Research* 59 (10), S. 1480–1487.

Abstract:

OBJECTIVE:

To examine effects of activity strategy training (AST), a structured rehabilitation program taught by occupational therapists and designed to teach adaptive strategies for symptom control and engagement in physical activity (PA).

METHODS:

A randomized controlled pilot trial was conducted at 4 sites (3 senior housing facilities and 1 senior center) in southeastern, lower Michigan. Fifty-four older adults with hip or knee osteoarthritis (mean +/- SD age 75.3+/-7.1 years) participated. At each site, older adults were randomly assigned to 1 of 2 programs: exercise plus AST (Ex + AST) or exercise plus health education (Ex + Ed). The programs involved 8 sessions over 4 weeks with 2 followup sessions over a 6-month period, and were conducted concurrently within each site. Pain, total PA and PA intensity (measured objectively by actigraphy and subjectively by the Community Healthy Activities Model Program for Seniors questionnaire), arthritis self-efficacy, and physical function were assessed at baseline and posttest.

RESULTS:

At posttest, participants who received Ex + AST had significantly higher levels of objective peak PA (P=0.02) compared with participants who received Ex + Ed. Although not statistically significant, participants in Ex + AST tended to have larger pain decreases, increased total objective and subjective PA, and increased physical function. No effects were found for arthritis self-efficacy.

CONCLUSION:

Although participants were involved in identical exercise programs, participants who received AST tended to have larger increases in PA at posttest compared with participants who received health education. Future studies will be needed to examine larger samples and long-term effects of AST.

Murray, Greg (2007):

Diurnal mood variation in depression: A signal of disturbed circadian function?

In: *J Affect Disord* 102 (1), S. 47–53.

Abstract:

BACKGROUND:

Diurnal variation in mood is a prominent symptom of depression, and is typically experienced as positive mood variation (PMV - mood being worse upon waking and better in the evening). The present study sought to advance understanding of PMV by measuring daily mood variation in non-clinical individuals with varying levels of depressed mood. Based on research into normative variation in mood and evidence that circadian amplitudes may be decreased in depression, it was hypothesised that compared to those with low levels of depression, individuals meeting Centre for Epidemiological Studies-Depression Scale (CES-D) cut-off for probable depression would exhibit an attenuated circadian component in diurnal variation of Positive Affect (PA).

METHOD:

Ninety-nine young healthy women (mean age=21.5, SD=3.0) living on a normal sleep-wake schedule provided mood reports every two hours between 0800 h and 2200 h for 7 days.

RESULTS:

The high depression group (CES-D > or = 23, n=22) exhibited a pattern of diurnal variation consistent with PMV (increased PA in the evening relative to the morning). As predicted, evidence was also found that the high depression group was characterized by a decreased circadian component to diurnal variation in PA relative to the low depression group (CES-D < 23, n=77).

CONCLUSIONS:

It is provisionally concluded that diurnal mood variation in depression can usefully be understood from the perspective of weakened circadian function. Findings are discussed in terms of limitations of the study's naturalistic design and future research avenues identified.

Murray, Caroline Sian (2011):

Are subjective accounts of itch to be relied on? The lack of relation between visual analogue itch scores and actigraphic measures of scratch.

In: *Acta dermato-venereologica* 91 (1), S. 18.

Abstract:

There is a widespread belief that subjective accounts of disease are key components of measures of disease severity and quality of life. In the present study we have set out to test this hypothesis using visual analogue scales (VAS) for itch, as a subjective measure, and actigraphy as an objective measure. One-hundred and seventeen itchy children and adults (and 25 controls) were studied for clusters of nights (total number 1,654) and actigraphy scores and VAS itch taken daily. Fifty-six percent of the night-to-night variation in actigraphy scores occurred between different individuals, while 44% was intra-subject. Neither age nor sex (children's or adults') predicted actigraphy scores, and the only significant predictor of actigraphy score was disease type ($p = 0.001$, $r^2 = 0.51$). In a multivariate model VAS itch score was not a significant determinant of actigraphy scores for either children or adults ($p = 0.26$). In order to see if there was a relation between VAS itch and actigraphy within the same patients (rather than between patients), 20 eczema patients wore the actigraph and scored VAS itch nightly for 42 nights. Little relationship was found between the actigraphy score and the VAS itch. Empirical autocorrelation analysis of VAS itch and actigraphy score reveal a clear autocorrelation for subjective VAS scores that was not found for the objective actigraphy score. Our data suggest a dissociation between scratch and perceived or recalled itch. One explanation is that VAS itch scores suffer from considerable anchoring, and context bias, and that their use in measures of disease severity is problematic.

Mutschler, J.; Von, Zitzewitz F.; Rossler, W.; Grosshans, M. (2012):

Application of electronic diaries in patients with schizophrenia and bipolar disorders.

In: *Psychiatr.Danub.* 24 (2), S. 206–210. Online verfügbar unter PM:22706420.

Abstract:

BACKGROUND: Despite the dissemination of second generation antipsychotics for schizophrenia and bipolar disorder, outcomes remain suboptimal, largely due to poor treatment and drug adherence. The primary aim of the current study was to assess the tolerability, validity and feasibility of the pocket-sized electronic diary Medicus(R). SUBJECTS AND METHODS: Our case observations attempted to evaluate eighteen patients suffering from schizophrenia and bipolar disorder. All of the patients were treated with the second generation antipsychotic quetiapine. We followed them up in two German medical centers over two years. RESULTS: The present results display an improvement of mood-stability in all patients treated with quetiapine. All patients were in regular contact to their psychiatrist over a period of 24 months. A complete description of the coherences between the symptoms was essential for estimation, which was conducted by Medicus(R). Moreover, Medicus(R) seem to be useful for improving compliance within a medication regimen. CONCLUSIONS: Although uncontrolled case observations can only be interpreted with caution, Medicus(R) seems to deserve further investigation and may hold the potential to optimize treatment and drug adherence in patients suffering from schizophrenia and bipolar disorders

Myers, Marting. (2008):

Recent advances in automated blood pressure measurement.

In: *Current Science Inc* 10 (5), S. 355–358. DOI: 10.1007/s11906-008-0067-1.

Abstract:

During the past 15 years, clinical outcome studies have consistently reported that home and 24-hour ambulatory blood pressure recordings provide a significantly better measure of cardiovascular risk than do manual blood pressure readings taken in the office or clinic. The advent of automated sphygmomanometers that record blood pressure with the patient alone in the examining room will be the next major change in our approach to recording blood pressure. These automated devices virtually eliminate the white coat response and their readings correlate significantly better with the ambulatory blood pressure compared

with manual office blood pressure readings. The principal finding from recent research into automated blood pressure measurement is that the presence of an observer during the actual reading in itself provokes the white coat response.

Myers, Martin G.; Valdivieso, Miguel; Kiss, Alexander (2008):

Optimum frequency of office blood pressure measurement using an automated sphygmomanometer.

In: *Blood Press Monit* 13 (6), S. 333–338.

Abstract:

OBJECTIVE:

To determine the optimum interval between serial blood pressure measurements using an automated BpTRU sphygmomanometer.

METHODS:

Two groups of 200 patients each had automated office measurements taken using the BpTRU device at either 1-min or 2-min intervals from the start of one reading to the start of the next reading with a 24-h ambulatory blood pressure (ABP) recording being performed. Another series of 50 patients had BpTRU readings taken at 1-min and 2-min intervals before and after 24-h ABP monitoring. The difference between the mean awake ABP and the mean automated office BP readings were compared for recordings taken at 1-min versus 2-min intervals.

RESULTS:

In the between-patient comparison (n=400), mean awake ABP was similar to automated BP recordings in the examining room at either 1-min or 2-min intervals except for a slightly lower (-4 mmHg) diastolic BP with the 1-min interval (P<0.01 vs. ABP). In the within-patient comparison (n=50), there was no consistent difference between automated BP readings taken in the examining room at 1-min versus 2-min intervals. Overall, the mean automated BP values tended to be slightly lower than the mean awake ABP.

CONCLUSION:

Automated measurement of BP in the office setting with devices such as the BpTRU can be taken as frequently as every 1 min without affecting the accuracy of the reading. Small differences in BP between the 1 and 2-min settings and between the automated BpTRU and ABP readings were within accepted clinical standards for validation criteria.

Myers, Martin G.; Valdivieso, Miguel; Kiss, Alexander (2009):

Use of automated office blood pressure measurement to reduce the white coat response.

In: *J Hypertens* 27 (2), S. 280–286. DOI: 10.1097/HJH.0b013e32831b9e6b.

Abstract:

OBJECTIVE\r\nTo examine the possibility of reducing the white coat response using an automated sphygmomanometer designed for office use, the BpTRU. Consecutive patients referred from physicians in the community to an ambulatory blood pressure (ABP) monitoring unit in an academic hospital were included in the study.\r\nPARTICIPANTS AND METHODS\r\nA total of 309 patients referred for diagnosis or management of hypertension were studied. Differences between mean awake ABP and BP readings taken by the patient's own physician using a manual sphygmomanometer or the automated BpTRU device with the patient resting alone in the ABP monitoring unit were compared.\r\nRESULTS\r\nBP recorded in the examining room using an automated device (132 +/- 19/75 +/- 12) was similar to the mean awake ABP (134 +/- 12/77 +/- 10) with both values being lower (P < 0.001) than the BP recorded on a routine visit to the patient's own family physician (152 +/- 18/87 +/- 11). The coefficient of correlation between the systolic/diastolic ABP and the automated office BP (r = 0.62/0.72) was higher (P < 0.001) than with the family physician's manual BP (r = 0.32/0.48). The prevalence of white coat hypertension in untreated patients (n = 146) was significantly (P < 0.001) lower with automated office BP (16%) compared with the routine family physician BP (55%).\r\nCONCLUSION\r\nThe white coat response associated with office BP measurements can be virtually eliminated by recording BP with the automated BpTRU device with patients resting alone in a quiet examining room.

Myin-Germeys, Inez (2012):

Psychiatry. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 636–650. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-036%26site%3dehost-live.

Abstract:

(from the chapter) The essence of psychiatric symptoms is that they are natural experiences emerging in the realm of normal daily life, often in interaction with contextual features. This central characteristic, however, is often overlooked. With increasingly sophisticated methods to investigate brain functions, genetic mechanisms, or neuropsychological performance, we know disappointingly little about the expression of psychopathological symptoms in daily life and the dynamic interplay between the person and his or her environment in psychiatry. Fortunately, there is a growing awareness that the study of psychiatric patients in the context of normal daily life may provide a powerful and necessary addition to more conventional and cross-sectional research strategies. A growing body of studies is using techniques such as experience sampling methods (ESM) or ecological momentary assessment (EMA) to study psychopathology in real life. This chapter consists of practical guidelines for ESM relevant to studying psychiatric patients, as well as an overview of topics in psychiatry for which daily life studies may be particularly relevant. Experience sampling research in psychopathology: opening the black box of daily life.

In: *Psychological Medicine* 39 (9), S. 1533–1547. DOI: 10.1017/S0033291708004947.

Abstract:

A growing body of research suggests that momentary assessment technologies that sample experiences in the context of daily life constitute a useful and productive approach in the study of behavioural phenotypes and a powerful addition to mainstream cross-sectional research paradigms. Momentary assessment strategies for psychopathology are described, together with a comprehensive review of research findings illustrating the added value of daily life research for the study of (1) phenomenology, (2) aetiology, (3) psychological models, (4) biological mechanisms, (5) treatment and (6) gene-environment interactions in psychopathology. Overall, this review shows that variability over time and dynamic patterns of reactivity to the environment are essential features of psychopathological experiences that need to be captured for a better understanding of their phenomenology and underlying mechanisms. The Experience Sampling Method (ESM) allows us to capture the film rather than a snapshot of daily life reality of patients, fuelling new research into the gene-environment-experience interplay underlying psychopathology and its treatment.

Myin-Germeys, Inez; van Os, Jim (2007):

Stress-reactivity in psychosis: evidence for an affective pathway to psychosis.

In: *Clinical Psychology Review* 27 (4), S. 409–424.

Abstract:

This paper will review a series of studies using the Experience Sampling Method that suggest that altered sensitivity to stress is an endophenotype for psychosis. The Experience Sampling Method is a structured diary technique allowing the assessment of emotional reactivity to stressors occurring in normal daily life. Elevated emotional reactivity to stress was found in subjects vulnerable to psychosis, suggesting that affective responses to stressors in the flow of daily life are an indicator of genetic and/or environmental liability to psychosis. Indeed, the small stressors in daily life associated with affective responses also predict more intense moment-to-moment variation of subtle positive psychotic experiences. Increased emotional reactivity was found to be independent from cognitive impairments, and argued to constitute evidence of an affective pathway to psychosis that may underlie a more episodic, reactive, good-outcome type of psychosis. Evidence for this hypothesis was found in data suggesting that the experience of stressful life events and early trauma were associated with increased stress-sensitivity, and that women were more likely to display elevated stress-reactivity. These findings are discussed in the light of recent biological and psychological mechanisms.

Work and Non-Work Physical Activity Predict Real-Time Smoking Level and Urges in Young Adults.

In: *Nicotine Tob Res. DOI:* 10.1093/ntr/ntu244.

Abstract:

INTRODUCTION: Physical activity (PA) and smoking are inversely related. However, evidence suggests that some types of PA, namely work-related PA, may show an opposite effect. Despite growing knowledge, there remains a paucity of studies examining the context of these behaviors in naturalistic settings or in young adults, a high-risk group for escalation. METHODS: Participants were 188 young adults (mean age = 21.32; 53.2% female; 91% current smokers) who participated in an electronic diary week to assess daily smoking and urges and a PA recall to examine daily PA. PA was coded into non-work-related and work-related activity to examine differential effects. We considered both participants' weekly average PA and their daily deviations from their average. RESULTS: Mixed-effects regression models revealed that higher weekly average non-work PA was associated with lower smoking level and urges. Daily deviations in non-work PA did not predict urges; however, increased daily non-work PA relative to participants' weekly average was associated with lower smoking for females but higher levels for males. Regarding work PA, only higher weekly average work PA was associated with higher smoking level for both genders; work PA did not predict urges. CONCLUSIONS: Results extend previous literature by documenting differential associations between non-work and work PA and young adult smoking and suggest that young adults engaged in work PA should be considered a high-risk group for escalation. Findings provide theoretical and clinical implications for the use of PA in intervention and highlight the necessity of considering PA as a multidimensional construct when examining its links to health behavior.

Diurnal blood pressure variation in patients with sleep apnea syndrome.

In: *Hypertens Res* 31 (2), S. 185–191.

Abstract:

Sleep apnea syndrome (SAS) is an important risk factor for hypertension and cardiovascular diseases. Diurnal blood pressure (BP) changes are evaluated by 24 h ambulatory blood pressure monitoring (ABPM). The purpose of this study was to clarify the relationship between diurnal BP variation and SAS severity, as well as the impact of antihypertensive therapy on diurnal BP variation. Patients seen at our clinic between April and September 2006 with excessive daytime sleepiness or apnea were enrolled. All patients had polysomnography and ABPM. Mean 24 h BP and nighttime BPs were significantly higher in the SAS group than in the non-SAS group. No significant differences were observed in daytime BPs between the two groups. SAS patients had a high mean 24-h BP and an elevated nighttime BP, both of which increased as SAS severity increased. Nighttime BPs were significantly higher in the moderate SAS group than in the non-SAS group. Nighttime BP and morning BP were significantly higher in the severe SAS group than in the non-SAS group. With respect to antihypertensive agents' effects on diurnal BP changes, there were no significant differences between the SAS and non-SAS groups. In conclusion, compared with non-SAS patients, patients with SAS had a higher 24-h BP, especially nighttime BP. Patients with moderate SAS tended to have elevated nighttime BP. In patients with severe SAS, elevated BP was sustained during the night despite the use of antihypertensive agents.

Smartphone-Assisted Prehospital Medical Information System for Analyzing Data on Prehospital Stroke Care.

In: *Stroke. DOI:* 10.1161/STROKEAHA.114.004872.

Abstract:

BACKGROUND AND PURPOSE: Optimizing prehospital stroke care is important because effective treatments for acute stroke require a narrow therapeutic time window. We developed a smartphone-assisted prehospital medical information system (SPMIS) to facilitate research on prehospital stroke care. METHODS: Prehospital medical information was input into the SPMIS application installed on smartphones by emergency medical staff, sent to a server through the Internet, and connected with in-hospital information. Using SPMIS, we analyzed data on 914 patients transferred to our institution by ambulance between April 2012 and March 2013. RESULTS: The data analyzed were the sensitivity and specificity of the prehospital diagnosis and prehospital stroke scale and the relationship between prehospital vital signs and forms of stroke. These analyses could be performed semiautomatically in a few hours. CONCLUSIONS: SPMIS enabled us to analyze the prehospital information of

patients with stroke in a short time with little effort. More large-scale studies on prehospital stroke care will become feasible using SPMIS, which may lead to advances in stroke treatment.

Monitoring sound to quantify snoring and sleep apnea severity using a smartphone: proof of concept.

In: *J Clin Sleep Med* 10 (1), S. 73–78. DOI: 10.5664/jcsm.3364.

Abstract:

STUDY OBJECTIVES: Habitual snoring is a prevalent condition that is not only a marker of obstructive sleep apnea (OSA) but can also lead to vascular risk. However, it is not easy to check snoring status at home. We attempted to develop a snoring sound monitor consisting of a smartphone alone, which is aimed to quantify snoring and OSA severity. METHODS: The subjects included 50 patients who underwent diagnostic polysomnography (PSG), of which the data of 10 patients were used for developing the program and that of 40 patients were used for validating the program. A smartphone was attached to the anterior chest wall over the sternum. It acquired ambient sound from the built-in microphone and analyzed it using a fast Fourier transform on a real-time basis. RESULTS: Snoring time measured by the smartphone highly correlated with snoring time measured by PSG (r = 0.93). The top 1 percentile value of sound pressure level (L1) determined by the smartphone correlated with the ambient sound L1 during sleep determined by PSG (r = 0.92). Moreover, the respiratory disturbance index estimated by the smartphone (smart-RDI) highly correlated with the apnea-hypopnea index (AHI) obtained by PSG (r = 0.94). The diagnostic sensitivity and specificity of the smart-RDI for diagnosing OSA (AHI >/= 15) were 0.70 and 0.94, respectively. CONCLUSIONS: A smartphone can be used for effectively monitoring snoring and OSA in a controlled laboratory setting. Use of this technology in a noisy home environment remains unproven, and further investigation is needed.

Nakano, Hiroshi; Tanigawa, Takeshi; Ohnishi, Yoshinobu; Uemori, Hidekazu; Senzaki, Kaoru; Furukawa, T.; Nishima, Sankei (2008):

Validation of a single-channel airflow monitor for screening of sleep-disordered breathing.

In: *European respiratory journal* 32 (4), S. 1060–1067.

Abstract:

A simple screening method for sleep-disordered breathing (SDB) is desirable for primary care practices. In the present study, a simple monitor, which utilises a new type of flow sensor and a novel algorithm, was prospectively validated. Home recording for 2 nights with the monitor only, followed by in-laboratory recording with the monitor together with polysomnography, were carried out in consecutive patients (n = 100) suspected of SDB. A subjective sleep log was also recorded. The signal was analysed using power spectral analysis, which yielded the flow respiratory disturbance index (flow-RDI). There was no recording failure at home. The reproducibility of the flow-RDI between the 2 nights at home was high (intraclass correlation coefficient = 0.92). The sensitivity and specificity of the in-laboratory flow-RDI to diagnose SDB were 0.96 and 0.82, 0.91 and 0.82, and 0.89 and 0.96, for apnoea/hypopnoea index (AHI) > or =5, > or =15 and > or =30 events x h(-1), respectively. The diagnostic ability in low-severity subgroups (female, normal weight, AHI <15 events x h(-1)) was almost comparable to that in the entire group. Excluding subjective waking time on the sleep log from the recording time had no significant effect on the flow-RDI. The single-channel monitor is considered feasible for ambulatory sleep disordered breathing monitoring because of its easy applicability, high reproducibility and relatively high agreement with polysomnography results.

Nakonezny, Paul A.; Byerly, Matthew J.; Rush, A. John (2008):

Electronic monitoring of antipsychotic medication adherence in outpatients with schizophrenia or schizoaffective disorder: an empirical evaluation of its reliability and predictive validity.

In: *Psychiatry Res* 157 (1), S. 259–263.

Abstract:

This study examined the reliability and predictive validity of electronic monitoring (EM) in assessing the oral antipsychotic medication adherence of outpatients with schizophrenia or schizoaffective disorder. Sixty-one adult outpatients with

schizophrenia or schizoaffective disorder who took a single oral antipsychotic medication were assessed monthly over a 6-month study period with EM of medication bottle opening. Symptom severity, as measured by the Positive and Negative Syndrome Scale (PANSS) total score, was assessed monthly over the 6-month study period. Cronbach's coefficient alpha revealed very high internal reliability (alpha=0.94). A high degree of test-retest reliability was found (beta ranged from 0.75 to 1.19 and r ranged from 0.63 to 0.90). As for predictive validity, greater mean EM adherence was significantly related to lower mean symptom severity.

Napolitano, Melissa A.; Borradaile, Kelley E.; Lewis, Beth A.; Whiteley, Jessica A.; Longval, Jaime L.; Parisi, Alfred F. et al. (2010):

Accelerometer use in a physical activity intervention trial.

In: *Contemporary clinical trials* 31 (6), S. 514–523. DOI: 10.1016/j.cct.2010.08.004.

Abstract:

This paper describes the application of best practice recommendations for using accelerometers in a physical activity (PA) intervention trial, and the concordance of different methods for measuring PA. A subsample (n = 63; 26%) of the 239 healthy, sedentary adults participating in a PA trial (mean age = 47.5; 82% women) wore the ActiGraph monitor at all 3 assessment time points. ActiGraph data were compared with self-report (i.e., PA weekly recall and monthly log) and fitness variables. Correlations between the PA recall and ActiGraph for moderate intensity activity ranged from 0.16-0.48 and from 0.28-0.42 for vigorous intensity activity. ActiGraph and fitness [estimated VO(2)(ml/kg/min)] had correlations of 0.15-0.45. The ActiGraph and weekly self-report were significantly correlated at all time points (correlations ranged from 0.23 to 0.44). In terms of detecting intervention effects, intervention groups recorded more minutes of at least moderate-intensity PA on the ActiGraph than the control group at 6 months (min = 46.47, 95% CI = 14.36-78.58), but not at 12 months. Limitations of the study include a small sample size and only 3 days of ActiGraph monitoring. To obtain optimal results with accelerometers in clinical trials, the authors recommend following best practice recommendations: detailed protocols for monitor use, calibration of monitors and validation of data quality, and use of validated equations for analysis. The ActiGraph has modest concordance with other assessment tools and is sensitive to change over time. However, until more information validating the use of accelerometry in clinical trials becomes available, properly administered self-report measures of PA should remain part of the assessment battery.

Naslund, John A.; Aschbrenner, Kelly A.; Barre, Laura K.; Bartels, Stephen J. (2014):

Feasibility of Popular m-Health Technologies for Activity Tracking Among Individuals with Serious Mental Illness.

In: *Telemed J E Health. DOI:* 10.1089/tmj.2014.0105.

Abstract:

Abstract Obesity prevalence is nearly double among individuals with serious mental illness (SMI), including schizophrenia spectrum disorders, bipolar disorder, or major depressive disorder, compared with the general population. Emerging mobile health (m-health) technologies are increasingly available and offer the potential to support lifestyle interventions targeting weight loss, yet the practical feasibility of using these technologies in this high-risk group has not been established. We evaluated the feasibility and acceptability of popular m-health technologies for activity tracking among overweight and obese individuals with SMI. We provided wearable activity monitoring devices (FitBit [San Francisco, CA] Zip or Nike Inc. [Beaverton, OR] FuelBand) and smartphones (Apple [Cupertino, CA] iPhone(R) 4S) for accessing the smartphone application for each device to participants with SMI enrolled in a weight loss program. Feasibility of these devices was measured by the frequency of use over time. Acceptability was measured through qualitative follow-up interviews with participants. Ten participants with SMI wore the devices for a mean of 89% (standard deviation=13%) of the days in the study. Five participants wore the devices 100% of the time. Participants reported high satisfaction, stating the devices were easy to use, helpful for setting goals, motivational, and useful for self-monitoring. Several participants liked the social connectivity feature of the devices where they could see each other's progress on the smartphone application, noting that "friendly" competition increased motivation to be more physically active. This study supports using popular m-health technologies for activity tracking among individuals with SMI. These findings can inform the design of weight loss interventions targeting this vulnerable patient population.

Nast, Daniel R.; Speer, William S.; Le Prell, Colleen G. (2014):

Sound level measurements using smartphone "apps": Useful or inaccurate?

In: *Noise Health* 16 (72), S. 251–256. DOI: 10.4103/1463-1741.140495.

Abstract:

Many recreational activities are accompanied by loud concurrent sounds and decisions regarding the hearing hazards associated with these activities depend on accurate sound measurements. Sound level meters (SLMs) are designed for this purpose, but these are technical instruments that are not typically available in recreational settings and require training to use properly. Mobile technology has made such sound level measurements more feasible for even inexperienced users. Here, we assessed the accuracy of sound level measurements made using five mobile phone applications or "apps" on an Apple iPhone 4S, one of the most widely used mobile phones. Accuracy was assessed by comparing application-based measurements to measurements made using a calibrated SLM. Whereas most apps erred by reporting higher sound levels, one application measured levels within 5 dB of a calibrated SLM across all frequencies tested.

Navarro, José; Arrieta, Carlos (2010):

Chaos in human behavior: The case of work motivation.

In: *The Spanish Journal of Psychology* 13 (01), S. 244–256.

Abstract:

This study considers the complex dynamics of work motivation. Forty-eight employees completed a work-motivation diary several times per day over a period of four weeks. The obtained time series were analysed using different methodologies derived from chaos theory (i.e. recurrence plots, Lyapunov exponents, correlation dimension and surrogate data). Results showed chaotic dynamics in 75% of cases. The findings confirm the universality of chaotic behavior within human behavior, challenge some of the underlying assumptions on which work motivation theories are based, and suggest that chaos theory may offer useful and relevant information on how this process is managed within organizations.

Precordial electrode placement for optimal ECG monitoring: Implications for ambulatory monitor devices and event recorders.

In: *J Electrocardiol. DOI:* 10.1016/j.jelectrocard.2014.04.003.

Abstract:

INTRODUCTION: Detection of QRS complexes, P-waves and atrial fibrillation f-waves in electrocardiographic (ECG) signals is critical for the correct diagnosis of arrhythmias. We aimed to find the best bipolar lead (BL) with the highest signal amplitude and shortest inter-electrode spacing. METHODS: ECG signals (120seconds) were recorded in 36 patients with 16 precordial electrodes placed in a standardized pattern. An average signal was analysed for each of 120 possible BLs obtained by calculating the difference between pairs of unipolar leads. Peak-to-peak amplitudes of QRS waves (50ms around R-peak) and P waves (270-70ms before R-peak) were calculated. For patients with atrial fibrillation, power of the fibrillatory (f) wave was used instead. Maximum values at each distance were considered and differentiation analysis was performed based on incremental changes (amplitude to distance). RESULTS: There was a significant correlation between distance and QRS-amplitude ($r=0.78$, $p<0.001$), P-wave amplitude ($r=0.60$, $p<0.01$) and f-wave power ($r=0.79$, $p<0.001$). The range of values was: QRS-amplitude 0.7-2.33mV, P-wave amplitude 0.07-0.18mV, and f-wave power 0.55-2.12mV2/s. The maximum value for the shortest distance was on a heart-aligned axis over the left ventricle for the QRS complex (1.9mV at 8.7cm) and over the atria for the P-wave (0.98mV) and f-waves (1.45mV2/s at 8cm, respectively). CONCLUSION: There is a strong positive correlation between electrode distance and ECG signal-amplitude. Distance of 8cm on a heart-aligned axis and over the relevant heart-chamber provides the highest signal amplitude for the shortest distance. These findings are essential for the design and use of ambulatory monitoring devices.

Nett, Ulrike E.; Goetz, Thomas; Hall, Nathan C. (2011):

Coping with boredom in school: An experience sampling perspective.

In: *Contemporary Educational Psychology* 36 (1), S. 49–59.

Abstract:

The present study explored students' use of boredom-related coping strategies at trait and state levels. Two trait-based dimensions of coping relevant to boredom were considered, namely approach – versus avoidance-oriented and cognitively – versus behaviorally-oriented coping strategies. The two dimensions were assessed in a self-report questionnaire administered to 537 grade 11 students (55.3% female, Mage = 17.15 years). Additionally, 79 of these participants completed state-based

boredom-related coping measures over a 2-week period using an experience sampling method. Analyses of the trait measures suggested that two contrasting, broad approaches characterized participants' strategies for coping with boredom, namely a cognitive-approach orientation and a behavioral-avoidance orientation. In both the trait- and state-based analyses, the cognitive-approach orientation was associated with lower levels of boredom. Implications for interventions promoting the use of cognitive-approach strategies for dealing with boredom in the classroom are discussed.

The challenge of low physical activity during the school day: at recess, lunch and in physical education.

In: *British Journal of Sports Medicine* 45 (10), S. 813–819. DOI: 10.1136/bjsm.2009.068072.

Abstract:

PURPOSE\r\nTo describe physical activity (PA) intensity across a school day and assess the percentage of girls and boys achieving recommended guidelines.\r\nMETHODS\r\nThe authors measured PA via accelerometry in 380 children (8-11 years) and examined data representing (1) the whole school day, (2) regular class time, (3) recess, (4) lunch and (5) scheduled physical education (PE). Activity was categorised as sedentary (SED), light physical activity (LPA) or moderate to vigorous physical activity (MVPA) using age-specific thresholds. They examined sex differences across PA intensities during each time period and compliance with recommended guidelines.\r\nRESULTS\r\nGirls accumulated less MVPA and more SED than boys throughout the school day (MVPA -10.6 min; SED +13.9 min) recess (MVPA -1.6 min; SED +1.7 min) and lunch (MVPA -3.1 min; SED +2.9 min). Girls accumulated less MVPA (-6.2 min), less LPA (-2.5 min) and more SED (+9.4 min) than boys during regular class time. Fewer girls than boys achieved PA guidelines during school (90.9% vs 96.2%), recess (15.7% vs 34.1%) and lunch (16.7% vs 37.4%). During PE, only 1.8% of girls and 2.9% of boys achieved the PA guidelines. Girls and boys accumulated similar amounts of MVPA, LPA and SED.\r\nCONCLUSION\r\nThe MVPA deficit in girls was due to their sedentary behaviour as opposed to LPA. Physical activity strategies that target girls are essential to overcome this deficit. Only a very small percentage of children met physical activity guidelines during PE. There is a great need for additional training and emphasis on PA during PE. In addition schools should complement PE with PA models that increase PA opportunities across the school day.

Neustifter, B.; Rathbun, S. L.; Shiffman, S. (2012):

Mixed-Poisson Point Process with Partially-Observed Covariates: Ecological Momentary Assessment of Smoking.

In: *J Appl.Stat.* 39 (4), S. 883–899. DOI: 10.1080/02664763.2011.626848.

Abstract:

Ecological Momentary Assessment is an emerging method of data collection in behavioral research that may be used to capture the times of repeated behavioral events on electronic devices, and information on subjects' psychological states through the electronic administration of questionnaires at times selected from a probability-based design as well as the event times. A method for fitting a mixed Poisson point process model is proposed for the impact of partially-observed, time-varying covariates on the timing of repeated behavioral events. A random frailty is included in the point-process intensity to describe variation among subjects in baseline rates of event occurrence. Covariate coefficients are estimated using estimating equations constructed by replacing the integrated intensity in the Poisson score equations with a design-unbiased estimator. An estimator is also proposed for the variance of the random frailties. Our estimators are robust in the sense that no model assumptions are made regarding the distribution of the time-varying covariates or the distribution of the random effects. However, subject effects are estimated under gamma frailties using an approximate hierarchical likelihood. The proposed approach is illustrated using smoking data

Newton, Julia L.; Gibson, G. John; Tomlinson, Mark; Wilton, Katharine; Jones, David (2006):

Fatigue in primary biliary cirrhosis is associated with excessive daytime somnolence.

In: *Hepatology* 44 (1), S. 91–98.

Abstract:

A significant proportion of patients with primary biliary cirrhosis (PBC) suffer from severe fatigue. The aim of this study was to characterize patterns of daytime sleep in patients with PBC (using both objective and subjective assessment approaches) and to

study the association between sleep abnormality and fatigue severity. Fatigue severity was assessed in 48 female subjects with PBC (using a disease-specific quality of life instrument (the PBC-40) and a generic fatigue measure (Fatigue Impact Scale [FIS]) as well as 48 case-matched normal controls. All participants also completed the Pittsburgh Sleep Quality Index (PSQI) and the Epworth Sleepiness Scale (ESS, which assesses daytime hypersomnolence). Objective sleep assessment was performed using accelerometry over 7 days. Global sleep quality assessed by the PSQI was significantly lower in the PBC group compared to controls (P < .0001). ESS scores were significantly higher in patients with PBC than controls (P = .0001), suggesting significantly greater daytime somnolence in the patients with PBC. Objective sleep assessment confirmed that subjects with PBC were sleeping on average almost twice as long as controls during the daytime. Both degree of daytime somnolence (ESS) and actual daytime sleep activity (accelerometry) correlated strongly with fatigue severity in the patient group (r2 = 0.5, P < .0001 and r2 = 0.2, P < .01, respectively). In conclusion, Sleep abnormality, in the form of excessive daytime somnolence, is present in a significant proportion of patients with PBC, with the degree of daytime somnolence correlating strongly with the degree of fatigue. Existing agents effective at reducing daytime somnolence (such as modafinil) hold potential for the treatment of fatigue in PBC.

Newton, Julia L.; Sheth, Amish; Shin, Jane; Pairman, Jessie; Wilton, Katharine; Burt, Jennifer A.; Jones, David E. J. (2009):

Lower ambulatory blood pressure in chronic fatigue syndrome.

In: *Psychosomatic Medicine* 71 (3), S. 361–365. DOI: 10.1097/PSY.0b013e31819ccd2a.

Abstract:

OBJECTIVE\r\nTo examine blood pressure circadian rhythm in subjects with chronic fatigue syndrome (CFS) and appropriate normal and fatigued controls to correlate parameters of blood pressure regulation with perception of fatigue in an observational cohort study. The cause of CFS remains unknown and there are no effective treatments.\r\nMETHODS\r\nTo address whether inactivity was a confounder, we performed a 24-hour ambulatory blood pressure monitoring in the following three subject groups: 1) CFS patients (Fukuda Diagnostic criteria) (n = 38); 2) normal controls (n = 120); and 3) a fatigue comparison group (n = 47) with the autoimmune liver disease primary biliary cirrhosis (PBC). All patients completed a measure of fatigue severity (Fatigue Impact Scale). In view of the different demographics between the patient groups, patients were age- and sex-matched on a case-by-case basis to normal controls and blood pressure parameters were compared.\r\nRESULTS\r\nCompared with the control population, the CFS group had significantly lower systolic blood pressure (p < .0001) and mean arterial blood pressure (p = .0002) and exaggerated diurnal variation (p = .009). There was a significant inverse relationship between increasing fatigue and diurnal variation of blood pressure in both the CFS and PBC groups (p < .05).\r\nCONCLUSION\r\nLower blood pressure and abnormal diurnal blood pressure regulation occur in patients with CFS. We would suggest the need for a randomized, placebo-controlled trial of agents to increase blood pressure such as midodrine in CFS patients with an autonomic phenotype.

Nezlek, John B. (2007):

A multilevel framework for understanding relationships among traits, states, situations and behaviours.

In: *European Journal of Personality* 21 (6), S. 789–810.

Abstract:

A conceptual and analytic framework for understanding relationships among traits, states, situations, and behaviours is presented. The framework assumes that such relationships can be understood in terms of four questions. (1) What are the relationships between trait and state level constructs, which include psychological states, the situations people experience and behaviour? (2) What are the relationships between psychological states, between states and situations and between states and behaviours? (3) How do such state level relationships vary as a function of trait level individual differences? (4) How do the relationships that are the focus of questions 1, 2, and 3 change across time? This article describes how to use multilevel random coefficient modelling (MRCM) to examine such relationships. The framework can accommodate different definitions of traits and dispositions (Allportian, processing styles, profiles, etc.) and different ways of conceptualising relationships between states and traits (aggregationist, interactionist, etc.).

Nezlek, John B. (2007):

Reactions to daily events as a function of familiarity with an environment.

In: *European Journal of Personality* 21 (6), S. 811–822.

Abstract:

Undergraduate participants provided measures of their psychological well-being and described the positive and negative events that occurred each day, once during the first and second semesters of an academic year. For four of the five measures of daily well-being, reactivity to negative events decreased from the first to second semester, whereas for four of the five measures of well-being, reactivity to positive events did not change over the year. These results suggest that familiarity with an environment moderates reactivity to negative daily events. As people become more familiar with an environment, negative events may elicit smaller decreases in well-being. In contrast, increases in well-being elicited by positive events appear to be unrelated to familiarity with the environment. More broadly, these differences suggest that the reactivity to positive and negative events reflect the operation of different processes. Copyright © 2007 John Wiley & Sons, Ltd.

Nezlek, John B. (2008):

An introduction to multilevel modeling for social and personality psychology.

In: *Social and Personality Psychology Compass* 2 (2), S. 842–860.

Abstract:

Multilevel modeling is a technique that has numerous potential applications for social and personality psychology. To help realize this potential, this article provides an introduction to multilevel modeling with an emphasis on some of its applications in social and personality psychology. This introduction includes a description of multilevel modeling, a rationale for this technique, and a discussion of applications of multilevel modeling in social and personality psychological research. Some of the subtleties of setting up multilevel analyses and interpreting results are presented, and software options are discussed.

Nezlek, John B. (2012):

Multilevel modeling analyses of diary-style data. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 357–383. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-020%26site%3dehost-live.

Abstract:

(from the chapter) Researchers who use ambulatory assessment methods and various types of diaries are increasingly (almost invariably) using some type of multilevel technique to analyze their data. This reflects the fact that the data collected in such studies are inherently multilevel. A sample of individuals provides data on a repeated basis, creating a multilevel data structure in which people constitute one level of analysis and the repeated measures they provide constitute another level, or levels, of analysis. In this chapter I discuss multilevel random coefficient modeling (MLM), the technique that is currently thought to be the best way to analyze such multilevel data structures. I introduce MLM and present ways of using MLM that are well suited for analyzing data generated in ambulatory assessment and diary studies. When writing this chapter, I tried to address the needs of two audiences: researchers who are quire familiar with MLM to analyze data collected using ambulatory assessment and other intensive repeated measures, and scholars (both new and established) who are not at all familiar with such applications. To address the needs of these different audiences I have provided sufficient introductory material to allow those who are unfamiliar to understand the basic principles involved, while describing more sophisticated applications for the benefit of those who are already familiar. Consequently, those who are familiar with MLM analyses of diary data may wish to skip or skim introductory sections and focus on sections dealing with specific topics or applications. I discuss MLM in terms of the types of multilevel data that are frequently collected in ambulatory assessment and diary research, although much of what I discuss can be applied to other types of data. Moreover, to illustrate certain points, I often refer to my own research. I have done this not because I am the only the person who has used MLM to analyze these types of data (quite the opposite; there are many experienced and knowledgeable scholars who have published MLM-based studies in this area); rather, I am more familiar with my own studies than I am with the work of others. Nezlek, John B.; Kafetsios, Konstantinos; Smith, C. Veronica (2008):

Emotions in Everyday Social Encounters Correspondence Between Culture and Self-Construal.

In: *Journal of Cross-Cultural Psychology* 39 (4), S. 366–372.

Abstract:

Relationships between self-construal and emotion experiences in social interactions were examined in two countries. Participants in Greece (a more collectivist culture) and the United Kingdom (a more individualist culture) described the social interactions they had each day for 7 days using a variant of the Rochester Interaction Record. For UK participants, independent self-construal was positively related to positive affect, whereas for Greek participants, independent self-construal was negatively related to positive affect. There were few relationships between interdependent self-construal and affect in either study. The results point to the interplay of cultural values and individual differences in self-construal and their relationships to people's affective experiences.

Ng, C. M.; Yiu, S. F.; Choi, K. L.; Choi, C. H.; Ng, Y. W.; Tiu, S. C. (2008):

Prevalence and significance of white-coat hypertension and masked hypertension in type 2 diabetics.

In: *Hong Kong medical journal= Xianggang yi xue za zhi/Hong Kong Academy of Medicine* 14 (6), S. 437–443.

Abstract:

OBJECTIVES:

To explore the prevalence of various categories of hypertension in diabetic patients, and assess any corresponding associations with end-organ complications.

DESIGN:

Cross-sectional study.

SETTING:

Tertiary centre of a regional hospital in Hong Kong.

PATIENTS:

All ambulatory type 2 diabetic patients attending our clinics from January 2002 to November 2004 were invited to participate in the protocol.

RESULTS:

A total of 133 diabetic patients were included; 82 had normal clinic blood pressures, 15 (18%) of whom had masked hypertension, the remaining 67 (82%) had 'normotension'. The remaining 51 patients had high clinic blood pressures, of whom 28 (55%) had white-coat hypertension and 23 (45%) had sustained hypertension. Urinary albumin excretion rate was higher in patients with masked hypertension (10 mg/day; range, 7-580 mg/day) and sustained hypertension (7 mg/day; 7-3360 mg/day) in comparison to those with white-coat hypertension (7 mg/day; 7-109 mg/day) or 'normotension' (7 mg/day; 7-181 mg/day) [P<0.01]. Likewise, the prevalence of albuminuria was significantly higher in patients with masked hypertension (40%) and sustained hypertension (26%) than in those with 'normotension' (6%) and white-coat hypertension (11%) [P<0.01]. The prevalence of left ventricular hypertrophy was significantly higher in subjects with masked hypertension (38%) and sustained hypertension (26%) compared to patients with 'normotension' (8%) or white-coat hypertension (11%) [P<0.01]. Left ventricular diastolic dysfunction was more prevalent in patients with masked hypertension (46%), sustained hypertension (48%), and white-coat hypertension (43%) in comparison to subjects with 'normotension' (18%) [P=0.01].

CONCLUSION:

Masked hypertension is associated with a higher prevalence of albuminuria, left ventricular diastolic dysfunction, and hypertrophy. White-coat hypertension carries a more benign prognosis than sustained hypertension and masked hypertension. Our cross-sectional study supports the recommendation to performing ambulatory blood pressure measurements in type 2 diabetic patients.

Assessment of Physical Activity and Energy Expenditure by GPS Combined With Accelerometry in Real-Life Conditions.

In: *J Phys.Act.Health* 10 (6), S. 880–888. Online verfügbar unter PM:23978833.

Abstract:

Background: Physical activity (PA) and related energy expenditure (EE) is often assessed by means of a single technique. Because of inherent limitations, single techniques may not allow for an accurate assessment both PA and related EE. The aim of this study was to develop a model to accurately assess common PA types and durations and thus EE in free-living conditions, combining data from global positioning system (GPS) and 2 accelerometers. Methods: Forty-one volunteers participated in the study. First, a model was developed and adjusted to measured EE with a first group of subjects (Protocol I, n = 12) who performed 6 structured and supervised PA. Then, the model was validated over 2 experimental phases with 2 groups (n = 12 and n = 17) performing scheduled (Protocol I) and spontaneous common activities in real-life condition (Protocol II). Predicted EE was compared with actual EE as measured by portable indirect calorimetry. Results: In protocol I, performed PA types could be recognized with little error. The duration of each PA type could be predicted with an accuracy below 1 minute. Measured and predicted EE were strongly associated (r = .97, P < .001). Conclusion: Combining GPS and 2 accelerometers allows for an accurate assessment of PA and EE in free-living situations

Fitness and physical activity in youth with type 1 diabetes mellitus in good or poor glycemic control.

In: *Pediatr Diabetes. DOI:* 10.1111/pedi.12117.

Abstract:

BACKGROUND: Patients with type 1 diabetes mellitus (T1DM) may experience poor muscle health as a result of chronic hyperglycemia. Despite this, muscle function in children with T1DM with good or poor glycemic control has yet to be examined in detail. OBJECTIVE: To assess differences in muscle-related fitness variables in children with T1DM with good glycemic control (T1DM-G), as well as those with poor glycemic control (T1DM-P), and non-diabetic, healthy controls. SUBJECTS: Eight children with T1DM-G [glycosylated hemoglobin (HbA1c) </= 7.5% for 9 months], eight children with T1DM-P (HbA1c >/= 9.0% for 9 months), and eight healthy controls completed one exercise session. METHODS: Anaerobic and aerobic muscle functions were assessed with a maximal isometric grip strength test, a Wingate test, and an incremental continuous cycling test until exhaustion. Blood samples were collected at rest to determine HbA1c at the time of testing. Physical activity was monitored over 7 d using accelerometry. RESULTS: Children with T1DM-P displayed lower peak oxygen consumption (VO2peak) values (mL/kg/min) compared to healthy controls (T1DM-P: 33.2 +/- 5.6, controls: 43.5 +/- 6.3, p < 0.01), while T1DM-G (43.5 +/- 6.3) had values similar to controls and T1DM-P. There was a negative relationship between VO2peak and HbA1c% (r = -0.54, p < 0.01). All groups were similar in all other fitness variables. There were no group differences in physical activity variables. CONCLUSION: Children with T1DM-G did not display signs of impaired muscle function, while children with T1DM-P have signs of altered aerobic muscle capacity.

Nica, Elena Irina; Links, Paul S. (2009):

Affective instability in borderline personality disorder: Experience sampling findings.

In: *Current Psychiatry Reports* 11 (1), S. 74–81.

Abstract:

Affective instability, defined as repeated, rapid, and abrupt shifts in mood, is considered the core pathology in borderline personality disorder. The temporal pattern of affective instability can be best captured with the experience sampling method-longitudinal assessment of people's affective states as they occur in real time and in their natural environment. A review of the experience sampling studies published to date for borderline personality disorder suggests the following mood variability pattern: intense negative mood, more frequent and abrupt mood changes than healthy controls and patients with major depression, and partial triggering of affect by external events. The method also has great potential to investigate the links between affective instability and other psychological and behavioral correlates of the disorder, such as suicide, lack of self-esteem, and erratic behaviors. However, the method requires systematic study to determine best data collection designs and mathematical models of mood variability.

Nicaise, Virginie; Marshall, Simon; Ainsworth, Barbara E. (2011):

Domain-specific physical activity and self-report bias among low-income Latinas living in San Diego County.

In: *J Phys Act Health* 8 (7), S. 881–890. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-19336-001&site=ehost-live.

Abstract:

BACKGROUND:

Evidence suggests that Latina women appear to be less physically active than women of other racial/ethnic groups. This study evaluated how different domains of physical activity (PA) contributed to overall levels of PA among low-income Latinas, the validity of Latinas' self-reported PA, and potential moderators of self-report bias in PA.

METHODS:

A community sample of 105 Latinas (mean age = 35.9 ± 9.0 years; mean body mass index = 31.6 ± 7.2) completed the long form Spanish-language version of the International Physical Activity Questionnaire (IPAQ), wore an accelerometer for seven days, and completed self-reported measures of acculturation and socioeconomic status.

RESULTS:

Ninety-six percent of IPAQ-reported moderate-intensity PA (MPA) was accrued during household activities, with only 4% accrued during leisure time. Seventy-two percent of participants met national recommendations for PA using IPAQ data, but only 20% met recommendations when measured by accelerometer. When bouts of MPA lasting >10 min were included, 0% met recommendations. Age appeared to moderate self-report bias of vigorous PA, and there were nonsignificant trends for acculturation and income to moderate MPA and vigorous-intensity PA, respectively.

CONCLUSIONS:

Data suggest that it is important to measure household activity of Latinas, and that the IPAQ yield overestimates of self-report PA.

Nichols, Jeanne F.; Aralis, Hilary; García Merino, Sonia; Barrack, Michelle T.; Stalker-Fader, Lindsay; Rauh, Mitchell J. (2010):

Utility of the actiheart accelerometer for estimating exercise energy expenditure in female adolescent runners.

Abstract:

There is a growing need to accurately assess exercise energy expenditure (EEE) in athletic populations that may be at risk for health disorders because of an imbalance between energy intake and energy expenditure. The Actiheart combines heart rate and uniaxial accelerometry to estimate energy expenditure above rest. The authors' purpose was to determine the utility of the Actiheart for predicting EEE in female adolescent runners (N = 39, age 15.7 ± 1.1 yr). EEE was measured by indirect calorimetry and predicted by the Actiheart during three 8-min stages of treadmill running at individualized velocities corresponding to each runner's training, including recovery, tempo, and 5-km-race pace. Repeated-measures ANOVA with Bonferroni post hoc comparisons across the 3 running stages indicated that the Actiheart was sensitive to changes in intensity ($p < .01$), but accelerometer output tended to plateau at race pace. Pairwise comparisons of the mean difference between Actiheart- and criterion-measured EEE yielded values of 0.0436, 0.0539, and 0.0753 kcal × kg-1 × min-1 during recovery, tempo, and race pace, respectively ($p < .0001$). Bland-Altman plots indicated that the Actiheart consistently underestimated EEE except in 1 runner's recovery bout. A linear mixed-model regression analysis with height as a covariate provided an improved EEE prediction model, with the overall standard error of the estimate for the 3 speeds reduced to 0.0101 kcal × kg-1 × min-1. Using the manufacturer's equation that combines heart rate and uniaxial motion, the Actiheart may have limited use in accurately assessing EEE, and therefore energy availability, in young, female competitive runners.

Nicolaï, Saskia P. A.; Teijink, Joep A. W.; Prins, Martin H. (2010):

Multicenter randomized clinical trial of supervised exercise therapy with or without feedback versus walking advice for intermittent claudication.

In: *Journal of vascular surgery* 52 (2), S. 348–355. DOI: 10.1016/j.jvs.2010.02.022.

Abstract:

OBJECTIVE\r\nThe initial treatment for intermittent claudication is supervised exercise therapy (SET). Owing to limited capacity and patient transports costs of clinic-based SET, a concept of SET provided by local physiotherapists was developed. We hypothesized that provision of daily feedback with an accelerometer in addition to SET would further increase walking distance.\r\nMETHODS\r\nThis multicenter randomized trial was set in vascular surgery outpatient clinics and included 304 patients with intermittent claudication. Patients were randomized to exercise therapy in the form of \"go home and walk\" advice (WA), SET, or SET with feedback. Local physiotherapists provided SET. The primary outcome measure was the change in absolute claudication distance. Secondary outcomes were the change in functional claudication distance and results on the Walking Impairment Questionnaire (WIQ) and Short-Form 36 (SF-36) Health Survey after 12 months.\r\nRESULTS\r\nIn 11 centers, 102, 109, and 93 patients were included, respectively, in the WA, SET, and SET with feedback groups, and data for 83, 93, and 76, respectively, could be analyzed. The median (interquartile range) change in walking distance between 12 months and baseline in meters was 110 (0-300) in the WA group, 310 (145-995) in the SET group, and 360 (173-697) in the SET with feedback group (P < .001 WA vs SET). WIQ scores and relevant domains of the SF-36 improved statistically significantly in the SET groups.\r\nCONCLUSIONS\r\nSET is more effective than WA in improving walking distance, WIQ scores, and quality of life for patients with intermittent claudication. Additional feedback with an accelerometer did not result in further improvement. SET programs should be made available for all patients with intermittent claudication.

Nielsen, Glen; Bugge, Anna; Hermansen, Bianca; Svensson, Jesper; Andersen, Lars Bo (2012):

School playground facilities as a determinant of children's daily activity: A cross-sectional study of Danish primary school children.

In: *J Phys Act Health* 9 (1), S. 104–114. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00272-012&site=ehost-live.

Abstract:

BACKGROUND:

This study investigates the influence of school playground facilities on children's daily physical activity.

METHODS:

Participants were 594 school children measured at preschool (age 6 to 7 years) and 3 years later in third grade (518 children age 9 to 10 years) from 18 schools in 2 suburban municipalities in Denmark. Physical activity data were obtained using accelerometers. These were related to the number of permanent play facilities in school grounds and the school playground area (m2).

RESULTS:

The number of play facilities in the school grounds was positively associated with all measures of children's activity. In preschool every 10 additional play facilities the children had access to was associated with an increase in the average accelerometer counts of 14% (r = .273, P < .001) in school time and 6.9% (r = .195, P < .001) overall. For the children in third grade, access to 10 additional play facilities was associated with an increase in school time activity level of 26% (r = .364, P < .001) and an increase in overall activity level of 9.4% (r = .211, P < .001). School playground area did not affect activity levels independently of the number of permanent play facilities.

CONCLUSION:

Increasing the number of play facilities in primary school playgrounds may increase the level of children's daily physical activity.

Nielsen, Karina; Cleal, Bryan (2010):

Predicting flow at work: investigating the activities and job characteristics that predict flow states at work.

In: *Journal of Occupational Health Psychology* 15 (2), S. 180–190. DOI: 10.1037/a0018893.

Abstract:

Flow (a state of consciousness where people become totally immersed in an activity and enjoy it intensely) has been identified as a desirable state with positive effects for employee well-being and innovation at work. Flow has been studied using both questionnaires and Experience Sampling Method (ESM). In this study, we used a newly developed 9-item flow scale in an ESM study combined with a questionnaire to examine the predictors of flow at two levels: the activities (brainstorming, planning, problem solving and evaluation) associated with transient flow states and the more stable job characteristics (role clarity,

influence and cognitive demands). Participants were 58 line managers from two companies in Denmark; a private accountancy firm and a public elder care organization. We found that line managers in elder care experienced flow more often than accountancy line managers, and activities such as planning, problem solving, and evaluation predicted transient flow states. The more stable job characteristics included in this study were not, however, found to predict flow at work.

Office, Home, and Ambulatory Blood Pressures as Predictors of Cardiovascular Risk.

In: *Hypertension. DOI:* 10.1161/HYPERTENSIONAHA.114.03292.

Abstract:

Ambulatory blood pressure (BP) is considered as the gold standard of BP measurement although it has not been shown to be more strongly associated with cardiovascular risk than is home BP. Our objective was to compare the prognostic value of office, home, and ambulatory BP for cardiovascular risk in 502 participants examined in 1992 to 1996. The end point was a composite of cardiovascular mortality, myocardial infarction, stroke, heart failure hospitalization, and coronary intervention. We assessed the prognostic value of each BP in multivariable-adjusted Cox models. The likelihood chi2 ratio value was used to test whether the addition of a BP variable improved the model's goodness of fit. After a follow-up of 16.1+/-3.9 years, 70 participants (13.9%) had experienced >/=1 cardiovascular event. Office (systolic/diastolic hazard ratio per 1/1 mm Hg increase in BP, 1.024/1.018; systolic/diastolic 95% confidence interval, 1.009-1.040/0.994-1.043), home (hazard ratio, 1.029/1.028; 95% confidence interval, 1.013-1.045/1.005-1.052), and 24-hour ambulatory BP (hazard ratio, 1.033/1.049; 95% confidence interval, 1.019-1.047/1.023-1.077) were predictive of cardiovascular events. When all 3 BP variables were included in the model simultaneously, only systolic/diastolic ambulatory BP was a significant predictor of cardiovascular events (P=0.002/<0.001). Home systolic/diastolic BP improved the fit of the model only marginally when added to a model including office BP (chi2=3.0/4.0, P=0.09/0.047). Ambulatory BP, however, improved the fit of model more clearly when added to office and home BP (chi2=9.0/12.3, P=0.001/<0.001). Our findings suggest that ambulatory BP is prognostically superior to office and home BP.

Nijsen, Tamara M. E.; Aarts, Ronald M.; Cluitmans, Pierre J. M.; Griep, Paul A. M. (2010):

Time-frequency analysis of accelerometry data for detection of myoclonic seizures.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 14 (5), S. 1197–1203. DOI: 10.1109/TITB.2010.2058123.

Abstract:

Four time-frequency and time-scale methods are studied for their ability of detecting myoclonic seizures from accelerometric data. Methods that are used are: the short-time Fourier transform (STFT), the Wigner distribution (WD), the continuous wavelet transform (CWT) using a Daubechies wavelet, and a newly introduced model-based matched wavelet transform (MOD). Real patient data are analyzed using these four time-frequency and time-scale methods. To obtain quantitative results, all four methods are evaluated in a linear classification setup. Data from 15 patients are used for training and data from 21 patients for testing. Using features based on the CWT and MOD, the success rate of the classifier was 80%. Using STFT or WD-based features, the classification success is reduced. Analysis of the false positives revealed that they were either clonic seizures, the onset of tonic seizures, or sharp peaks in \"normal\" movements indicating that the patient was making a jerky movement. All these movements are considered clinically important to detect. Thus, the results show that both CWT and MOD are useful for the detection of myoclonic seizures. On top of that, MOD has the advantage that it consists of parameters that are related to seizure duration and intensity that are physiologically meaningful. Furthermore, in future work, the model can also be useful for the detection of other motor seizure types.

Detection of subtle nocturnal motor activity from 3-D accelerometry recordings in epilepsy patients.

In: *Biomedical Engineering, IEEE Transactions on* 54 (11), S. 2073–2081.

Abstract:

This paper presents a first step towards reliable detection of nocturnal epileptic seizures based on 3-D accelerometry (ACM) recordings. The main goal is to distinguish between data with and without subtle nocturnal motor activity, thus reducing the amount of data that needs further (more complex) analysis for seizure detection. From 15 ACM signals (measured on five

positions on the body), two features are computed, the variance and the jerk. In the resulting 2-D feature space, a linear threshold function is used for classification. For training and testing, the algorithm ACM data along with video data is used from nocturnal registrations in seven mentally retarded patients with severe epilepsy. Per patient, the algorithm detected 100% of the periods of motor activity that are marked in video recordings and the ACM signals by experts. From all the detections, 43%-89% was correct (mean =65%). We were able to reduce the amount of data that need to be analyzed considerably. The results show that our approach can be used for detection of subtle nocturnal motor activity. Furthermore, our results indicate that our algorithm is robust for fluctuations across patients. Consequently, there is no need for training the algorithm for each new patient.

Variability and predictors of negative mood intensity in patients with borderline personality disorder and recurrent suicidal behavior: multilevel analyses applied to experience sampling methodology.

In: *Journal of Abnormal Psychology* 119 (2), S. 433–439. DOI: 10.1037/a0018696.

Abstract:

Variability in mood swings is a characteristic of borderline personality disorder (BPD) and is associated with suicidal behavior. This study investigated patterns of mood variability and whether such patterns could be predicted from demographic and suicide-related psychological risk factors. Eighty-two adults with BPD and histories of recurrent suicidal behavior were recruited from 3 outpatient psychiatric programs in Canada. Experience sampling methodology (ESM) was used to assess negative mood intensity ratings on a visual analogue scale, 6 random times daily, for 21 days. Three-level models estimated variability between times (52.8%), days (22.2%), and patients (25.1%) and supported a quadratic pattern of daily mood variability. Depression scores predicted variability between patients' initial rating of the day. Average daily mood patterns depended on levels of hopelessness, suicide ideation, and sexual abuse history. Patients reporting moderate to severe sexual abuse and elevated suicide ideation were characterized by worsening moods from early morning up through evening, with little or no relief; patients reporting mild sexual abuse and low suicide ideation reported improved mood throughout the day. These patterns, if replicated in larger ESM studies, may potentially assist the clinician in determining which patients require close monitoring.

Self-assessment tool of disease activity of rheumatoid arthritis by using a smartphone application.

In: *Telemed J E Health* 20 (3), S. 235–240. DOI: 10.1089/tmj.2013.0162.

Abstract:

Abstract Objectives: The disease activities of rheumatoid arthritis (RA) tend to fluctuate between visits to doctors, and a self-assessment tool can help patients accommodate to their current status at home. The aim of the present study was to develop a novel modality to assess the disease activity of RA by a smartphone without the need to visit a doctor. Subjects and Methods: This study included 65 patients with RA, 63.1+/-11.9 years of age. The 28-joint disease activity score (DAS28) was measured for all participants at each clinic visit. The patients assessed their status with the modified Health Assessment Questionnaire (mHAQ), a self-assessed tender joint count (sTJC), and a self-assessed swollen joint count (sSJC) in a smartphone application. The patients' trunk acceleration while walking was also measured with a smartphone application. The peak frequency, autocorrelation (AC) peak, and coefficient of variance of the acceleration peak intervals were calculated as the gait parameters. Results: Univariate analyses showed that the DAS28 was associated with mHAQ, sTJC, sSJC, and AC ($p<0.05$). In a stepwise linear regression analysis, mHAQ (beta=0.264, $p<0.05$), sTJC (beta=0.581, $p<0.001$), and AC (beta=-0.157, $p<0.05$) were significantly associated with DAS28 in the final model, and the predictive model explained 67% of the DAS28 variance. Conclusions: The results suggest that noninvasive self-assessment of a combination of joint symptoms, limitations of daily activities, and walking ability can adequately predict disease activity of RA with a smartphone application.

Nishiguchi, Shu; Yamada, Minoru; Nagai, Koutatsu; Mori, Shuhei; Kajiwara, Yuu; Sonoda, Takuya et al. (2012):

Reliability and validity of gait analysis by Android-based smartphone.

In: *Telemedicine and e-Health* 18 (4), S. 292–296. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-12413-005&site=ehost-live;shu.n@ks2.ecs.kyoto-u.ac.jp.

Abstract:

Smartphones are very common devices in daily life that have a built-in tri-axial accelerometer. Similar to previously developed accelerometers, smartphones can be used to assess gait patterns. However, few gait analyses have been performed using smartphones, and their reliability and validity have not been evaluated yet. The purpose of this study was to evaluate the reliability and validity of a smartphone accelerometer. Thirty healthy young adults participated in this study. They walked 20m at their preferred speeds, and their trunk accelerations were measured using a smartphone and a tri-axial accelerometer that was secured over the L3 spinous process. We developed a gait analysis application and installed it in the smartphone to measure the acceleration. After signal processing, we calculated the gait parameters of each measurement terminal: peak frequency (PF), root mean square (RMS), autocorrelation peak (AC), and coefficient of variance (CV) of the acceleration peak intervals. Remarkable consistency was observed in the test–retest reliability of all the gait parameter results obtained by the smartphone ($p < 0.001$). All the gait parameter results obtained by the smartphone showed statistically significant and considerable correlations with the same parameter results obtained by the tri-axial accelerometer (PF $r = 0.99$, RMS $r = 0.89$, AC $r = 0.85$, CV $r = 0.82$; $p < 0.01$). Our study indicates that the smartphone with gait analysis application used in this study has the capacity to quantify gait parameters with a degree of accuracy that is comparable to that of the tri-axial accelerometer. Nock, Matthew K.; Prinstein, Mitchell J.; Sterba, Sonya K. (2009):

Revealing the form and function of self-injurious thoughts and behaviors: A real-time ecological assessment study among adolescents and young adults.

In: *Journal of Abnormal Psychology* 118 (4), S. 816–827. DOI: 10.1037/a0016948.

Abstract:

Self-injurious behaviors are among the leading causes of death worldwide. However, the basic nature of self-injurious thoughts and behaviors (SITBs) is not well understood because prior studies have relied on long-term, retrospective, aggregate, self-report assessment methods. The authors used ecological momentary assessment methods to measure suicidal and nonsuicidal SITBs as they naturally occur in real time. Participants were 30 adolescents and young adults with a recent history of self-injury who completed signal- and event-contingent assessments on handheld computers over a 14-day period, resulting in the collection of data on 1,262 thought and behavior episodes. Participants reported an average of 5.0 thoughts of nonsuicidal self-injury (NSSI) per week, most often of moderate intensity and short duration (1-30 min), and 1.6 episodes of NSSI per week. Suicidal thoughts occurred less frequently (1.1 per week), were of longer duration, and led to self-injurious behavior (i.e., suicide attempts) less often. Details are reported about the contexts in which SITBs most often occur (e.g., what participants were doing, who they were with, and what they were feeling before and after each episode). This study provides a first glimpse of how SITBs are experienced in everyday life and has significant implications for scientific and clinical work on self-injurious behaviors.

Nolan, M.; Mitchell, J. R.; Doyle-Baker, P. K. (2013):

Validity of the Apple iPhone/iPod Touch(R) as an Accelerometer-Based Physical Activity Monitor: A Proof-of-Concept Study.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23575387.

Abstract:

BACKGROUND: The popularity of smartphones has led researchers to ask if they can replace traditional tools for assessing free-living physical activity. Our purpose was to establish proof-of-concept that a smartphone could record acceleration during physical activity, and those data could be modeled to predict activity type (walking or running), speed (km.h-1), and energy expenditure (METs). METHODS: An application to record and email accelerations was developed for the Apple iPhone/iPod Touch(R). Twenty-five healthy adults performed treadmill walking (4.0 km.h-1 to 7.2 km.h-1) and running (8.1 km.h-1 to 11.3 km .h-1) wearing the device. Criterion energy expenditure measurements were collected via metabolic cart. RESULTS: Activity type was classified with 99% accuracy. Speed was predicted with a bias of 0.02 km h-1 (SEE: 0.57 km.h-1) for walking, -0.03 km.h-1 (SEE: 1.02 km.h-1) for running. Energy expenditure was predicted with a bias of 0.35 METs (SEE: 0.75 METs) for walking, -0.43 METs (SEE: 1.24 METs) for running. CONCLUSION: Our results suggest that an iPhone/iPod Touch(R) can predict aspects of

locomotion with accuracy similar to other accelerometer-based tools. Future studies may leverage this and the additional features of smartphones to improve data collection and compliance

A more active lifestyle in persons with a recent spinal cord injury benefits physical fitness and health.

In: *Spinal Cord* 50 (4), S. 320–323. DOI: 10.1038/sc.2011.152.

Abstract:

STUDY DESIGN: A prospective cohort study. OBJECTIVES: To study the longitudinal relationship between objectively measured everyday physical activity level, and physical fitness and lipid profile in persons with a recent spinal cord injury (SCI). SETTING: A rehabilitation centre in the Netherlands and the participant's home environment. METHODS: Data of 30 persons with a recent SCI were collected at the start of active rehabilitation, 3 months later, at discharge from inpatient rehabilitation, and 1 year after discharge. Physical activity level (duration of dynamic activities as % of 24 h) was measured with an accelerometry-based activity monitor. Regarding physical fitness, peak oxygen uptake (VO(2)peak) and peak power output (POpeak) were determined with a maximal wheelchair exercise test, and upper extremity muscle strength was measured with a handheld dynamometer. Fasting blood samples were taken to determine the lipid profile. RESULTS: An increase in physical activity level was significantly related to an increase in VO(2)peak and POpeak, and an increase in physical activity level favourably affected the lipid profile. A nonsignificant relation was found with muscle strength. CONCLUSION: Everyday physical activity seems to have an important role in the fitness and health of persons with a recent SCI. An increase in physical activity level was associated with an increase in physical fitness and with a lower risk of cardiovascular disease

Noonan, Michael J.; Markham, Andrew; Newman, Chris; Trigoni, Niki; Buesching, Christina D.; Ellwood, Stephen A.; MacDonald, David W. (2014):

Climate and the individual: inter-annual variation in the autumnal activity of the European badger (Meles meles).

In: *PLoS One* 9 (1), S. e83156. DOI: 10.1371/journal.pone.0083156.

Abstract:

We establish intra-individual and inter-annual variability in European badger (Meles meles) autumnal nightly activity in relation to fine-scale climatic variables, using tri-axial accelerometry. This contributes further to understanding of causality in the established interaction between weather conditions and population dynamics in this species. Modelling found that measures of daylight, rain/humidity, and soil temperature were the most supported predictors of ACTIVITY, in both years studied. In 2010, the drier year, the most supported model included the SOLAR*RH interaction, RAIN, and 30cmTEMP (w = 0.557), while in 2012, a wetter year, the most supported model included the SOLAR*RH interaction, and the RAIN*10cmTEMP (w = 0.999). ACTIVITY also differed significantly between individuals. In the 2012 autumn study period, badgers with the longest per noctem activity subsequently exhibited higher Body Condition Indices (BCI) when recaptured. In contrast, under drier 2010 conditions, badgers in good BCI engaged in less per noctem activity, while badgers with poor BCI were the most active. When compared on the same calendar dates, to control for night length, duration of mean badger nightly activity was longer (9.5 hrs +/-3.3 SE) in 2010 than in 2012 (8.3 hrs +/-1.9 SE). In the wetter year, increasing nightly activity was associated with net-positive energetic gains (from BCI), likely due to better foraging conditions. In a drier year, with greater potential for net-negative energy returns, individual nutritional state proved crucial in modifying activity regimes; thus we emphasise how a 'one size fits all' approach should not be applied to ecological responses.

Nosen, Elizabeth; Woody, Sheila R. (2013):

Brief psycho-education affects circadian variability in nicotine craving during cessation.

In: *Drug Alcohol Depend*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-08847-001%26site%3dehost-live.

Abstract:

BACKGROUND: Nicotine cravings are a key target of smoking cessation interventions. Cravings demonstrate circadian variation during abstinence, often peaking during the morning and evening hours. Although some research has also shown diurnal variation in the efficacy of nicotine replacement medications, little research has examined how brief psychosocial interventions affect temporal patterns of craving during abstinence. The present study examined the impact of two brief psycho-education interventions on circadian variations in cravings during a 24-h period. METHOD: 176 adult smokers interested in quitting participated in two lab sessions. During the first session, participants received (a) mindfulness psycho-education that encouraged acceptance of cravings as a normal, tolerable part of quitting that people should not expect to perfectly control, (b) standard cessation psycho-education, or (c) no psycho-education. Half the sample initiated a cessation attempt the following day. Dependent variables were assessed using ecological momentary assessment (24-h of monitoring, immediately after first lab session) and questionnaires four days later. RESULTS: Partially consistent with hypotheses, both forms of psycho-education were associated with differential diurnal variation in cravings during cessation. Relative to those receiving no psycho-education, standard smoking cessation psycho-education decreased morning cravings. Psycho-education encouraging acceptance of cravings was associated with lower craving in both the morning and evening, albeit only among successfully abstinent smokers. CONCLUSIONS: Results demonstrate that brief non-pharmacological interventions can affect circadian craving patterns during smoking cessation. Further investigation of mechanisms of change and of the impact of psycho-education on cessation outcomes is warranted. Nusbaum, Emily C.; Silvia, Paul J.; Beaty, Roger E.; Burgin, Chris J.; Hodges, Donald A.; Kwapil, Thomas R. (2013):

Listening Between the Notes: Aesthetic Chills in Everyday Music Listening.

In: *Psychology of Aesthetics, Creativity, and the Arts*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-44712-001%26site%3dehost-live.

Abstract:

Who gets chills—a pleasurable feeling of goose bumps—in response to music, and why? The current study used experience sampling to examine within-person variability in aesthetic chills. For one week, 106 undergraduate participants responded to 10 daily surveys, delivered via their cell phones, about their momentary activities, emotions, and environment, with an emphasis on whether they were listening to music and were experiencing chills. At the within-person level, music listening context and emotional states during music listening influenced whether or not people got chills. Chills were more likely when people listened to music that they chose and that they were listening to closely. Chills were also more likely when people were listening to music while happy or while sad, but not while worried. Overall, the study illustrates how music listening context and other within-person differences contribute to aesthetic chills in people's everyday environments. Nyan, M. N.; Tay, F. E. H.; Tan, A. W. Y.; Seah, K. H. W. (2006):

Distinguishing fall activities from normal activities by angular rate characteristics and high-speed camera characterization.

In: *Med Eng Phys* 28 (8), S. 842–849. DOI: 10.1016/j.medengphy.2005.11.008.

Abstract:

Distinguishing sideways and backward falls from normal activities of daily living using angular rate sensors (gyroscopes) was explored in this paper. Gyroscopes were secured on a shirt at the positions of sternum (S), front of the waist (FW) and right underarm (RU) to measure angular rate in lateral and sagittal planes of the body during falls and normal activities. Moreover, the motions of the fall incidents were captured by a high-speed camera at a frame rate of 250 frames per second (fps) to study the body configuration during fall. The high-speed camera and the sensor data capture system were activated simultaneously to synchronize the picture frame of high-speed camera and the sensor data. The threshold level for each sensor was set to distinguish fall activities from normal activities. Lead time of fall activities (time after threshold value is surpassed to the time when the hip hits the ground) and relative angle of body configuration (angle beta between the vertical line and the line from the center point of the foot or the center point between the two legs to that of the waist) at the threshold level were studied. For sideways falls, lead times of sensors at positions FW and S were about 200-220ms and 135-182ms, respectively. The lead time of the slippery backward fall (about 98ms) from the sensor at position RU was shorter than that of the sideways falls from the sensors at positions FW and S. The relative angle of body configuration at threshold level for sideways and backward falls were about 40-43 degrees for the sensor at position FW, about 43-52 degrees for the sensor at position S and about 54 degrees for the sensor at position RU, respectively. This is the first study that investigates fall dynamics in detection of fall before the person hits the ground using angular rate sensors (gyroscopes).

Nyberg, Gisela A.; Nordenfelt, Anja M.; Ekelund, Ulf; Marcus, Claude (2009):

Physical activity patterns measured by accelerometry in 6- to 10-yr-old children.

In: *Med Sci Sports Exerc* 41 (10), S. 1842–1848. DOI: 10.1249/MSS.0b013e3181a48ee6.

Abstract:

PURPOSE\r\nTo examine differences in patterns of objectively measured physical activity (PA) among weekdays and weekend days and across different time blocks during the day in relation to age and gender. This knowledge is important when planning preventive initiatives aimed at increasing levels of PA in children.\r\nMETHODS\r\nThis is a cross-sectional analysis in 653 girls and 640 boys (6-10 yr) measured during 1 wk with accelerometry. Periods of the day were divided into school time (8:00 a.m. to 1:30 p.m.), after school care time (1:30-4:00 p.m.), and evening time (4:00-9:00 p.m.). Multivariate ANOVA was used to analyze mean PA.\r\nRESULTS\r\nMean daily PA differed significantly across age groups (6-10 yr) in both boys and girls (P < 0.001). Mean (SE) daily PA was significantly lower during weekends compared with weekdays in all age groups (girls 782 (6.7) vs 681 (7.7) counts per min (CPM), P < 0.001; boys 853 (7.1) vs 729 (8.0) CPM, P < 0.001). This decline was similar across low, medium, and highly active children. Mean PA was highest during after school care time on weekdays (girls 879 (9.8) and boys 990 (10.0) CPM) compared with all other periods. The difference in mean PA between boys and girls was highest during school time (P < 0.001) and after school care time (P < 0.001).\r\nCONCLUSIONS\r\nThe decline in PA in children may start already at the age of 6 yr. The school setting may be an important arena for targeting activity levels in girls because the difference in PA levels between girls and boys is most pronounced during school time. In both girls and boys, PA levels are disproportionally low during weekends and might be important targets for interventions aimed to increase PA.

Comparison of apomorphine and levodopa infusions in four patients with Parkinson's disease with symptom fluctuations.

In: *Acta neurologica Scandinavica* 119 (5), S. 345–348. DOI: 10.1111/j.1600-0404.2008.01104.x.

Abstract:

BACKGROUND\r\nMotor fluctuations in patients with advanced Parkinson's disease may be successfully treated with subcutaneous apomorphine infusion or intraduodenal levodopa/carbidopa infusion. No comparative trials of these two alternatives were performed.\r\nAIMS OF THE STUDY\r\nWe present a subanalysis from a randomized crossover clinical trial where levodopa infusion as monotherapy was compared with any other combination of pharmacotherapy in fluctuating patients. Four patients used apomorphine infusion and oral levodopa in the comparator arm. The results of these four patients are presented in detail.\r\nMETHODS\r\nThe duration of the trial was 3 + 3 weeks. Patients were video-recorded half-hourly on two non-consecutive days of both treatment arms. Blinded video ratings were used. Patient self-assessments of motor function and quality-of-life (QoL) parameters were captured using an electronic diary.\r\nRESULTS\r\nRatings in moderate to severe \"off\" state ranged 0-44% on apomorphine infusion and 0-6% on levodopa infusion. Moderate to severe dyskinesias were not recorded in any of the treatments. QoL was reported to be improved in all patients on duodenal levodopa infusion.\r\nCONCLUSIONS\r\nMonotherapy with duodenal infusion of levodopa was more efficacious and brought greater QoL than combination therapy with apomorphine infusion in these fluctuating patients.

The effects of neighborhood density and street connectivity on walking behavior: the Twin Cities walking study.

In: *Epidemiologic Perspectives & Innovations* 4 (1), S. 16.

Abstract:

A growing body of health and policy research suggests residential neighborhood density and street connectivity affect walking and total physical activity, both of which are important risk factors for obesity and related chronic diseases. The authors report

results from their methodologically novel Twin Cities Walking Study; a multilevel study which examined the relationship between built environments, walking behavior and total physical activity. In order to maximize neighborhood-level variation while maintaining the exchangeability of resident-subjects, investigators sampled 716 adult persons nested in 36 randomly selected neighborhoods across four strata defined on density and street-connectivity - a matched sampling design. Outcome measures include two types of self-reported walking (from surveys and diaries) and so-called objective 7-day accelerometry measures. While crude differences are evident across all outcomes, adjusted effects show increased odds of travel walking in higher-density areas and increased odds of leisure walking in low-connectivity areas, but neither density nor street connectivity are meaningfully related to overall mean miles walked per day or increased total physical activity. Contrary to prior research, the authors conclude that the effects of density and block size on total walking and physical activity are modest to non-existent, if not contrapositive to hypotheses. Divergent findings are attributed to this study's sampling design, which tends to mitigate residual confounding by socioeconomic status.

Factors related to students' engaged reading in high school science classrooms.

In: *Dissertation Abstracts International Section A: Humanities and Social Sciences* 73 (11-A(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99090-374%26site%3dehost-live.

Abstract:

Using emergent motivation theory, this study analyzes the relationships between high school students' perceptions of their reading skills, task challenge, and personal control over assigned reading activities and their reading engagement (i.e., interest, enjoyment, and concentration) during science instruction. The study also examines how these relationships differ between struggling and proficient readers. Further, the study examines the association between students' experiences of conditions of anxiety, apathy, boredom or relaxation and flow on their reading engagement during science instruction. Finally, the study investigates the relationship between reading engagement and science achievement. The experience sampling method (ESM) was used with a sample of 244 high school students in grades 9–12 to measure students' perceptions of skill, challenge, and control, and their reading engagement during science instruction. Hierarchical linear modeling (HLM) was employed with repeated-measures analysis of students' momentary experiences of skill, challenge, control, and engagement during reading. Results show that when students perceive having both high reading skills and high control, they exhibit deeper reading engagement than when they perceive having both low reading skills and low control. These feelings of control were noticeably important for struggling readers as compared to proficient readers. It was also found that students experience deeper reading engagement during flow (i.e., when students perceive they have high reading skills and the reading task is highly challenging), but reading engagement decreases significantly whenever students experience conditions of anxiety or apathy when reading science materials. Finally, reading engagement was positively related to science achievement. Educational implications of the results are presented. Limitations of the study are discussed and suggestions for future research are described. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

Ockendon, M.; Gilbert, R. E. (2012):

Validation of a novel smartphone accelerometer-based knee goniometer.

In: *J Knee.Surg.* 25 (4), S. 341–345. DOI: 10.1055/s-0031-1299669.

Abstract:

Loss of full knee extension following anterior cruciate ligament surgery has been shown to impair knee function. However, there can be significant difficulties in accurately and reproducibly measuring a fixed flexion of the knee. We studied the interobserver and the intraobserver reliabilities of a novel, smartphone accelerometer-based, knee goniometer and compared it with a long-armed conventional goniometer for the assessment of fixed flexion knee deformity. Five healthy male volunteers (age range 30 to 40 years) were studied. Measurements of knee flexion angle were made with a telescopic-armed goniometer (Lafayette Instrument, Lafayette, IN) and compared with measurements using the smartphone (iPhone 3GS, Apple Inc., Cupertino, CA) knee goniometer using a novel trigonometric technique based on tibial inclination. Bland-Altman analysis of validity and reliability including statistical analysis of correlation by Pearson's method was undertaken. The iPhone goniometer had an interobserver correlation (r) of 0.994 compared with 0.952 for the Lafayette. The intraobserver correlation was r = 0.982 for the iPhone (compared with 0.927). The datasets from the two instruments correlate closely (r = 0.947) are proportional and have mean difference of only -0.4 degrees (SD 3.86 degrees). The Lafayette goniometer had an intraobserver reliability +/- 9.6 degrees. The interobserver reliability was +/- 8.4 degrees. By comparison the iPhone had an interobserver reliability +/- 2.7 degrees and an intraobserver reliability +/- 4.6 degrees. We found the iPhone goniometer to be a reliable tool for the measurement of subtle knee flexion in the clinic setting

How does coping help people resist lapses during smoking cessation?

In: *Health Psychol* 26 (1), S. 77.

Abstract:

OBJECTIVES:

To determine whether types of coping strategies have differential effects on preventing lapses and lowering urge levels and to investigate mechanisms by which coping strategies prevent lapses during smoking cessation.

DESIGN:

Sixty-one respondents performed ecological momentary assessment using palm-top computers and tape recorders to report their coping strategies and urge levels before and after temptations to smoke. Multilevel linear regression models were used to compare the effects of individual strategy types with the average strategy.

MAIN OUTCOME MEASURES:

Lapses versus resisted temptations and changes in urge levels.

RESULTS:

Number of strategies significantly predicted resisting smoking and change in urge levels. Compared with the effect of the average strategy, movement/exercise was marginally worse at preventing lapses, and food/drink was marginally related to higher postcoping urge levels.

CONCLUSION:

Although using multiple coping strategies helps people resist the urge to smoke, no particular coping strategy works better than any other. Coping strategies prevent lapses by reducing high urge levels during temptations.

O'Connell, Kathleen A.; Schwartz, Joseph E.; Shiffman, Saul (2008):

Do resisted temptations during smoking cessation deplete or augment self-control resources?

In: *Psychol Addict Behav* 22 (4), S. 486–495. DOI: 10.1037/0893-164X.22.4.486.

Abstract:

A resource depletion model of self-control posits that for some period following performance of a task requiring self-control, self-control will be reduced and thus less available for use in a subsequent task. Using 2 substantial data sets collected in real time from individuals who were trying to quit smoking (1,660 and 9,516 temptation episodes collected from 61 and 248 individuals, respectively), we evaluated this model by testing the hypotheses that the number and length of resisted temptations and the intensity of the most recently reported urge during the prior 4 hr predict decreased self-control and increased likelihood of lapsing. Survival and multilevel regression modeling showed that contrary to the hypothesis, the number of recently resisted temptations predicted a lower risk of lapsing in both samples. Duration of resisted temptations had no significant effect in either sample. Intensity of most recently reported urge predicted lapsing in 1 data set but not in the other. Overall, there was little support for the resource depletion model. The protective effect of successfully resisting temptations was an unexpected but provocative finding.

Can actigraphy measure sleep fragmentation in children?

In: *Archives of disease in childhood* 95 (12), S. 1031–1033.

Abstract:

OBJECTIVE:

The gold standard assessment for sleep quality is polysomnography (PSG). However, actigraphy has gained popularity as an ambulatory monitor. We aimed to assess the value of actigraphy in measuring sleep fragmentation in children.

METHODS:

130 children aged 2-18 years referred for assessment for sleep disordered breathing (SDB) were recruited. The arousal index (AI) scored from PSG was compared to the actigraphic fragmentation index (FI) and number of wake bouts/h.

RESULTS:

The ability of actigraphic measures to correctly classify a child as having an AI>10 events/h rated as fair for the FI and poor for wake bouts/h (area under the receiver operator characteristic curve, 0.73 and 0.67, respectively).

CONCLUSION:

Actigraphy provides only a fair indication of the level of arousal from sleep in children. While the limitations of actigraphy prevent it from being a diagnostic tool for SDB, it still has a role in evaluating sleep/wake schedules in children.

Offer, Shira (2013):

Family time activities and adolescents' emotional well-being.

In: *J Marriage and Family* 75 (1), S. 26–41. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-01775-004%26site%3dehost-live;shira.offer@biu.ac.il.

Abstract:

The literature is divided on the issue of what matters for adolescents' well-being, with one approach focusing on quality and the other on routine family time. Using the experience sampling method, a unique form of time diary, and survey data drawn from the 500 Family Study (N = 237 adolescents with 8,122 observations), this study examined the association between family time and adolescents' emotional well-being as a function of the type of activities family members engaged in during their time together. Hierarchical linear model analyses revealed that eating meals together was beneficial to adolescents' emotional well-being, especially when fathers were present. Family leisure was also beneficial to teens' well-being. By contrast, productive family time (e.g., homework) was associated with lower emotional well-being, as was maintenance family time (e.g., household chores), but only when adolescents engaged in it with both parents. Offer, Shira (2014):

The costs of thinking about work and family: Mental labor, work–family spillover, and gender inequality among parents in dual-earner families.

In: *Sociological Forum* 29 (4), S. 916–936. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-52537-008%26site%3dehost-live.

Abstract:

One of the aspects unaccounted for in previous assessments of employed parents 'distribution of time is the mental dimension of tasks and demands. This aspect, referred to as mental labor, is conceptualized as the planning, organization, and management of everyday activities. Using the experience sampling method, a unique form of time diary, and survey data from the 500 Family Study (N = 402 mothers with 16,451 signals and 291 fathers with 11,322 signals), this study examined the prevalence, context, and emotional correlates of mental labor among parents in dual-earner families. Results show that fathers reported thinking more frequently about job-related matters than mothers but these concerns did not spill over into unpaid work. By contrast, mothers' job-related thoughts tended to spill over into unpaid work and free-time activities. When engaging in mental labor, mothers and fathers were equally likely to think about family matters, but these thoughts were only detrimental to emotional well-being in mothers. Among both mothers and fathers, paid work was relatively insulated from thoughts about family matters. Overall, findings highlight mothers' double burden and suggest that mental labor may contribute to mothers' emotional stress and gender inequality among dual-earner families. Offer, Shira (2014):

Time with children and employed parents' emotional well-being.

In: *Soc Sci Res* 47, S. 192–203. DOI: 10.1016/j.ssresearch.2014.05.003.

Abstract:

Using the experience sampling method and survey data from the 500 Family Study this study examined how parents feel when they spend time with their children and whether their emotional experiences differ by type of activity and the parent's gender. I found that mothers spent more time in childcare than fathers but this disparity was primarily due to mothers' more frequent engagement in activities that were not child-centered (i.e., non-focused and passive childcare). Multilevel models further showed that engagement in these activities was related to higher positive affect. Shared meals and leisure activities were particularly beneficial to parents' emotional well-being and the likelihood of engaging in them was not affected by parents' paid work hours. By contrast, routine childcare was associated with increased stress and lower engagement but only among mothers. Mothers were also less likely to provide childcare in conjunction with their spouse. These findings reveal the subtle dimensions of the unequal division of childcare by gender.

The misdiagnosis of hypertension: the role of patient anxiety.

In: *Archives of internal medicine* 168 (22), S. 2459–2465. DOI: 10.1001/archinte.168.22.2459.

Abstract:

BACKGROUND\r\nThe white coat effect (defined as the difference between blood pressure [BP] measurements taken at the physician's office and those taken outside the office) is an important determinant of misdiagnosis of hypertension, but little is known about the mechanisms underlying this phenomenon. We tested the hypothesis that the white coat effect may be a conditioned response as opposed to a manifestation of general anxiety.\r\nMETHODS\r\nA total of 238 patients in a hypertension clinic wore ambulatory blood pressure monitors on 3 separate days 1 month apart. At each clinic visit, BP readings were manually triggered in the waiting area and the examination room (in the presence and absence of the physician) and were compared with the mercury sphygmomanometer readings taken by the physician in the examination room. Patients completed trait and state anxiety measures before and after each BP assessment.\r\nRESULTS\r\nA total of 35% of the sample was normotensive, and 9%, 37%, and 19% had white coat, sustained, and masked hypertension, respectively. The diagnostic category was associated with the state anxiety measure ($F(3,237) = 6.4$, $P < .001$) but not with the trait anxiety measure. Patients with white coat hypertension had significantly higher state anxiety scores ($t = 2.67$, $P < .01$), with the greatest difference reported during the physician measurement. The same pattern was observed for BP changes, which generally paralleled the changes in state anxiety ($t = 4.86$, $P < .002$ for systolic BP; $t = 3.51$, $P < .002$ for diastolic BP).\r\nCONCLUSIONS\r\nThese findings support our hypothesis that the white coat effect is a conditioned response. The BP measurements taken by physicians appear to exacerbate the white coat effect more than other means. This problem could be addressed with uniform use of automated BP devices in office settings.

Ohira, Tetsuya; Tanigawa, Takeshi; Tabata, Minako; Imano, Hironori; Kitamura, Akihiko; Kiyama, Masahiko et al. (2009):

Effects of habitual alcohol intake on ambulatory blood pressure, heart rate, and its variability among Japanese men.

In: *Hypertension* 53 (1), S. 13–19. DOI: 10.1161/HYPERTENSIONAHA.108.114835.

Abstract:

We sought to examine effects of habitual alcohol intake on ambulatory blood pressure (BP), heart rate (HR), and HR variability among Japanese men. Subjects were 539 men aged 35 to 65 years from rural and urban communities. Ambulatory BP and HR were monitored with an automated, portable, noninvasive multibiomedical recorder. Power spectral analysis of the RR intervals on the ECG was performed every 5 minutes. Compared with nondrinkers, moderate drinkers (alcohol intake 23 to 45 g/d) and heavy drinkers (alcohol intake >or=46 g/d) showed higher age- and field-adjusted mean values of systolic and diastolic BPs during the morning and while awake, but there were no differences in BPs over 24-hour periods and while asleep among the alcohol intake categories. Alcohol intake was positively associated with mean values of sleep-morning differences and daytime variability in BPs, HRs while awake and asleep, and low frequency:high frequency ratio while asleep. The results were virtually unchanged after adjustment for body mass index, smoking, and diabetes mellitus. Compared with the nondrinkers, age- and field-adjusted odds ratios of the morning BP surge (excess elevation of BP in the morning: morning systolic BP minus sleep systolic BP >or=37 mm Hg) for light (alcohol intake 0 to 22 g/d), moderate, and heavy drinkers were 0.96 (95% CI: 0.34 to 2.78), 1.68 (95% CI: 0.64 to 4.38), and 2.73 (95% CI: 1.12 to 6.67), respectively. Habitual alcohol intake was associated with increased BP in the morning, HR while awake and asleep, and sympathetic activity while asleep, which may explain some of the mechanisms of the relationship between heavy alcohol intake and risk of cardiovascular diseases.

Ojiambo R; Cuthill R, Budd H.; Konstabel, K.; Casajús, J. A.; González-Agüero A; Anjila, E. et al. (2011):

Impact of methodological decisions on accelerometer outcome variables in young children.

In: *International Journal of Obesity* 35 (Suppl 1), S. S98-S103. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-18468-011&site=ehost-live;Yannis.Pitsiladis@glasgow.ac.uk.

Abstract:

BACKGROUND:

The impact of accelerometer-related methodological decisions relating to the assessment of physical activity and sedentary time has not been conclusively determined in young children.

OBJECTIVES:

To determine the effects of epoch and cutoff points on the assessment of physical activity and sedentary time and to determine the accelerometer wear time required to achieve reliable accelerometer data in children.

DESIGN:

Children were recruited from centres at Ghent, Glasgow, Gothenburg and Zaragoza.

METHODS:

Physical activity was assessed for 1 week in 86 children (41 girls, 45 boys; mean age 7±2 years) by uniaxial accelerometry. The epoch was set at 15 s and reintegrated to 30 and 60 s. Time spent sedentary and in moderate and vigorous physical activity (MVPA) was assessed using a range of cutoff points. Number of days required to achieve 80% reliability was predicted using the Spearman-Brown Prophecy formula.

RESULTS:

The Reilly cutoff points (<1100 counts per min (CPM)) indicated less sedentary time per day when comparing 15 vs 30 s and 15 vs 60 s epochs: 570±91 vs 579±93 min and 570±91 vs 579±94 min, respectively; P<0.05. Pate cutoff points (>420 counts per 15 s) reported more MVPA time per day compared with Sirard (890 counts per 15 s) and Puyau cutoff points (>3200 counts per min) using 15 s epoch: 78 (4-197) min (median (range) vs 18 (1-80) min and 24 (1-100) min, respectively; P<0.001. Compliance with guidelines of at least 60 min MVPA was 84, 78 and 73% for Pate cutoff points using 15, 30 and 60 s epochs, respectively, but 0% for Sirard and Puyau cutoff points across epochs. The number of days required to achieve 80% reliability for CPM, sedentary and MVPA time was 7.4-8.5 days.

CONCLUSION:

Choice of epoch and cutoff point significantly influenced the classification of sedentary and MVPA time and observed compliance to the MVPA guidelines.

Ojiambo, R.; Konstabel, K.; Veidebaum, T.; Reilly, J.; Verbestel, V.; Huybrechts, I. et al. (2012):

Validity of uni-axial versus tri-axial accelerometers in the assessment of free-living energy expenditure in young children: The IDEFICS Validation Study.

In: *J Appl.Physiol* (0161-7567 (Linking)). DOI: 10.1152/japplphysiol.01290.2011.

Abstract:

One of the aims of Identification and Prevention of Dietary- and Lifestyle-Induced Health Effects in Children and Infants (IDEFICS) validation study is to validate field measures of physical activity (PA) and Energy expenditure (EE) in young children. This study compared the validity of uni-axial accelerometry with heart-rate (HR) monitoring vs. tri-axial accelerometry against doubly labeled water (DLW) criterion method for assessment of free-living EE in young children. 49 European children (25 female, 24 male) aged 4-10 years (mean age 7 +/- 2 years) were assessed by uni-axial ActiTrainer with HR, uni-axial 3DNX and tri-axial 3DNX accelerometry. Total energy expenditure (TEE) was estimated using DLW over a 1 week period. The longitudinal axis of both devices and tri-axial 3DNX counts per minute (CPM) were significantly (P<0.05) associated with physical activity level (PAL) (r = 0.51 ActiTrainer, r = 0.49 uni-axial-3DNX and r = 0.42 tri-axial summation operator3DNX). 86% of the variance in TEE could be predicted by a model combining body mass (Partial r(2) = 71%; P<0.05), CPM-ActiTrainer (Partial r(2) = 11%; P<0.05) and difference between HR at moderate and sedentary activities (ModHR - SedHR; Partial r(2) = 4%; P<0.05) The standard error (S.E) of TEE estimate for ActiTrainer and 3DNX models ranged from 0.44-0.74 MJ/d or approximately 7-11% of the average TEE. The S.E of activity-induced energy expenditure (AEE) model estimates ranged from 0.38-0.57 MJ/d or 24-26% of the average AEE. It is concluded that the comparative validity of hip-mounted uni-axial and tri-axial accelerometers for assessing PA and EE is similar

Okifuji, Akiko; Bradshaw, David H.; Donaldson, Gary W.; Turk, Dennis C. (2011):

Sequential analyses of daily symptoms in women with fibromyalgia syndrome.

In: *J Pain* 12 (1), S. 84–93. DOI: 10.1016/j.jpain.2010.05.003.

Abstract:

UNLABELLED\r\nFibromyalgia syndrome (FMS) is a chronic musculoskeletal pain disorder characterized by generalized pain, chronic fatigue, sleep disturbance, and a range of other symptoms having no definitive pathology. Consequently, patient evaluations rely on self-report. Ecological Momentary Assessment (EMA) allows frequent real-time collection of self-report measures, removing recall bias and increasing external validity. We studied 81 females with FMS aged 18 to 42 years. Participants carried EMA devices (Palm Pilot M100) programmed to request ratings to 8 FMS symptoms/conditions 3 times daily for 30 days. Completeness of response rates varied across participants and over time. Controlling for immediately previous fatigue (ie, fatigue rating from the immediately preceding rating), unit increases in immediately previous pain and immediately previous emotional distress predicted 9 and 7% increases, respectively, in current fatigue. Controlling for immediately previous emotional distress, a unit increase in immediately previous pain predicted 7% increase in current emotional distress. Controlled for immediately previous pain, a unit increase in immediately previous fatigue predicted a 7% increase in current pain, enhanced by prior diurnal effects; immediately previous emotional distress was not significant. Collectively these results suggest an asymmetry in which emotional stress and pain may increase fatigue, fatigue but not emotional distress may increase pain, and pain but not fatigue may increase emotional distress. Despite small effects and person-to-person variability, these findings suggest that longitudinal data collection by EMA may reveal sequential or causal explanatory patterns with important clinical implications.\r\nPERSPECTIVE\r\nUnderstanding how multiple symptoms covary in FMS is essential for optimal treatment planning. Our results show small but significant temporal relations among pain, fatigue, and emotional distress. Our results also provide support for the use of EMA as a viable data collection method that allows longitudinal, real-time assessment of multiple FMS symptoms.

Olesen, Line Gronholt; Kristensen, Peter Lund; Ried-Larsen, Mathias; Grontved, Anders; Froberg, Karsten (2014):

Physical activity and motor skills in children attending 43 preschools: a cross-sectional study.

In: *BMC Pediatr* 14 (1), S. 229. DOI: 10.1186/1471-2431-14-229.

Abstract:

BACKGROUND: Little is known about health characteristics and the physical activity (PA) patterns in children attending preschools. The objective of this study was to describe the gender differences in relation to body mass index (BMI), motor skills (MS) and PA, including PA patterns by the day type and time of day. Additionally, the between-preschool variation in mean PA was estimated using the intraclass correlation. METHODS: We invited 627 children 5-6 years of age attending 43 randomly selected preschools in Odense, Denmark. Aiming and catching MS was assessed using subtests of the Movement Assessment Battery for Children (Second Edition) and motor coordination MS was assessed by the Kiphard-Schilling body coordination test, Korperkoordination Test fur Kinder. PA was measured using accelerometry. The PA patterns were analysed using mixed models. RESULTS: No gender differences in the BMI or norm-referenced MS risk classification, or the average weekly PA level or patterns of PA were observed. However, boys performed better in the aiming and catching score ($p < 0.01$) and in the motor coordination score ($p < 0.05$) on average. Girls performed better in the balance subtest ($p < 0.001$). Relative to the norm-referenced classification of MS, the Danish sample distribution was significantly well for aiming and catching but poorer for the motor coordination test.The total sample and the least active children were most active on weekdays, during preschool time and in the late afternoon at the weekend. However, a relatively larger decrease in PA from preschool to weekday leisure time was observed in children in the lowest PA quartile compared to children in the highest PA quartile. Finally, the preschool accounted for 19% of the total variance in PA, with significant gender differences. CONCLUSIONS: Results of this study could provide a valuable reference material for studies monitoring future trends in obesity, MS and PA behaviour in Denmark and other countries.Knowledge about sources of variation in PA among preschool children is scarce and our findings need to be replicated in future studies. A potentially important finding is the large between-preschool variation in PA, indicating that especially girls are very susceptible to the environment offered for PA during preschool attendance.

Olino, T. M.; McMakin, D. L.; Morgan, J. K.; Silk, J. S.; Birmaher, B.; Axelson, D. A. et al. (2013):

Reduced reward anticipation in youth at high-risk for unipolar depression: A preliminary study.

In: *Dev.Cogn Neurosci.* (1878-9293 (Linking)). DOI: 10.1016/j.dcn.2013.11.005.

Abstract:

Offspring of depressed parents are at risk for depression and recent evidence suggests that reduced positive affect (PA) may be a marker of risk. We investigated whether self-reports of PA and fMRI-measured striatal response to reward, a neural correlate of PA, are reduced in adolescent youth at high familial risk for depression (HR) relative to youth at low familial risk for depression (LR). Functional magnetic resonance imaging assessments were conducted with 14 HR and 12 LR youth. All youth completed an ecological momentary assessment protocol to measure PA in natural settings and a self-report measure of depression symptomatology. Analyses found that HR youth demonstrated lower striatal response than LR youth during both reward anticipation and outcome. However, after controlling for youth self-reports of depression, HR youth demonstrated lower striatal response than LR youth only during reward anticipation. No significant differences were found between HR and LR youth on subjective ratings of PA or depressive symptoms. Results are consistent with previous findings that reduced reward response is a marker of risk for depression, particularly during reward anticipation, even in the absence of (or accounting for) disrupted subjective mood. Further examinations of prospective associations between reward response and depression onset are needed

Oliver, Melody; Schluter, Philip J.; Schofield, Grant M.; Paterson, Janis (2011):

Factors related to accelerometer-derived physical activity in Pacific children aged 6 years.

In: *Asia-Pacific Journal of Public Health* 23 (1), S. 44–56.

Abstract:

The objective of this study was to investigate potential factors related to Pacific children's moderate-to-vigorous physical activity (MVPA). A total of 393 Pacific children aged 6 years and their mothers were invited to participate. Participants wore accelerometers over 8 days; height, weight, and waist circumference were measured, and mothers reported on individual, social, and perceived environmental factors. Generalized estimation equation models were used to identify associates of children's daily MVPA. In all, 135 children and 91 mothers were included in analyses. Children spent 24% of time in MVPA; 99% of days had ≥60 minutes of MVPA. Higher maternal MVPA, male sex, longer sunlight hours, and rain-free days were associated with children's MVPA. Approaches for improving activity in Pacific children may be most efficacious if strategies for inclement weather and the encouragement of activity in mothers and, in particular, their daughters are included. Also, 60 minutes of daily MVPA may be insufficient to protect Pacific children from increased body size.

Oliver, Melody; Schofield, Grant M.; Badland, Hannah M.; Shepherd, Janine (2010):

Utility of accelerometer thresholds for classifying sitting in office workers.

In: *Prev Med* 51 (5), S. 357–360.

Abstract:

OBJECTIVE:

To investigate the utility of a variety of Actical accelerometer count thresholds for determining sitting time in a sample of office workers.

METHODS:

Data were collected from 21 participants in Auckland, New Zealand, between December 2009 and January 2010. Participants wore a hip-mounted Actical accelerometer and thigh-mounted activPAL inclinometer (criterion) for a 48-h period. Raw inclinometer and accelerometer data for each 15s epoch of wear time were matched by date and time. Candidate accelerometer count thresholds for sitting classification were compared with the criterion measure using receiver operating characteristic analyses. Agreement in sitting time classification was determined using Bland-Altman methodology.

RESULTS:

Significant differences in area under the curve (AUC) values by threshold criteria were found ($p<0.001$). A threshold of 0 counts provided the highest combined sensitivity and specificity (AUC 0.759, 95%CI 0.756, 0.761). The 95% limits of agreement for time spent sitting were wide, at 328min (range -30.8, 297.5).

CONCLUSION:

A threshold of 0 counts/15s epoch with Actical accelerometers is likely to yield the most accurate quantification of sitting in office-based workers, however the wide limits of agreement found indicate limited utility of this threshold to accurately distinguish sitting time in office-based workers.

Olsen, Lene Kjaer; Kamper, Anne-Lise; Svendsen, Jesper Hastrup; Bang, Lia Evi; Frimodt-Moller, Marie; Kelbaek, Henning et al. (2014):

High incidence of secondary hypertension in patients referred for renal denervation - the Copenhagen experience.

In: *Blood Press. DOI:* 10.3109/08037051.2013.867655.

Abstract:

Percutaneous renal denervation is a new treatment option for patients with resistant hypertension and little is known about the eligibility of patients referred. 100 consecutive patients were referred for renal denervation from March 2011 through September 2012. Clinical data were prospectively extracted from letters and documents from referring clinics and from our physical examination. Of the 100 patients included, 68 were men and the mean age was 60 (+/- 12) years. Office blood pressure was 176 (+/- 28)/99 (+/- 19) mmHg and 24-h ambulatory blood pressure 156 (+/- 20)/88 (+/- 13) mmHg. The mean number of antihypertensive agents was 4.0 (+/- 1.6). Nearly four-fifths (82%) of the patients were categorized as having resistant hypertension based on the criteria stated by The American Heart Association's stated criteria. Nine patients declined interest in renal denervation before completing the clinical workup program. Thus, 91 patients were screened, and of those 51 were found to be candidates for renal denervation. Forty patients were not candidates, of which secondary hypertension was the most common cause (n = 10). Only 51% of patients referred for renal denervation were eligible for treatment. The prevalence of secondary hypertension was 10% of the referred population. Secondary hypertension should therefore be considered in the evaluation of candidates for renal denervation.

O'Malley, Grace; Clarke, Mike; Burls, Amanda; Murphy, Sinead; Murphy, Nuala; Perry, Ivan J. (2014):

A smartphone intervention for adolescent obesity: study protocol for a randomised controlled non-inferiority trial.

In: *Trials* 15, S. 43. DOI: 10.1186/1745-6215-15-43.

Abstract:

BACKGROUND: There are few evidence-based mobile health solutions for treating adolescent obesity. The primary aim of this parallel non-inferiority trial is to assess the effectiveness of an experimental smartphone application in reducing obesity at 12 months, compared to the Temple Street W82GO Healthy Lifestyles intervention. METHODS/DESIGN: The primary outcome measure is change in body mass index standardised deviation score at 12 months. The secondary aim is to compare the effect of treatment on secondary outcomes, including waist circumference, insulin sensitivity, quality of life, physical activity and psychosocial health. Adolescents with a body mass index at or above the 98th percentile (12 to 17 years) will be recruited from the Obesity clinic at Temple Street Children's University Hospital in Dublin, Ireland. W82GO is a family-based lifestyle change intervention delivered in two phases over 12 months. In the current study, participants will be randomised for phase two of treatment to either usual care or care delivered via smartphone application. One hundred and thirty-four participants will be randomised between the two study arms. An intention-to-treat analysis will be used to compare treatment differences between the groups at 12 months. DISCUSSION: The results of this study will be disseminated via open access publication and will provide important information for clinicians, patients and policy makers regarding the use of mobile health interventions in the management of adolescent obesity. TRIAL REGISTRATION: Clinicaltrials.gov NCT01804855.

The experience of music in congenital amusia.

In: *Music Perception* 30 (1), S. 1–18. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-24024-001%26site%3dehost-live;d.omigie@gold.ac.uk.

Abstract:

Individuals with congenital amusia have difficulty recognizing and discriminating melodies. While much research has focused on the perceptual deficits of congenital amusics, the extent to which these deficits have an impact on the ability to engage with and appreciate music remains unexplored. The current study used experience sampling methodology to identify distinct patterns of music-related behavior in individuals with amusia and matched controls. Cluster analysis was used to group individuals according to the similarity of their behavior, regardless of their status as amusic or control. This yielded a two-cluster solution: one cluster comprising 59% of the amusic sample and 6% of controls and the other comprising 41% of the amusic sample and 94% of controls. Comparisons of the two clusters in terms of specific aspects of music listening behavior revealed differences in levels of music engagement and appreciation. Further comparisons provided support for the existence of amusic subgroups

showing distinct attitudes toward music. The findings are discussed in relation to social, contextual, and demographic factors. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Lifestyle monitoring with the use of an earphone-type thermometer, an ambulatory blood pressure monitoring and a new wristwatch-type pulsimeter with accelerometer.

In: *Clin Exp Hypertens* 36 (2), S. 97–102. DOI: 10.3109/10641963.2014.892120.

Abstract:

Abstract We investigated the relationship among 24-h blood pressure (BP), pulse rate (PR) and core temperature by using an ambulatory BP monitoring, a new wristwatch-type pulsimeter with accelerometer (WPA) and an ear thermometer simultaneously. Our results suggest that the ear temperature which reflects the core body temperature was lowest at base PR during sleep and 75% of normotensives and 54% of subjects without hypertensive medication had a significant correlation between BP and PR. Diabetic subjects showed a significantly higher PR during sleep than non-diabetic subjects. Three types of equipments, especially a new WPA, are expected to be useful for daily lifestyle monitoring to evaluate risk of complications of hypertension and diabetes.

Momentary assessment research in psychosis.

In: *Psychological Assessment* 21 (4), S. 498–505. DOI: 10.1037/a0017077.

Abstract:

There is an expanding interest to study psychosis in the realm of daily life. The study of the person in the context of daily life may provide a powerful addition to more conventional and cross-sectional research strategies in the study of psychosis. This article first discusses the nature of experience sampling research in psychosis and demonstrates the feasibility and validity of studies using the experience sampling method (ESM) in this patient group. Second, the article presents a review of all ESM research in psychosis with a special focus on (a) the phenomenology, (b) the etiology, and (c) psychological models of psychosis. Variability over time and the dynamic interplay with the environment were found to be essential features of the positive symptoms of psychosis, whereas behavioral patterns as well as self-reported affect in daily life reality might be essential when studying negative symptomatology. ESM contributes to a better understanding of the interplay between psychotic experiences and environmental features, such as stress or cannabis exposure. Finally, the study of symptomatic variability may fuel new research into psychological models and treatment of psychosis and the study of the person-environment interplay may foster new Gene x Environment interaction studies.

Oorschot, M.; Lataster, T.; Thewissen, V.; Lardinois, M.; van Os, J.; Delespaul, P. A. E. G.; Myin-Germeys, I. (2012):

Symptomatic remission in psychosis and real-life functioning.

In: *The British Journal of Psychiatry* 201 (3), S. 215–220. DOI: 10.1037/t16410-000;

Abstract:

Background: In 2005 Andreasen proposed criteria for remission in schizophrenia. It is unclear whether these criteria reflect symptom reduction and improved social functioning in daily life. Aims: To investigate whether criteria for symptomatic remission reflect symptom reduction and improved functioning in real life, comparing patients meeting remission criteria, patients not meeting these criteria and healthy controls. Method: The Experience Sampling Method (ESM), a structured diary technique, was used to explore real-life symptoms and functioning in 177 patients with (remitted and non-remitted) schizophrenia spectrum disorders and 148 controls. Results: Of 177 patients, 70 met criteria for symptomatic remission. These patients reported significantly fewer positive and negative symptoms and better mood states compared with patients not in remission. Furthermore, patients in remission spent more time in goal-directed activities and had less preference for being alone when they were with others. However, the patient groups did not differ on time spent in social company and doing nothing, and both the remission and non-remission groups had lower scores on functional outcome measures compared with the control group. Conclusions: The study provides an ecological validation for the symptomatic remission criteria, showing that patients who met the criteria reported fewer positive symptoms, better mood states and partial recovery of reward experience compared with those not in remission. However, remission status was not related to functional recovery, suggesting that the current focus on

symptomatic remission may reflect an overly restricted goal. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

The linear mixed model and the hierarchical Ornstein–Uhlenbeck model: Some equivalences and differences.

In: *British Journal of Mathematical and Statistical Psychology* 64 (1), S. 134–160.

Abstract:

We focus on comparing different modelling approaches for intensive longitudinal designs. Two methods are scrutinized, namely the widely used linear mixed model (LMM) and the relatively unexplored Ornstein-Uhlenbeck (OU) process based state-space model. On the one hand, we show that given certain conditions they result in equivalent outcomes. On the other hand, we consider it important to emphasize that their perspectives are different and that one framework might better address certain types of research questions than the other. We show that, compared to a LMM, an OU process based approach can cope with modelling inter-individual differences in aspects that are more substantively interesting. However, the estimation of the LMM is faster and the model is more straightforward to implement. The models are illustrated through an experience sampling study.

Adolescent Report of Lifestyle Counseling.

In: *Child Obes. DOI:* 10.1089/chi.2013.0131.

Abstract:

Abstract Background: Physician counseling on lifestyle factors has been recommended as one way to help combat the obesity epidemic in the United States. The aim of this study was to examine the frequency of lifestyle counseling among healthy weight, overweight, and obese adolescents and determine the contributions of adolescent weight and physical activity. Methods: Self-reported surveys on dietary and physical activity counseling, along with measured height, weight, and physical activity data by accelerometry were collected on 76 adolescents ages 11-14 years. General linear models tested for associations of reported lifestyle counseling by weight category, adjusting for physical activity, age, gender, race/ethnicity, and parent education. Results: Half (47%) of the subjects were overweight or obese. Frequency of lifestyle counseling varied by weight category, with obese adolescents reporting greater amounts of lifestyle counseling across all topics than their peers. Obese adolescents received more dietary (beta=0.88; standard error [SE]=0.25; p=0.001) and physical activity (beta=0.80; SE=0.28; p=0.006) counseling than healthy weight youth, as well as being told to increase their physical activity more often (beta=0.96; SE=0.29; p=0.001). There were no differences in lifestyle counseling between overweight and healthy weight subjects. Adolescents with greater daily moderate-to-vigorous physical activity reported less physical activity counseling (beta=-0.02; SE=0.008; p=0.05). Conclusions: Despite universal recommendations to counsel adolescents on lifestyle, only obese adolescents consistently report receiving such counseling. Given known difficulties in reversing obesity after onset, efforts should ensure that all adolescents receive lifestyle counseling.

Pickles and ice cream! Food cravings in pregnancy: hypotheses, preliminary evidence, and directions for future research.

In: *Front Psychol* 5, S. 1076. DOI: 10.3389/fpsyg.2014.01076.

Abstract:

Women in the United States experience an increase in food cravings at two specific times during their life, (1) perimenstrually and (2) prenatally. The prevalence of excess gestational weight gain (GWG) is a growing concern due to its association with adverse health outcomes in both mothers and children. To the extent that prenatal food cravings may be a determinant of energy intake in pregnancy, a better understanding of craving etiology could be crucial in addressing the issue of excessive GWG. This paper reviews the available literature to corroborate and/or dispute some of the most commonly accepted hypotheses regarding the causes of food cravings during pregnancy, including a role of (1) hormonal changes, (2) nutritional deficits, (3) pharmacologically active ingredients in the desired foods, and (4) cultural and psychosocial factors. An existing model of perimenstrual chocolate craving etiology serves to structure the discussion of these hypotheses. The main hypotheses

discussed receive little support, with the notable exception of a postulated role of cultural and psychosocial factors. The presence of cravings during pregnancy is a common phenomenon across different cultures, but the types of foods desired and the adverse impact of cravings on health may be culture-specific. Various psychosocial factors appear to correlate with excess GWG, including the presence of restrained eating. Findings strongly suggest that more research be conducted in this area. We propose that future investigations fall into one of the four following categories: (1) validation of food craving and eating-related measures specifically in pregnant populations, (2) use of ecological momentary assessment to obtain real time data on cravings during pregnancy, (3) implementation of longitudinal studies to address causality between eating disorder symptoms, food cravings, and GWG, and (4) development of interventions to ensure proper prenatal nutrition and prevent excess GWG.

Combined influence of epoch length, cut-point and bout duration on accelerometry-derived physical activity.

In: *Int J Behav Nutr Phys Act* 11 (1), S. 34. DOI: 10.1186/1479-5868-11-34.

Abstract:

BACKGROUND: It is difficult to compare accelerometer-derived estimates of moderate-to-vigorous physical activity (MVPA) between studies due to differences in data processing procedures. We aimed to evaluate the effects of accelerometer processing options on total and bout-accumulated time spent in MVPA in adults. METHODS: 267 participants from the ProActive Trial provided 1236 days of valid physical activity (PA) data, collected using a 5-s epoch with ActiGraph GT1M accelerometers. We integrated data over 5-s to 60-s epoch lengths (EL) and applied two-level mixed effects regression models to MVPA time, defined using 1500 to 2500 counts/minute (cpm) cut-points (CP) and bout durations (BD) from 1 to 15 min. RESULTS: Total MVPA time was lower on longer EL and higher CP (47 vs 26 min/day and 26 vs 5 min/day on 1500 vs 2500 cpm on 5-s and 60-s epoch, respectively); this could be approximated as MVPA = exp[2.197 + 0.279*log(CP) + 6.120*log(EL) - 0.869*log(CP)*log(EL)] with an 800 min/day wear-time. In contrast, EL was positively associated with time spent in bout-accumulated MVPA; the approximating equation being MVPA = exp[54.679 - 6.268*log(CP) + 6.387*log(EL) - 10.000*log(BD) - 0.162*log(EL)*log(BD) - 0.626*log(CP)*log(EL) + 1.033*log(CP)*log(BD)]. BD and CP were inversely associated with MVPA, with higher values attenuating the influence of EL. CONCLUSIONS: EL, CP and BD interact to influence estimates of accelerometer-determined MVPA. In general, higher CP and longer BD result in lower MVPA but the direction of association for EL depends on BD. Reporting scaling coefficients for these key parameters across their frequently used ranges would facilitate comparisons of population-level accelerometry estimates of MVPA.

Failure to validate the Health Survey for England physical activity module in a cardiac population.

In: *Health Policy* 84 (2), S. 262–268.

Abstract:

OBJECTIVES:

The Health Survey for England physical activity module interview, although not validated, is used as a performance indicator to see if people are achieving current physical activity targets and is the primary source of information for physical activity related policy making. The aim of this study was to assess the validity of the Health Survey for England physical activity module as a measure of physical activity in older adults with coronary heart disease.

METHODS:

Seventy-two older adults who had experienced a cardiac event completed the Health Survey for England physical activity interview and wore an accelerometer for seven consecutive days. Physical activity classification levels were derived from accelerometry and from the Health Survey for England physical activity interview, together with the number of episodes in which participants were moderately active for 30 min or more.

RESULTS:

The Health Survey for England physical activity interview exhibited high sensitivity (1.0) and specificity (0.76) for people engaged in high levels of physical activity, moderate sensitivity (0.40) and specificity (0.56) for people engaged in medium levels of physical activity and low sensitivity (0.35) and high specificity (0.92) for people engaged in low levels of physical activity. Compared with the accelerometer, the survey misclassified 63% of participants.

CONCLUSIONS:

The Health Survey for England physical activity interview misclassified true activity levels in older adults with heart disease by overestimating actual activity in the less active participants. Similar biases on self-report physical activity measures have been demonstrated in the general population, suggesting that the Health Survey for England physical activity module interview may be providing inaccurate information on national activity levels.

Ortega, Francisco B.; Ruiz, Jonatan R.; Sjöström, Michael (2007):

Physical activity, overweight and central adiposity in Swedish children and adolescents: the European Youth Heart Study.

In: *Int J Behav Nutr Phys Act* 4 (1), S. 61.

Abstract:

Background

The aim of this work was to study the associations of physical activity (PA) and other factors predisposing to overweight, with overweight and central adiposity in children and adolescents.

Methods

A total of 557 Swedish children (9.5 ± 0.3 y) and 517 adolescents (15.6 ± 0.4 y) from the European Youth Heart Study participated in this study. Logistic regression analyses were used to examine the associations of PA, as measured by accelerometry, and other determinants (i.e. television viewing, birth weight, maternal educational level and parental overweight) with total and central adiposity. Body mass index and waist circumference cut-off values proposed by the IOTF and the Bogalusa Heart Study (i.e. waist measures for predicting risk factors clustering, hereinafter called high-risk waist circumference), respectively, were used. Fatness was estimated from skinfold thicknesses and dichotomized using the 85th sex- and age-specific percentile (high/low).

Results

Children and adolescents who had a low level (first tertile) of vigorous PA, were more likely to be overweight (including obesity) and to have a high-risk waist circumference, than those with a high level (third tertile) of vigorous PA. Similarly, those subjects who had a low or middle level (second tertile) of total PA were more likely to be overweight than those who had a high level of total PA. Among the PA variables, only vigorous PA was associated with high total fatness. Birth weight and television viewing, were also associated with higher odds of having a high-risk waist circumference, but these associations were attenuated once either total or vigorous PA variable was included in the model. Those subjects who had two overweight parents were more likely to be overweight and to have a high-risk waist circumference independently of PA variables, compared to those whose parents were not overweight.

Conclusion

Low levels of total PA and especially vigorous PA may play an important role in the development of overweight and excess of central adiposity in children and adolescents, independently of a number of factors such as television viewing and birth weight. In addition, the data suggest that the association between television viewing and central fat deposition could be attenuated if enough vigorous PA is accumulated. Longitudinal and intervention studies are needed to confirm these findings.

Ortega, Francisco B.; Ruiz, Jonatan R.; Hurtig-Wennlöf, Anita; Vicente-Rodriguez, Germán; Rizzo, Nico S.; Castillo, Manuel J.; Sjöström, Michael (2010):

Cardiovascular fitness modifies the associations between physical activity and abdominal adiposity in children and adolescents: the European Youth Heart Study.

In: *British Journal of Sports Medicine* 44 (4), S. 256–262.

Abstract:

OBJECTIVE:

To examine the associations between physical activity (PA) and abdominal adiposity, as measured by waist circumference, in children and adolescents, and to test whether cardiovascular fitness (CVF) modifies these associations.

METHODS:

PA components were measured by accelerometry in 1075 individuals aged 9 or 15 years old. CVF was measured by a maximal cycling test. Self-reported maternal educational level, body mass index, children's birth weight and television viewing were used as confounders.

RESULTS:

Linear regression did not show any association between the PA variables and waist circumference, after controlling for sex, age and height. When stratifying by CVF level (low/high), time spent at vigorous PA was inversely associated with waist circumference (p < or = 0.05) in the low CVF group. Unexpectedly, in the high CVF group, the PA variables were positively associated with waist circumference (p < or = 0.05). In both groups, the results were unchanged after controlling for the confounders. CVF was inversely associated with waist circumference, after controlling for all PA variables (p < or = 0.01) and confounders (p < or = 0.01).

CONCLUSION:

CVF is inversely associated with abdominal adiposity and seems to modify the associations between PA and abdominal adiposity. In low-fit children and adolescents, time spent in vigorous PA seems to be the key component linked to abdominal adiposity. This finding should be considered in further development of lifestyle intervention strategies. The results found in the high-fit group need to be confirmed.

Ortega, Francisco B.; Ruiz, Jonatan R.; Labayen, Idoia; Martinez-Gomez, David; Vicente-Rodriguez, German; Cuenca-Garcia, Magdalena et al. (2014):

Health inequalities in urban adolescents: role of physical activity, diet, and genetics.

In: *Pediatrics* 133 (4), S. e884-95. DOI: 10.1542/peds.2013-1665.

Abstract:

OBJECTIVE: Coordinated European projects relying on standardized methods are needed to identify health inequalities across Europe. This study aimed to compare fitness, fatness, and cardiometabolic risk between urban adolescents from the south and center-north of Europe and to explore whether physical activity (PA) and other factors might explain these differences. METHODS: The Healthy Lifestyle in Europe by Nutrition in Adolescence cross-sectional project comprised 3528 adolescents from the south (4 cities) and central-north (6 cities) of Europe, 1089 of whom provided blood samples for analysis. Fitness (strength, speed-agility, and cardiorespiratory fitness), total and abdominal fatness (anthropometry and bioelectrical impedance), and cardiometabolic risk (z scores including fitness, fatness, blood lipids, insulin resistance, and blood pressure) were assessed. The analyses were adjusted for socioeconomic factors, objectively measured PA (accelerometry), total energy intake and diet quality, and genetic variants of the FTO rs9939609 polymorphism. RESULTS: Adolescents from southern Europe were less fit and fatter according to all markers (P < .001). Differences in cardiometabolic risk scores were not consistent. Adolescents from the south were less active and this would largely explain the differences observed in speed-agility and cardiorespiratory fitness. Differences in total and abdominal fatness could not be explained by PA, energy intake, diet quality, or FTO rs9939609 polymorphism. CONCLUSIONS: Fitness and fatness levels indicate that urban adolescents from the south are less healthy than those from central-northern Europe. Our data suggest that differences in PA might explain differences in important health-related fitness components, yet factors explaining the differences in fatness encountered remain unknown.

Ortiz-Tudela, Elisabet; Iurisci, Ida; Beau, Jacques; Karaboue, Abdoulaye; Moreau, Thierry; Rol, Maria Angeles et al. (2014):

The circadian rest-activity rhythm, a potential safety pharmacology endpoint of cancer chemotherapy.

In: *Int J Cancer* 134 (11), S. 2717–2725. DOI: 10.1002/ijc.28587.

Abstract:

The robustness of the circadian timing system (CTS) was correlated to quality of life and predicted for improved survival in cancer patients. However, chemotherapy disrupted the CTS according to dose and circadian timing in mice. A continuous and repeated measures longitudinal design was implemented here to characterize CTS dynamics in patients receiving a fixed circadian-based chemotherapy protocol. The rest-activity rhythm of 49 patients with advanced cancer was monitored using a wrist actigraph for 13 days split into four consecutive spans of 3-4 days each, i.e., before, during, right after and late after a fixed chronotherapy course. The relative amount of activity in bed vs. out of bed (I<O, main endpoint), the autocorrelation coefficient r24, the relative 24-hr amplitude (Amp), interdaily stability (IS) and intradaily variability (IV) were compared according to study span. Circadian disruption (I<O </= 97.5%) resulted from the administration of the fixed chronotherapy protocols, with all five rest-activity rhythm parameters being worsened in the whole group of patients (p < 0.05). Mean parameter values subsequently recovered to near baseline values. The occurrence of circadian disruption on chemotherapy was associated with a higher risk of clinically relevant fatigue (p = 0.028) or body weight loss (p = 0.05). Four CTS dynamic patterns characterized treatment response including no change (9.5% of the patients); improvement (14.3%); alteration and complete recovery (31%) or sustained deterioration (45%), possibly due to inadequate chronotherapy dosing and/or timing. Improved clinical tolerability could result from the minimization of circadian disruption through the personalization of chronotherapy delivery.

Ortiz-Tudela, Elisabet; Martinez-Nicolas, Antonio; Diaz-Mardomingo, Carmen; Garcia-Herranz, Sara; Pereda-Perez, Inmaculada; Valencia, Azucena et al. (2014):

The characterization of biological rhythms in mild cognitive impairment.

In: *Biomed Res Int* 2014, S. 524971. DOI: 10.1155/2014/524971.

Abstract:

INTRODUCTION: Patients with dementia, especially Alzheimer's disease, present several circadian impairments related to an accelerated perturbation of their biological clock that is caused by the illness itself and not merely age-related. Thus, the objective of this work was to elucidate whether these circadian system alterations were already present in patients with mild cognitive impairment (MCI), as compared to healthy age-matched subjects. METHODS: 40 subjects (21 patients diagnosed with MCI, 74.1 +/- 1.5 y.o., and 19 healthy subjects, 71.7 +/- 1.4 y.o.) were subjected to ambulatory monitoring, recording wrist skin temperature, motor activity, body position, and the integrated variable TAP (including temperature, activity, and position) for one week. Nonparametrical analyses were then applied. RESULTS: MCI patients exhibited a significant phase advance with respect to the healthy group for the following phase markers: temperature M5 (mean +/- SEM: 04:20 +/- 00:21 versus 02:52 +/- 00:21) and L10 (14:35 +/- 00:27 versus 13:24 +/- 00:16) and TAP L5 (04:18 +/- 00:14 versus 02:55 +/- 00:30) and M10 (14:30 +/- 00:18 versus 13:28 +/- 00:23). CONCLUSIONS: These results suggest that significant advances in the biological clock begin to occur in MCI patients, evidenced by an accelerated aging of the circadian clock, as compared to a healthy population of the same age.

Ortlieb, Sandra; Dias, Andre; Gorzelniak, Lukas; Nowak, Dennis; Karrasch, Stefan; Peters, Annette et al. (2014):

Exploring patterns of accelerometry-assessed physical activity in elderly people.

In: *Int J Behav Nutr Phys Act* 11 (1), S. 28. DOI: 10.1186/1479-5868-11-28.

Abstract:

BACKGROUND: Elderly people obtain significant health benefits from physical activity (PA), but the role of activity patterns has scarcely been researched. The present study aims to describe the patterns of PA among different intensities of activity in elderly people. We assess how patterns differ between more and less active groups ('rare', 'average', and 'frequent'), and explore whether and how various PA parameters are associated with functional exercise capacity (FEC). METHODS: PA was measured in 168 subjects (78 males; 65-89 years of age), using a triaxial GT3X accelerometer for ten consecutive days. Subjects were divided into three groups by activity and the groups were compared. A multiple linear regression model was used to predict FEC. RESULTS: Participants greater than or equal to 80 years are most prone to being sedentary for long periods, while women and the obese are the groups most likely to spend insufficient time in moderate to vigorous PA (MVPA). Rarely active elderly people had a decreased proportion of long bouts of MVPA and light PA and of short bouts in sedentary behavior than frequently active subjects did ($p < 0.001$). As predictors of FEC, younger age, lower BMI, male sex, better lung function, absence of multimorbidity, longer times and longer bouts of MVPA emerged as significant parameters ($r2 = 0.54$). Patterns of MVPA explained most of the variance. CONCLUSIONS: PA patterns provide information beyond reports of activity alone. MVPA in elderly people may be increased by increasing the proportion of long bouts, in order to increase FEC as well as average PA. However, health conditions may limit PA. In rarely active people (often with reduced FEC, worse lung function, and diagnosis of multimorbidity or disability), longer periods of time in light PA may be sufficient to increase the overall level of activity.

Ortlieb, S.; Gorzelniak, L.; Dias, A.; Schulz, H.; Horsch, A. (2013):

Recommendations for collecting and processing accelerometry data in elderly people.

In: *Stud.Health Technol.Inform.* 192 (0926-9630 (Linking)), S. 1175. Online verfügbar unter PM:23920949.

Abstract:

Due to the large variety of methods for collecting and analyzing accelerometer data to assess physical activity, it is difficult to compare results from different studies. Therefore, this work aims to provide recommendations for the collection and processing of such data in older people, focusing on the assessment of wearing time and intensity levels

Osse, Robert Jan; Tulen, Joke H. M.; Hengeveld, Michiel W.; Bogers, Ad J J C (2009):

Screening methods for delirium: early diagnosis by means of objective quantification of motor activity patterns using wrist-actigraphy.

In: *Interactive cardiovascular and thoracic surgery* 8 (3), S. 344-8; discussion 348. DOI: 10.1510/icvts.2008.192278.

Abstract:

Delirium after cardiac surgery is a risk factor for adverse outcome and even death. Disturbance of motor activity is a core feature of delirium, but hypoactive delirium often remains unrecognized. We explored wrist-actigraphy as a tool to objectively quantify postoperative recovery of 24-h rest-activity patterns to improve the early recognition of delirium after surgery. Motor activity was recorded by wrist-actigraphy after cardiac surgery in 88 patients over 65 years of age. Patients were assessed daily by using the CAM-ICU. Our final analyses were based on 32 non-delirious patients and 38 patients who were delirious on the first day after surgery. The delirious patients showed lower mean activity levels during the first postoperative night ($P<0.05$), reduced restlessness during the first day ($P<0.05$), and a lower mean activity of the 5 h with lowest activity within the first 24 h ($P=0.01$), as compared to the non-delirious patients. Already at a very early stage after cardiac surgery, a difference in motor activity was observed between patients with and without a delirium. As an unobtrusive method, actigraphy has the potential to be a screening method that may lead to early diagnosis and treatment of delirium.

O'Toole, Joanne E.; Sinclair, Martha I.; Leder, Karin (2009):

Collecting household water usage data: telephone questionnaire or diary?

In: *BMC medical research methodology* 9 (1), S. 72.

Abstract:

Background

Quantitative Microbial Risk Assessment (QMRA), a modelling approach, is used to assess health risks. Inputs into the QMRA process include data that characterise the intensity, frequency and duration of exposure to risk(s). Data gaps for water exposure assessment include the duration and frequency of urban non-potable (non-drinking) water use. The primary objective of this study was to compare household water usage results obtained using two data collection tools, a computer assisted telephone interview (CATI) and a 7-day water activity diary, in order to assess the effect of different methodological survey approaches on derived exposure estimates. Costs and logistical aspects of each data collection tool were also examined.

Methods

A total of 232 households in an Australian dual reticulation scheme (where households are supplied with two grades of water through separate pipe networks) were surveyed about their water usage using both a CATI and a 7-day diary. Householders were questioned about their use of recycled water for toilet flushing, garden watering and other outdoor activities. Householders were also questioned about their water use in the laundry. Agreement between reported CATI and diary water usage responses was assessed.

Results

Results of this study showed that the level of agreement between CATI and diary responses was greater for more frequent water-related activities except toilet flushing and for those activities where standard durations or settings were employed. In addition, this study showed that the unit cost of diary administration was greater than for the CATI, excluding consideration of the initial selection and recruitment steps.

Conclusion

This study showed that it is possible to successfully 'remotely' coordinate diary completion providing that adequate instructions are given and that diary recording forms are well designed. In addition, good diary return rates can be achieved using a monetary incentive and the diary format allows for collective recording, rather than an individual's estimation, of household water usage. Accordingly, there is merit in further exploring the use of diaries for collection of water usage information either in combination with a mail out for recruitment, or potentially in the future with Internet-based recruitment (as household Internet uptake increases).

An ecological perspective on smoking among Asian American college students: the roles of social smoking and smoking motives.

In: *Psychol Addict Behav* 22 (4), S. 514–523. DOI: 10.1037/a0012964.

Abstract:

Using electronic diaries, the present study examined the roles of social smoking and smoking motives in relation to cigarette use patterns among Asian American college smokers. Multilevel modeling results showed that participants smoked more cigarettes when smoking with peers than when smoking alone. Participants' coping (but not social) motives moderated the within-person associations between smoking with peers and the cigarettes smoked during a smoking episode. The findings support the utility of an ecological perspective in examining the dynamic interaction between smoking motives and the social settings of cigarette use, and call for further research on the social smoking behaviors in diverse populations.

Ottaviani, C.; Couyoumdjian, A. (2013):

Pros and cons of a wandering mind: a prospective study.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 524. DOI: 10.3389/fpsyg.2013.00524.

Abstract:

Mind wandering (MW) has recently been associated with both adaptive (e.g., creativity enhancement) and maladaptive (e.g., mood worsening) consequences. This study aimed at investigating whether proneness to MW was prospectively associated with negative health outcomes. At time 0, 21 women, 19 men; mean age = 24.5 (4.9) underwent a 5-min baseline electrocardiogram (ECG), a 20-min laboratory tracking task with thought probes, and personality questionnaires. At time 1 (1 year follow-up), the same participants underwent a 24-h Ecological Momentary Assessment characterized by ambulatory ECG recording and electronic diaries. First, we examined if the likelihood of being a "mind wanderer" was associated with specific personality dispositions. Then, we tested if the occurrence of episodes of MW in the lab would be correlated with frequency of MW in daily life. Finally, multiple regression models were used to test if MW longitudinally acted as a risk factor for health, accounting for the effects of biobehavioral variables. Among dispositional traits, the frequency of MW episodes in daily life was inversely associated with the capacity of being mindful (i.e., aware of the present moment and non-judging). There was a positive correlation between frequency of MW in the lab and in daily life, suggesting that it is a stable disposition of the individual. When differentiated from perseverative cognition (i.e., rumination and worry), MW did not predict the presence of health risk factors 1 year later, however, a higher occurrence of episodes of MW was associated with short-term adverse consequences, such as increased 24-h heart rate (HR) on the same day and difficulty falling asleep the subsequent night. Present findings suggest that MW may be associated with short term "side effects" but argue against a long term dysfunctional view of this cognitive process

Vascular profile, delayed recovery, inflammatory process, and ambulatory blood pressure: Laboratory-to-life generalizability.

In: *International Journal of Psychophysiology* 66 (1), S. 56–65.

Abstract:

Impaired recovery and plasma concentration of intercellular adhesion molecule-1 (sICAM-1) were both highlighted as plausible and more established markers of cardiovascular disease, respectively. Hemodynamic patterns during recovery and their link with circulating levels of sICAM-1 were examined as predictors of 24-h blood pressure (ABP). Impedance cardiography measures and beat-to-beat BP were recorded in 45 healthy subjects during a 10-min baseline, four tasks, and four 10-min recovery periods. sICAM-1 levels at rest were determined by ELISA. ABP measures were obtained combining data from a work and an off day. Hierarchical regressions showed that patterns of compensatory changes in cardiac output and total peripheral resistance during recovery improved the prediction of ABP above and beyond resting and recovery BP, or reactivity hemodynamic patterns. Stress-induced recovery was essentially vascular in nature and a more vascular profile was associated with higher ABP and higher circulating levels of sICAM-1. The results suggest a link between recovery hemodynamics and cardiovascular risk.

The use of accelerometry in adolescents and its implementation with non-wear time activity diaries in free-living conditions.

In: *Journal of Sports Sciences* 29 (1), S. 103–113.

Abstract:

The aim of this study was to evaluate the use of a non-wearing time activity diary (hereafter non-wear activity diary) when using accelerometry in adolescents to provide insight into their physical activity levels. In total, 213 Belgian adolescents (89 boys, 124 girls) were eligible for this study. Adolescents wore an accelerometer for seven consecutive days and kept a non-wear activity diary. On the last day, they completed the International Physical Activity Questionnaire for Adolescents. The differences between the accelerometer data with and without use of the non-wear activity diary were significant for all physical activity intensities according to the Wilcoxon signed rank test. Bland-Altman plots showed that with more time spent in any physical activity intensity, the difference between including and not including the non-wear activity diary increased. The correlation coefficient between the International Physical Activity Questionnaire for Adolescents and the accelerometer data increased when the non-wear activity diary was included. Differences in the percentage of adolescents reaching the physical activity recommendations between the accelerometer data only and the accelerometer with the non-wear activity diary were significant. We conclude that if the non-wear activity diary data are not included, some adolescents could be misclassified as not being physically active according to the physical activity recommendations. It is therefore recommended to use a non-wear activity diary for gaining insight into the physical activity levels of individuals.

Overall, Nickola C.; Sibley, Chris G. (2010):

Convergent and discriminant validity of the Accommodation Scale: Evidence from three diary studies.

In: *Personality and Individual Differences* 48 (3), S. 299–304.

Abstract:

Three independent diary studies supported the convergent and discriminant validity of the Accommodation Scale (Rusbult, Verette, Whitney, Slovik, & Lipkus, 1991) by testing whether questionnaire-measured accommodation predicted individual differences in accommodation during naturally-occurring relationship interactions. First, across the three samples, questionnaire-measured accommodation predicted levels of diary-reported accommodation within – and only within – interactions in which participants were experiencing conflict. Second, questionnaire-measured accommodation within family relationships predicted accommodation within interactions with family members but not within interactions with friends. Third, the effects were evident controlling for global self and relationship evaluations. This research highlights the utility of diary methodology to test whether questionnaires capture the specific situation-behavior linkages they are designed to measure.

Owen, N. (2012):

Ambulatory monitoring and sedentary behaviour: a population-health perspective.

In: *Physiol Meas* 33 (11), S. 1801–1810. DOI: 10.1088/0967-3334/33/11/1801.

Abstract:

Opportunities for sedentary-behaviour research using device-based measures are proposed, addressing four main topics: first, there is an explanation of how sedentary behaviours can most usefully be understood, emphasizing how they are distinct from lack of moderate-to-vigorous physical activity (the major focus of current national and international public-health guidelines), together with an account of the evidence on the relationships of sedentary behaviour with risk biomarkers and health outcomes; this highlights how device-based measurement is leading to rapid research advances. Second, the case is made for the utility of a behavioural epidemiology framework and an ecological model of sedentary behaviour to guide measurement-development initiatives. Third, the main elements of such a research agenda and the logic of their interrelationships are described. Fourth, and in conclusion, novel research opportunities arising within this perspective and likely future benefits are outlined

Paez, Sadye; Maloney, Ann; Kelsey, Kristine; Wiesen, Chris; Rosenberg, Angela (2009):

Parental and environmental factors associated with physical activity among children participating in an active video game.

In: *Pediatric Physical Therapy* 21 (3), S. 245–253.

Abstract:

PURPOSE:

Parental and intervention-specific environmental supports were examined as potential reinforcers for physical activity and use of a video game, Dance Dance Revolution (DDR), among a cohort of 7- to 8-year-old children.

METHODS:

Sixty children were randomized to an intervention (n = 40) or a control (n = 20) group. Physical activity was measured with accelerometry and DDR logs. Parental support for their child's physical activity was assessed via a questionnaire. DDR-specific environmental supports were captured on an environmental home screen and the DDR log.

RESULTS:

At baseline, the absence of other video games and parent DDR participation was associated with child participation in DDR. At follow-up, DDR participation of siblings and friends was associated with child participation in DDR.

CONCLUSION:

The primary findings of this study suggest that parental and peer participation in DDR may play a role in children's initial and sustained participation in DDR.

Page, Eric; Cazeau, Serge; Ritter, Philippe; Galley, Daniel; Casset, Cyrille (2007):

Physiological approach to monitor patients in congestive heart failure: application of a new implantable device-based system to monitor daily life activity and ventilation.

In: *EP Europace*.

Abstract:

AIMS:

We examine an expert system designed to permanently monitor patients with congestive heart failure (CHF) using data of a dual-sensor pacemaker and to allow warning of significant changes in physiological indices.

METHODS AND RESULTS:

This study included 67 implanted patients divided into two groups: a control group without history of CHF (n = 19) who had received DDDR pacemakers (DDD group) and a test group (n = 48) who had received cardiac resynchronization therapy systems (CRT group) for severe CHF (NYHA III or IV, LVEF <40%). The embedded monitoring system measures minute ventilation (MV) and activity (ACT) at rest and at exercise. All devices collect data, and all adverse medical events were recorded. Data are stored daily for up to 3 months. The mean ACT was similar for both groups. Mean rest and exercise MV were significantly higher in CRT group. On 195 periods of 1-month follow-up in the CRT group, 31 events were suspected, 22 were true positive, 9 were false-positive, and 3 clinical adverse events were not predicted (sensitivity: 88%, specificity: 94.7%, positive predictive value: 71%, negative predictive value: 98.2%)

CONCLUSION:

A new diagnostic expert system that holds promise for the long-term ambulatory monitoring of CHF was developed.

Page, Angie S.; Cooper, Ashley R.; Griew, Pippa; Davis, Laura; Hillsdon, Melvyn (2009):

Independent mobility in relation to weekday and weekend physical activity in children aged 10-11 years: The PEACH Project.

In: *Int J Behav Nutr Phys Act* 6. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-30448-001%26site%3dehost-live;m.hillsdon@bris.ac.uk;laura.davis@bris.ac.uk;pippa.griew@bris.ac.uk;ashley.cooper@bris.ac.uk;a.s.page@bris.ac.uk.

Abstract:

Background: Children's independent mobility has fallen in recent years and may in part explain reported declines in physical activity in young people. This cross-sectional study investigated whether independent mobility in boys and girls was related to objectively measured physical activity. Methods: Thirteen hundred and seven 10–11 year old boys and girls from 23 schools in a large UK city took part. Measures included objectively recorded physical activity (accelerometer (Actigraph GT1M)), height (m) and weight (kg), a newly developed scale for local (Local-IM) and area independent mobility (Area-IM), minutes of daylight after school, level of neighborhood deprivation and pubertal status. Results: Boys had greater Local-IM, Area-IM and physical activity (average weekday and weekend counts per minute) compared to girls. In linear regression analyses (adjusting for minutes of daylight after school, neighborhood deprivation, pubertal status and body mass index) higher scores for Local-IM and Area-IM were significantly ($p < 0.01$) related to higher levels of physical activity on weekdays for boys and girls. For weekend physical activity, only Local-IM in girls remained significant ($p < 0.05$) in the model. Conclusion: Independent mobility appears to be an important independent correlate of weekday physical activity for both boys and girls. Pagels, Peter; Boldemann, Cecilia; Raustorp, Anders (2011):

Comparison of pedometer and accelerometer measures of physical activity during preschool time on 3-to 5-year-old children.

In: *Acta Paediatr* 100 (1), S. 116–120.

Abstract:

AIMS:

To compare pedometer steps with accelerometer counts and to analyse minutes of engagement in light, moderate and vigorous physical activity in 3- to 5-year-old children during preschool time.

METHODS:

Physical activity was recorded during preschool time for five consecutive days in 55 three- to five-year-old children. The children wore a Yamax SW200 pedometer and an Actigraph GTIM Monitor.

RESULTS:

The average time spent at preschool was 7.22 h/day with an average step of 7313 (±3042). Steps during preschool time increased with increasing age. The overall correlation between mean step counts and mean accelerometer counts ($r = 0.67$, $p < 0.001$), as well as time in light to vigorous activity ($r = 0.76$, $p < 0.001$), were moderately high. Step counts and moderate to vigorous physical activity minutes were poorly correlated in 3 years old ($r = 0.19$, $p < 0.191$) and moderately correlated ($r = 0.50$, $p < 0.001$) for children 4 to 5 years old.

CONCLUSION:

Correlation between the preschool children's pedometer-determined step counts and total engagement in physical activity during preschool time was moderately high. Children's step counts at preschool were low, and the time spent in moderate and vigorous physical activity at preschool was very short.

Palatini, Paolo (2008):

Heart rate as predictor of outcome.

In: *Blood Press Monit* 13 (3), S. 167–168.

Abstract:

Reduced heart rate recovery (HRR) after exercise is associated with increased mortality in cardiac and pulmonary diseases. We sought to evaluate the association between HRR after the 6-minute walk test (6MWT) and outcomes in patients with connective tissue disease-associated pulmonary hypertension (CTD-PH). Data were obtained by review of the medical records. HRR was defined as the difference in heart rate at the end of the 6MWT and after 1 minute (HRR1), 2 minutes (HRR2), and 3 minutes (HRR3) of rest. All patients with pulmonary hypertension and a diagnosis of systemic sclerosis, systemic lupus erythematosus, or mixed connective tissue disease who underwent the 6MWT between August 1, 2009, and October 30, 2011, were included ($n = 66$). By Kaplan-Meier analysis, HRR1, HRR2, and HRR3 at different cutoff points were all good predictors, with HRR1 of <16 being the best predictor of time to clinical worsening (log-rank $P < 0.0001$), hospitalization (log-rank $P = 0.0001$), and survival (log-rank $P < 0.003$). By proportional hazards regression, patients with HRR1 of <16 were at increased risk of clinical worsening (hazard ratio [HR]: 6.4 [95% confidence interval (CI): 2.6-19.2]; $P < 0.0001$], hospitalization (HR: 6.6 [95% CI: 2.4-23]; $P < 0.0001$), and death (HR: 4.5 [95% CI: 1.6-15.7]; $P = 0.003$). Patients in the highest tercile (HRR1 of ≥19) were unlikely to have a clinical

worsening event (HR: 0.1 [95% CI: 0.04-0.5]; P = 0.001], to be hospitalized (HR: 0.1 [95% CI: 0.02-0.5]; P = 0.001), or to die (HR: 0.3 [95% CI: 0.07-0.9]; P = 0.04]. In conclusion, in patients with CTD-PH, abnormal HRR1 (defined as HRR1 of <16) after the 6MWT is a strong predictor of clinical worsening, time to clinical worsening, survival, and hospitalization.

Palatini, Paolo (2014):

How Should We Manage a Patient with Masked Hypertension?

In: *High Blood Press Cardiovasc Prev. DOI:* 10.1007/s40292-014-0044-5.

Abstract:

A number of studies have shown that masked hypertension (MH) confers an increased risk of target organ damage and of cardiovascular events suggesting that patients with MH would benefit from antihypertensive treatment. However, there is no general agreement about how this condition should be diagnosed. Although ambulatory blood pressure monitoring (ABPM) and self blood pressure measurement (SBPM) provide different and complementary clinical information, the recently published ESH/ESC guidelines for the management of arterial hypertension suggest that for initial assessment of the patient, SBPM may be more suitable in primary care and ABPM in specialist care. If SBPM provides borderline values it is advisable to confirm the diagnosis of MH with ABPM. As the prevalence of MH declines with repeated ABPMs the diagnosis of MH should be based on at least two ABPMs. Patients with MH should undergo a careful diagnostic work-up to assess the existence of additional risk factors including a worsened metabolic profile and the presence of target organ involvement. Treatment of the patient with MH should initially be addressed to improve the patient's lifestyle in order to decrease out-of-office blood pressure and to ameliorate metabolic data. If non-pharmacological measures are insufficient to normalize blood pressure, MH may benefit from pharmacological treatment but no clinical trial has been implemented as yet with the specific purpose of testing this hypothesis. Despite this lack of evidence, the 2013 ESH/ESC guidelines have recommended that in patients with MH also drug treatment should be considered because in patients with MH the risk of adverse outcome is very close to that in sustained hypertension. When ambulatory blood pressure is measured, pharmacological treatment may be modulated according to whether blood pressure is elevated during daytime hours or during sleep.

Palatini, P.; Saladini, F.; Mos, L.; Benetti, E.; Bortolazzi, A.; Cozzio, S.; Casiglia, E. (2012):

Obesity is a strong determinant of hypertensive target organ damage in young-to-middle-age patients.

In: *Int.J.Obes.(Lond)* (0307-0565 (Linking)). DOI: 10.1038/ijo.2012.32.

Abstract:

OBJECTIVE:To examine the impact of overweight and obesity on development of target organ damage in the early stage of hypertension.SUBJECTS:Participants were 727 young-to-middle-age subjects screened for stage 1 hypertension and followed for 8 years.MEASUREMENTS:Ambulatory blood pressure (BP), albumin excretion rate and echocardiographic data were obtained at entry, every 5 years and/or before starting antihypertensive treatment.RESULTS:During the follow-up, hypertension needing treatment was developed by 54.7% of the subjects with normal weight, 66.6% of those with overweight and 73.0% of those with obesity (P<0.001). Kaplan-Meier curves showed that patients with obesity or overweight progressed to sustained hypertension earlier than those with normal weight (P<0.001). At study end, rate of organ damage was 10.7% in the normal weight, 16.4% in the overweight and 30.1% in the obese subjects (P<0.001). In a multivariable logistic regression analysis, overweight (P=0.008) and obesity (P<0.001) were significant predictors of final organ damage. Inclusion of changes in 24-h BP and body mass index, and of baseline organ damage did not virtually modify these associations (P=0.002 and <0.001, respectively). Obesity was a significant predictor of both left ventricular hypertrophy (P<0.001) and microalbuminuria (P=0.015) with an odds ratio (95% confidence interval) of 8.5 (2.7-26.8) and 3.5 (1.3-9.6), respectively.CONCLUSION:These data indicate that in hypertensive subjects obesity has deleterious effects on the cardiovascular system already at an early age. Preventive strategies addressed to achieve weight reduction should be implemented at a very early stage in young people with excess adiposity and high BP.International Journal of Obesity advance online publication, 6 March 2012; doi:10.1038/ijo.2012.32

Pallin, Michael; O'Hare, Emer; Zaffaroni, Alberto; Boyle, Patricia; Fagan, Ciara; Kent, Brian et al. (2014):

Comparison of a novel non-contact biomotion sensor with wrist actigraphy in estimating sleep quality in patients with obstructive sleep apnoea.

In: *J Sleep Res. DOI:* 10.1111/jsr.12126.

Abstract:

Ambulatory monitoring is of major clinical interest in the diagnosis of obstructive sleep apnoea syndrome. We compared a novel non-contact biomotion sensor, which provides an estimate of both sleep time and sleep-disordered breathing, with wrist actigraphy in the assessment of total sleep time in adult humans suspected of obstructive sleep apnoea syndrome. Both systems were simultaneously evaluated against polysomnography in 103 patients undergoing assessment for obstructive sleep apnoea syndrome in a hospital-based sleep laboratory (84 male, aged 55 +/- 14 years and apnoea-hypopnoea index 21 +/- 23). The biomotion sensor demonstrated similar accuracy to wrist actigraphy for sleep/wake determination (77.3%: biomotion; 76.5%: actigraphy), and the biomotion sensor demonstrated higher specificity (52%: biomotion; 34%: actigraphy) and lower sensitivity (86%: biomotion; 94%: actigraphy). Notably, total sleep time estimation by the biomotion sensor was superior to actigraphy (average overestimate of 10 versus 57 min), especially at a higher apnoea-hypopnoea index. In post hoc analyses, we assessed the improved apnoea-hypopnoea index accuracy gained by combining respiratory measurements from polysomnography for total recording time (equivalent to respiratory polygraphy) with total sleep time derived from actigraphy or the biomotion sensor. Here, the number of misclassifications of obstructive sleep apnoea severity compared with full polysomnography was reduced from 10/103 (for total respiratory recording time alone) to 7/103 and 4/103 (for actigraphy and biomotion sensor total sleep time estimate, respectively). We conclude that the biomotion sensor provides a viable alternative to actigraphy for sleep estimation in the assessment of obstructive sleep apnoea syndrome. As a non-contact device, it is suited to longitudinal assessment of sleep, which could also be combined with polygraphy in ambulatory studies.

Palmas, Walter; Moran, Andrew; Pickering, Thomas; Eimicke, Joseph P.; Teresi, Jeanne; Schwartz, Joseph E. et al. (2006):

Ambulatory pulse pressure and progression of urinary albumin excretion in older patients with type 2 diabetes mellitus.

In: *Hypertension* 48 (2), S. 301–308.

Abstract:

We studied whether ambulatory blood pressure monitoring added to office blood pressure in predicting progression of urine albumin excretion over 2 years of follow-up in a multiethnic cohort of older people with type-2 diabetes mellitus. Participants in the Informatics for Diabetes Education and Telemedicine study underwent a baseline evaluation that included office and 24-hour ambulatory blood pressure measurement and a spot urine measurement of albumin-to-creatinine ratio (ACR). Measurements of albumin-to-creatinine ratio were repeated 1 and 2 years later. In bivariate analyses, ambulatory 24-hour pulse pressure was the blood pressure variable most strongly associated with follow-up ACR. Repeated-measures mixed linear models (n = 1040) were built adjusting for baseline ACR ratio, clustered randomization, time to follow-up, and multiple covariates. When both were entered into the model, ambulatory 24-hour pulse pressure and office pulse pressure were independently associated with follow-up ACR (beta [SE] = 0.010 [0.002], P < 0.001, and 0.004 [0.001], P = 0.002, respectively). Cox proportional hazards models examined associations with progression of albuminuria in 954 participants without macroalbuminuria at baseline, adjusting for all of the covariates independently associated with follow-up ACR in mixed linear models. Ambulatory 24-hour pulse pressure, but not office pulse pressure, was independently associated with progression of albuminuria (P = 0.015 and 0.052, respectively). The adjusted hazards ratio (95% CI) per each 10-mm Hg increment in ambulatory pulse pressure was 1.23 (1.04 to 1.42). In conclusion, ambulatory pulse pressure may provide additional information to predict progression of albuminuria in elderly diabetic subjects above and beyond office blood pressure.

Palmas, Walter; Pickering, Thomas; Eimicke, Joseph P.; Moran, Andrew; Teresi, Jeanne; Schwartz, Joseph E. et al. (2007):

Value of ambulatory arterial stiffness index and 24-h pulse pressure to predict progression of albuminuria in elderly people with diabetes mellitus.

In: *Am J Hypertens* 20 (5), S. 493–500.

Abstract:

BACKGROUND:

Ambulatory 24-h pulse pressure predicts progression of albuminuria in people with diabetes mellitus. It is not known whether the ambulatory arterial stiffness index (AASI) may add to that prediction.

METHODS:

We compared the multivariate-adjusted association of AASI and 24-h pulse pressure with progression of urine albumin excretion during follow-up in a multiethnic cohort of older people with type-2 diabetes mellitus. The baseline evaluation included office and 24-h ambulatory blood pressure (BP) measurements, and a spot urine measurement of albumin-to-creatinine ratio (ACR). The ACR measurements were repeated annually during 3 years.

RESULTS:

The AASI was >or=0.55 units in 47% of those exhibiting progression of albuminuria, and in 37% of those without progression (P = .004), whereas 24-h pulse pressure was >or=65 mm Hg in 50% and 38% of those with and without progression, respectively (P = .001). In repeated measures mixed linear model (n = 1043), after adjustment for several covariates including office pulse pressure, AASI in the fourth quartile was independently associated with higher follow-up ACR (P = .024). However, that association did not persist after adjusting for 24-h pulse pressure, which was an independent predictor (P < .001). Cox proportional hazards models examined progression of albuminuria in 957 participants without macroalbuminuria at baseline. The hazard ratio (95% CI) for AASI >or=0.55 units was 1.37 (1.02-1.83) after multivariable adjustment, including office pulse pressure. But AASI was not an independent predictor after adjustment for ambulatory pulse pressure, which was again an independent predictor (P = .033).

CONCLUSIONS:

Ambulatory 24-h pulse pressure outperformed AASI in predicting progression of albuminuria in elderly people with type 2 diabetes

Palmier Claus, J. E.; Dunn, G.; Taylor, H.; Morrison, A. P.; Lewis, S. W. (2013):

Cognitive self consciousness and metacognitive beliefs: Stress sensitization in individuals at ultra-high risk of developing psychosis.

In: *British Journal of Clinical Psychology* 52 (1), S. 26–41. DOI: 10.1037/t15492-000;

Abstract:

Objective: Metacognitive beliefs (MCB) may guide information and attention processes, increasing affective and symptomatic reactions to stressful events. Cognitive self-consciousness (CSC; i.e., a preoccupation with one s thoughts) may increase awareness of MCB, potentially triggering the onset of psychotic symptoms. This study tested the hypotheses that (1), MCB would moderate affective and symptomatic reactions to stress in individuals at ultra-high risk (UHR) of developing psychosis, and (2), greater CSC would precede worsening in psychotic symptoms in individuals with strong MCB. Method: Twenty-seven individuals at UHR of developing psychosis completed a self-report diary when prompted by an electronic wristwatch several times each day for 6 days (experience sampling). Results: MCB moderated the association between affective, but not symptomatic, responses to social stress. CSC preceded the subsequent occurrence of hallucinations in individuals who reported strong beliefs about the need to control their thoughts. Conclusions: The data suggest that MCB sensitize an individual to social stressors. CSC may represent times where an individual is aware that their thoughts are uncontrollable, and therefore contradicting their MCB, motivating them to make an external attribution. The findings have implications for improving the effectiveness of interventions for people experiencing hallucinations. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Palmier-Claus, J. E.; Ainsworth, J.; MacHin, M.; Barrowclough, C.; Dunn, G.; Barkus, E. et al. (2012):

The feasibility and validity of ambulatory self-report of psychotic symptoms using a smartphone software application.

In: *BMC Psychiatry* 12 (1471-244X (Linking)), S. 172. DOI: 10.1186/1471-244X-12-172.

Abstract:

BACKGROUND: Semi-structured interview scales for psychosis are the gold standard approach to assessing psychotic and other symptoms. However, such assessments have limitations such as recall bias, averaging, insensitivity to change and variable interrater reliability. Ambulant, real-time self-report assessment devices may hold advantages over interview measures, but it needs to be shown that the data thus collected are valid, and the collection method is acceptable, feasible and safe. We report on a monitoring system for the assessment of psychosis using smartphone technology. The primary aims were to: i) assess validity through correlations of item responses with those on widely accepted interview assessments of psychosis, and ii) examine compliance to the procedure in individuals with psychosis of varying severity. METHODS: A total of 44 participants (acute or remitted DSM-4 schizophrenia and related disorders, and prodromal) completed 14 branching self-report items concerning key psychotic symptoms on a touch-screen mobile phone when prompted by an alarm at six pseudo-random times, each day, for one week. Face to face PANSS and CDS interviews were conducted before and after the assessment period blind to the ambulant data. RESULTS: Compliance as defined by completion of at least 33% of all possible data-points over seven days was 82%. In the 36 compliant participants, 5 items (delusions, hallucinations, suspiciousness, anxiety, hopelessness) showed moderate to strong (rho 0.6-0.8) associations with corresponding items from interview rating scales. Four items showed no significant correlation with rating scales: each was an item based on observable behaviour. Ambulant ratings showed excellent test-retest reliability and sensitivity to change. CONCLUSIONS: Ambulatory monitoring of symptoms several times daily using

smartphone software applications represents a feasible and valid way of assessing psychotic phenomena for research and clinical management purposes. Further evaluation required over longer assessment periods, in clinical trials and service settings

Palmier-Claus, J. E.; Dunn, G.; Lewis, S. W. (2012):

Emotional and symptomatic reactivity to stress in individuals at ultra-high risk of developing psychosis.

In: *Psychological Medicine* 42 (5), S. 1003–1012. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-08848-011&site=ehost-live;Jasper.Palmier-Claus@manchester.ac.uk.

Abstract:

Background: The stress-vulnerability model of psychosis continues to be influential. The aim of this study was to compare emotional and symptomatic responses to stress in individuals at ultra-high risk (UHR) of developing psychosis, in age- and gender-matched healthy controls, and in patients with non-affective psychosis. Method: A total of 27 UHR, 27 psychotic and 27 healthy individuals completed the experience sampling method, an ambulant diary technique, where they were required to fill in self-assessment questions about their emotions, symptoms and perceived stress at semi-random times of the day for 6 days. Questionnaire and interview assessments were also completed. Results: Multilevel regression analyses showed that individuals at UHR of developing psychosis reported greater negative emotions in response to stress than the healthy individuals. Against the initial hypotheses, the UHR individuals also experienced greater emotional reactivity to stress when compared with the patient group. No significant differences were observed between the patients and the non-clinical sample. Stress measures significantly predicted the intensity of psychotic symptoms in UHR individuals and patients, but the extent of this did not significantly differ between the groups. Conclusions: Individuals at UHR of developing psychosis may be particularly sensitive to everyday stressors. This effect may diminish after transition to psychosis is made and in periods of stability. Subtle increases in psychotic phenomena occur in response to stressful events across the continuum of psychosis. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Palmier-Claus, J. E.; Dunn, G.; Taylor, H.; Morrison, A. P.; Lewis, S. W. (2013):

Cognitive-self consciousness and metacognitive beliefs: Stress sensitization in individuals at ultra-high risk of developing psychosis.

In: *Br.J Clin.Psychol.* 52 (1), S. 26–41. DOI: 10.1111/j.2044-8260.2012.02043.x.

Abstract:

Objective: Metacognitive beliefs (MCB) may guide information and attention processes, increasing affective and symptomatic reactions to stressful events. Cognitive self-consciousness (CSC; i.e., a preoccupation with one's thoughts) may increase awareness of MCB, potentially triggering the onset of psychotic symptoms. This study tested the hypotheses that (1), MCB would moderate affective and symptomatic reactions to stress in individuals at ultra-high risk (UHR) of developing psychosis, and (2), greater CSC would precede worsening in psychotic symptoms in individuals with strong MCB. METHOD: Twenty-seven individuals at UHR of developing psychosis completed a self-report diary when prompted by an electronic wristwatch several times each day for 6 days (experience sampling). RESULTS: MCB moderated the association between affective, but not symptomatic, responses to social stress. CSC preceded the subsequent occurrence of hallucinations in individuals who reported strong beliefs about the need to control their thoughts. CONCLUSIONS: The data suggest that MCB sensitize an individual to social stressors. CSC may represent times where an individual is aware that their thoughts are uncontrollable, and therefore contradicting their MCB, motivating them to make an external attribution. The findings have implications for improving the effectiveness of interventions for people experiencing hallucinations

Palmier-Claus, J. E.; Taylor, P. J.; Gooding, P.; Dunn, G.; Lewis, S. W. (2012):

Affective variability predicts suicidal ideation in individuals at ultra-high risk of developing psychosis: an experience sampling study.

In: *Br.J.Clin.Psychol.* 51 (1), S. 72–83. DOI: 10.1111/j.2044-8260.2011.02013.x.

Abstract:

OBJECTIVE: There is a suggestion in the literature that more variable affect increases suicidal ideation through the repeated re-activation of latent suicidal cognitions. The hypothesis that affective variability would be a better predictor of suicidal ideation and related behaviour than affect level was tested in individuals at ultra-high risk of developing psychosis. This study also examined the prediction that affective variability is a suicide-specific mechanism and would not predict levels of attenuated psychotic phenomena. METHOD: Twenty-seven ultra-high risk individuals were required to complete ambulant ratings of their affect when prompted by an electronic wristwatch for six days (the experience sampling method). In the debriefing session, participants were assessed with a semi-structured interview (the Comprehensive Assessment of At-Risk Mental State), which assessed the severity and frequency of suicidality and psychosis-related phenomena. RESULTS: The variability of negative and positive affect was predictive of the frequency of suicidal thoughts and behaviour. More variable negative, but not positive affect, was also associated with more severe suicidal ideation and related behaviour. Affect variability was not significantly related to the severity of attenuated psychotic phenomena. CONCLUSION: Affective variability appears to be a specific risk factor for suicidal ideation in individuals at ultra-high risk of developing psychosis. Early intervention should focus on providing individuals with skills for regulating their own affect

Pan, W.; Kwak, S.; Li, F.; Wu, C.; Chen, Y.; Yamamoto, Y.; Cai, D. (2013):

Actigraphy monitoring of symptoms in patients with Parkinson's disease.

In: *Physiol Behav* (0031-9384 (Linking)). DOI: 10.1016/j.physbeh.2013.05.044.

Abstract:

Although the Unified Parkinson's Disease Rating Scale (UPDRS) is the "gold-standard" tool in assessing the severity of symptoms in patients with Parkinson's disease (PD), not all activity-related disease symptoms can be accurately captured by the well-established clinical rating scale. Using an alternative approach, this study examined the level of physical activity measured by actigraphy over time and whether change in physical activity was associated with disease severity assessed by UPDRS. We used a longitudinal design in which physical activity and disease severity were assessed repeatedly during a 4-month interval, over a 3-year observational period, in a sample of 61 patients with idiopathic PD and a control group of 32 neurologically intact individuals. Physical activity data during awake-time were analyzed using the power-law exponent (PLE) method. Correlational relationships between changes in maxima values of PLE and scores of total UPDRS, UPDRS-part II (Activities of Daily Living), and UPDRS-part III (Motor Examination) in patients with PD were examined. Results show an increase in maxima values of PLE and the UPDRS total score in PD patients and that there is a positive association between changes in maxima values and total UPDRS score ($r=0.746$, $p=0.032$), UPDRS-part II score ($r=0.687$, $p=0.027$), and UPDRS-part III score ($r=0.893$, $p=0.018$). There was no significant change in the level of physical activity over time for the controls. Findings from this study indicate that change in physical activity, as captured by actigraphy, is associated with increased severity in patients' clinical symptoms of PD over time. Thus, these data suggest that, when used in conjunction with the conventional UPDRS measure, an actigraphic measure of physical activity may provide clinicians an adjunct measurement approach to monitor patients' activity-based disease progression or responses to treatment in outpatient clinic settings

Papp, Lauren M.; Pendry, Patricia; Adam, Emma K. (2009):

Mother-adolescent physiological synchrony in naturalistic settings: within-family cortisol associations and moderators.

In: *Journal of Family Psychology* 23 (6), S. 882–894. DOI: 10.1037/a0017147.

Abstract:

In this study, the authors examined parent-adolescent cortisol associations in 45 families with adolescent children (24 girls; M age = 15.78 years, SD = 1.44 years). Family members' salivary cortisol levels were measured seven times a day on 2 typical weekdays. Family members provided reports of demographic and health variables, and adolescents rated parent-child relationship characteristics. After accounting for the effects of time of day and relevant demographic and health control variables on cortisol levels, hierarchical linear models indicated the presence of significant covariation over time in mother-adolescent cortisol (i.e., physiological synchrony). Furthermore, moderating tests revealed that mother-adolescent cortisol synchrony was strengthened among dyads characterized by mothers and adolescents spending more time together, and in families rated higher on levels of parent-youth shared activities and parental monitoring or supervision. Analysis of momentary characteristics indicated that maternal presence at the time of cortisol sampling lowered adolescent cortisol levels but did not account for mother-adolescent cortisol synchrony. Within-family physiological synchrony was amplified in momentary contexts of elevated maternal negative affect and elevated adolescent negative affect.

Parati, Gianfranco; Schumacher, Helmut; Bilo, Grzegorz; Mancia, Giuseppe (2010):

Evaluating 24-h antihypertensive efficacy by the smoothness index: a meta-analysis of an ambulatory blood pressure monitoring database.

In: *J Hypertens* 28 (11), S. 2177–2183. DOI: 10.1097/HJH.0b013e32833e1150.

Abstract:

OBJECTIVE\r\nThe aim of this meta-analysis was to compare the 24-h antihypertensive efficacy of different treatments using the smoothness index.\r\nMETHODS\r\nData were taken from the telmisartan ambulatory blood pressure monitoring (ABPM) clinical programme. Eleven clinical trials that randomized mild-to-moderate hypertensive patients to treatment with telmisartan 40/80 mg, losartan 50 mg, valsartan 80/160 mg, ramipril 10 mg, amlodipine 5 mg monotherapy, or with an angiotensin receptor blocker (ARB) and hydrochlorothiazide (HCTZ) 12.5/25 mg, were included. Treatment duration ranged from 4 to 14 weeks. The smoothness index was calculated according to the published formula.\r\nRESULTS\r\nAltogether, 5188 patients were included (65% men; 52% were using telmisartan as monotherapy or in combination with HCTZ). Telmisartan 80 mg had a higher smoothness index than losartan, valsartan or ramipril (P < 0.05), and was comparable with amlodipine. All combination therapies had a higher smoothness index than monotherapy; the largest value was observed with telmisartan 80 mg and HCTZ 12.5 mg. Overall, the smoothness index was lower in men, older patients, black patients, smokers and in those with lower baseline blood pressure (P < 0.05).\r\nCONCLUSION\r\nThe smoothness index was affected by age, race, sex, behavioural and haemodynamic factors. It was also able to differentiate the 24-h blood pressure effects of antihypertensive drugs, with telmisartan and amlodipine achieving the highest values, possibly because of their long plasma half-lives. All combination therapies had a higher smoothness index than monotherapy. An understanding of the relative effects of different antihypertensives on the smoothness index may help to differentiate their effectiveness in reducing blood pressure-related cardiovascular risk.

Park, Min-Jeong; Kim, Hee-Seung; Kim, Kyung-Soo (2009):

Cellular phone and Internet-based individual intervention on blood pressure and obesity in obese patients with hypertension.

In: *International journal of medical informatics* 78 (10), S. 704–710. DOI: 10.1016/j.ijmedinf.2009.06.004.

Abstract:

PURPOSE\r\nThe present study evaluated whether an intervention using a short message service (SMS) by cellular phone and Internet would improve blood pressure, weight control, and serum lipids of obese patients with hypertension during 8 weeks.\r\nMETHODS\r\nThis is a quasi-experimental design with pre- and follow-up tests. Participants were recruited from the family medicine outpatient department of tertiary care hospital located in an urban city of South Korea. Twenty-eight patients were assigned to an intervention group and 21 to a control group. The goal of intervention was to bring blood pressure, body weight, and serum lipids levels close to normal ranges. Patients in the intervention group were requested to record their blood pressure and body weight in a weekly web based diary through the Internet or by cellular phones. The researchers sent optimal recommendations as an intervention to each patient, by both cellular phone and Internet weekly. The intervention was applied for 8 weeks.\r\nRESULTS\r\nSystolic (SBP) and diastolic blood pressures (DBP) significantly decreased by 9.1 and 7.2 mmHg respectively at 8 weeks from the baseline in the intervention group (p<0.05). However, after 8 weeks from the baseline both SBP and DBP in the control group had not changed significantly. Yet, There were significant mean decreases in body weight and waist circumference by 1.6 kg (p<0.05) and 2.8 cm (p<0.05) in the intervention group, respectively. In the control group increases in body weight and waist circumference (p<0.05) mean changes were also significant. High density lipoprotein cholesterol (HDL-C) significantly increased, with a mean change of 3.7 mg/dl at 8 weeks from baseline in the intervention group (p<0.05). The mean change of HDL-C in the control group was, however, not significant.\r\nCONCLUSION\r\nDuring 8 weeks using this web-based intervention by way of cellular phone and Internet SMS improved blood pressure, body weight, waist circumference, and HDL-C in patients with obese hypertension.

Park, Yu Rang; Yoon, Young Jo; Jang, Tae Hun; Seo, Hwa Jeong; Kim, Ju Han (2014):

CCR+: Metadata Based Extended Personal Health Record Data Model Interoperable with the ASTM CCR Standard.

In: *Healthc Inform Res* 20 (1), S. 39–44. DOI: 10.4258/hir.2014.20.1.39.

Abstract:

OBJECTIVES: Extension of the standard model while retaining compliance with it is a challenging issue because there is currently no method for semantically or syntactically verifying an extended data model. A metadata-based extended model, named CCR+,

was designed and implemented to achieve interoperability between standard and extended models. METHODS: Furthermore, a multilayered validation method was devised to validate the standard and extended models. The American Society for Testing and Materials (ASTM) Community Care Record (CCR) standard was selected to evaluate the CCR+ model; two CCR and one CCR+ XML files were evaluated. RESULTS: In total, 188 metadata were extracted from the ASTM CCR standard; these metadata are semantically interconnected and registered in the metadata registry. An extended-data-model-specific validation file was generated from these metadata. This file can be used in a smartphone application (Health Avatar CCR+) as a part of a multilayered validation. The new CCR+ model was successfully evaluated via a patient-centric exchange scenario involving multiple hospitals, with the results supporting both syntactic and semantic interoperability between the standard CCR and extended, CCR+, model. CONCLUSIONS: A feasible method for delivering an extended model that complies with the standard model is presented herein. There is a great need to extend static standard models such as the ASTM CCR in various domains: the methods presented here represent an important reference for achieving interoperability between standard and extended models.

Parke, Michael R.; Seo, Myeong-Gu; Sherf, Elad N. (2014):

Regulating and Facilitating: The Role of Emotional Intelligence in Maintaining and Using Positive Affect for Creativity.

In: *J Appl Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-56222-001%26site%3dehost-live.

Abstract:

Although past research has identified the effects of emotional intelligence on numerous employee outcomes, the relationship between emotional intelligence and creativity has not been well established. We draw upon affective information processing theory to explain how two facets of emotional intelligence—emotion regulation and emotion facilitation—shape employee creativity. Specifically, we propose that emotion regulation ability enables employees to maintain higher positive affect (PA) when faced with unique knowledge processing requirements, while emotion facilitation ability enables employees to use their PA to enhance their creativity. We find support for our hypotheses using a multimethod (ability test, experience sampling, survey) and multisource (archival, self-reported, supervisor-reported) research design of early career managers across a wide range of jobs. Parker, Kathy P.; Bliwise, Donald L.; Ribeiro, Maria; Jain, Sanjay R.; Vena, Catherine I.; Kohles-Baker, Mary Kay et al. (2008):

Sleep/wake patterns of individuals with advanced cancer measured by ambulatory polysomnography.

In: *Journal of Clinical Oncology* 26 (15), S. 2464–2472.

Abstract:

PURPOSE:

Sleep/wake disturbances are prevalent in patients with advanced cancer, but 24-hour polysomnography (PSG) examinations of these patterns have not been undertaken. The purpose of this study was to describe these sleep/wake patterns using continuous PSG and to explore relationships with selected demographic and clinical variables.

PATIENTS AND METHODS:

The sample included patients with advanced cancer (solid tumors); those with neurologic disorders or psychosis, substance abuse, or brain metastasis were excluded. The final sample included 114 participants with a mean age of 51.1 years (+/- 9.1 years). Participants underwent continuous, ambulatory PSG for 42 hours in their home environments. Standard PSG measures were calculated. Analysis included data from 2 nights and the intervening day. Descriptive statistics were used to summarize sleep/wake parameters of the average of the 2 nights and the intervening day. Nonparametric analyses were used to detect differences and relationships among the variables.

RESULTS:

Compared with normative data, participants had reduced quantity and quality of nocturnal sleep and episodes of sleep scattered throughout the day. Increased daytime sleep was negatively associated with several key parameters of nocturnal sleep quantity and quality. Women, whites, and those who were married/partnered and had more education had better nocturnal sleep. Cancer type and selected medications may be risk factors for disturbed sleep and waking.

CONCLUSION:

Participants experienced severe difficulty with "state maintenance", or the ability to maintain both the sleep and waking states. Research designed to identify the etiology of these problems is needed to develop effective interventions.

Parkinson, Brian; Simons, Gwenda (2009):

Affecting others: social appraisal and emotion contagion in everyday decision making.

In: *Pers Soc Psychol Bull* 35 (8), S. 1071–1084. DOI: 10.1177/0146167209336611.

Abstract:

In a diary study of interpersonal affect transfer, 41 participants reported on decisions involving other people over 3 weeks. Reported anxiety and excitement were reliably related to the perceived anxiety and excitement of another person who was present during decision making. Risk and importance appraisals partially mediated effects of other's anxiety on own anxiety as predicted by social appraisal theory. However, other's emotion remained a significant independent predictor of own emotion after controlling for appraisals, supporting the additional impact of more direct forms of affect transfer such as emotion contagion. Significant affect-transfer effects remained even after controlling for participants' perceptions of the other's emotion in addition to all measured appraisals, confirming that affect transfer does not require explicit registration of someone else's feelings. This research provides some of the clearest evidence for the operation of both social appraisal and automatic affect transfer in everyday social life.

Parrish, Brendt P.; Zautra, Alex J.; Davis, Mary C. (2008):

The role of positive and negative interpersonal events on daily fatigue in women with fibromyalgia, rheumatoid arthritis, and osteoarthritis.

In: *Health Psychol* 27 (6), S. 694–702. DOI: 10.1037/0278-6133.27.6.694.

Abstract:

OBJECTIVE\r\nThe current study tested whether daily interpersonal events predicted fatigue from one day to the next among female chronic pain patients.\r\nDESIGN\r\nSelf-reported fatigue, daily events, pain, sleep quality, depressive symptoms, and functional health across 30 days were assessed in women with rheumatoid arthritis (RA: n = 89), Osteoarthritis (OA: n = 76), and Fibromyalgia syndrome (FM: n = 90).\r\nMAIN OUTCOME MEASURES\r\nSelf-report fatigue measured on a 0 to 100 scale and fatigue affect from PANAS-X (Watson & Clark, 1994).\r\nRESULTS\r\nMultilevel analyses showed that both higher average levels of and daily increases in negative events predicted more fatigue, whereas daily increases in positive events predicted less fatigue. Across all pain conditions, increases in negative events continued to predict higher fatigue on the following day. Moreover, for participants with FM or RA, increases in positive events also predicted increased fatigue the following day. Daily increases in fatigue, in turn, predicted poorer functional health on both the same day and the next day.\r\nCONCLUSION\r\nThese results indicate that both on average and on a daily basis, interpersonal events influence levels of fatigue beyond common physical and psychological correlates of chronic pain and highlight differences between chronic pain groups.

Parry, Monica J. E.; McFetridge-Durdle, Judith (2006):

Ambulatory impedance cardiography: a systematic review.

In: *Nursing research* 55 (4), S. 283–291.

Abstract:

BACKGROUND:

Standard noninvasive impedance cardiography has been used to examine the cardiovascular responses of individuals to a wide range of stimuli in critical care and laboratory settings. It has been shown to be a reliable alternative to invasive thermodilution techniques and an acceptable alternative to the use of a pulmonary artery catheter. Ambulatory impedance cardiography provides a similar assessment of cardiac function to standard noninvasive impedance cardiography, but it does so while individuals engage in activities of daily living. It offers portability and the option of managing complex patients in outpatient settings.

OBJECTIVE:

To critically examine through a literature analysis the validity, reliability, and sensitivity of ambulatory impedance cardiography for the assessment of cardiac performance during activities of daily living.

METHODS:

The Cochrane Database of Systematic Reviews (CDSR), The Cochrane Database of Methodology Reviews (CDMR), The Cochrane Central Register of Controlled Trials (CENTRAL), Database of Abstracts of Reviews of Effects (DARE), National Health Service Economic Evaluation Database (NHS EED), Health Technology Assessment (HTA), and The Cochrane Methodology Register (CMR; 1966-2005); MEDLINE (1950-2005); and CINAHL (1982-2005) were searched using the following terms: ambulatory cardiac performance, impedance cardiac performance, AIM cardiac performance monitor, thoracic electrical bio-impedance, impedance cardiography, ambulatory impedance monitor, bio-impedance technology, ambulatory impedance cardiography, bio-electric impedance; also included were reference lists of retrieved articles. Studies were selected if they used an ambulatory impedance monitor to examine one or more of the following cardiovascular responses: pre-ejection period (PEP), left ventricular ejection time (LVET), stroke volume (SV), or a combination of these.

RESULTS:

Studies have been predominantly descriptive and have been focused on a young, male population with a normal body mass index (BMI; 25-29 kg/m). Inconsistencies in determining specific markers of cardiac function (e.g., PEP and SV) across studies necessitated that results be reported by outcome for each study separately.

DISCUSSION:

Ambulatory impedance monitors are valid and reliable instruments used for the physiologic measurement of cardiac performance. Sensitivity is established utilizing within-individual measurements of relative change. This is especially important in light of an aging population and technical advances in healthcare. Further research is warranted using nursing interventions that focus on an older, female population who have a BMI greater than 30 kg/m. Availability of noninvasive ambulatory measures of cardiac function has the potential to improve care for a variety of patient populations, including those with hypertension, heart failure, pain, anxiety, and depressive symptoms.

Pasipanodya, E. C.; Parrish, B. P.; Laurenceau, J. P.; Cohen, L. H.; Siegel, S. D.; Graber, E. C.; Belcher, A. J. (2012):

Social Constraints on Disclosure Predict Daily Well-Being in Couples Coping With Early-Stage Breast Cancer.

In: *J Fam.Psychol.* (0893-3200 (Linking)). DOI: 10.1037/a0028655.

Abstract:

According to the social-cognitive processing model (Lepore, 2001), social constraints on disclosure can limit an individual's ability to communicate openly with others and consequently have negative effects on psychological adjustment, especially in the context of stressful experiences such as the diagnosis and treatment of cancer. The goal of the present study was to examine the influence of social constraints on daily event sharing, individual well-being, and relationship well-being in couples coping with breast cancer. Forty-five patients recently diagnosed and treated for early stage breast cancer and their spouses reported perceptions of spousal constraints on patient disclosure and completed a 7-day electronic diary. Analyses revealed that patient-reported social constraints, independent of the spouse's report, were linked to reduced patient sharing of both cancer-related and other important daily events. Patient and spouse perceptions of social constraints, independent of their shared consensus, predicted reduced daily individual well-being indexed by self-esteem and negative affect, as well as reduced daily relationship well-being indexed by relationship happiness and intimacy. Moreover, many of the aforementioned effects on daily well-being remained after controlling for global marital quality. Overall, these findings reveal that individual perceptions of social constraints have a negative influence on both patient and spouse daily well-being outcomes. Pasyugina, Irina; Koval, Peter; Leersnyder, Jozefien; Mesquita, Batja; Kuppens, Peter (2014):

Distinguishing between level and impact of rumination as predictors of depressive symptoms: An experience sampling study.

In: *Cogn Emot*, S. 1–11. DOI: 10.1080/02699931.2014.932755.

Abstract:

Rumination-repetitively thinking about one's emotional state, its causes and consequences-exacerbates negative mood and plays an important role in the aetiology and maintenance of depression. Yet, it is unclear whether increased vulnerability to depression is associated with simply how much a person ruminates, or the short-term impact rumination has on a person's

negative mood. In the current study, we distinguish between the level versus the impact of rumination, and we examine how each uniquely predicts changes in depressive symptoms over time in an undergraduate sample. Using experience sampling, we assessed students' (N = 101) subjective experiences of positive and negative affect and their use of rumination and distraction in daily life for seven days. Participants also reported their depressive symptoms before and after the experience sampling. Increases in depressive symptoms over the week were predicted by how much people ruminated, but not by its impact on negative mood.

Patel, Kushang V.; Dansie, Elizabeth J.; Turk, Dennis C. (2013):

Impact of chronic musculoskeletal pain on objectively measured daily physical activity: a review of current findings.

In: *Pain Manag* 3 (6), S. 467–474. DOI: 10.2217/pmt.13.46.

Abstract:

SUMMARY Chronic pain affects a wide range of outcomes that are typically assessed using self-reported methodologies, which are susceptible to recall biases, current mood and pain intensity. Physical activity (PA) is an important component of the pain experience that can be objectively assessed with accelerometers, which are small, lightweight devices that measure the duration, frequency and intensity of PA over time. Accelerometry provides opportunities to compare actual and perceived PA, to design individually customized treatments, to monitor treatment progress, and to evaluate treatment efficacy. Thus, this technology can provide a more refined understanding of the relationships among symptoms, perceptions, mood, environmental circumstances and PA. The current paper examines patterns of PA in chronic musculoskeletal pain conditions and identifies potential clinical applications for accelerometry.

Physical activity and sedentary activity patterns among children and adolescents: A latent class analysis approach.

In: *J Phys Act Health* 8 (4), S. 457–467. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-09108-001&site=ehost-live.

Abstract:

Background: While much is known about the overall levels of physical activity and sedentary activity among youth, few studies have attempted to define clusters of such behaviors. The purpose of this study was to identify and describe unique classes of youth based on their participation in a variety of physical activity and sedentary behaviors. Methods: Latent class analysis was used to characterize segments of youth based on patterns of self-reported and accelerometer-measured participation in 12 behaviors. Children and adolescents (N = 720) from 6th-11th grade were included in the analysis. Differences in class membership were examined using multinomial logistic regression. Results: Three distinct classes emerged for boys and girls. Among boys, the 3 classes were characterized as “Active” (42.1%), “Sedentary” (24.9%), and “Low Media/Moderate Activity” (33.0%). For girls, classes were “Active” (18.7%), “Sedentary” (47.6%), and “Low Media/Functional Activity” (33.7%). Significant differences were found between the classes for a number of demographic indicators including the proportion in each class who were classified as overweight or obese. Conclusions: The behavioral profiles of the classes identified in this study can be used to suggest possible audience segments for intervention and to tailor strategies appropriately. Paul, David R.; Kramer, Matthew; Stote, Kim S.; Spears, Karen E.; Moshfegh, Alanna J.; Baer, David J.; Rumpler, William V. (2008):

Estimates of adherence and error analysis of physical activity data collected via accelerometry in a large study of free-living adults.

In: *BMC medical research methodology* 8 (1), S. 38.

Abstract:

Background

Activity monitors (AM) are small, electronic devices used to quantify the amount and intensity of physical activity (PA). Unfortunately, it has been demonstrated that data loss that occurs when AMs are not worn by subjects (removals during

sleeping and waking hours) tend to result in biased estimates of PA and total energy expenditure (TEE). No study has reported the degree of data loss in a large study of adults, and/or the degree to which the estimates of PA and TEE are affected. Also, no study in adults has proposed a methodology to minimize the effects of AM removals.

Methods

Adherence estimates were generated from a pool of 524 women and men that wore AMs for 13 – 15 consecutive days. To simulate the effect of data loss due to AM removal, a reference dataset was first compiled from a subset consisting of 35 highly adherent subjects (24 HR; minimum of 20 hrs/day for seven consecutive days). AM removals were then simulated during sleep and between one and ten waking hours using this 24 HR dataset. Differences in the mean values for PA and TEE between the 24 HR reference dataset and the different simulations were compared using paired t-tests and/or coefficients of variation.

Results

The estimated average adherence of the pool of 524 subjects was 15.8 ± 3.4 hrs/day for approximately 11.7 ± 2.0 days. Simulated data loss due to AM removals during sleeping hours in the 24 HR database ($n = 35$), resulted in biased estimates of PA ($p < 0.05$), but not TEE. Losing as little as one hour of data from the 24 HR dataset during waking hours results in significant biases ($p < 0.0001$) and variability (coefficients of variation between 7 and 21%) in the estimates of PA. Inserting a constant value for sleep and imputing estimates for missing data during waking hours significantly improved the estimates of PA.

Conclusion

Although estimated adherence was good, measurements of PA can be improved by relatively simple imputation of missing AM data.

Pavlickova, Hana; Turnbull, Oliver H.; Myin-Germeys, Inez; Bentall, Richard P. (2014):

The inter-relationship between mood, self-esteem and response styles in adolescent offspring of bipolar parents: An experience sampling study.

In: *Psychiatry Res. DOI:* 10.1016/j.psychres.2014.11.046.

Abstract:

The response styles theory of depression (Nolen-Hoeksema, 1991) proposes three main strategies individuals employ in response to low mood: rumination, active coping (distraction and problem-solving) and risk taking. Although recent research has suggested this theory has utility in understanding the symptoms of bipolar disorder (BD), the role of these processes in conferring vulnerability to the condition is poorly understood. Twenty-three adolescent children of patients with BD and 25 offspring of well parents completed the Experience Sampling Method (ESM; Csikszentmihalyi and Larson, 1987) diary for six days. Longitudinal analyses were carried out to examine inter-relationships between mood, self-esteem and response styles. Increased negative as well as positive mood resulted in greater rumination in both groups. Low self-esteem triggered greater risk-taking at the subsequent time point in the at-risk group, while negative affect instigated increased active coping in the control group. In both groups, engagement in risk-taking improved mood at the subsequent time point, whilst rumination dampened self-esteem. Differential longitudinal associations between mood, self-esteem and response styles between at-risk and control children suggest early psychological vulnerability in the offspring of BD parents, with important indications for early intervention.

Trigger factors and premonitory features of migraine attacks: summary of studies.

In: *Headache* 54 (10), S. 1670–1679. DOI: 10.1111/head.12468.

Abstract:

OBJECTIVE: In this second of a 2-part series, we review the available literature on trigger factors and premonitory features in migraine. BACKGROUND: In the absence of biological markers of preceding attacks of migraine, trigger factors and premonitory symptoms are valuable though methodologically challenging phenomena to study. DESIGN/METHODS: We focus on selected studies of retrospective surveys, diary studies, and clinical trials. We review the heterogeneity of selected studies and their conclusions performed to date and highlight that prospective electronic diary studies provide most reliable information that can be used for future development of preemptive therapy. CONCLUSION: We conclude that trigger factors and premonitory symptoms are very common, but that the frequency estimates vary widely based on the study approach and population. We recommend that multimodal approaches are necessary for the comprehensive study of predictive biophenotypes as determined by triggers and premonitory symptoms, including retrospective and prospective cohort studies and case-crossover studies.

A mixed methods pilot study to investigate the impact of a hospital-specific iPhone application (iTreat) within a British junior doctor cohort.

In: *Health Informatics J* 20 (1), S. 59–73. DOI: 10.1177/1460458213478812.

Abstract:

We present a pilot study to investigate the impact of introducing a hospital-specific smartphone application into a cohort of British junior doctors. We created the iPhone application 'iTreat' that contained disease management and antibiotic dosing guidelines specific to our hospital, together with a postgraduate education department really simple syndication feed, a contact number phonebook and a favourites section. This intervention was trialled in a group of 39 foundation grade junior doctors, in a UK hospital, for a time period of 4 months. Mixed methods data capture, utilising survey and semi-structured interviews, was used to evaluate application usage patterns and potential barriers to endorsement of smartphone technology in the hospital setting. Sixty eight per cent of participants felt the application saved them time during clinical activities, with a decrease in the frequency of participants not referring to hospital clinical guidelines. The findings from this pilot study point towards the internal hospital environment as having a major impact upon smartphone usage. Participants viewed smartphone use as unprofessional in the ward-based setting, with a perceived negative attitude from other healthcare staff. An understanding of how healthcare staff choose to utilise smartphones in the clinical environment is crucial to enable the successful assimilation of smartphone technology into the hospital setting. This pilot study provides experience and parameters for future substantive studies being carried out by this group.

Pe, Madeline Lee; Raes, Filip; Koval, Peter; Brans, Karen; Verduyn, Philippe; Kuppens, Peter (2013):

Interference resolution moderates the impact of rumination and reappraisal on affective experiences in daily life.

In: *Cognition and Emotion* 27 (3), S. 492–501. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-10381-010%26site%3dehost-live;madeline.pe@ppw.kuleuven.be.

Abstract:

Research has shown that cognitive control processes play a central role in emotion regulation. While most research has examined whether individual differences in such processes are related to the use of these strategies, a crucial next step involves examining whether such differences influence their impact on people's feelings, especially in normal daily life. The present study examined whether impairments in cognitive control (measured using an affective interference resolution task) moderate the impact of using rumination and reappraisal on affective experiences in everyday life (assessed using experience sampling methods). Multilevel analyses revealed that difficulties removing previously relevant negative information from working memory were associated with a larger increase in negative affect following rumination, and smaller increase and decrease in positive and negative affect, respectively, following reappraisal. These findings show that impaired interference resolution for negative information aggravates the deleterious effects of rumination and curbs the benefits of reappraisal in daily life. Smartphone Preventive Health Care: Parental Use of an Immunization Reminder System.

In: *J Pediatr.Health Care* (0891-5245 (Linking)). DOI: 10.1016/j.pedhc.2012.09.005.

Abstract:

INTRODUCTION: This study examined the feasibility of using a smartphone application recall/reminder system for immunizations given in pediatric primary care. METHOD: The study used a typical descriptive study design. A convenience sample of parents and caregivers was recruited from a primary care pediatric office in a middle-class suburban area. Participants used an Android smartphone application ("Call the Shots") that served as a reminder/recall system for vaccinations and offered an embedded tool kit to obtain reliable information about vaccines. RESULTS: A total of 262 persons accessed the application's Web site. The application was downloaded and used by 45 of those persons during the study; six persons completed the survey. DISCUSSION: Data are insufficient to fully evaluate the usefulness of the "Call the Shots" smartphone application. However, initial results and feedback have been positive, and the application should be launched in Apple's platform to reach a wider test audience

A smartphone-supported weight loss program: design of the ENGAGED randomized controlled trial.

In: *BMC Public Health* 12 (1471-2458 (Linking)), S. 1041. DOI: 10.1186/1471-2458-12-1041.

Abstract:

ABSTRACT: BACKGROUND: Obesity remains a major public health challenge, demanding cost-effective and scalable weight management programs. Delivering key treatment components via mobile technology offers a potential way to reduce expensive in-person contact, thereby lowering the cost and burden of intensive weight loss programs. The ENGAGED study is a theory-guided, randomized controlled trial designed to examine the feasibility and efficacy of an abbreviated smartphone-supported weight loss program. METHODS/DESIGN: Ninety-six obese adults (BMI 30-39.9 kg/m2) will be randomized to one of three treatment conditions: (1) standard behavioral weight loss (STND), (2) technology-supported behavioral weight loss (TECH); or (3) self-guided behavioral weight loss (SELF). All groups will aim to achieve a 7% weight loss goal by reducing calorie and fat intake and progressively increasing moderate intensity physical activity to 175 minutes/week. STND and TECH will attend 8 group sessions and receive regular coaching calls during the first 6 months of the intervention; SELF will receive the Group Lifestyle Balance Program DVD's and will not receive coaching calls. During months 1-6, TECH will use a specially designed smartphone application to monitor dietary intake, body weight, and objectively measured physical activity (obtained from a Blue-tooth enabled accelerometer). STND and SELF will self-monitor on paper diaries. Linear mixed modeling will be used to examine group differences on weight loss at months 3, 6, and 12. Self-monitoring adherence and diet and activity goal attainment will be tested as mediators. DISCUSSION: ENGAGED is an innovative weight loss intervention that integrates theory with emerging mobile technologies. We hypothesize that TECH, as compared to STND and SELF, will result in greater weight loss by virtue of improved behavioral adherence and goal achievement. TRIAL REGISTRATION: NCT01051713

Persaud, Navindra (2008):

How can I tell how I think till I see what I say?

In: *Conscious Cogn* 17 (4), S. 1375; discussion 1376-7. DOI: 10.1016/j.concog.2008.05.005.

Abstract:

Descriptive Experience Sampling is a clever method for determining the form of everyday thoughts. Results using this method show that people report that some of their thoughts are unsymbolic. Here I ask three questions: (1) Does this merely show that people know what they are thinking about but not what they are thinking? (2) Why do people have difficulty determining the form of their thoughts? (3) How does the act of reporting the form of thoughts affect the recall of those thoughts?

Peter, P.; Martin, U.; Sharma, A.; Dunne, F. (2006):

Effect of treatment with nebivolol on parameters of oxidative stress in type 2 diabetics with mild to moderate hypertension.

In: *Journal of clinical pharmacy and therapeutics* 31 (2), S. 153–159. DOI: 10.1111/j.1365-2710.2006.00718.x.

Abstract:

AIM\r\nThe aim of this study was to examine the effect of the cadioselective B(1)-adrenoceptor blocker nebivolol on glycaemic control, lipid profile and markers of oxidative stress in patients with type 2 diabetes over a 6-month period.\r\nMETHODS\r\nTwenty-six patients with mild to moderate hypertension (140-160 mmHg systolic, 90-105 mmHg diastolic) confirmed on 24-h blood pressure monitoring, were treated with nebivolol 5 mg daily for 6 months. Total serum cholesterol, triglycerides, high-density lipoprotein (HDL) cholesterol and low-density lipoprotein (LDL) subfractions, lipid hydroperoxides (LHPs) and total antioxidant capacity (TAC) were measured before and after 6 months of treatment.\r\nRESULTS\r\nNebivolol, as expected, reduced mean daytime systolic and diastolic pressures on ambulatory monitoring (149 +/- 9 to 140 +/- 13 mmHg, P = 0.02 and 84 +/- 7 to 77 +/- 9 mmHg, P < 0.001). There were no significant changes in serum cholesterol or triglycerides following treatment but a significant increase in HDL cholesterol was noted (1.12 +/- 0.19 to 1.25 +/- 0.36 mmol/L, P = 0.008). Patients showed a highly significant reduction in TAC from 501 +/- 57 to 422 +/- 29 trolox equivalent (P < 0.001). Baseline LHPs were very high and showed no significant change over the 6-month period (18.7 +/- 7.4 and 18.7 +/- 10.9 micromol/L). The LDL score increased significantly from 1.7 +/- 0.7 to 2.3 +/- 0.7 (P = 0.0002) at 6 months suggesting a change to a more atherogenic lipid profile. Neither weight nor glycaemic control changed during treatment.\r\nCONCLUSION\r\nNebivolol appears to be lipid neutral and may even have a positive effect on HDL cholesterol. Despite this it may promote the formation of potentially atherogenic LDL subfractions possibly as a result of reduced antioxidant defences. Further studies are needed to clarify the changes observed in parameters of oxidative stress.

Peters, Madelon L.; Crombez, Geert (2007):

Assessment of attention to pain using handheld computer diaries.

In: *Pain Medicine* 8 (s3), S. S110-S120.

Abstract:

Electronic diary assessment of pain and disability has become increasingly popular in adult chronic pain research but use of this methodology with children has received limited attention. The aim of this study was to compare two formats of a prospective daily diary (handheld computer=e-diary; paper diary=p-diary) on children's compliance, accuracy, and acceptability ratings. Sixty children, ages 8-16 (M=12.3) with headaches or juvenile idiopathic arthritis, were randomized to receive either e-diaries administered via home visits (n=30) or p-diaries (n=30) handed out during clinic visits for return by mail. Results demonstrated significant mean differences in diary entries completed between groups, with children with e-diaries completing more days (M=6.6) compared to children with p-diaries (M=3.8), P<0.001. Diaries returned by children in the p-diary group contained significantly more errors and omissions compared to diaries returned by children in the e-diary group (which contained none), P<0.001. Children rated both diary formats as highly acceptable and easy to use. A significant gender x diary format interaction (P<0.01) was found for compliance where boys demonstrated greater compliance with the e-diary format. Findings demonstrated that the e-diary was feasible to use with children and showed significantly greater compliance and accuracy in diary recording compared to traditional paper diaries in a population of children with recurrent pain.

Peters, E.; Lataster, T.; Greenwood, K.; Kuipers, E.; Scott, J.; Williams, S. et al. (2012):

Appraisals, psychotic symptoms and affect in daily life.

In: *Psychol.Med.* 42 (5), S. 1013–1023. DOI: 10.1017/S0033291711001802.

Abstract:

BACKGROUND: Psychological models of psychosis were examined using Experience Sampling Methods (ESM) to explore relationships between dimensions and appraisals of key symptoms and affect. METHOD: Individuals were signalled to complete ESM booklets 10 times per day for six consecutive days; 534 data points were obtained from 12 out-patients with psychosis. RESULTS: Although only 3.6% of spontaneous thoughts were psychosis related, these predicted more negative and less positive affect. Delusions and hallucinations, when present, were rated at a moderate level of intensity, and intensity was associated with distress, interference and preoccupation. Symptom dimensions were related to each other, with weaker associations with delusional conviction, which, it is hypothesized, may represent a separate factor. Conviction and appraisals relating to insight and decentring ('my problems are something to do with the way my mind works') were highly variable. Decentring appraisals of delusions, but not insight, were associated with less distress. Appraisals about the power of voices were strong predictors of negative affect and symptom distress. CONCLUSIONS: This study demonstrates that ESM is a useful methodology to capture 'online' variability in psychotic phenomenology and provides evidence supporting cognitive models, which posit that psychotic symptoms are multi-dimensional phenomena, shaped by appraisals that, in turn, predict their emotional and behavioural sequelae

Peterson, Kristina M. (2012):

An ecological momentary investigation of spousal interactions and affect in couples with Chronic Low Back Pain.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (12-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99120-039&site=ehost-live.

Abstract:

Supportive relationships enhance mood and patient adjustment (Stanton, Revenson, & Tennen, 2007). However, unsupportive or critical relationships lead to relapse and poor outcomes in both mental and physical disorders (Wearden et al., 2000). The converse is also true. Patient adjustment, specifically patient mood, influences the amount of support or criticism given by spouses (Gotlib & Beach, 1995; Revenson, 1994). Both spouses in couples with Chronic Low Back Pain (CLBP) have higher than average rates of depression (Schwartz & Ehde, 2000) and marital discord (Leonard, Cano, & Johansen, 2006). Therefore, relational models describing how depression and unsupportive behavior develop in both spouses are necessary for understanding problems that these couples face. We examined bidirectional relationships between spousal affect and behavior in a sample of 105 married couples with one spouse experiencing CLBP. Ecological momentary assessment (EMA; Shiffman, Stone, & Hufford, 2008) with electronic diaries was used to obtain reports of patient and spouse affect as well as criticism and support for five times a day over 2 weeks. Hierarchical linear modeling was used to investigate both concurrent and lagged associations between behavior (criticism and support) and depressed affect. As hypothesized, both within- and cross-spouse

associations between criticism and depressed affect were significant when both criticism and depressed affect were measured at the same time point. Contrary to expectations, only some within- and cross-spouse associations between support and depressed affect were significant at the same time point. Results from lagged models of criticism and depressed affect suggested that there are bidirectional relationships between spouse criticism and spouse depressed affect; as well, they highlighted the role of spouse depressed affect in predicting patient criticism. Lagged models of support were similar to those for criticism. These results highlight the implications of being critical and providing support as well as the role of spouse affect in generating marital conflict. Results also call for the importance of expanding theory and interventions to address not only patient affect but also spouse depressed affect as it may be a stress generating vehicle leading to both spouse and patient criticism and support.

Peterson, M. S.; Lawman, H. G.; Wilson, D. K.; Fairchild, A.; van Horn, M. L. (2012):

The Association of Self-Efficacy and Parent Social Support on Physical Activity in Male and Female Adolescents.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0029129.

Abstract:

Objective: Previous research has shown that cognitive factors may account for the relationship between interpersonal factors and health behaviors. Given these findings, the current study sought to further explore the direct and indirect relationship between parental social support and adolescent physical activity (PA). Method: Data were collected from 1,421 sixth graders (73% Black, 54% females, 71% on free or reduced lunch) in South Carolina. Measures for emotional social support, instrumental social support, and adolescent self-efficacy (SE) were assessed and PA was assessed via accelerometry. Results: Parent instrumental social support was directly related to girls' PA and parent emotional social support was inversely related to girls' PA. Parent instrumental social support was indirectly related to boys' PA through boys' SE. The covaried association of SE with PA was significant for boys and marginal for girls. Conclusions: SE for overcoming barriers may be an important construct for understanding the relationship between parent instrumental social support and boys' PA in underserved populations. The mechanisms for engaging in PA may be different for adolescent girls and boys.

Petrini, P.; Rylander, C. (2009):

Clinical safety surveillance study of the safety and efficacy of long-term home treatment with ReFacto® utilizing a computer-aided diary: a Nordic multicentre study.

In: *Haemophilia* 15 (1), S. 175–183.

Abstract:

A Nordic multicentre, open-label, non-interventional postmarketing surveillance study was carried out during a period of 24 months evaluating safety and efficacy of ReFacto as prophylactic or on-demand replacement therapy in patients with haemophilia A treated by self-medication. Fifty-seven patients were enrolled and studied for safety; efficacy was evaluated in 39 patients who received ReFacto for 24 months and recorded sufficient diary data on a hand-held computer. The compliance of using the device was good in small children, variable in adults and poor in teenagers. The fact that the overall compliance was low constituted a limitation of the number of patients with reliable diary data. Overall safety was rated as excellent or good by the clinicians for all patients at all visits and overall efficacy at 24 months evaluated to be excellent (74%) or good (26%). It was noticed that >/=50% of patients/parents reported no absences from school or work owing to bleeding episodes during the study period. Among patients on regular prophylaxis, 6 of the 30 patients (20%) receiving ReFacto experienced no bleeding episodes. A median of four bleeding episodes occurred during the 24-month study period, and 93% of the episodes were resolved with </=2 ReFacto infusions. In the 7 on-demand patients, there was a median of 18 bleeding episodes, 87% of which resolved with </=2 ReFacto infusions. Interestingly, 42% of the ReFacto infusions taken by the patients classified to the on-demand group were registered as prophylactic treatment. In conclusion, ReFacto demonstrated good safety and efficacy in prophylaxis as well as treatment of bleeding episodes.

Multiplexed homogeneous assays of proteolytic activity using a smartphone and quantum dots.

In: *Anal Chem* 86 (6), S. 3195–3202. DOI: 10.1021/ac500131r.

Abstract:

Semiconductor quantum dot (QD) bioconjugates, with their unique and highly advantageous physicochemical and optical properties, have been extensively utilized as probes for bioanalysis and continue to generate widespread interest for these applications. An important consideration for expanding the utility of QDs and making their use routine is to make assays with QDs more accessible for laboratories that do not specialize in nanomaterials. Here, we show that digital color imaging of QD photoluminescence (PL) with a smartphone camera is a viable, easily accessible readout platform for quantitative, multiplexed, and real-time bioanalyses. Red-, green-, and blue-emitting CdSeS/ZnS QDs were conjugated with peptides that were labeled with a deep-red fluorescent dye, Alexa Fluor 647, and the dark quenchers, QSY9 and QSY35, respectively, to generate Forster resonance energy transfer (FRET) pairs sensitive to proteolytic activity. Changes in QD PL caused by the activity of picomolar to nanomolar concentrations of protease were detected as changes in the red-green-blue (RGB) channel intensities in digital color images. Importantly, measurements of replicate samples made with smartphone imaging and a sophisticated fluorescence plate reader yielded the same quantitative results, including initial proteolytic rates and specificity constants. Homogeneous two-plex and three-plex assays for the activity of trypsin, chymotrypsin, and enterokinase were demonstrated with RGB imaging. Given the ubiquity of smartphones, this work largely removes any instrumental impediments to the adoption of QDs as routine tools for bioanalysis in research laboratories and is a critical step toward the use of QDs for point-of-care diagnostics. This work also adds to the growing utility of smartphones in analytical methods by enabling multiplexed fluorimetric assays within a single sample volume and across multiple samples in parallel.

Pfaltz, Monique C.; Grossman, Paul; Michael, Tanja; Margraf, Jürgen; Wilhelm, Frank H. (2010):

Physical activity and respiratory behavior in daily life of patients with panic disorder and healthy controls.

In: *International journal of psychophysiology : official journal of the International Organization of Psychophysiology* 78 (1), S. 42–49. DOI: 10.1016/j.ijpsycho.2010.05.001.

Abstract:

Panic disorder (PD) has been linked in laboratory investigations to respiratory alterations, particularly persistent respiratory variability. However, studies of PD respiratory pattern outside the laboratory are rare, have not controlled for the confounding influence of varying levels of physical activity, and have not addressed whether abnormalities in respiratory pattern vary depending on the intensity of physical activity. Cognitive and biological theories of PD, in fact, predict that respiratory alterations may be particularly pronounced when patients are physically active. This study assessed physical activity and respiratory pattern of 26 PD patients and 26 healthy controls (HC) during two waking periods of daily life (9:00-21:00) one week apart. Respiratory data were stratified for predefined levels of physical activity (inactivity, minimal movement, slow/moderate/fast walking, and running) and analyzed using linear mixed models. Groups did not generally differ in respiratory measures, although PD patients did show elevated variability of absolute levels of tidal volume during minimal movement and slow walking (root mean squared successive differences). Other ways of analyzing tidal volume variability based on relative levels, percentage of sighing, or pooled activity levels did not substantiate this finding. Amount of time spent at different activity levels did not differ between groups, which is at variance with studies linking anticipatory anxiety with motoric agitation, and PD with self-reported avoidance of exercise. In conclusion, results provided little evidence for respiratory abnormalities or central respiratory dysregulation in PD at varying levels of activity, although instability of tidal volume regulation during low activity remains a possibility. Our research approach indicates the usefulness of stratification of real life data on the basis of levels of activity, as well as how ambulatory assessment strategies, complementarily to laboratory studies, may improve understanding of biological and psychological factors contributing to development and maintenance of PD and other anxiety disorders.

Pfaltz, Monique C.; Michael, Tanja; Grossman, Paul; Blechert, Jens; Wilhelm, Frank H. (2009):

Respiratory pathophysiology of panic disorder: an ambulatory monitoring study.

In: *Psychosomatic Medicine* 71 (8), S. 869–876. DOI: 10.1097/PSY.0b013e3181b492ff.

Abstract:

OBJECTIVE\r\nTo assess the external validity of laboratory baselines in panic disorder (PD), frequently associated with respiratory pattern abnormalities like increased respiratory variability and sighing, implying a stable pathophysiologic trait

characteristic.\r\nMETHODS\r\nPhysical activity and a variety of breath-by-breath volumetric, timing, and variability measures of respiration were recorded in the daily life of 26 patients with PD and 26 healthy controls (HC), using a novel ambulatory monitoring system optimized for reliable assessment of respiratory pattern. Data were stratified for physical activity to eliminate its confounding effects.\r\nRESULTS\r\nGroups showed strong and consistent diurnal patterns in almost all respiratory variables. However, patients with PD did not differ from HC regarding any of the respiratory timing, volumetric and variability measures, with negligible group effect sizes for all measures. Patients with fewer self-reported respiratory symptoms of anxiety exhibited more pronounced rapid shallow breathing as well as diminished total breath time and its variability.\r\nCONCLUSIONS\r\nDespite state-of-the-art ambulatory assessment and sufficient statistical power to detect respiratory alterations previously observed in the laboratory, we found no evidence for such alterations in PD patients' daily life. Neither the total PD group nor patients with particularly pronounced respiratory symptomatology displayed increased respiratory variability. These results caution against interpreting results from laboratory baselines in PD as reflecting a stable trait characteristic. Rather, they likely represent a state-trait interaction due to enhanced reactivity of PD patients to novel environments. These results challenge aspects of respiratory theories of PD that were based on laboratory findings.

Pfaltz, Monique C.; Michael, Tanja; Grossman, Paul; Margraf, Jürgen; Wilhelm, Frank H. (2010):

Instability of physical anxiety symptoms in daily life of patients with panic disorder and patients with posttraumatic stress disorder.

In: *J Anxiety Disord* 24 (7), S. 792–798. DOI: 10.1016/j.janxdis.2010.06.001.

Abstract:

The present study examined severity as well as degree and temporal pattern of instability of DSM-IV-based bodily symptoms of anxiety (BSA) in daily life of 26 panic disorder (PD) patients, 17 posttraumatic stress disorder (PTSD) patients, and 28 healthy controls (HC) during 1 week, using electronic diaries. The ecological momentary assessment around every 3h during wake times was accepted well by patients. Compared to HC, patient groups exhibited elevated instability of BSA. BSA instability was more pronounced in PTSD than PD ($p<0.005$), even after controlling for mean symptom level. Numbers of symptomatic episodes were comparable in PTSD and PD, but the duration of symptom-free episodes was shorter in PTSD than PD. Results indicate that PTSD patients are particularly burdened by fluctuations in somatic symptoms of anxiety, implying perceived unpredictability and uncontrollability. Electronic diaries can be applied in innovative ways to provide novel insights into the phenomenology of anxiety disorders that may not be captured well by retrospective interviews and questionnaires.

Phd, S. K.; Flowers, S. R.; Strotman, D.; Sil, S.; Ting, T. V.; Schikler, K. N. (2012):

Physical activity monitoring in adolescents with juvenile fibromyalgia: Findings from a clinical trial of cognitive behavioral therapy.

In: *Arthritis Care Res (Hoboken.)* (2151-464X (Linking)). DOI: 10.1002/acr.21849.

Abstract:

Juvenile fibromyalgia (JFM) is a chronic musculoskeletal pain condition that is associated with reduced physical function. Recent research has demonstrated that cognitive-behavioral therapy (CBT) is effective in improving daily functioning among adolescents with JFM. However, it is not known whether these improvements were accompanied by increased physical activity levels. Objectives: To analyze secondary data from a randomized clinical trial of CBT to examine if CBT was associated with improvement in objectively measured physical activity and whether actigraphy indices corresponded with self-reported functioning among adolescents with JFM. Methods: Participants were 114 adolescents (ages 11-18) recruited from pediatric rheumatology clinics that met criteria for JFM and were enrolled in a clinical trial. Subjects were randomly (1:1) assigned to receive either CBT or fibromyalgia education (FE). Participants wore a hip-mounted accelerometer for one week as part of their baseline and post-treatment assessments. Results: The final sample included 68 subjects (94% female; mean age = 15.2 years) for whom complete actigraphy data was obtained. Actigraphy measures were not found to correspond with self-reported improvements in functioning. While self-reported functioning improved in the CBT condition compared to FE, no significant changes were seen in either group for activity counts, sedentary, moderate or vigorous activity. The CBT group had significantly lower peak and light activity at post-treatment. Conclusions: Actigraphy monitoring provides a unique source of information about patient outcomes. CBT intervention was not associated with increased physical activity in adolescents with JFM indicating that combining CBT with interventions to increase physical activity may enhance treatment effects. Phelan, Suzanne; Roberts, Marta; Lang, Wei; Wing, Rena R. (2007):

Empirical evaluation of physical activity recommendations for weight control in women.

In: *Med Sci Sports Exerc* 39 (10), S. 1832.

Abstract:

PURPOSE:

Recent recommendations advise 30-60 min of physical activity per day to prevent weight gain and 60-90 min to prevent weight regain. No studies have used objective measures of physical activity to verify these public health recommendations. The purpose of this study was to use objective measures to quantify the amount and intensity of physical activity in a weight-loss-maintainer group and an always-normal-weight group, and, thus,empirically evaluate the recommendations for prevention of weight gain versus regain.

METHODS:

The weight-loss-maintainer group (N = 135) lost >or= 30.6 kg, maintained >or= 10% weight loss for 14.2 yr, and had a BMI of 22.0 kg.m(-2). The always-normal-weight group (N = 102) had a BMI of 21.1 kg.m(-2) and no history of overweight. Accelerometry was used to assess the amount and intensity of physical activity.

RESULTS:

The weight-loss-maintainer group spent significantly more minutes per day than the always-normal-weight group in physical activity (58.6 vs 52.1; P = 0.0001), largely because of more time spent in higher-intensity activities (24.4 vs 16.9; P = 0.02). The majority of individuals in the always-normal-weight group engaged in 30-60 min.d(-1) of physical activity, whereas a greater proportion of individuals in the weight-loss-maintainer group engaged in > 60 min (P = 0.002).

CONCLUSIONS:

Findings support current recommendations that more activity may be needed to prevent weight regain than to prevent weight gain. Including some higher-intensity activity may also be advisable for weight-loss maintenance.

Phillips, Karran A.; Epstein, David H.; Preston, Kenzie L. (2013):

Daily temporal patterns of heroin and cocaine use and craving: Relationship with business hours regardless of actual employment status.

In: *Addict Behav* 38 (10), S. 2485–2491. DOI: 10.1037/t07774-000;

Abstract:

Real-time monitoring of behavior using Ecological Momentary Assessment (EMA) has provided detailed data about daily temporal patterns of craving and use in cigarette smokers. We have collected similar data from a sample of cocaine and heroin users. Here we analyzed it in the context of its relationship with a societal construct of daily temporal organization: 9-to-5 business hours. In a 28-week prospective study, 112 methadone-maintained polydrug-abusing individuals initiated an electronic-diary entry and provided data each time they used cocaine, heroin, or both during weeks 4 to 28. EMA data were collected for 10,781 person-days and included: 663 cocaine-craving events, 710 cocaine-use events, 288 heroin-craving events, 66 heroin-use events, 630 craving-both-drugs events, and 282 use-of-both-drugs events. At baseline, 34% of the participants reported full-time employment in the preceding 3-year period. Most participants' current employment status fluctuated throughout the study. In a generalized linear mixed model (SAS Proc Glimmix), cocaine use varied by time of day relative to business hours ($p < 0.0001$) and there was a significant interaction between Day of the Week and Time Relative to Business Hours ($p < 0.002$) regardless of current work status. Cocaine craving also varied by time of day relative to business hours ($p < 0.0001$), however, there was no significant interaction between Day of the Week and Time Relative to Business Hours ($p = .57$). Heroin craving and use were mostly reported during business hours, but data were sparse. Cocaine craving is most frequent during business hours while cocaine use is more frequent after business hours. Cocaine use during business hours, but not craving, seems suppressed on most weekdays, but not weekends, suggesting that societal conventions reflected in business hours influence drug-use patterns even in individuals whose daily schedules are not necessarily dictated by employment during conventional business hours. Phillips, K. A.; Epstein, D. H.; Mezghanni, M.; Vahabzadeh, M.; Reamer, D.; Agage, D.; Preston, K. L. (2013):

Smartphone Delivery of Mobile HIV Risk Reduction Education.

In: *AIDS Res.Treat.* 2013 (2090-1240 (Linking)), S. 231956. DOI: 10.1155/2013/231956.

Abstract:

We sought to develop and deploy a video-based smartphone-delivered mobile HIV Risk Reduction (mHIVRR) intervention to individuals in an addiction treatment clinic. We developed 3 video modules that consisted of a 10-minute HIVRR video, 11 acceptability questions, and 3 knowledge questions and deployed them as a secondary study within a larger study of ecological momentary and geographical momentary assessments. All 24 individuals who remained in the main study long enough completed the mHIVRR secondary study. All 3 videos met our a priori criteria for acceptability "as is" in the population: they achieved median scores of </=2.5 on a 5-point Likert scale; </=20% of the individuals gave them the most negative rating on the scale; a majority of the individuals stated that they would not prefer other formats over video-based smartphone-delivered one (all P < 0.05). Additionally, all of our video modules met our a priori criteria for feasibility: </=20% of data were missing due to participant noncompliance and </=20% were missing due to technical failure. We concluded that video-based mHIVRR education delivered via smartphone is acceptable, feasible and may increase HIV/STD risk reduction knowledge. Future studies, with pre-intervention assessments of knowledge and random assignment, are needed to confirm these findings

Substance use and hepatitis C: an ecological momentary assessment study.

In: *Health Psychol* 33 (7), S. 710–719. DOI: 10.1037/hea0000087.

Abstract:

OBJECTIVE: The objective of this study was to assess craving and mood related to opioid and cocaine use among asymptomatic hepatitis C virus (HCV)+ and HCV- methadone patients who have not started antiviral treatment. METHODS: In this 28-week prospective ecological momentary assessment (EMA) study, 114 methadone-maintained, heroin- and cocaine-abusing individuals reported from the field in real time on their mood, craving, exposure to drug-use triggers, and drug use via handheld computers. RESULTS: Sixty-one percent were HCV+; none were overtly symptomatic or receiving HCV treatment. HCV status was not associated with age, sex, race, or past-30-day or lifetime heroin or cocaine use. In event-contingent EMA entries, HCV+ individuals more often attributed use to having been bored, worried, or sad; feeling uncomfortable; or others being critical of them compared with HCV- participants. In randomly prompted EMA entries, HCV+ participants reported significantly more exposure to drug-use triggers, including handling >/=$10, seeing cocaine or heroin, seeing someone being offered/use cocaine or heroin, being tempted to use cocaine, and wanting to see what would happen if they used just a little cocaine or heroin. CONCLUSIONS: HCV+ individuals experienced more negative moods and more often cited these negative moods as causes for drug use. HCV+ individuals reported greater exposure to environmental drug-use triggers, but they did not more frequently cite these as causes for drug use. The EMA data reported here suggest that HCV+ intravenous drug users may experience more labile mood and more reactivity to mood than HCV- intravenous drug users. The reason for the difference is not clear, but HCV status may be relevant to tailoring of treatment.

Feasibility of text messaging for ecological momentary assessment of marijuana use in college students.

In: *Psychol Assess. DOI:* 10.1037/a0036612.

Abstract:

Measuring self-reported substance use behavior is challenging due to issues related to memory recall and patterns of bias in estimating behavior. Limited research has focused on the use of ecological momentary assessment (EMA) to evaluate marijuana use. This study assessed the feasibility of using short message service (SMS) texting as a method of EMA with college-age marijuana users. Our goals were to evaluate overall response/compliance rates and trends of data missingness, response time, baseline measures (e.g., problematic use) associated with compliance rates and response times, and differences between EMA responses of marijuana use compared to timeline followback (TLFB) recall. Nine questions were texted to participants on their personal cell phones 3 times a day over a 2-week period. Overall response rate was high (89%). When examining predictors of the probability of data missingness with a hierarchical logistic regression model, we found evidence of a higher propensity for missingness for Week 2 of the study compared to Week 1. Self-regulated learning was significantly associated with an increase in mean response time. A model fit at the participant level to explore response time found that more time spent smoking marijuana related to higher response times, while more time spent studying and greater "in the moment" academic motivation and craving were associated with lower response times. Significant differences were found between the TLFB and EMA, with greater reports of marijuana use reported through EMA. Overall, results support the feasibility of using SMS text messaging as an EMA method for college-age marijuana users. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Low sensitivity to alcohol: relations with hangover occurrence and susceptibility in an ecological momentary assessment investigation.

In: *J Stud.Alcohol Drugs* 73 (6), S. 925–932. Online verfügbar unter PM:23036210.

Abstract:

OBJECTIVE: The current investigation tested whether low sensitivity to alcohol, as measured by the Self-Rating of the Effects of Alcohol (SRE) form, is associated with hangover occurrence or resistance, two potentially important predictors of later problematic drinking outcomes. METHOD: Drinkers who reported using alcohol at least four times in the past month (N = 402) completed the SRE at baseline and used ecological momentary assessment methods with an electronic diary to record drinking behaviors and related experiences over 21 days. Each morning, the diary assessed prior-night drinking behaviors and the presence of current hangover. RESULTS: After adjustments for sex, body weight, age, and smoking status, higher SRE scores (indicating lower alcohol sensitivity) predicted hangover occurrence on postdrinking mornings (odds ratio [OR] = 1.24 per interquartile range [IQR], p = .003). However, when the number of drinks consumed in the drinking episode was covaried, SRE scores were negatively associated with hangover (OR = 0.67 per IQR, p <.001). An interaction between SRE scores and the number of drinks consumed indicated that low-sensitivity drinkers tend to be differentially resistant to hangover at a given number of drinks. Higher SRE scores were associated with consuming more drinks on average (generalized estimating equations coefficient = 2.20 per IQR, p <.001). CONCLUSIONS: Individuals lower in alcohol sensitivity appear to be more resistant to hangovers per unit of alcohol. However, they are also more likely to engage in excessive drinking, and this may account for their increased odds of experiencing hangover during an arbitrary monitoring period. Heavy consumption, hangover resistance, and hangover frequency may each be manifestations of low sensitivity to alcohol, an established risk factor for alcohol use disorder

Piasecki, Thomas M.; Cooper, M. Lynne; Wood, Phillip K.; Sher, Kenneth J.; Shiffman, Saul; Heath, Andrew C. (2013):

Dispositional Drinking Motives: Associations With Appraised Alcohol Effects and Alcohol Consumption in an Ecological Momentary Assessment Investigation.

In: *Psychological Assessment*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-41148-001%26site%3dehost-live.

Abstract:

Alcohol use can be understood as a strategic behavior, such that people choose to drink based on the anticipated affective changes produced by drinking relative to those produced by alternative behaviors. This study investigated whether people who report drinking for specific reasons via the Drinking Motives Questionnaire–Revised (DMQ-R; Cooper, 1994) actually experience the alcohol effects they purportedly seek. As a secondary goal, we examined relations between drinking motives and indices of the amount of alcohol consumed. Data were drawn from 3,272 drinking episodes logged by 393 community-recruited drinkers during a 21-day Ecological Momentary Assessment investigation. After accounting for selected covariates, DMQ-R enhancement motives uniquely predicted real-time reports of enhanced drinking pleasure. DMQ-R coping motives were associated with reports of increased drinking-contingent relief and punishment. Enhancement motives uniquely predicted consuming more drinks per episode and higher peak intra-episode estimated blood alcohol concentration. The findings extend the evidence for the validity of the DMQ-R motive scores by demonstrating that internal drinking motives (enhancement and coping) are related to the experienced outcomes of drinking in the manner anticipated by theory. Piasecki, Thomas M.; Jahng, Seungmin; Wood, Phillip K.; Robertson, Brandon M.; Epler, Amee J.; Cronk, Nikole J. et al. (2011):

The subjective effects of alcohol–tobacco co-use: An ecological momentary assessment investigation.

In: *Journal of Abnormal Psychology* 120 (3), S. 557.

Abstract:

Alcohol and tobacco use covary at multiple levels of analysis, and co-use of the 2 substances may have profound health consequences. To characterize the motivationally relevant processes contributing to co-use, the current study used ecological momentary assessment (EMA) to examine the subjective consequences of naturally occurring simultaneous use of alcohol and tobacco. Current smokers who reported frequently drinking alcohol (N=259) used electronic diaries to monitor their daily experiences for 21 days. Participants responded to prompted assessments and also initiated recordings when they smoked a

cigarette or completed the first drink in a drinking episode. Momentary reports of smoking and alcohol consumption were associated with one another, and these effects remained after adjustment for occasion- and person-level covariates. When participants consumed alcohol, they reported increased pleasure and decreased punishment from the last cigarette. Smoking was associated with small increases in pleasure from the last drink. Ratings of buzzed and dizzy were synergistically affected by co-use of alcohol and tobacco. Co-use was also followed by higher levels of craving for both alcohol and tobacco. Results point to the importance of reward and incentive processes in ongoing drug use and suggest that alcohol intensifies real-time reports of the motivational consequences of smoking more strongly than smoking affects corresponding appraisals of alcohol effects.

Piasecki, Thomas M.; McCarthy, Danielle E.; Fiore, Michael C.; Baker, Timothy B. (2008):

Alcohol consumption, smoking urge, and the reinforcing effects of cigarettes: an ecological study.

In: *Psychology of Addictive Behaviors* 22 (2), S. 230.

Abstract:

Smokers (N=74) who volunteered for a smoking cessation study monitored their daily experiences for up to 6 weeks prior to the quit date. Self-reports from 7,707 diary records were used to examine the associations among alcohol consumption (present in 607 diary records), situational factors, smoking, urge to smoke, and subjective consequences of smoking. Alcohol use, smoking urge, and the subjective effects of smoking were context dependent. Momentary reports of smoking and alcohol consumption were associated with one another. Alcohol use predicted smoking even when contextual factors were covaried. Alcohol use was associated with more frequent reports of urge to smoke. Alcohol was also associated with more frequent reports that the last cigarette produced a rush/buzz, was good tasting, and reduced the urge. However, effects for rush/buzz and urge reduction were qualified by interactions between alcohol use and the latency since smoking. Rush/buzz tended to be associated with alcohol use, regardless of smoking recency. Alcohol was associated with urge reduction only when the cigarette being appraised was smoked more than 15 minutes prior to the diary entry.

Piasecki, Thomas M.; Richardson, Alison E.; Smith, Shawn M. (2007):

Self-monitored motives for smoking among college students.

In: *Psychology of Addictive Behaviors* 21 (3), S. 328.

Abstract:

College student smokers (N = 50) were asked to carry electronic diaries for 14 days and record smoking events (n = 1,139). They indicated why they were smoking each cigarette on a checklist of potential motives. Results suggest that a desire to reduce craving (62.8% of occasions) and habit/automatic processes (42.8%) were the most frequent motives. More dependent and daily smokers were especially likely to endorse smoking to reduce craving and for habit/automatic reasons and were less likely to cite coping with negative emotion as a reason for smoking. Dependent and daily smokers were more likely to endorse at least 1 dependence-like motive and were less likely to exclusively attribute smoking to nondependence motives. Self-monitored motives appeared valid, according with conceptually related states, activities, and events in the diary records. Diary-recorded motives were compared with smokers' responses to a retrospective motives questionnaire administered at baseline. The 2 assessment modes produced discrepant estimates of the most influential motivational processes. Questionnaire responses incompletely forecast conceptually similar diary-reported motives. Dependence and daily smoking showed a different pattern of associations with diary-based versus retrospective motives measures.

Frequency and correlates of diary-measured hangoverlike experiences in a college sample.

In: *Psychol Addict Behav* 24 (1), S. 163–169. DOI: 10.1037/a0017148.

Abstract:

A sample of college students, oversampled for smoking (N = 127, 43% smokers), monitored their daily experiences using electronic diaries over 14 days. We examined the frequency and correlates of liberally defined hangoverlike experiences (HLEs) using data from 1,595 person-days (1,325 after abstention from drinking and 270 after drinking, including 125 HLEs). More than 40% of the sample reported at least one HLE, and nearly half of all drinking episodes were followed by HLE. Endorsement of HLE

was more likely as the number of drinks increased and was associated with modest elevations of hangover symptoms. Gender did not predict rates of overall HLE endorsement, but male students were less likely than female students to report an HLE after a drinking episode and showed a weaker relation between number of drinks and HLE. Smokers were more likely to report HLE, but there was no evidence that smoking status was associated with increased HLE susceptibility. Self-reported parental alcohol problems were associated with more frequent HLE and incrementally predicted HLE endorsement when number of drinks was covaried. The findings suggest that HLE is a common outcome of college drinking and attest to the feasibility of using electronic diaries to assess its episode- and person-level correlates.

Smoking Antecedents: Separating Between- and Within-Person Effects of Tobacco Dependence in a Multiwave Ecological Momentary Assessment Investigation of Adolescent Smoking.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt132.

Abstract:

INTRODUCTION: Ecological momentary assessment (EMA) investigations have shown that the antecedents of smoking vary with individual differences in tobacco dependence. This has been interpreted as indicating that the transition to dependence is characterized by an erosion of external stimulus control over smoking. Rigorously testing this requires collecting multiple waves of EMA data, permitting separation of the influence of between- and within-person tobacco dependence variation in multilevel models. METHODS: Adolescents (n = 313, 9th or 10th grade at baseline) participated in up to four waves of week-long EMA assessment over the course of 2 years as part of a larger longitudinal, observational study. At each wave, participants recorded contextual features and subjective states in response to prompted diary assessments and when smoking. They completed a youth-specific form of the Nicotine Dependence Syndrome Scale at each wave. RESULTS: In cross-sectional multilevel analyses, smoking was less contingent on alcohol/drug use and was more common at home and in the morning for adolescents at higher levels of dependence. Multiwave analyses demonstrated that these effects were largely attributable to between-person variation in dependence, although parameter estimates for intraindividual dependence x antecedent effects tended to be in the predicted direction. DISCUSSION: Findings provided partial support for the contention that the antecedents of smoking shift as an individual progresses to higher levels of dependence. Distinctive choices concerning smoking settings also appear to reflect between-person differences in propensity to dependence. More generally, the findings illustrate the value of using multilevel modeling and repeated EMA assessments to investigate the correlates of tobacco dependence at different levels of analysis

Piasecki, T. M.; Wood, P. K.; Shiffman, S.; Sher, K. J.; Heath, A. C. (2012):

Responses to alcohol and cigarette use during ecologically assessed drinking episodes.

In: *Psychopharmacology (Berl)* (0033-3158 (Linking)). DOI: 10.1007/s00213-012-2721-1.

Abstract:

RATIONALE: Tobacco and alcohol are frequently used together, and this may be partly explained by a distinct profile of subjective effects associated with co-administration. Ecological momentary assessment studies have examined effects of naturally occurring co-use, but, to date, have not assessed differing effects as alcohol levels rise and fall. OBJECTIVES: The objective of the study was to describe subjective states and appraisals of cigarette and alcohol effects reported during the entirety of real-world drinking episodes. METHODS: Currently-smoking frequent drinkers (N = 255) carried electronic diaries for 21 days. Analyses focused on reports made during 2,046 drinking episodes. Signaled prompts intensively oversampled moments in the hours following consumption of the first drink in an episode. Multilevel regression analyses were used to predict ratings of buzz, dizziness, excitement, and sluggishness as a function of person-level and contextual covariates, estimated blood alcohol concentration (eBAC) level, ascending vs. descending eBAC, smoking, and their interactions. Appraisals of cigarette and alcohol effects were also examined within this framework. RESULTS: Buzz, excitement, and pleasure from alcohol and cigarettes were prominent features of real-world drinking episodes. Smoking was associated with enhanced buzz and excitement when eBAC was high and descending. Smoking slightly accentuated the relation between eBAC and ratings of drinking pleasure among women, but this relation was somewhat weakened by smoking among men. CONCLUSIONS: Smoking during drinking episodes may be partly explained by a persistence of stimulant alcohol effects beyond the blood alcohol concentration peak. Acute effects of nicotine and tobacco use on the descending limb deserve further scrutiny in experimental alcohol challenge research

Pickering, Thomas G.; Gerin, William; Schwartz, Joseph E.; Spruill, Tanya M.; Davidson, Karina W. (2008):

Franz Volhard lecture: should doctors still measure blood pressure? The missing patients with masked hypertension.

In: *J Hypertens* 26 (12), S. 2259–2267. DOI: 10.1097/HJH.0b013e32831313c4.

Abstract:

The traditional reliance on blood pressure (BP) measurement in the medical setting misses a significant number of individuals with masked hypertension, who have normal clinic BP but persistently high daytime BP when measured out of the office. We suggest that masked hypertension may be a precursor of clinically recognized sustained hypertension and is associated with increased cardiovascular risk compared with consistent normotension. We discuss factors that may contribute to clinic-daytime BP differences as well as the changing relationship between these two measures over time. Anxiety at the time of BP measurement and having been diagnosed as hypertensive appear to be two possible mechanisms. The identification of individuals with masked hypertension is of great clinical importance and requires out-of-office BP screening. Ambulatory BP monitoring is the best established technique for doing this, but home monitoring may be applicable in the future.

Pickering, Thomas G.; Miller, Nancy Houston; Ogedegbe, Gbenga; Krakoff, Lawrence R.; Artinian, Nancy T.; Goff, David (2008):

Call to Action on Use and Reimbursement for Home Blood Pressure Monitoring A Joint Scientific Statement From the American Heart Association, American Society of Hypertension, and Preventive Cardiovascular Nurses Association.

In: *Hypertension* 52 (1), S. 10–29.

Abstract:

Home blood pressure monitoring (HBPM) overcomes many of the limitations of traditional office blood pressure (BP) measurement and is both cheaper and easier to perform than ambulatory BP monitoring. Monitors that use the oscillometric method are currently available that are accurate, reliable, easy to use, and relatively inexpensive. An increasing number of patients are using them regularly to check their BP at home, but although this has been endorsed by national and international guidelines, detailed recommendations for their use have been lacking. There is a rapidly growing literature showing that measurements taken by patients at home are often lower than readings taken in the office and closer to the average BP recorded by 24-hour ambulatory monitors, which is the BP that best predicts cardiovascular risk. Because of the larger numbers of readings that can be taken by HBPM than in the office and the elimination of the white-coat effect (the increase of BP during an office visit), home readings are more reproducible than office readings and show better correlations with measures of target organ damage. In addition, prospective studies that have used multiple home readings to express the true BP have found that home BP predicts risk better than office BP (Class IIa; Level of Evidence A). This call-to-action article makes the following recommendations: (1) It is recommended that HBPM should become a routine component of BP measurement in the majority of patients with known or suspected hypertension; (2) Patients should be advised to purchase oscillometric monitors that measure BP on the upper arm with an appropriate cuff size and that have been shown to be accurate according to standard international protocols. They should be shown how to use them by their healthcare providers; (3) Two to 3 readings should be taken while the subject is resting in the seated position, both in the morning and at night, over a period of 1 week. A total of >/=12 readings are recommended for making clinical decisions; (4) HBPM is indicated in patients with newly diagnosed or suspected hypertension, in whom it may distinguish between white-coat and sustained hypertension. If the results are equivocal, ambulatory BP monitoring may help to establish the diagnosis; (5) In patients with prehypertension, HBPM may be useful for detecting masked hypertension; (6) HBPM is recommended for evaluating the response to any type of antihypertensive treatment and may improve adherence; (7) The target HBPM goal for treatment is <135/85 mm Hg or <130/80 mm Hg in high-risk patients; (8) HBPM is useful in the elderly, in whom both BP variability and the white-coat effect are increased; (9) HBPM is of value in patients with diabetes, in whom tight BP control is of paramount importance; (10) Other populations in whom HBPM may be beneficial include pregnant women, children, and patients with kidney disease; and (11) HBPM has the potential to improve the quality of care while reducing costs and should be reimbursed.

Pieper, Suzanne; Brosschot, Jos F.; van der Leeden, Rien; Thayer, Julian F. (2007):

Cardiac effects of momentary assessed worry episodes and stressful events.

In: *Psychosomatic Medicine* 69 (9), S. 901–909.

Abstract:

OBJECTIVE:

To hypothesize that increased heart rate (HR) and decreased heart rate variability (HRV) occurs not only during stressful events but also during episodes in which stress is cognitively represented, but not necessarily present, i.e., during worry.

METHODS:

Ambulatory HR and HRV of 73 female and male teachers were recorded for 4 days, during which they reported, on an hourly basis using computerized diaries, the number and characteristics of worry episodes and stressful events. Multilevel regression models were used, controlling for biobehavioral variables.

RESULTS:

Compared with neutral periods, worry episodes and stressful events had independent effects on HR (2.00 beats/min and 2.75 beats/min, respectively) and HRV (-1.07 ms and -1.05, respectively). Neither psychological traits nor biobehavioral variables influenced these results. Effects were most pronounced for work-related worry on HR (9.16 beats/min) and HRV (-1.19 ms), and for worry about anticipated future stress on HR (4.79 beats/min).

CONCLUSIONS:

Worry in daily life might have substantial cardiac effects in addition to the effects of stressful events, especially in the form of work-related and anticipatory stress, the latter being a type of stress that has been largely neglected in stress research.

Pierdomenico, Sante D.; Cuccurullo, Franco (2011):

Prognostic value of white-coat and masked hypertension diagnosed by ambulatory monitoring in initially untreated subjects: an updated meta analysis.

In: *Am J Hypertens* 24 (1), S. 52–58.

Abstract:

BACKGROUND:

The prognostic relevance of white-coat hypertension (WCH) and masked hypertension (MH) is controversial. The aim of this study was to perform an updated meta-analysis on the prognostic value of WCH and MH diagnosed by ambulatory monitoring in initially untreated subjects.

METHODS:

We searched for articles evaluating cardiovascular outcome in WCH or MH or sustained hypertension (SH) in comparison with normotension, investigating untreated subjects at baseline or performing separate analysis for untreated or treated subjects, and reporting adjusted hazard ratio (HR) and 95% confidence interval (CI).

RESULTS:

Eight studies were identified. Five whole studies and untreated groups of three others were included in the meta-analysis. The pooled population consisted of 7,961 subjects who experienced 696 events. When compared with normotension, the overall adjusted HR was 0.96 (95% CI 0.65-1.42) for WCH (P = 0.85), 2.09 (1.55-2.81) for MH (P = 0.0001), and 2.59 (2.0-3.35) for SH (P = 0.0001). There was no significant difference between WCH and normotension according to normotensive subjects source (same or different study population) and follow-up length. Where reported, prevalence of drug therapy was higher in subjects with WCH than in those with normotension at follow-up.

CONCLUSIONS:

Cardiovascular risk is not significantly different between WCH and normotension, regardless of normotensive population type and follow-up length. However, at follow-up drug therapy was more frequent in WCH than in normotension and its possible impact on outcome should be evaluated in future studies. MH shows significantly higher risk than normotension, although the best way for its detection and treatment remains to be established.

Pierin, Angela M. G.; Ignez, Edna C.; Jacob Filho, Wilson; Barbato, Alfonso Júlio Guedes; Mion Jr, Décio (2008):

Blood pressure measurements taken by patients are similar to home and ambulatory blood pressure measurements.

In: *Clinics (Sao Paulo)* 63 (1), S. 43–50.

Abstract:

OBJECTIVE:

To compare blood pressure measurements taken at home by physicians, nurses, and patients with office blood pressure measurement , ambulatory blood pressure monitoring and home blood pressure measurement.

METHODS:

A total of 44 patients seen by a home care program were studied. Protocol 1 a) blood pressure was measured by the patient, a physician and a nurse during a regular home visit (Home1); b) home blood pressure measurement was measured for 4 days (HBPM1); c) office blood pressure measurement was measured by a physician, a nurse, and the patient; and by 24-hour ambulatory blood pressure monitoring. Protocol 2 blood pressure was measured by the patient, a physician, and a nurse during a special home visit in the presence of a physician and a nurse only (Home2); and b) home blood pressure measurement was taken for the second time (HBPM2). Echocardiography, guided by a two-dimensional echocardiograph, was performed.

RESULTS:

Protocol 1: a) office blood pressure measurement and Home1 were significantly higher than ambulatory blood pressure monitoring, except for systolic and diastolic office blood pressure measurement taken by the patient or a family member, systolic blood pressure taken by a nurse, and diastolic blood pressure taken by a physician. b) ambulatory blood pressure monitoring and HBPM1 were similar. Protocol 2: a) HBPM2 and Home2 were similar. b) Home2 was significantly lower than Home1, except for diastolic blood pressure taken by a nurse or the patient. There were significant relationships between: a) diastolic blood pressure measured by the patient and the thickness of the interventricular septum, posterior wall, and left ventricular mass; and b) ambulatory and HBPM2 diastolic and systolic blood pressure taken by a physician (home2) and left ventricular mass. Therefore, the data indicate that home blood pressure measurement and ambulatory blood pressure monitoring had good prognostic values relative to "office measurement."

CONCLUSION:

This study showed that the measurement most similar to home blood pressure measurement and ambulatory blood pressure monitoring was blood pressure measured by the patient, and that home blood pressure measurement and ambulatory blood pressure monitoring had good prognostic value relative to "office measurements".

Pieterse, Chine; Schutte, Rudolph; Schutte, Aletta E. (2014):

Autonomic activity and leptin in Africans and whites: the SABPA study.

In: *J Hypertens* 32 (4), S. 826–833. DOI: 10.1097/HJH.0000000000000110.

Abstract:

OBJECTIVES: Evidence exists that leptin enhances sympathetic activity and may thereby contribute to the development of obesity-related hypertension. Sympathetic activation also seems more prominent in Africans than whites. We compared leptin levels, and different markers of autonomic activity between Africans and whites, and determined whether a relationship exists between leptin and autonomic activity. METHODS: The study included 409 African and white school teachers (aged, 44.6 +/- 9.6 years). We determined leptin in serum and measured ambulatory blood pressure. Markers reflecting autonomic activity included renin, cortisol, baroreflex sensitivity, ambulatory heart rate and heart rate variability (HRV) components (assessed by 24-h ECG recordings in the frequency and geometric domain). RESULTS: Africans had higher leptin levels, BMI, blood pressure and heart rate (all P < 0.001) as well as lower HRV triangular index and HRV total power (P < 0.001). After also adjusting for BMI in multivariate regression analyses, in African men, renin (beta = 0.228; P = 0.033), night-time heart rate (beta = 0.184; P = 0.034), HRV triangular index (beta = -0.230; P = 0.010) and HRV total power (beta = -0.214; P = 0.046) associated with leptin. In white men, leptin associated with 24-h heart rate (beta = 0.376; P < 0.001), as well as day and night-time heart rate (both P < 0.01), HRV triangular index (beta = -0.335; P < 0.001) and HRV total power (beta = -0.403; P < 0.001). In African women, we observed an association of leptin with the total power component of HRV (beta = -0.221; P = 0.015) and a borderline association with renin (beta = 0.219; P = 0.057). No significant associations were apparent in the white women. CONCLUSION: We found that leptin is independently associated with different markers of autonomic activity, especially in men.

Piferi, Rachel L.; Lawler, Kathleen A. (2006):

Social support and ambulatory blood pressure: an examination of both receiving and giving.

In: *International journal of psychophysiology : official journal of the International Organization of Psychophysiology* 62 (2), S. 328–336. DOI: 10.1016/j.ijpsycho.2006.06.002.

Abstract:

The relationship between the social network and physical health has been studied extensively and it has consistently been shown that individuals live longer, have fewer physical symptoms of illness, and have lower blood pressure when they are a member of

a social network than when they are isolated. Much of the research has focused on the benefits of receiving social support from the network and the effects of giving to others within the network have been neglected. The goal of the present research was to systematically investigate the relationship between giving and ambulatory blood pressure. Systolic blood pressure, diastolic blood pressure, mean arterial pressure, and heart rate were recorded every 30 min during the day and every 60 min at night during a 24-h period. Linear mixed models analyses revealed that lower systolic and diastolic blood pressure and mean arterial pressure were related to giving social support. Furthermore, correlational analyses revealed that participants with a higher tendency to give social support reported greater received social support, greater self-efficacy, greater self-esteem, less depression, and less stress than participants with a lower tendency to give social support to others. Structural equation modeling was also used to test a proposed model that giving and receiving social support represent separate pathways predicting blood pressure and health. From this study, it appears that giving social support may represent a unique construct from receiving social support and may exert a unique effect on health.

Piira, Olli-Pekka; Huikuri, Heikki V.; Tulppo, Mikko P. (2011):

Effects of emotional excitement on heart rate and blood pressure dynamics in patients with coronary artery disease.

In: *Autonomic Neuroscience* 160 (1), S. 107–114.

Abstract:

The incidence of adverse cardiovascular events is higher among spectators of exciting sports events, but the mechanistic link between the events is not known. We assessed the heart rate (HR) and blood pressure (BP) dynamics of enthusiastic male ice hockey spectators (60 ± 9 years) with coronary artery disease (CAD) during Finnish national league ice hockey play-off final matches. Twenty-four-hour ambulatory ECG (n = 55) and BP (n = 17) were recorded at the time of the match and on a control day. Beat-to-beat R-R intervals and BP were recorded during the match and a bicycle exercise at equal HR levels (n = 21). Systolic and diastolic BP were significantly higher 1h before, during, and 1h after the match than on the control day, e.g., the highest systolic BP was 180 ± 14 vs. 145 ± 15 and diastolic 103 ± 13 vs. 82 ± 11 mmHg ($p<0.001$ for both). HR was higher throughout the match ($p<0.05$) and remained elevated 2h after the match ($p<0001$), and measures of HR variability were decreased during the match ($p<0.01$). Low-frequency variability in BP was higher during the match than during the exercise test ($p<0.01$). The results show that cardiac vagal outflow is attenuated and vasomotor sympathetic activity elevated during exciting sports events and BP dynamics differ from those occurring during physical exercise at equal HRs. The autonomic reactions may partly explain the vulnerability to cardiovascular events caused by this type of leisure-time emotional excitement.

Pishva, Ehsan; Drukker, Marjan; Viechtbauer, Wolfgang; Decoster, Jeroen; Collip, Dina; van Winkel, Ruud et al. (2014):

Epigenetic genes and emotional reactivity to daily life events: a multi-step gene-environment interaction study.

In: *PLoS One* 9 (6), S. e100935. DOI: 10.1371/journal.pone.0100935.

Abstract:

Recent human and animal studies suggest that epigenetic mechanisms mediate the impact of environment on development of mental disorders. Therefore, we hypothesized that polymorphisms in epigenetic-regulatory genes impact stress-induced emotional changes. A multi-step, multi-sample gene-environment interaction analysis was conducted to test whether 31 single nucleotide polymorphisms (SNPs) in epigenetic-regulatory genes, i.e. three DNA methyltransferase genes DNMT1, DNMT3A, DNMT3B, and methylenetetrahydrofolate reductase (MTHFR), moderate emotional responses to stressful and pleasant stimuli in daily life as measured by Experience Sampling Methodology (ESM). In the first step, main and interactive effects were tested in a sample of 112 healthy individuals. Significant associations in this discovery sample were then investigated in a population-based sample of 434 individuals for replication. SNPs showing significant effects in both the discovery and replication samples were subsequently tested in three other samples of: (i) 85 unaffected siblings of patients with psychosis, (ii) 110 patients with psychotic disorders, and iii) 126 patients with a history of major depressive disorder. Multilevel linear regression analyses showed no significant association between SNPs and negative affect or positive affect. No SNPs moderated the effect of pleasant stimuli on positive affect. Three SNPs of DNMT3A (rs11683424, rs1465764, rs1465825) and 1 SNP of MTHFR (rs1801131) moderated the effect of stressful events on negative affect. Only rs11683424 of DNMT3A showed consistent directions of effect in the majority of the 5 samples. These data provide the first evidence that emotional responses to daily life stressors may be moderated by genetic variation in the genes involved in the epigenetic machinery.

Pitchford, E. Andrew; Yun, Joonkoo (2010):

The accuracy of pedometers for adults with Down syndrome.

In: *Adapted Physical Activity Quarterly* 27 (4), S. 321–336.

Abstract:

The purpose of this study was to examine the accuracy of spring-levered and piezoelectric pedometers for adults with and without Down syndrome (DS). Twenty adults with DS and 24 adults without a disability walked for two minute periods on a predetermined indoor course at a self-selected, slower and faster pace. Pedometer recorded and criterion observed steps were compared to determine pedometer error. There was a significant interaction between pedometer model and walking speed. Piezoelectric pedometers demonstrated significantly less measurement error than spring-levered pedometers, particularly at slower walking speeds. There were also significant differences in pedometer error between adults with and without DS. The study concludes that pedometer measurement error is significantly different for adults with DS but also that piezoelectric pedometers can be used in the future to measure walking activity for adults with and without DS.

Pitetti, Kenneth H.; Beets, Michael W.; Flaming, Judy (2009):

Accuracy of pedometer steps and time for youth with intellectual disabilities during dynamic movements.

Abstract:

Pedometer accuracy for steps and activity time during dynamic movement for youth with intellectual disabilities (ID) were examined. Twenty-four youth with ID (13 girls, 13.1 +/- 3.2 yrs; 11 boys, 14.7 +/- 2.7 yrs) were videotaped during adapted physical education class while wearing a Walk4Life 2505 pedometer in five locations around the waist. Researchers viewed each videotape and recorded observed steps and activity time. Observed findings were compared with pedometer recorded steps and time. On average, pedometer registered steps were underestimated by approximately 14% +/- 16.5%, whereas pedometer registered time was overestimated by approximately 8.7% +/- 21.8%. The findings indicate that the accuracy of pedometers may be compromised during dynamic movement for youth with ID.

Plasqui, G.; Bonomi, A. G.; Westerterp, K. R. (2013):

Daily physical activity assessment with accelerometers: new insights and validation studies.

In: *Obes.Rev.* (1467-7881 (Linking)). DOI: 10.1111/obr.12021.

Abstract:

The field of application of accelerometry is diverse and ever expanding. Because by definition all physical activities lead to energy expenditure, the doubly labelled water (DLW) method as gold standard to assess total energy expenditure over longer periods of time is the method of choice to validate accelerometers in their ability to assess daily physical activities. The aim of this paper was to provide a systematic overview of all recent (2007-2011) accelerometer validation studies using DLW as the reference. The PubMed Central database was searched using the following keywords: doubly or double labelled or labeled water in combination with accelerometer, accelerometry, motion sensor, or activity monitor. Limits were set to include articles from 2007 to 2011, as earlier publications were covered in a previous review. In total, 38 articles were identified, of which 25 were selected to contain sufficient new data. Eighteen different accelerometers were validated. There was a large variability in accelerometer output and their validity to assess daily physical activity. Activity type recognition has great potential to improve the assessment of physical activity-related health outcomes. So far, there is little evidence that adding other physiological measures such as heart rate significantly improves the estimation of energy expenditure

Plowman, Lydia; Stevenson, Olivia (2012):

Using mobile phone diaries to explore children's everyday lives.

In: *Childhood: A Global Journal of Child Research* 19 (4), S. 539–553. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31692-010%26site%3dehost-live;lydia.plowman@stir.ac.uk.

Abstract:

This article describes a novel approach to experience sampling as a response to the challenges of researching the everyday lives of young children at home. Parents from 11 families used mobile phones to send the research team combined picture and text messages to provide 'experience snapshots' of their child's activities six times on each of three separate days. The article describes how the method aligns with an ecocultural approach, illustrates the variation in children's experiences and provides sufficient detail for researchers to adapt the method for the purposes of collecting data in other contexts. The article summarizes the benefits and shortcomings from the perspectives of families and researchers. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Pluess, Michael; Conrad, Ansgar; Wilhelm, Frank H. (2009):

Muscle tension in generalized anxiety disorder: a critical review of the literature.

In: *J Anxiety Disord* 23 (1), S. 1–11. DOI: 10.1016/j.janxdis.2008.03.016.

Abstract:

BACKGROUND\r\nGeneralized anxiety disorder (GAD) is a prevalent, disabling, and often chronic disorder. With a typical recovery rate of only about 40% with current psychological treatments a better understanding of potential psychophysiological mechanisms is vital.\r\nMETHODS\r\nSince the most discriminative somatic symptom of GAD compared to other anxiety disorders is muscle tension this review qualitatively examines the literature on muscle tension as it relates to GAD and muscle relaxation therapy for GAD patients.\r\nRESULTS\r\nMuscle tension in GAD is poorly understood. Experimental studies refute the often-assumed direct relationship between anxiety and muscle tension. However, muscle relaxation therapies have been as effective as cognitive interventions directly addressing the defining symptom worry.\r\nCONCLUSIONS\r\nMuscle tension in its objective and subjective representations may play a role in GAD through various pathways that are testable. Future research needs to better examine the different aspects and functions of muscle tension in GAD.

Poerio, G. L.; Totterdell, P.; Miles, E. (2013):

Mind-wandering and negative mood: does one thing really lead to another?

In: *Conscious.Cogn* 22 (4), S. 1412–1421. DOI: 10.1016/j.concog.2013.09.012.

Abstract:

Mind-wandering is closely connected with negative mood. Whether negative mood is a cause or consequence of mind-wandering remains an important, unresolved, issue. We sought to clarify the direction of this relationship by measuring mood before and after mind-wandering. We also measured the affective content, time-orientation and relevance of mind-wandering to current concerns to explore whether the link between mind-wandering and negative mood might be explained by these characteristics. A novel experience-sampling technique with smartphone application prompted participants to answer questions about mind-wandering and mood across 7 days. While sadness tended to precede mind-wandering, mind-wandering itself was not associated with later mood and only predicted feeling worse if its content was negative. We also found prior sadness predicted retrospective mind-wandering, and prior negative mood predicted mind-wandering to current concerns. Our findings provide new insight into how mood and mind-wandering relate but suggest mind-wandering is not inherently detrimental to well-being

Pogue, Velvie; Rahman, Mahboob; Lipkowitz, Michael; Toto, Robert; Miller, Edgar; Faulkner, Marquetta et al. (2009):

Disparate estimates of hypertension control from ambulatory and clinic blood pressure measurements in hypertensive kidney disease.

In: *Hypertension* 53 (1), S. 20–27. DOI: 10.1161/HYPERTENSIONAHA.108.115154.

Abstract:

Ambulatory blood pressure (ABP) monitoring provides unique information about day-night patterns of blood pressure (BP). The objectives of this article were to describe ABP patterns in African Americans with hypertensive kidney disease, to examine the joint distribution of clinic BP and ABP, and to determine associations of hypertensive target organ damage with clinic BP and ABP. This study is a cross-sectional analysis of baseline data from the African American Study of Kidney Disease Cohort Study. Masked hypertension was defined by elevated daytime (>or= 135/85 mm Hg) or elevated nighttime (>or= 120/70 mm Hg) ABP in those with controlled clinic BP (<140/90 mm Hg); nondipping was defined by a <or= 10% decrease in mean nighttime systolic

BP; reverse dipping was defined by a higher nighttime than daytime systolic BP. Of the 617 participants (mean age: 60.2 years; 62% male; mean estimated glomerular filtration rate: 43.8 mL/min per 1.73 m(2)) with both clinic BP and ABP, 498 participants (80%) had a nondipping or reverse dipping profile. Of the 377 participants with controlled clinic BP (61%), 70% had masked hypertension. Compared with those with controlled clinic BP or white-coat hypertension, target organ damage (proteinuria and left ventricular hypertrophy) was more common in those with elevated nighttime BP, masked hypertension, or sustained hypertension. In conclusion, clinic BP provides an incomplete and potentially misleading assessment of the severity of hypertension in African Americans with hypertensive kidney disease, in large part because of increased nighttime BP. Whether lowering nighttime BP improves clinical outcomes is unknown but should be tested given the substantial burden of BP-related morbidity in this population.

Poh, Choo Hean; Gasiorowska, Anita; Allen, Larissa; Navarro-Rodriguez, Tomás; Mizyed, Ibraheem; Powers, Jeannette et al. (2010):

Reassessment of the principal characteristics of gastroesophageal reflux during the recumbent period using integrated actigraphy-acquired information.

In: *The American journal of gastroenterology* 105 (5), S. 1024–1031. DOI: 10.1038/ajg.2009.636.

Abstract:

OBJECTIVES\r\nCharacterization of gastroesophageal reflux (GERD) events during the sleep period has been hampered by lack of any patient-friendly technique that allows accurate assessment of sleep duration and awakening time, without confining patients to a sleep laboratory. Our aim was to compare principal reflux characteristics during the upright, recumbent-awake, and recumbent-asleep periods as well as to determine the effect of sleep awakenings on the principal reflux characteristics of the recumbent-asleep period using novel technology that allows integration of recorded actigraphy data into collected pH information.\r\nMETHODS\r\nPatients with heartburn at least three times a week for the previous 3 months were invited to participate in this study. All participants were evaluated by the demographics and the GERD Symptom Checklist questionnaires. Thereafter, patients underwent ambulatory 24-h esophageal pH monitoring concomitantly with actigraphy. A novel technique was used to superimpose simultaneously recorded raw actigraphy data over pH data, resulting in more accurate information about reflux events during upright, recumbent-awake, recumbent-asleep, and conscious awakening periods as well as the relationship between symptoms and acid reflux events in the aforementioned periods.\r\nRESULTS\r\nThirty-nine subjects (M/F: 26/13, mean age 56.6+/-14 years) with an abnormal pH test were enrolled into the study. The recumbent period appeared heterogeneous and was clearly divided into recumbent-awake (123.0+/-20.2 min) and recumbent-asleep (485.6+/-23.6 min) periods. The percent total time pH<4, the mean number of acid reflux events, and the number of symptoms associated with reflux events were significantly greater in the recumbent-awake as compared with the recumbent-asleep period. The mean duration of an acid reflux event was not different among upright, recumbent-awake, and recumbent-asleep periods. However, short-duration reflux events during the sleep period were associated with conscious awakenings as compared with those during sleep (0.74+/-0.11 min vs. 1.64+/-0.3 min, P=0.01).\r\nCONCLUSIONS\r\nThe recumbent period is divided into recumbent-awake and recumbent-asleep periods. The recumbent-awake period has significantly different principal reflux characteristics than the recumbent-asleep period. Duration of an acid reflux event during the recumbent-asleep period is not uniformly prolonged. Short-duration acid reflux events during the sleep period are likely due to conscious awakenings.

Poh, M. Z.; Loddenkemper, T.; Reinsberger, C.; Swenson, N. C.; Goyal, S.; Sabtala, M. C. et al. (2012):

Convulsive seizure detection using a wrist-worn electrodermal activity and accelerometry biosensor.

In: *Epilepsia* (0013-9580 (Linking)). DOI: 10.1111/j.1528-1167.2012.03444.x.

Abstract:

The special requirements for a seizure detector suitable for everyday use in terms of cost, comfort, and social acceptance call for alternatives to electroencephalography (EEG)-based methods. Therefore, we developed an algorithm for automatic detection of generalized tonic-clonic (GTC) seizures based on sympathetically mediated electrodermal activity (EDA) and accelerometry measured using a novel wrist-worn biosensor. The problem of GTC seizure detection was posed as a supervised learning task in which the goal was to classify 10-s epochs as a seizure or nonseizure event based on 19 extracted features from EDA and accelerometry recordings using a Support Vector Machine. Performance was evaluated using a double cross-validation method. The new seizure detection algorithm was tested on >4,213 h of recordings from 80 patients and detected 15 (94%) of 16 of the GTC seizures from seven patients with 130 false alarms (0.74 per 24 h). This algorithm can potentially provide a convulsive seizure alarm system for caregivers and objective quantification of seizure frequency

Sensor monitoring to measure and support daily functioning for independently living older people: a systematic review and road map for further development.

In: *J Am Geriatr Soc* 61 (12), S. 2219–2227.

Abstract:

OBJECTIVES: To study sensor monitoring (use of a sensor network placed in the home environment to observe individuals' daily functioning (activities of daily living and instrumental activities of daily living)) as a method to measure and support daily functioning for older people living independently at home. DESIGN: Systematic review. SETTING: Participants' homes. PARTICIPANTS: Community-dwelling individuals aged 65 and older. MEASUREMENTS: A systematic search in PubMed, Embase, PsycINFO, INSPEC, and The Cochrane Library was performed for articles published between 2000 and October 2012. All study designs, studies that described the use of wireless sensor monitoring to measure or support daily functioning for independently living older people, studies that included community-dwelling individuals aged 65 and older, and studies that focused on daily functioning as a primary outcome measure were included. RESULTS: Seventeen articles met the inclusion criteria. Nine studies used sensor monitoring solely as a method for measuring daily functioning and detecting changes in daily functioning. These studies focused on the technical investigation of the sensor monitoring method used. The other studies investigated clinical applications in daily practice. The sensor data could enable healthcare professionals to detect alert conditions and periods of decline and could enable earlier intervention, although limited evidence of the effect of interventions was found in these studies because of a lack of high methodological quality. CONCLUSION: Studies on the effectiveness of sensor monitoring to support people in daily functioning remain scarce. A road map for further development is proposed.

Pollak, John P. (2013):

The Photographic Affect Meter: A novel application to measure momentary emotional states.

In: *Dissertation Abstracts International Section A: Humanities and Social Sciences* 73 (8-A(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99030-112%26site%3dehost-live.

Abstract:

Emotion plays an ever-present role in human existence, impacting nearly every behavior and decision in some way. Research in the behavioral sciences is rife with exploration of emotion and the role it plays in everything from business decision making to health-related behavior. However, affect, the feeling or experience of emotion, is complex and presents many challenges to those interested in measuring it, often resulting in a disconnect between the way emotion is experienced and felt and the way that researchers measure it. This dissertation addresses the challenges of measuring emotion through the presentation of the design, development, and validation of a novel measure of affect. The Photographic Affect Meter, PAM, is a digital measure of affect in which subjects choose from a grid of photos the one that best represents their current emotional state. The objective of PAM is to provide researchers with a means of measuring affect that is brief, reliable, and effective when used in situ. PAM was developed through an extensive iterative design process anchored in Human-Computer Interaction research, drawing inspiration from Affective Computing and Design literature. PAM was then rigorously validated via three separate studies. In the first two studies, subjects were assessed using both PAM and one of three widely accepted measure of affect (PANAS, Russell's Affect Grid, or the Self Assessment Manikin). In the third study, subjects were induced with negative, neutral, or positive affect and then assessed using PAM. In each of the studies, PAM results were found to be consistent with expectation, establishing the validity and reliability of the measure. While the success of this approach has implications for researchers in Affective Computing, Emotion, Design, and Ecological Momentary Assessment, the primary contribution of this work is the introduction of a novel measure of affect that is ready to be deployed in a wide variety of studies. Possemato, K.; Kaier, E.; Wade, M.; Lantinga, L. J.; Maisto, S. A.; Ouimette, P. (2012):

Assessing daily fluctuations in posttraumatic stress disorder symptoms and substance use with interactive voice response technology: Protocol compliance and reactions.

In: *Psychol.Serv.* 9 (2), S. 185–196. DOI: 10.1037/a0027144.

Abstract:

PTSD symptoms and substance use commonly co-occur, but information is limited regarding their interplay. We used ecological momentary assessment (EMA) to capture fluctuations in PTSD symptoms and drinking within and across days. Fifty Iraq and Afghanistan War veterans completed four daily Interactive Voice Response (IVR) assessments of PTSD and substance use with cell phones for 28 days. The aims of this study were to (1) describe participant compliance and reactions to the protocol and (2) identify participant characteristics and protocol reactions that predict compliance. Protocol compliance was high, with participants completing an average of 96 out of a total of 112 IVR assessments (86%). While some participants perceived that the IVR assessments increased their drinking (21%) and PTSD symptoms (60%), self-report measures showed significant decreases in PTSD symptoms and nonsignificant decreases in drinking over the assessment period. Analyses revealed demographic (e.g., older than 24, full-time employment, more education), clinical (e.g., less binge drinking, less avoidance symptoms), and perceived benefit from participation predicted better protocol compliance. Results can guide future research on participant predictors of compliance with intensive EMA methods. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Potvin, Marie-Julie; Rouleau, Isabelle; Audy, Julie; Charbonneau, Simon; Giguère, Jean-François (2011):

Ecological prospective memory assessment in patients with traumatic brain injury.

In: *Brain injury* 25 (2), S. 192–205.

Abstract:

PRIMARY OBJECTIVE:

Prospective memory (PM) impairments are often observed after traumatic brain injury (TBI). Although PM is crucial for daily functioning, few sensitive, valid and ecological clinical tests are available. To address these concerns, the authors developed a PM task, the TEMP, using naturalistic stimuli, in which each PM phase and component is evaluated independently in time- and event-based conditions.

MAIN OUTCOMES AND RESULTS:

The results show that moderate and severe TBI patients (n = 30), evaluated after spontaneous neurological recovery, experienced problems in learning the delayed intentions content and retrieving these intentions in the right context (prospective component), especially in the time-based condition. They also recalled fewer associated actions (retrospective component), but only in the time-based condition. Correlations revealed that the retrospective component was mainly supported by episodic retrospective memory processes, while the prospective component was supported by episodic retrospective memory processes, along with attentional and executive functions. Moreover, there was a significant correlation between performance on the TEMP and results on a questionnaire assessing PM functioning in daily living completed by participants' relatives.

CONCLUSIONS:

The TEMP therefore appears to be a sensitive tool for assessing PM problems that combines internal and ecological validity.

Poulin, Michael J.; Brown, Stephanie L.; Ubel, Peter A.; Smith, Dylan M.; Jankovic, Aleksandra; Langa, Kenneth M. (2010):

Does a helping hand mean a heavy heart? Helping behavior and well-being among spouse caregivers.

In: *Psychology and Aging* 25 (1), S. 108–117. DOI: 10.1037/a0018064.

Abstract:

Being a caregiver for an ill or disabled loved one is widely recognized as a threat to the caregiver's quality of life. Nonetheless, research indicates that helping behavior, broadly construed, promotes well-being. Could helping behavior in a caregiving context promote well-being as well? In the present study, we used ecological momentary assessment to measure active helping behavior and both positive and negative affect in 73 spouse caregivers. Results indicate that when controlling for care recipient illness status and functional impairment and caregiver \"on call\" caregiving time, active helping predicted greater caregiver positive affect--especially for individuals who perceived themselves as interdependent with their spouse. In addition, although both helping and on-call time predicted greater negative affect for caregivers who perceived low interdependence, helping was unrelated to negative affect among caregivers perceiving high interdependence. Helping valued loved ones may promote caregivers' well-being.

Activity and affect: Repeated within-participant assessment in people after joint replacement surgery.

In: *Rehabilitation Psychology* 54 (1), S. 83–90. DOI: 10.1037/a0014864.

Abstract:

OBJECTIVE:

Between-participant research has shown that high negative affectivity predicts greater activity limitations and vice versa. This study examined both between- and within-participant associations of negative and positive affectivity with activity levels using ecological momentary assessment.

METHOD:

Participants were 25 people who had undergone joint replacement surgery 12 months previously. Participants made multiple reports of their activity and positive and negative affectivity over a single day using a computerized diary. Activity was also objectively recorded using an activity monitor. The following day, participants made a self-report of their activity over the measurement day and general positive and negative affectivity levels were recorded.

RESULTS:

Higher self-reported walking time over the whole measurement day was associated with higher general positive affectivity but not negative affectivity. However, using ecological momentary assessment, higher diary reports of negative affectivity predicted increased activity levels while positive affectivity neither predicted nor was predicted by activity.

CONCLUSION:

These findings demonstrate the importance of within-participant methodology in detecting subtle and immediate effects of individuals' mood on behavior that may differ from findings investigating between-participant effects over longer time periods.

Powell, D. J.; Liossi, C.; Moss-Morris, R.; Schlotz, W. (2013):

Unstimulated cortisol secretory activity in everyday life and its relationship with fatigue and chronic fatigue syndrome: A systematic review and subset meta-analysis.

In: *Psychoneuroendocrinology* (0306-4530 (Linking)). DOI: 10.1016/j.psyneuen.2013.07.004.

Abstract:

The hypothalamic-pituitary-adrenal (HPA) axis is a psychoneuroendocrine regulator of the stress response and immune system, and dysfunctions have been associated with outcomes in several physical health conditions. Its end product, cortisol, is relevant to fatigue due to its role in energy metabolism. The systematic review examined the relationship between different markers of unstimulated salivary cortisol activity in everyday life in chronic fatigue syndrome (CFS) and fatigue assessed in other clinical and general populations. Search terms for the review related to salivary cortisol assessments, everyday life contexts, and fatigue. All eligible studies (n=19) were reviewed narratively in terms of associations between fatigue and assessed cortisol markers, including the cortisol awakening response (CAR), circadian profile (CP) output, and diurnal cortisol slope (DCS). Subset meta-analyses were conducted of case-control CFS studies examining group differences in three cortisol outcomes: CAR output; CAR increase; and CP output. Meta-analyses revealed an attenuation of the CAR increase within CFS compared to controls (d=-.34) but no statistically significant differences between groups for other markers. In the narrative review, total cortisol output (CAR or CP) was rarely associated with fatigue in any population; CAR increase and DCS were most relevant. Outcomes reflecting within-day change in cortisol levels (CAR increase; DCS) may be the most relevant to fatigue experience, and future research in this area should report at least one such marker. Results should be considered with caution due to heterogeneity in one meta-analysis and the small number of studies

Prajapati, Sanjay K.; Gage, William H.; Brooks, Dina; Black, Sandra E.; McIlroy, William E. (2011):

A novel approach to ambulatory monitoring investigation into the quantity and control of everyday walking in patients with subacute stroke.

In: *Neurorehabilitation and Neural Repair* 25 (1), S. 6–14.

Abstract:

BACKGROUND:

Promoting whole body activities, such as walking, can help improve recovery after stroke. However, little information exists regarding the characteristics of daily walking in patients enrolled in rehabilitation poststroke. The objectives of this study were to: (1) examine the quantity of walking and duration of individual bouts of walking during an inpatient day, (2) compare standard laboratory symmetry measures with measures of symmetry captured throughout the day, and (3) investigate the association between quantity of walking and indices of stroke severity.

METHODS:

The study examined ambulatory activity among 16 inpatients with subacute stroke who were bilaterally instrumented with a wireless accelerometer above the ankle for approximately 8 continuous hours.

RESULTS:

On average, patients demonstrated 47.5 minutes (standard deviation [SD] = 26.6 minutes) of total walking activity and walking bout durations of 54.4 s (SD = 21.5 s). A statistically significant association was found between the number of walking bouts to total walking time (r = .76; P = .006) and laboratory gait speed (r = .51; P = .045) and between laboratory gait speed and balance impairment (r = .60; P = .013). Also, a significant increase in gait asymmetry was observed during day-long measurement compared with the standard laboratory-based assessment (P = .006).

CONCLUSIONS:

Rather modest amounts of daily walking were found for these ambulatory inpatients, consistent with previous reports about patients after stroke. Bouts of walking were short in duration, and the gait was more asymmetrical, compared with a standard gait assessment. Unobtrusive monitoring of daily walking exposes the characteristics and temporal qualities of poststroke ambulation.

Pramana, Gede; Parmanto, Bambang; Kendall, Philip C.; Silk, Jennifer S. (2014):

The SmartCAT: An m-Health Platform for Ecological Momentary Intervention in Child Anxiety Treatment.

In: *Telemed J E Health. DOI:* 10.1089/tmj.2013.0214.

Abstract:

Abstract Introduction: Cognitive behavioral therapy (CBT) for child anxiety, although efficacious, typically requires 16-20 weekly sessions with a therapist. Brief CBT (BCBT; eight sessions) for child anxiety is promising but may have less favorable outcomes owing to reduced session time. Mobile health (m-health) has the potential to improve BCBT efficacy by delivering ecological momentary intervention to engage youth in learning and practicing CBT skills in their everyday lives (in vivo). Materials and Methods: We developed an m-health platform entitled SmartCAT (Smartphone-enhanced Child Anxiety Treatment). SmartCAT consists of (1) a smartphone application (app) that cues youth to use the CBT skills taught in sessions, (2) an online portal that allows therapists to monitor skill use, to send cues and treatment-related materials, to engage youth in real-time via secure messages, and to manage rewards, and (3) a communication protocol that allows real-time bidirectional exchange between the app and the portal. A pilot study with nine youth (9-14 years old) examined the platform's feasibility as an adjunct to BCBT. Results: SmartCAT was found to be capable of supporting BCBT for child anxiety and received positive feedback from both therapists and youth patients. Patients rated the app as highly usable (mean=1.7 on a 1-7 scale, with 1="easy"). Patients completed 5.36 skills coach entries per session (standard deviation=1.95) and took an average of 3.14 min (standard deviation=0.98 min) to complete the entries. Conclusions: A smartphone app is feasible within CBT for child anxiety. Users found SmartCAT both acceptable and easy to use. Integrating an m-health platform within BCBT for anxious children may facilitate involvement in treatment and dissemination of effective procedures.

Prejbisz, Aleksander; Florczak, Elzbieta; Pregowska-Chwala, Barbara; Klisiewicz, Anna; Kusmierczyk-Droszcz, Beata; Zielinski, Tomasz et al. (2014):

Relationship between obstructive sleep apnea and markers of cardiovascular alterations in never-treated hypertensive patients.

In: *Hypertens Res. DOI:* 10.1038/hr.2014.43.

Abstract:

We addressed a question if there is a relationship between severity of newly diagnosed obstructive sleep apnea (OSA) and markers of cardiovascular alterations in middle-aged untreated hypertensive patients. In 121 consecutive patients with never-treated essential hypertension (mean age 35.9+/-10.1 years; 97 men and 24 women) evaluation of office and ambulatory blood pressure (BP) measurements, metabolic syndrome (MS) components and markers of alterations in cardiovascular system

including left ventricular structure and function, carotid artery wall intima-media thickness (cIMT) and urinary albumin excretion (UAE) was performed. OSA was classified as mild (apnea/hypopnea index (AHI) 5-15 events h-1) or moderate-to-severe (AHI >15 events h-1). Mild and moderate-to-severe OSA were diagnosed in 30% and 20% of patients, respectively. No differences in nighttime BP levels and decline between patients with and without OSA were observed. The patients with moderate-to-severe OSA were characterized by higher cIMT (0.74+/-0.16 vs. 0.60+/-0.15 mm; P=0.001), UAE (14.5+/-6.9 vs. 10.0+/-8.0 mg 24 h-1; P=0.014), relative wall thickness (0.42+/-0.05 vs. 0.39+/-0.05; P=0.023) and by a higher degree of diastolic dysfunction (E'-wave velocity 11.4+/-3.2 vs. 15.5+/-3.8 m s-1; P<0.001) as compared with the patients without OSA. In multivariate analysis, AHI independently of BP and MS components correlated with UAE, relative wall thickness and E'-wave velocity. In the middle-aged never-treated hypertensive patients, moderate-to-severe OSA correlates with markers of cardiovascular alterations independently of BP levels and MS components.Hypertension Research advance online publication, 13 March 2014; doi:10.1038/hr.2014.43.

Preston, Kenzie L.; Epstein, David H. (2011):

Stress in the daily lives of cocaine and heroin users: Relationship to mood, craving, relapse triggers, and cocaine use.

In: *Psychopharmacology* 218 (1), S. 29–37. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-23834-003&site=ehost-live;kpreston@intra.nida.nih.gov.

Abstract:

Rationale: Quantitative real-time data on the stress experienced by drug misusers in their daily lives may provide additional insight into stress's role in drug use. Objective: The purpose of this study is to evaluate stress in relation to craving, mood, relapse-trigger exposure, and cocaine use in cocaine-dependent outpatients. Methods: Methadone-maintained cocaine- and heroin-abusing outpatients (N = 114) provided ecological momentary assessment data on handheld computers. Ratings of stress were compared to those of craving and mood and past-hour exposure to putative drug-use triggers in randomly prompted entries and in the 5 h prior to participant-initiated cocaine use reports. Results: Stress had significant positive relationships with current ratings of craving for cocaine, heroin, and tobacco and with ratings of tiredness, boredom, and irritation, and had significant negative relationships with ratings of happiness and relaxation. Stress was significantly greater in entries in which participants also reported past-hour exposure to negative-mood triggers, most of the drug-exposure triggers, or any trigger involving thoughts about drugs (e.g., tempted out of the blue). The linear increase in stress during the 5-h preceding individual episodes of cocaine use was not significant (p = 0.12), though there was a trend for such an increase before the use episodes that participants attributed to stressful states when they occurred (p = 0.87). Conclusions: The findings suggest a complex role of stress in addiction. Stress reported in real time in the natural environment showed strong cross-sectional momentary relationships with craving, mood, and exposure to drug-use trigger. However, the prospective association between stress ratings and cocaine-use episodes was, at best, weak. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Preston, Kenzie L.; Vahabzadeh, Massoud; Schmittner, John; Lin, Jia-Ling; Gorelick, David A.; Epstein, David H. (2009):

Cocaine craving and use during daily life.

In: *Psychopharmacology* 207 (2), S. 291–301. DOI: 10.1007/s00213-009-1655-8.

Abstract:

RATIONALE\r\nCraving is often assumed to cause ongoing drug use and relapse and is a major focus of addiction research. However, its relationship to drug use has not been adequately documented.\r\nOBJECTIVES\r\nThe aim of this study was to investigate the relationship between craving and drug use in real time and in the daily living environments of drug users.\r\nMETHODS\r\nIn a prospective, longitudinal, cohort design (ecological momentary assessment), 112 cocaine-abusing individuals in methadone maintenance treatment rated their craving and mood at random times (two to five times daily, prompted by electronic diaries) as they went about their everyday activities. They also initiated an electronic diary entry each time they used cocaine. Drug use was monitored by thrice-weekly urine testing.\r\nRESULTS\r\nDuring periods of urine-verified cocaine use, ratings of cocaine craving increased across the day and were higher than during periods of urine-verified abstinence. During the 5 h prior to cocaine use, ratings of craving significantly increased. These patterns were not seen in ratings of heroin craving or mood (e.g., feeling happy or bored).\r\nCONCLUSIONS\r\nCocaine craving is tightly coupled to cocaine use in users' normal environments. Our findings provide previously unavailable support for a relationship that has been seriously questioned in some theoretical accounts. We discuss what steps will be needed to determine whether craving causes use.

Preziosa, Alessandra; Grassi, Alessandra; Gaggioli, Andrea; Riva, Giuseppe (2009):

Therapeutic applications of the mobile phone.

In: *British Journal of Guidance & Counselling* 37 (3), S. 313–325.

Abstract:

As the availability of new communication technologies increases, mental health professionals have incorporated these innovations into their practice and research. Up to now several studies have presented promising results in using the power and convenience of the Internet for clinical care. While multiple contributions focus on the potential and the advantages of therapies delivered through the Internet, mental health practitioners may take into account new technological opportunities to improve their practice. Mobile phone diffusion is expanding worldwide at breath-taking speed. In fewer than 20 years, mobile phones have gone from being rare and expensive pieces of equipment used primarily by the business elite, to a pervasive low-cost personal item. In many countries, mobile phones now outnumber land-line telephones, with most adults and many children now owning mobile phones. With high levels of mobile telephone penetration, a mobile culture has evolved, where the phone becomes a key social and cultural tool. The purpose of this paper is to explore the potentialities that mobile phones may offer in clinical care. The paper will investigate in which areas of clinical interventions mobile phones have already been successfully applied. Moreover, the paper will discuss these opportunities by presenting the results of two different studies based on the use of the mobile phone for anxiety management.

Priebe, Kathlen; Kleindienst, Nikolaus; Zimmer, Josepha; Koudela, Susanne; Ebner-Priemer, Ulrich; Bohus, Martin (2013):

Frequency of Intrusions and Flashbacks in Patients With Posttraumatic Stress Disorder Related to Childhood Sexual Abuse: An Electronic Diary Study.

In: *Psychological Assessment*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-26310-001%26site%3dehost-live.

Abstract:

Intrusions and flashbacks are core features of posttraumatic stress disorder (PTSD). The frequency of these symptoms is usually assessed through retrospective questionnaires, which may be subject to recall bias of unknown magnitude. Electronic diaries that enable real-time assessment have been used to address recall biases in several psychiatric disorders. However, to our knowledge, this is the first study to apply this method to assess intrusions and flashbacks in PTSD related to childhood sexual abuse (CSA). Female patients with PTSD related to CSA (n = 28) were provided with electronic diaries for repeated real-time assessment of intrusions and flashbacks over the period of 1 week. At the end of this period, they were asked to retrospectively report how many such symptoms they recalled having experienced over the past week. The total number of symptoms reported in the electronic diaries (74.5 -[illegible] 62.0 intrusions and 24.4 -[illegible] 36.0 flashbacks for the week) was substantially higher than those reported in previous studies. Furthermore, electronic diaries revealed the occurrence of about 50% more intrusions and flashbacks than did the retrospective assessment (74.5 vs. 49.5 for intrusions, and 24.4 vs. 13.4 for flashbacks). Such high frequencies are not captured with existing assessment instruments and suggest a possible ceiling effect. Future research needs to clarify whether these high numbers are specific to highly symptomatic PTSD patients or might generalize to other populations of PTSD patients. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Prince, Stéphanie A.; Adamo, Kristi B.; Hamel, Meghan E.; Hardt, Jill; Connor Gorber, Sarah; Tremblay, Mark (2008):

A comparison of direct versus self-report measures for assessing physical activity in adults: a systematic review.

In: *Int J Behav Nutr Phys Act* 5, S. 56. DOI: 10.1186/1479-5868-5-56.

Abstract:

BACKGROUND\r\nAccurate assessment is required to assess current and changing physical activity levels, and to evaluate the effectiveness of interventions designed to increase activity levels. This study systematically reviewed the literature to determine the extent of agreement between subjectively (self-report e.g. questionnaire, diary) and objectively (directly measured; e.g. accelerometry, doubly labeled water) assessed physical activity in adults.\r\nMETHODS\r\nEight electronic databases were searched to identify observational and experimental studies of adult populations. Searching identified 4,463 potential articles. Initial screening found that 293 examined the relationship between self-reported and directly measured physical activity and met the eligibility criteria. Data abstraction was completed for 187 articles, which described comparable data and/or comparisons, while 76 articles lacked comparable data or comparisons, and a further 30 did not meet the review's eligibility requirements. A risk of bias assessment was conducted for all articles from which data was abstracted.\r\nRESULTS\r\nCorrelations between self-

report and direct measures were generally low-to-moderate and ranged from -0.71 to 0.96. No clear pattern emerged for the mean differences between self-report and direct measures of physical activity. Trends differed by measure of physical activity employed, level of physical activity measured, and the gender of participants. Results of the risk of bias assessment indicated that 38% of the studies had lower quality scores.\r\nCONCLUSION\r\nThe findings suggest that the measurement method may have a significant impact on the observed levels of physical activity. Self-report measures of physical activity were both higher and lower than directly measured levels of physical activity, which poses a problem for both reliance on self-report measures and for attempts to correct for self-report - direct measure differences. This review reveals the need for valid, accurate and reliable measures of physical activity in evaluating current and changing physical activity levels, physical activity interventions, and the relationships between physical activity and health outcomes.

Prioreschi, A.; Hodkinson, B.; Avidon, I.; Tikly, M.; McVeigh, J. A. (2013):

The clinical utility of accelerometry in patients with rheumatoid arthritis.

In: *Rheumatology.(Oxford)* (1462-0324 (Linking)). DOI: 10.1093/rheumatology/ket216.

Abstract:

Objectives. To assess habitual physical activity levels in patients with RA compared with healthy control participants and to compare these measures with health-related quality of life and disease activity in the RA patients.Methods. Fifty RA patients [age 48 (13) years] and 22 BMI, sex and geographically matched control participants were recruited. Habitual physical activity was measured using an Actical accelerometer worn on the hip for 2 consecutive weeks. Patients completed the Short Form-36 (SF-36) and modified Health Assessment Questionnaires (HAQ-DI). Disease activity was assessed using the Simplified Disease Activity Index (SDAI). RA patients were further categorized as more physically active (n = 25) and less physically active (n = 25) according to their average activity counts.Results. The RA group spent more time in sedentary activity than the control group (71% vs 62% of the day respectively, P = 0.002) and had bimodal decreases in diurnal physical activity compared with the control group in the morning (P < 0.001) and late afternoon (P < 0.001). HAQ-DI, when adjusted for age and disease duration, was negatively correlated with physical activity in the RA group (r = -0.343, P = 0.026). The more physically active patients scored better than the less physically active patients on every component of the SF-36.Conclusion. Patients with RA lead a significantly more sedentary lifestyle than healthy controls and show diurnal differences in physical activity due to morning stiffness and fatigue. Higher levels of habitual physical activity may be protective of functional capacity and are highly associated with improved health-related quality of life in RA patients

Prioreschi, Alessandra; Hodkinson, Bridget; Tikly, Mohammed; McVeigh, Joanne A. (2014):

Changes in physical activity measured by accelerometry following initiation of DMARD therapy in rheumatoid arthritis.

In: *Rheumatology (Oxford). DOI:* 10.1093/rheumatology/ket457.

Abstract:

Objective. The aim of this study was to assess changes in habitual physical activity levels in response to DMARD therapy in RA patients.Methods. Eighteen drug-naive RA patients were prospectively assessed at baseline and following 3 months of DMARD therapy for habitual physical activity by accelerometry, disease activity using the clinical disease activity index (CDAI) and functional disability using the modified HAQ (mHAQ). Baseline physical activity was also compared with an equal number of healthy control participants matched for age, sex and BMI.Results. Following 3 months of DMARD therapy, in parallel with significant improvements in CDAI scores (P < 0.001) and HAQ scores (P < 0.001), accelerometry measures in the RA cohort showed that the average activity counts in sedentary thresholds decreased (P = 0.012), while average activity counts within higher-intensity thresholds increased (P = 0.039). Multiple regression analysis showed that the change in moderate activity was associated with a decrease in CRP (beta = - 0.922, P = 0.026) while the decrease in sedentary activity and increase in moderate activity were associated with decreased morning stiffness of the joints (beta = 0.694, P = 0.035 and beta = -0.927, P = 0.024, respectively). At baseline, RA patients were less physically active than control participants in the morning (P = 0.048) and in the late afternoon (P = 0.016), but these diurnal differences were no longer significant after the DMARD intervention.Conclusion. These findings suggest that accelerometry may potentially be a viable objective method of assessing changes in physical disability in response to various disease-modifying drugs.

Probst-Hensch, Nicole M.; Imboden, Medea; Felber Dietrich, Denise; Barthélemy, Jean-Claude; Ackermann-Liebrich, Ursula; Berger, Wolfgang et al. (2008):

Glutathione S-transferase polymorphisms, passive smoking, obesity, and heart rate variability in nonsmokers.

In: *Environmental health perspectives* 116 (11), S. 1494–1499. DOI: 10.1289/ehp.11402.

Abstract:

BACKGROUND\r\nDisturbances of heart rate variability (HRV) may represent one pathway by which second-hand smoke (SHS) and air pollutants affect cardiovascular morbidity and mortality. The mechanisms are poorly understood.\r\nOBJECTIVES\r\nWe investigated the hypothesis that oxidative stress alters cardiac autonomic control. We studied the association of polymorphisms in oxidant-scavenging glutathione S-transferase (GST) genes and their interactions with SHS and obesity with HRV.\r\nMETHODS\r\nA total of 1,133 nonsmokers > 50 years of age from a population-based Swiss cohort underwent ambulatory 24-hr electrocardiogram monitoring and reported on lifestyle and medical history. We genotyped GSTM1 and GSTT1 gene deletions and a GSTP1 (Ile105Val) single nucleotide polymorphism and analyzed genotype-HRV associations by multiple linear regressions.\r\nRESULTS\r\nHomozygous GSTT1 null genotypes exhibited an average 10% decrease in total power (TP) and low-frequency-domain HRV parameters. All three polymorphisms modified the cross-sectional associations of HRV with SHS and obesity. Homozygous GSTM1 null genotypes with > 2 hr/day of SHS exposure exhibited a 26% lower TP [95% confidence interval (CI), 11 to 39%], versus a reduction of -5% (95% CI, -22 to 17%) in subjects with the gene and the same SHS exposure compared with GSTM1 carriers without SHS exposure. Similarly, obese GSTM1 null genotypes had, on average, a 22% (95% CI, 12 to 31%) lower TP, whereas with the gene present obesity was associated with only a 3% decline (95% CI, -15% to 10%) compared with nonobese GSTM1 carriers.\r\nCONCLUSIONS\r\nGST deficiency is associated with significant HRV alterations in the general population. Its interaction with SHS and obesity in reducing HRV is consistent with an impact of oxidative stress on the autonomous nervous system.

Pronk, N. P.; Katz, A. S.; Lowry, M.; Payfer, J. R. (2012):

Reducing occupational sitting time and improving worker health: the Take-a-Stand Project, 2011.

In: *Prev.Chronic.Dis.* 9 (1545-1151 (Electronic)), S. E154. Online verfügbar unter PM:23057991.

Abstract:

BACKGROUND: Prolonged sitting time is a health risk. We describe a practice-based study designed to reduce prolonged sitting time and improve selected health factors among workers with sedentary jobs. COMMUNITY CONTEXT: We conducted our study during March-May 2011 in Minneapolis, Minnesota, among employees with sedentary jobs. METHODS: Project implementation occurred over 7 weeks with a baseline period of 1 week (period 1), an intervention period of 4 weeks (period 2), and a postintervention period of 2 weeks (period 3). The intervention group (n = 24) received a sit-stand device during period 2 designed to fit their workstation, and the comparison group (n = 10) did not. We used experience-sampling methods to monitor sitting behavior at work during the 7 weeks of the project. We estimated change scores in sitting time, health risk factors, mood states, and several office behaviors on the basis of survey responses. OUTCOME: The Take-a-Stand Project reduced time spent sitting by 224% (66 minutes per day), reduced upper back and neck pain by 54%, and improved mood states. Furthermore, the removal of the device largely negated all observed improvements within 2 weeks. INTERPRETATION: Our findings suggest that using a sit-stand device at work can reduce sitting time and generate other health benefits for workers

Community attitudes to the appropriation of mobile phones for monitoring and managing depression, anxiety, and stress.

In: *J Med Internet Res* 12 (5).

Abstract:

BACKGROUND:

The benefits of self-monitoring on symptom severity, coping, and quality of life have been amply demonstrated. However, paper and pencil self-monitoring can be cumbersome and subject to biases associated with retrospective recall, while computer-based monitoring can be inconvenient in that it relies on users being at their computer at scheduled monitoring times. As a result, nonadherence in self-monitoring is common. Mobile phones offer an alternative. Their take-up has reached saturation point in most developed countries and is increasing in developing countries; they are carried on the person, they are usually turned on,

and functionality is continually improving. Currently, however, public conceptions of mobile phones focus on their use as tools for communication and social identity. Community attitudes toward using mobile phones for mental health monitoring and self-management are not known.

OBJECTIVE:

The objective was to explore community attitudes toward the appropriation of mobile phones for mental health monitoring and management.

METHODS:

We held community consultations in Australia consisting of an online survey (n = 525), focus group discussions (n = 47), and interviews (n = 20).

RESULTS:

Respondents used their mobile phones daily and predominantly for communication purposes. Of those who completed the online survey, the majority (399/525 or 76%) reported that they would be interested in using their mobile phone for mental health monitoring and self-management if the service were free. Of the 455 participants who owned a mobile phone or PDA, there were no significant differences between those who expressed interest in the use of mobile phones for this purpose and those who did not by gender ($\chi 2(1)$, = 0.98, P = .32, phi = .05), age group ($\chi 2(4)$, = 1.95, P = .75, phi = .06), employment status ($\chi 2(2)$, = 2.74, P = .25, phi = .08) or marital status ($\chi 2(4)$, = 4.62, P = .33, phi = .10). However, the presence of current symptoms of depression, anxiety, or stress affected interest in such a program in that those with symptoms were more interested ($\chi(2)$ (1), = 16.67, P < .001, phi = .19). Reasons given for interest in using a mobile phone program were that it would be convenient, counteract isolation, and help identify triggers to mood states. Reasons given for lack of interest included not liking to use a mobile phone or technology, concerns that it would be too intrusive or that privacy would be lacking, and not seeing the need. Design features considered to be key by participants were enhanced privacy and security functions including user name and password, ease of use, the provision of reminders, and the availability of clear feedback.

CONCLUSIONS:

Community attitudes toward the appropriation of mobile phones for the monitoring and self-management of depression, anxiety, and stress appear to be positive as long as privacy and security provisions are assured, the program is intuitive and easy to use, and the feedback is clear.

Provenzano, David A.; Fanciullo, Gilbert J.; Jamison, Robert N.; McHugo, Gregory J.; Baird, John C. (2007):

Computer assessment and diagnostic classification of chronic pain patients.

In: *Pain Medicine* 8 (s3), S. S167-S175.

Abstract:

OBJECTIVE:

In order to establish a diagnosis of chronic pain, emphasis is placed on a patient's report of the pain's intensity, location, and character. The aim of this study was to evaluate the feasibility of a computer assessment method to collect self-reports of pain that were then used in discriminant analyses to distinguish among chronic pain diagnoses.

METHODS:

A convenience sample of 511 patients from two university-based pain clinics completed a computer pain assessment battery that elicited demographic information, pain drawings, pain and emotion intensity ratings, and intensity ratings of verbal descriptors. Patients classified themselves into one of six chronic pain diagnoses. Discriminant analyses were performed in an attempt to identify the unique features of patients' pain experience associated with each of the diagnostic categories.

RESULTS:

Pain drawings successfully classified patients into three of the diagnostic categories (back, head, and neck pain). In a second analysis, two pain descriptors (cramping and stabbing) separated rheumatoid arthritis patients from those with either fibromyalgia or neural pain. One descriptor of pain (cramping) and one descriptor of emotion (frustration) together distinguished between fibromyalgia and neural pain.

CONCLUSIONS:

1) Computer assessment of a range of patient symptoms is feasible in the pain clinic. 2) Discriminant analysis based on pain drawings can distinguish among patient-reported diagnoses of back pain, headache, and neck pain. 3) Discriminant analysis based on three verbal descriptors can help to distinguish among diagnoses of fibromyalgia, neuralgia, and rheumatoid arthritis. 4) However, in general, most computerized descriptive information is not useful in distinguishing differences among pain patient diagnostic groups.

Pruitt, Leslie A.; Glynn, Nancy W.; King, Abby C.; Guralnik, Jack M.; Aiken, Erin K.; Miller, Gary; Haskell, William L. (2008):

Use of accelerometry to measure physical activity in older adults at risk for mobility disability.

In: *J Aging Phys Act* 16 (4), S. 416–434. Online verfügbar unter http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2895565/.

Abstract:

We explored using the ActiGraph accelerometer to differentiate activity levels between participants in a physical activity (PA, n=54) or `successful aging' (SA) program (n = 52). The relationship between a PA questionnaire for older adults (CHAMPS) and accelerometry variables was also determined. Individualized accelerometry count thresholds (THRESH(IND)) measured during a 400-m walk were used to identify "meaningful activity." Participants then wore the ActiGraph for 7 days. Results indicated more activity bouts·d(−1) ≥ 10 min above THRESH(IND) in the PA group compared to SA group (1.1 ± 2.0 vs 0.5 ± 0.8, p = 0.05) and more activity counts·d(−1) above THRESH(IND) for the PA group (28,101 ± 27,521) compared to the SA group (17,234 ± 15,620, p = 0.02). Correlations between activity counts·hr(−1) and CHAMPS ranged from 0.27 – 0.42, p<0.01. The ActiGraph and THRESH(IND) may be useful for differentiating PA levels in older adults at risk for mobility disability.

Pryce, R.; Johnson, M.; Goytan, M.; Passmore, S.; Berrington, N.; Kriellaars, D. (2012):

The Relationship Between Ambulatory Performance and Self-rated Disability in Patients with Lumbar Spinal Stenosis.

In: *Spine (Phila Pa 1976.)* (0362-2436 (Linking)). DOI: 10.1097/BRS.0b013e31824a8314.

Abstract:

ABSTRACT: Study Design. cross-sectionalObjective. To identify the relationship between performance measures derived from accelerometry and subjective reports of pain, disability and health in patients with lumbar spinal stenosis (LSS).Summary of Background Data. Accelerometers have emerged as a measure of performance, providing the ability to characterize the pattern and magnitude of real life activity, and sedentarism. Pain and loss of function, particularly ambulation, are common in LSS. The extent that pain, perceived disability and self-rated health relate to performance in patients with LSS is not well known.Methods. Self-reported pain, disability (Oswestry Disability Index, Roland-Morris Disability Questionnaire, Disabilities of Arm Shoulder and Hand) and health (Short Form-36) were collected from patients with LSS (n = 33). Physical activity, ambulation and inactivity performance measures were derived from 7-day accelerometer records. Correlation and step-wise regression were used.Results. The physical function subscale of the Short Form-36, a non-pathology specific outcome, had the best overall correlation to physical activity and ambulation (average r = 0.53) compared to pain (average r = 0.32) and disability (average r = -0.45) outcomes. Stepwise regression models for performance were predominantly single variable (4 of 8 models); pain was not selected as a predictor. A second non-pathology specific outcome, the Disabilities of Arm Shoulder and Hand, improved the prediction of performance in 5 of 8 models.Conclusions. Subjective measures of pain and disability had limited ability to account for real life performance in LSS patients. Future research is required to identify determinants of performance in LSS since barriers to activity may not be disease specific

Feedback system based on plantar pressure for monitoring toe-walking strides in children with cerebral palsy.

In: *Am J Phys Med Rehabil* 93 (2), S. 122–129. DOI: 10.1097/PHM.0b013e3182a54207.

Abstract:

OBJECTIVE: The aim of this study was to develop a feedback system to assist gait rehabilitation of cerebral palsy (CP) toe walkers with dynamic equinus. DESIGN: Plantar pressure of the forefoot and the heel was collected by sensorized insoles embedded in custom-built shoes and transmitted to a smartphone via Bluetooth. Dynamic foot pressure index of each stride was calculated by purpose-designed software running in the smartphone to distinguish toe-walking strides from normal strides in real time. An auditory signal would be produced to alert the patient each time a toe-walking stride was detected. RESULTS: For CP toe walkers, the one-way analysis of variance indicated a significant difference ($F_{1,14} = 19.492$, $P = 0.001$) in dynamic foot pressure index between the affected side (31.4 +/- 12.0) and the unaffected side (58.6 +/- 2.5). In addition, the validation test showed that this system can distinguish toe-walking strides from normal strides of children with CP with an accuracy of 95.3%. CONCLUSIONS: This system was able to monitor the toe-walking strides of children with CP in real time and had the potential to enhance rehabilitation training efficiency and correct toe-walking gait in children with CP with dynamic equinus.

A Bivariate Mixed-Effects Location-Scale Model with application to Ecological Momentary Assessment (EMA) data.

In: *Health Serv Outcomes Res Methodol* 14 (4), S. 194–212.

Abstract:

A bivariate mixed-effects location-scale model is proposed for estimation of means, variances, and covariances of two continuous outcomes measured concurrently in time and repeatedly over subjects. Modeling the two outcomes jointly allows examination of BS and WS association between the outcomes and whether the associations are related to covariates. The variance-covariance matrices of the BS and WS effects are modeled in terms of covariates, explaining BS and WS heterogeneity. The proposed model relaxes assumptions on the homogeneity of the within-subject (WS) and between-subject (BS) variances. Furthermore, the WS variance models are extended by including random scale effects. Data from a natural history study on adolescent smoking are used for illustration. 461 students, from 9th and 10th grades, reported on their mood at random prompts during seven consecutive days. This resulted in 14,105 prompts with an average of 30 responses per student. The two outcomes considered were a subject's positive affect and a measure of how tired and bored they were feeling. Results showed that the WS association of the outcomes was negative and significantly associated with several covariates. The BS and WS variances were heterogeneous for both outcomes, and the variance of the random scale effects were significantly different from zero.

Punzi, Henry A. (2014):

Efficacy and safety of olmesartan/amlodipine/hydrochlorothiazide in patients with hypertension not at goal with mono, dual or triple drug therapy: results of the CHAMPiOn study.

In: *Ther Adv Cardiovasc Dis* 8 (1), S. 12–21. DOI: 10.1177/1753944713520062.

Abstract:

OBJECTIVE: To assess the efficacy and safety of once daily olmesartan medoxomil (OM)/amlodipine besylate (AM)/hydrochlorothiazide (HCTZ) 40/10/25 mg in patients with hypertension not at goal with mono, dual or triple drug therapy. METHODS: This was a single-center, prospective, open-label, blinded-endpoint study. After a 1-week screening visit, 40 patients were enrolled into the study and given once daily treatment with OM/AM/HCTZ after the patients underwent baseline ambulatory blood pressure monitoring (ABPM) on their original therapy. The primary endpoint was changes from baseline in mean 24 h ABPM [systolic blood pressure (SBP)] after the first day of therapy with OM/AM/HCTZ 40/10/25 mg. Secondary endpoints were changes from baseline in mean 24 h ABPM [diastolic blood pressure (DBP)] after the first day of therapy with OM/AM/HCTZ 40/10/25 mg; mean changes from baseline in trough seated SBP (SeSBP) at day 1 and SeSBP at weeks 1, 2, 3 and 4; mean changes from baseline in trough seated DBP (SeDBP) at day 1 and SeDBP at weeks 1, 2, 3 and 4; and the percentage of subjects achieving mean 24 h, daytime and night-time ABPM BP goals. RESULTS: The baseline paired t-test systolic ABPM was 134.0 +/- 2.77 mmHg and day 1 was 128.6 +/- 2.47 mmHg with a treatment difference of -5.55 +/- 1.3 mmHg ($p<0.0001$). At week 1, paired t-test ABPM SBP reduction was 117.7 +/- 2.0 mmHg with a treatment difference of -16.5 +/- 1.8 mmHg ($p < 0.0001$). At week 2, paired t-test ABPM SBP reduction was 115.8 +/- 1.8 mmHg with a treatment difference of -18.4 +/- 2.0 mmHg ($p < 0.0001$). At week 3, paired t-test ABPM SBP reduction was 115.5 +/- 1.9 mmHg with a treatment difference of -18.6 +/- 2.0 mmHg ($p < 0.0001$). At week 4, paired t-test ABPM SBP reduction was 115.5 +/- 1.8 mmHg with a treatment difference of -18.6 +/- 2.2 mmHg ($p < 0.0001$). The baseline paired t-test SeSBP was 142 +/- 2.43 mmHg and day 1 was 132 +/- 2.59 mmHg with a treatment difference of -9.78 +/- 1.51 mmHg ($p < 0.0001$). At week 1, paired t-test SeSBP reduction was 124.0 +/- 1.6 mmHg with a treatment difference of -17.9 +/- 1.8 mmHg ($p < 0.0001$). At week 2, paired t-test SeSBP reduction was 120.3 +/- 1.7 mmHg with a treatment difference of -21.5 +/- 2.1 mmHg ($p < 0.0001$). At week 3, paired t-test SeSBP reduction was 118.5 +/- 1.8 mmHg with a treatment difference of -23.3 +/- 1.7 mmHg ($p < 0.0001$). At week 4, paired t-test SeSBP reduction was 119.6 +/- 1.7 mmHg with a treatment difference of -22.2 +/- 1.9 mmHg ($p < 0.0001$). CONCLUSION: Treatment with OM/AM/HCTZ achieved superior (SBP) ABPM reductions compared with mono, dual or triple drug therapy, resulting in all patients achieving systolic ABPM goal without ABPM documented hypotension.

Pusuroglu, Hamdi; Akgul, Ozgur; Erturk, Mehmet; Ozal, Ender; Celik, Omer; Gul, Mehmet et al. (2014):

A comparative analysis of leukocyte and leukocyte subtype counts among isolated systolic hypertensive, systo-diastolic hypertensive and nonhypertensive patients.

In: *Kardiol Pol. DOI:* 10.5603/KP.a2014.0044.

Abstract:

BACKGROUND: Isolated systolic hypertension (ISHT) is a subtype of hypertension (HT) that often exhibits wide pulse pressure, and pulse pressure has a strong predictive value for future adverse cardiovascular events. Previous studies have shown the effects of : leukocyte count on prognosis of ischemic heart disease and HT. METHODS: Thus, in this cross-sectional study, we analyzed the relationship between leukocyte counts and subtypes in HT and non-HT groups. The study population consisted of 960 consecutive patients who were admitted to the outpatient clinic of our hospital. After ambulatory blood pressure (ABP) values were assessed, the participants were divided into three groups: isolated systolic hypertensives (98), systo-diastolic hypertensives (405), and nonhypertensives (457). RESULTS: The subjects in the ISHT group were older than those in the systo-diastolic HT and non-HT groups (64+/-10, 53+/-12, and 52+/-13, respectively; p<0.001). The leukocyte and neutrophil counts and neutrophil/lymphocyte (NL) ratios were significantly different in all groups. In subgroup analysis, the leukocyte count, neutrophil count, and N/L ratio were higher in the ISHT and systo-diastolic HT groups than in the non-HT group (p<0.001 for all). The leukocyte count, neutrophil count, and N/L ratio were significantly higher in the ISHT group than in the systo-diastolic HT group (p=0.023, p=0.007, p=0.010, respectively). Neutrophil count (p=0.012; OR=1.229, 95% Cl 1.046-1.444) was independent risk factors for ISHT in multivariate logistic regression analysis. CONCLUSIONS: The leukocyte and neutrophil counts and N/L ratios were higher in the ISHT group than in the systo-diastolic HT and non-HT groups. High neutrophil count was an independent predictor of ISHT.

Putnam, Katherine M.; McSweeney, Lauren B. (2008):

Depressive symptoms and baseline prefrontal EEG alpha activity: a study utilizing Ecological Momentary Assessment.

In: *Biol Psychol* 77 (2), S. 237–240.

Abstract:

Prefrontal cortex (PFC) electroencephalography (EEG) alpha asymmetry has been found in individuals with major depression. However, EEG activity has never been examined in regard to specific depressive symptoms. We examine the relationship between resting baseline PFC alpha activity and both rumination and self-esteem in a depressed outpatient group (N=6) and a healthy control group (N=7) using high-density EEG sampling and multiple longitudinal self report measures, i.e. Ecological Momentary Assessment (EMA). Symptom measures were collected five times daily for 7 days, i.e. 35 assessments. Using a mixed-level analysis, significant Group x Hemisphere interactions for PFC sites and both rumination and self-esteem were found. Within the depressed group, lower bilateral PFC activity predicted higher levels of rumination, and lower right PFC activity predicted higher levels of self-esteem. There were no significant effects for the control group. Results indicate that specific symptoms of depression are uniquely associated with patterns of PFC EEG alpha activity.

Patterns, entropy, and predictability of human mobility and life.

In: *PLoS One* 7 (12), S. e51353. DOI: 10.1371/journal.pone.0051353.

Abstract:

Cellular phones are now offering an ubiquitous means for scientists to observe life: how people act, move and respond to external influences. They can be utilized as measurement devices of individual persons and for groups of people of the social context and the related interactions. The picture of human life that emerges shows complexity, which is manifested in such data in properties of the spatiotemporal tracks of individuals. We extract from smartphone-based data for a set of persons important locations such as "home", "work" and so forth over fixed length time-slots covering the days in the data-set (see also [1], [2]). This set of typical places is heavy-tailed, a power-law distribution with an exponent close to -1.7. To analyze the regularities and stochastic features present, the days are classified for each person into regular, personal patterns. To this are superimposed fluctuations for each day. This randomness is measured by "life" entropy, computed both before and after finding the clustering so as to subtract the contribution of a number of patterns. The main issue that we then address is how predictable individuals are in their mobility. The patterns and entropy are reflected in the predictability of the mobility of the life both individually and on average. We explore the simple approaches to guess the location from the typical behavior, and of exploiting the transition probabilities with time from location or activity A to B. The patterns allow an enhanced predictability, at least up to a few hours into the future from the current location. Such fixed habits are most clearly visible in the working-day length

Chinese city children and youth's walking behavior.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S29-40.

Abstract:

PURPOSE: Although walking has been demonstrated as one of the best forms for promoting physical activity (PA), little is known about Chinese city children and youth's walking behavior. The purpose of this study was therefore to assess ambulatory PA behavior of Chinese city children and youth. METHOD: The daily steps of 2,751 children and youth (1,415 boys, 1,336 girls; aged 9 to 17 years old, M(age) = 154.78 +/- 44.63 months) from 11 cities in China were recorded using ActiGraph GT3X accelerometers for 7 consecutive days. RESULTS: The most active walking day was on Friday (M +/- SD = 11,183 +/- 5,130 steps), followed by Monday (M +/- SD = 10,780 +/- 4,921), Thursday (M +/- SD = 10,705 +/- 4,607), Tuesday (M +/- SD = 10,687 +/- 5,038), Wednesday (M +/- SD = 10,428 +/- 4,697), Saturday (M +/- SD = 9,734 +/- 5,582), and Sunday (M +/- SD = 9,303 +/- 5,569). Participants walked more steps during weekdays (M +/- SD = 10,615 +/- 4,411) than they did during weekend days (M +/- SD = 9,444 +/- 5,224; t = 15.71, p < .01, d = 0.34); boys walked more steps (M +/- SD = 10,847 +/- 4,322) than did girls (M +/- SD = 9,938 +/- 4,282; t = 4.92, p < .01, d = 0.22). The most active age was 11 years old in boys (M +/- SD = 12,984 +/- 4,897) and 10 years old in girls (M +/- SD = 11,745 +/- 4,721), and older children walked fewer steps. The data suggest that depending on age (9 to 17 years old), a range of 5.71% to 35.73%, 29.70% to 56.65%, and 15.96% to 47.62% boys and 22.86% to 40.14%, 29.41% to 46.26%, and 12.94% to 40.14% girls met 3 different health-related criteria for daily steps, respectively. CONCLUSION: Boys walked more than girls walked, but a majority of the Chinese city children and youth did not meet the recommended health-related steps/day.

Quinn, Francis; Johnston, Marie; Johnston, Derek W. (2013):

Testing an integrated behavioural and biomedical model of disability in N-of-1 studies with chronic pain.

In: *Psychology & Health* 28 (12), S. 1391–1406. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-38540-004%26site%3dehost-live;francis.quinn@rgu.ac.uk.

Abstract:

Background: Previous research has supported an integrated biomedical and behavioural model explaining activity limitations. However, further tests of this model are required at the within-person level, because while it proposes that the constructs are related within individuals, it has primarily been tested between individuals in large group studies. We aimed to test the integrated model at the within-person level. Method: Six correlational N-of-1 studies in participants with arthritis, chronic pain and walking limitations were carried out. Daily measures of theoretical constructs were collected using a hand-held computer (PDA), the activity was assessed by self-report and accelerometer and the data were analysed using time-series analysis. Results: The biomedical model was not supported as pain impairment did not predict activity, so the integrated model was supported partially. Impairment predicted intention to move around, while perceived behavioural control (PBC) and intention predicted activity. PBC did not predict activity limitation in the expected direction. Conclusions: The integrated model of disability was partially supported within individuals, especially the behavioural elements. However, results suggest that different elements of the model may drive activity (limitations) for different individuals. The integrated model provides a useful framework for understanding disability and suggests interventions, and the utility of N-of-1 methodology for testing theory is illustrated. Quittner, Alexandra L.; Modi, Avani C.; Lemanek, Kathleen L.; Ievers-Landis, Carolyn E.; Rapoff, Michael A. (2008):

Evidence-based assessment of adherence to medical treatments in pediatric psychology.

In: *Journal of Pediatric Psychology* 33 (9), S. 916-36; discussion 937-8. DOI: 10.1093/jpepsy/jsm064.

Abstract:

OBJECTIVES\r\nAdherence to medical regimens for children and adolescents with chronic conditions is generally below 50% and is considered the single, greatest cause of treatment failure. As the prevalence of chronic illnesses in pediatric populations increases and awareness of the negative consequences of poor adherence become clearer, the need for reliable and valid measures of adherence has grown.\r\nMETHODS\r\nThis review evaluated empirical evidence for 18 measures utilizing three assessment methods: (a) self-report or structured interviews, (b) daily diary methods, and (c) electronic monitors.\r\nRESULTS\r\nTen measures met the \"well-established\" evidence-based (EBA) criteria.\r\nCONCLUSIONS\r\nSeveral recommendations for improving adherence assessment were made. In particular, consideration should be given to the use of

innovative technologies that provide a window into the \"real time\" behaviors of patients and families. Providing written treatment plans, identifying barriers to good adherence, and examining racial and ethnic differences in attitudes, beliefs and behaviors affecting adherence were strongly recommended.

Rabbitts, J. A.; Holley, A. L.; Karlson, C. W.; Palermo, T. M. (2013):

Bidirectional Associations Between Pain and Physical Activity in Adolescents.

In: *Clin.J Pain* (0749-8047 (Linking)). DOI: 10.1097/AJP.0b013e31829550c6.

Abstract:

OBJECTIVES:: The objectives were to: (1) examine temporal relationships between pain and activity in youth, specifically, whether physical activity affects pain intensity and whether intensity of pain affects subsequent physical activity levels on a daily basis, and (2) examine clinical predictors of this relationship. METHODS:: Participants were 119 adolescents (59 with chronic pain and 60 healthy) aged 12 to 18 years, 71% female. Adolescents completed 10 days of actigraphic monitoring of physical activity and daily electronic diary recordings of pain intensity, medication use, sleep quality, and mood. Linear mixed models assessed daily associations among physical activity and pain. Daily mean (average count/min) and peak (highest daily level) activity were used for analyses. Medication use, sleep quality, and mood ratings were included as covariates, and age, sex, and body mass index percentile were adjusted for. RESULTS:: Higher pain intensity was associated with lower peak physical activity levels on the next day (t641=-2.25, P=0.03) and greater medication use predicted lower mean physical activity levels the same day (t641=-2.10, P=0.04). Higher mean physical activity levels predicted lower pain intensity ratings at the end of the day (t705=-2.92, P=0.004), but only in adolescents with chronic pain. DISCUSSION:: Youth experiencing high pain intensity limit their physical activity level on a day-to-day basis. Activity was related to subsequent pain intensity, and may represent an important focus in chronic pain treatment. Further study of the effect of medications on subsequent activity is needed

Practical physical activity measurement in youth: a review of contemporary approaches.

In: *World J Pediatr* 8 (3), S. 207–216. DOI: 10.1007/s12519-012-0359-z.

Abstract:

BACKGROUND: The accurate evaluation of physical activity levels amongst youth is critical for quantifying physical activity behaviors and evaluating the effect of physical activity interventions. The purpose of this review is to evaluate contemporary approaches to physical activity evaluation amongst youth. DATA SOURCES: The literature from a range of sources was reviewed and synthesized to provide an overview of contemporary approaches for measuring youth physical activity. RESULTS: Five broad categories are described: selfreport, instrumental movement detection, biological approaches, direct observation, and combined methods. Emerging technologies and priorities for future research are also identified. CONCLUSIONS: There will always be a trade-off between accuracy and available resources when choosing the best approach for measuring physical activity amongst youth. Unfortunately, cost and logistical challenges may prohibit the use of "gold standard" physical activity measurement approaches such as doubly labelled water. Other objective methods such as heart rate monitoring, accelerometry, pedometry, indirect calorimetry, or a combination of measures have the potential to better capture the duration and intensity of physical activity, while self-reported measures are useful for capturing the type and context of activity

Rahman, Khairunnessa; Burton, Alexander; Galbraith, Sally; Lloyd, Andrew; Vollmer-Conna, Ute (2011):

Sleep-wake behavior in chronic fatigue syndrome.

In: *Sleep: Journal of Sleep and Sleep Disorders Research* 34 (5), S. 671–678. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-16230-017&site=ehost-live;ute@unsw.edu.au.

Abstract:

Study Objectives: Disturbances of the internal biological clock manifest as fatigue, poor concentration, and sleep disturbances—symptoms reminiscent of chronic fatigue syndrome (CFS) and suggestive of a role for circadian rhythm disturbance in CFS. We examined circadian patterns of activity, sleep, and cortisol secretion in patients with CFS. Design: Case-control study, 5-day behavioral observation. Setting: Natural setting/home environment Participants: 15 patients with CFS and 15 healthy subjects of similar age, sex, body mass index (BMI), and activity levels. Interventions: N/A Measurements: Self-report questionnaires were used to obtain medical history and demographic information and to assess health behaviors, somatic and psychological

symptoms, and sleep quality. An actiwatch accelerometer recorded activity and sleep patterns over 5 days with concurrent activity and symptom logs. Diurnal salivary cortisol secretion was measured. Additionally, overnight heart rate monitoring and pain sensitivity assessment was undertaken. Results: Ratings of symptoms, disability, sleep disturbance, and pain sensitivity were greater in patients with CFS. No between-group differences were found in the pattern or amount of sleep, activity, or cortisol secretion. Afternoon activity levels significantly increased evening fatigue in patients but not control subjects. Low nocturnal heart rate variability was identified as a biological correlate of unrefreshing sleep. Conclusions: We found no evidence of circadian rhythm disturbance in CFS. However, the role of autonomic activity in the experience of unrefreshing sleep warrants further assessment. The activity symptom-relationship modelled here is of clinical significance in the approach to activity and symptom management in the treatment of CFS. Raj, Rishi; Ussavarungsi, Kamonpun; Nugent, Kenneth (2014):

Accelerometer-based devices can be used to monitor sedation/agitation in the intensive care unit.

In: *J Crit Care. DOI:* 10.1016/j.jcrc.2014.05.014.

Abstract:

PURPOSE: Monitoring sedation/agitation levels in patients in the intensive care unit (ICU) are important to direct treatment and to improve outcomes. This study was designed to determine the potential use of accelerometer-based sensors/devices to objectively measure sedation/agitation in patients admitted to the ICU. MATERIALS AND METHODS: Accelerometer-based devices (actigraphs) were placed on nondominant wrists of 86 patients in the ICU after informed consent. The sedation/agitation levels were classified as deep sedation, light sedation, alert and calm, mild agitation and severe agitation, and measured at regular intervals. The sedation/agitation levels were correlated with the accelerometer data (downloaded raw actigraphy data). RESULTS: The sedation/agitation levels correlated strongly with the accelerometer readings represented by mean actigraphy counts (r = 0.968; P = .007) and the proportion of time spent moving as determined by actigraphy (r = 0.979; P = .004). CONCLUSIONS: Accelerometer data correlate strongly with the sedation/agitation levels of patients in the ICUs, and appropriately designed accelerometer-based sensors/devices have the potential to be used for automating objective and continuous monitoring of sedation/agitation levels in patients in the ICU.

Web-based collaborative care for type 2 diabetes: a pilot randomized trial.

In: *Diabetes Care* 32 (2), S. 234–239. DOI: 10.2337/dc08-1220.

Abstract:

OBJECTIVE\r\nTo test Web-based care management of glycemic control using a shared electronic medical record with patients who have type 2 diabetes.\r\nRESEARCH DESIGN AND METHODS\r\nWe conducted a trial of 83 adults with type 2 diabetes randomized to receive usual care plus Web-based care management or usual care alone between August 2002 and May 2004. All patients had GHb > or =7.0%, had Web access from home, and could use a computer with English language-based programs. Intervention patients received 12 months of Web-based care management. The Web-based program included patient access to electronic medical records, secure e-mail with providers, feedback on blood glucose readings, an educational Web site, and an interactive online diary for entering information about exercise, diet, and medication. The primary outcome was change in GHb.\r\nRESULTS\r\nGHb levels declined by 0.7% (95% CI 0.2-1.3) on average among intervention patients compared with usual-care patients. Systolic blood pressure, diastolic blood pressure, total cholesterol levels, and use of in-person health care services did not differ between the two groups.\r\nCONCLUSIONS\r\nCare management delivered through secure patient Web communications improved glycemic control in type 2 diabetes.

Dynamic factor analysis: Modeling person-specific process. In: Todd D. Little (Hg.): The Oxford handbook of quantitative methods (Vol 2): Statistical analysis.

New York, NY US: Oxford University Press (Oxford library of psychology), S. 441–457. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-01010-021%26site%3dehost-live.

Abstract:

(from the chapter) Modern data collection technologies are providing large data sets, with many repeated observations of many individuals on many variables—and new opportunities for application of analytical techniques that consider individuals as unique, complex, multivariate, dynamic entities. In this chapter we review the conceptual and technical background for dynamic factor analysis and provide a primer for application to multivariate time series data. Step-by-step procedures are illustrated using daily diary data obtained from three women over 100+ days. Specifically, we provide background on and demonstrate (l) formulation of DFA research questions; (2) study design and data collection; (3) variable selection and data pre-processing procedures; (4) the fitting and evaluation of person-specific DFA models; and (5) examination of between-person differences/similarities. We conclude by pointing to some extensions that might be elaborated and used to articulate additional complexities of within-person process. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (chapter)

Behavioral Landscapes and Change in Behavioral Landscapes: A Multiple Time-Scale Density Distribution Approach.

In: *Res Hum.Dev.* 10 (1), S. 88–110. DOI: 10.1080/15427609.2013.760262.

Abstract:

In developmental arenas, it is well accepted that multiple observations are needed to obtain a robust characterization of individuals' behavioral tendencies across time and context. In this paper, we fuse core ideas from the study of lifespan development with intraindividual variability based approaches to personality and methods used to characterize the topography of geographic landscapes. We generalize the notion of density distributions into bivariate and multivariate space and draw parallels between the resulting behavioral landscapes and geographic landscapes. We illustrate through an empirical example how multiple time-scale study designs, measures of intraindividual variability, and methods borrowed from geography can be used to describe both an individual's behavioral landscape and changes in the behavioral landscape

Ram, Nilam; Gerstorf, Denis (2009):

Time-structured and net intraindividual variability: tools for examining the development of dynamic characteristics and processes.

In: *Psychology and Aging* 24 (4), S. 778–791. DOI: 10.1037/a0017915.

Abstract:

The study of intraindividual variability is the study of fluctuations, oscillations, adaptations, and \"noise\" in behavioral outcomes that manifest on microtime scales. This article provides a descriptive frame for the combined study of intraindividual variability and aging/development. At the conceptual level, we show that the study of intraindividual variability provides access to dynamic characteristics-construct-level descriptions of individuals' capacities for change (e.g., lability)--and to dynamic processes--the systematic changes that individuals exhibit in response to endogenous and exogenous influences (e.g., regulation). At the methodological level, we review how quantifications of net intraindividual variability and models of time-structured intraindividual variability are used to measure and describe dynamic characteristics and processes. At the research design level, we point to the benefits of measurement-burst study designs, wherein data are obtained across multiple time scales, for the study of development.

Seizure detection, seizure prediction, and closed-loop warning systems in epilepsy.

In: *Epilepsy Behav* 37C, S. 291–307. DOI: 10.1016/j.yebeh.2014.06.023.

Abstract:

Nearly one-third of patients with epilepsy continue to have seizures despite optimal medication management. Systems employed to detect seizures may have the potential to improve outcomes in these patients by allowing more tailored therapies and might, additionally, have a role in accident and SUDEP prevention. Automated seizure detection and prediction require algorithms which employ feature computation and subsequent classification. Over the last few decades, methods have been developed to detect seizures utilizing scalp and intracranial EEG, electrocardiography, accelerometry and motion sensors,

electrodermal activity, and audio/video captures. To date, it is unclear which combination of detection technologies yields the best results, and approaches may ultimately need to be individualized. This review presents an overview of seizure detection and related prediction methods and discusses their potential uses in closed-loop warning systems in epilepsy.

Alcohol craving in adolescents: bridging the laboratory and natural environment.

In: *Psychopharmacology (Berl)* (0033-3158 (Linking)). DOI: 10.1007/s00213-013-3372-6.

Abstract:

RATIONALE: Initial lab studies suggest that adolescent drinkers crave alcohol when presented with alcohol cues. Whether this effect generalizes to the natural environment, however, remains unknown, and studies have not examined whether craving predicts drinking among youths. OBJECTIVES: This study builds on existing research by pairing controlled lab-based cue reactivity assessments (CRAs) with data collected in the natural environment using ecological momentary assessment (EMA) methods. We examined whether alcohol cues evoke craving among adolescent drinkers in the lab and natural environment, and tested the clinical relevance of craving during adolescence by examining the prospective association between craving and alcohol use. METHODS: Non-treatment-seeking adolescent drinkers (N = 42; ages 15 to 20 years) completed a lab-based CRA followed by a 1-week EMA monitoring period. During the EMA period, youth were prompted randomly throughout the day to record momentary data on craving and contextual factors (e.g., alcohol cues, peers present). RESULTS: Alcohol cues elicited craving in the lab, and this effect generalized to the natural environment, especially among adolescents with more alcohol problems. In addition, craving predicted subsequent drinking levels in the natural environment. CONCLUSIONS: This study demonstrates the utility of pairing lab paradigms with EMA methods to better characterize adolescents' reactivity to alcohol cues. Results implicate craving as a clinically meaningful motivator for drinking among adolescents and highlight a potentially important target of pharmacological or behavioral intervention

Ramos-Castro, J.; Moreno, J.; Miranda-Vidal, H.; Garcia-Gonzalez, M. A.; Fernandez-Chimeno, M.; Rodas, G.; Capdevila, L. (2012):

Heart rate variability analysis using a seismocardiogram signal.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 5642–5645. DOI: 10.1109/EMBC.2012.6347274.

Abstract:

Seismocardiography is a simple and non invasive method of recording cardiac activity from the movements of the body caused by heart pumping. In this preliminary study we use a smartphone to record this acceleration and estimate the heart rate. We compare the heart rate variability parameters from the seismocardiogram and ECG reference signal. The results show a great similarity and are strongly influenced by the instability in the sampling frequency of the device. The differences between RR series are lower than 10 ms

Rancourt, Diana; Leahey, Tricia M.; Larose, Jessica Gokee; Crowther, Janis H. (2015):

Effects of weight-focused social comparisons on diet and activity outcomes in overweight and obese young women.

In: *Obesity (Silver Spring)* 23 (1), S. 85–89. DOI: 10.1002/oby.20953.

Abstract:

OBJECTIVE: To investigate social comparison processes as a potential mechanism by which social networks impact young women's weight control thoughts and behaviors and to examine whether social comparisons with close social ties (i.e., friends) have a greater influence on weight control outcomes relative to more emotionally distant ties. METHODS: Using Ecological Momentary Assessment, overweight young adult women (N = 46; M age = 19; M BMI = 29) reported the nature and effects of weight-focused social comparisons on dieting and exercising intentions and on behaviors during their daily routine. RESULTS: Relative to social comparisons to targets of the same weight, weight-focused comparisons to both thinner and heavier individuals led to increased thoughts of dieting and exercising. Moreover, comparisons to thinner targets also increased the likelihood of engaging in actual dieting and exercising behaviors. Weight comparisons to friends amplified these effects. CONCLUSIONS: Weight-focused social comparisons may be one mechanism by which social networks impact weight control thoughts and behaviors. Obesity interventions with young adults may achieve better outcomes by harnessing social comparison processes in treatment.

Using ecological momentary assessment to examine interpersonal and affective predictors of loss of control eating in adolescent girls.

In: *Int J Eat Disord. DOI:* 10.1002/eat.22333.

Abstract:

OBJECTIVE: Pediatric loss of control (LOC) eating is predictive of partial- and full-syndrome binge eating disorder. The interpersonal model proposes that LOC eating is used to cope with negative mood states resulting from interpersonal distress, possibly on a momentary level. We therefore examined temporal associations between interpersonal problems, negative affect, and LOC eating among overweight adolescent girls using ecological momentary assessment (EMA). METHOD: Thirty overweight and obese (>/=85th body mass index (BMI) percentile; BMI: M = 36.13, SD = 7.49 kg/m2) adolescent females (Age: M = 14.92, SD = 1.54 y; 60.0% African American) who reported at least two LOC episodes in the past month completed self-report momentary ratings of interpersonal problems, state affect, and LOC eating for 2 weeks. A series of 2-level multilevel models with centering within subjects was conducted. RESULTS: Between- and within-subjects interpersonal problems (p's < .05), but not between- (p = .12) or within- (p = .32) subjects negative affect predicted momentary LOC eating. At the between-subjects level, interpersonal problems significantly predicted increases in negative affect (p < 001). DISCUSSION: Naturalistic data lend support to the predictive value of interpersonal problems for LOC eating among adolescents. Interventions targeting interpersonal factors on a momentary basis may be useful during this developmental stage. (c) 2014 Wiley Periodicals, Inc. (Int J Eat Disord 2014;).

Raselli, Carla; Broderick, Joan E. (2007):

The association of depression and neuroticism with pain reports: a comparison of momentary and recalled pain assessment.

In: *Journal of Psychosomatic Research* 62 (3), S. 313–320.

Abstract:

OBJECTIVE:

Pain assessment has been shown to be affected by depression, neuroticism, and recall bias. The purpose of this study was to determine whether momentary pain assessment, compared with recalled pain reports, would diminish the influence of neuroticism and depression on the measurement of pain.

METHODS:

Patients with chronic pain (n=66) completed depression (Beck Depression Inventory II) and neuroticism (NEO Personality Inventory) questionnaires, made weekly recall pain ratings, judged their change in pain from 1 week to the next over a 4-week period, and collected momentary reports of pain intensity and pain unpleasantness over a 2-week period.

RESULTS

Analyses showed that neuroticism and depression correlated with pain intensity and pain unpleasantness at low levels for both momentary and recalled pain reports. Neuroticism and depression did not influence the accuracy of recalled pain (difference between momentary and recalled data). Both neuroticism and depression were systematically associated with ratings of judged change in pain even when actual changes in pain were controlled. Specifically, for increased levels of baseline depression and neuroticism, patients displayed a pattern of judging recent pain as more severe than pain in the previous week following several weeks of symptom monitoring.

CONCLUSION:

There was little evidence for neuroticism and depression affecting either recall or momentary pain ratings or influencing the accuracy of recall ratings. However, neuroticism and depression did influence pain assessment when the task involved rating change in pain-a measure widely used in clinical research.

Ratcliff, Chelsea G.; Lam, Cho Y.; Arun, Banu; Valero, Vincente; Cohen, Lorenzo (2014):

Ecological momentary assessment of sleep, symptoms, and mood during chemotherapy for breast cancer.

In: *Psychooncology. DOI:* 10.1002/pon.3525.

Abstract:

OBJECTIVE: This study examined the association of sleep before and during a chemotherapy (CT) cycle for breast cancer with symptoms and mood during a CT cycle. METHODS: Twenty women undergoing CT for breast cancer completed the Pittsburgh Sleep Quality Index (PSQI) 1 h prior to a CT infusion. For 3 weeks following infusion, participants estimated sleep efficiency, minutes to sleep (sleep latency), number of nocturnal awakenings (sleep fragmentation (SF)), and sleep quality (SQ) each morning and rated symptoms (nausea, fatigue, numbness, and difficulty thinking) and mood three times daily (morning, afternoon, and evening) via ecological momentary assessments using automated handheld computers. RESULTS: The results showed that disturbed sleep (PSQI score > 5) prior to CT infusion was associated with greater fatigue, and more negative and anxious mood throughout the 3-week CT cycle, and good pre-CT infusion sleep (PSQI score < 5) buffered anxious mood in the first days following infusion. Time-lagged analyses controlling for mood/symptom ratings reported the previous evening revealed that longer sleep latency and greater SF were associated with greater daytime fatigue; poorer SQ and greater SF were antecedents of worse morning negative mood, and greater SF was associated with feeling more passive and drowsy. No evening symptom or mood ratings were related to subsequent SQ. CONCLUSIONS: These findings suggest that disturbed sleep before and after a CT infusion exacerbates fatigue, and negative, anxious, and drowsy mood during a CT cycle. Reducing sleep disturbance may be an important way to improve quality of life during CT. Copyright (c) 2014 John Wiley & Sons, Ltd.

Ratcliff, Megan B.; Zeller, Meg H.; Inge, Thomas H.; Hrovat, Kathleen B.; Modi, Avani C. (2014):

Feasibility of ecological momentary assessment to characterize adolescent postoperative diet and activity patterns after weight loss surgery.

In: *Surg Obes Relat Dis. DOI:* 10.1016/j.soard.2014.01.034.

Abstract:

BACKGROUND: Adherence to postoperative lifestyle recommendations may be associated with weight outcomes among weight loss surgery (WLS) patients, but it is difficult to objectively assess and has not been reported among adolescents. Methods of assessment that are ecologically valid and provide important contextual information related to adherence are needed. The objective of this pilot study was to demonstrate the feasibility of using a form of ecological momentary assessment (i.e., daily phone diaries; DPD) to assess postoperative diet and activity patterns among a sample of adolescent WLS patients to determine adherence to best-practice lifestyle recommendations. SETTING: University Hospital. METHODS: Eight adolescent WLS patients completed 3 consecutive DPDs at 12 and 18 months postsurgery. RESULTS: Ninety-four percent of DPD's were completed with an average 20.9+/-5.0 activities/day. Although adolescents engaged in recommended lifestyle behaviors (e.g.,>/=30 min moderate physical activity/d; duration of meals/snacks>/=20 min) some of the time, few were adherent to postoperative physical activity and dietary recommendations the majority of the time. CONCLUSION: The DPD provides a feasible and informative methodology for assessing adherence behaviors among adolescent WLS patients. It is a relatively low burden method that may be useful in identifying behavioral targets for postoperative intervention. Adherence to postoperative lifestyle recommendations may be a serious concern among this cohort. These preliminary data shed light on potential targets for postoperative intervention. Targeting nonadherence is essential in not only improving health outcomes but in deciphering the true potential effectiveness of WLS in this at-risk population.

Rathbun, S. L.; Song, X.; Neustifter, B.; Shiffman, S. (2013):

Survival Analysis with Time-Varying Covariates Measured at Random Times by Design.

In: *J R Stat.Soc.Ser.C.Appl.Stat.* 62 (3), S. 419–434. DOI: 10.1111/j.1467-9876.2012.01064.x.

Abstract:

Ecological momentary assessment (EMA) is a method for collecting real-time data in subjects' environments. It often uses electronic devices to obtain information on psychological state through administration of questionnaires at times selected from a probability-based sampling design. This information can be used to model the impact of momentary variation in psychological state on the lifetimes to events such as smoking lapse. Motivated by this, a probability-sampling framework is proposed for estimating the impact of time-varying covariates on the lifetimes to events. Presented as an alternative to joint modeling of the covariate process as well as event lifetimes, this framework calls for sampling covariates at the event lifetimes and at times selected according to a probability-based sampling design. A design-unbiased estimator for the cumulative hazard is substituted into the log likelihood, and the resulting objective function is maximized to obtain the proposed estimator. This estimator has two quantifiable sources of variation, that due to the survival model and that due to sampling the covariates. Data from a nicotine patch trial are used to illustrate the proposed approach

Raustorp, Anders; Boldemann, Cecilia; Johansson, Maria; Mårtensson, Fredrika (2010):

Objectively measured physical activty level a during a physical education class: A pilot study with Swedish youth.

In: *International journal of adolescent medicine and health* 22 (4), S. 469–476.

Abstract:

The aim of this study is to advance our knowledge of the contribution of a typical physical education (PE) class to children's daily physical activity.

METHODS:

The pilot project is a part of a survey study comprising 11 fourth grader classes (250 pupils). One class of 19 pupils (9 girls) participated in the pilot study. Daily step counts were measured by Yamax pedometers during four consecutive weekdays. During PE class, the participants wore a second pedometer and an Actigraph GT1M accelerometer.

RESULTS:

The total average step count during PE class was 2512, average 74 steps/min. The counts for the whole day were 16668, and 19 steps/min respectively. The total share of moderate-vigorous physical activity (MVPA) of the PE class was 50.4% (52.5% and 48.3% for boys and girls respectively). There was an inverse correlation between daily mean step count and contribution of PE class step to daily mean step (r = -0.64, p = .003).

CONCLUSION:

The contribution of PE class to MVPA was in high in both boys and girls. Considering the suggested independent role of physical fitness for cardiovascular health in children, the PE class must be seen as an important health factor, especially for otherwise inactive children.

Rawson, Eric S.; Walsh, Talia M. (2010):

Estimation of resistance exercise energy expenditure using accelerometry.

In: *Med Sci Sports Exerc* 42 (3), S. 622–628. DOI: 10.1249/MSS.0b013e3181b64ef3.

Abstract:

UNLABELLED\r\nResistance exercise is recommended by the major health and sports medicine organizations to maintain good health, but resistance exercise energy expenditure is difficult to measure. Accelerometers offer a viable alternative to estimate energy expenditure during resistance exercise because they are cost effective and do not restrict motion or exercise choice.\r\nPURPOSE\r\n: To estimate resistance exercise energy expenditure using accelerometry and to determine whether there are differences in counts of activity during resistance exercise on the basis of accelerometer location.\r\nMETHODS\r\nThirty men and women (21.6 yr) performed two sets of 10 repetitions of each of eight exercises. During the exercise protocol, participants wore accelerometers (ActiGraph GT1M) on the wrist, waist, and ankle and a portable metabolic system (CosMed K4b(2)).\r\nRESULTS\r\nActivity counts (mean +/- SD) were different between the wrist (61,282 +/- 8358), the ankle (26,886 +/- 3998), and the waist (6565 +/- 2445). Resistance exercise energy expenditure was significantly associated with ankle (r = 0.50; P < 0.01) and waist (r = 0.77; P < 0.001) accelerometer counts, and there was a trend for an association between resistance exercise energy expenditure and wrist accelerometer counts (r = 0.31; P = 0.10). Total waist accelerometer counts explained 59% of the variance (R(2) = 0.59) in energy expenditure. A regression equation to predict resistance exercise energy expenditure including sex, fat-free mass, and counts of activity from the waist accelerometer explained 90% (R(2) = 0.90) of the variance in energy expenditure.\r\nCONCLUSION\r\nResistance exercise energy expenditure can be estimated using a uniaxial accelerometer worn at the waist, along with the sex, and fat-free mass, of the participant.

Polymorphisms of the mu-opioid receptor and dopamine D4 receptor genes and subjective responses to alcohol in the natural environment.

In: *Journal of Abnormal Psychology* 119 (1), S. 115–125. DOI: 10.1037/a0017550.

Abstract:

Polymorphisms of the mu-opioid receptor (OPRM1) and dopamine D4 receptor (DRD4) genes are associated with subjective responses to alcohol and urge to drink under laboratory conditions. This study examined these associations in the natural environment using ecological momentary assessment. Participants were non-treatment-seeking heavy drinkers (n = 112, 52%

female, 61% alcohol dependent) who enrolled in a study of naltrexone effects on craving and drinking in the natural environment. Data were culled from 5 consecutive days of drinking reports prior to medication randomization. Analyses revealed that, after drinking, carriers of the Asp40 allele of the OPRM1 gene reported higher overall levels of vigor and lower levels negative mood, as compared to homozygotes for the Asn40 variant. Carriers of the long allele (i.e., >or=7 tandem repeats) of the DRD4 endorsed greater urge to drink than homozygotes for the short allele. Effects of OPRM1 and DRD4 variable-number-of-tandem-repeats genotypes appear to be alcohol dose-dependent. Specifically, carriers of the DRD4-L allele reported slight decreases in urge to drink at higher levels of estimated blood alcohol concentration (eBAC), and Asp40 carriers reported decreases in vigor and increases in negative mood as eBAC rose, as compared to carriers of the major allele for each gene. Self-reported vigor and urge to drink were positively associated with alcohol consumption within the same drinking episode. This study extends findings on subjective intoxication, urge to drink, and their genetic bases from controlled laboratory to naturalistic settings.

Rea, Mark S.; Brons, Jennifer A.; Figueiro, Mariana G. (2011):

Measurements of light at night (LAN) for a sample of female school teachers.

In: *Chronobiology International* 28 (8), S. 673–680. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-21647-004&site=ehost-live;ream@rpi.edu.

Abstract:

Epidemiological studies have shown an association between rotating shiftwork and breast cancer (BC) risk. Recently, light at night (LAN) measured by satellite photometry and by self-reports of bedroom brightness has been shown to be associated with BC risk, irrespective of shiftwork history. Importance has been placed on these associations because retinal light exposures at night can suppress the hormone melatonin and/or disrupt circadian entrainment to the local 24-h light-dark cycle. The present study examined whether it was valid to use satellite photometry and self-reports of brightness to characterize light, as it might stimulate the circadian system and thereby affect BC incidence. Calibrated photometric measurements were made at the bedroom windows and in the bedrooms of a sample of female school teachers, who worked regular dayshifts and lived in a variety of satellite-measured sky brightness categories. The light levels at both locations were usually very low and were independent of the amount of satellite-measured light. Calibrated photometric measurements were also obtained at the corneas of these female school teachers together with calibrated accelerometer measurements for seven consecutive days and evenings. Based upon these personal light exposure and activity measurements, the female teachers who participated in this study did not have disrupted light-dark cycles like those associated with rotating shiftworkers who do exhibit a higher risk for BC. Rather, this sample of female school teachers had 24-h light-dark and activity-rest patterns very much like those experienced by dayshift nurses examined in an earlier study who are not at an elevated risk of BC. No relationship was found between the amount of satellite-measured light levels and the 24-h light-dark patterns these women experienced. It was concluded from the present study that satellite photometry is unrelated to personal light exposures as they might affect melatonin suppression and/or circadian disruption. More generally, photometric devices calibrated in terms of the operational characteristics of the human circadian system must be used to meaningfully link LAN and BC incidence. Read, Scott A.; Collins, Michael J.; Vincent, Stephen J. (2014):

Light exposure and physical activity in myopic and emmetropic children.

In: *Optom Vis Sci* 91 (3), S. 330–341. DOI: 10.1097/OPX.0000000000000160.

Abstract:

PURPOSE: To objectively assess daily light exposure and physical activity levels in myopic and emmetropic children. METHODS: One hundred two children (41 myopes and 61 emmetropes) aged 10 to 15 years old had simultaneous objective measures of ambient light exposure and physical activity collected over a 2-week period during school term, using a wrist-worn actigraphy device (Actiwatch 2). Measures of visible light illuminance and physical activity were captured every 30 seconds, 24 hours a day over this period. Mean hourly light exposure and physical activity for weekdays and weekends were examined. To ensure that seasonal variations did not confound comparisons, the light and activity data of the 41 myopes was compared with 41 age- and gender-matched emmetropes who wore the Actiwatch over the same 2-week period. RESULTS: Mean light exposure and physical activity for all 101 children with valid data exhibited significant changes with time of day and day of the week ($p < 0.0001$). On average, greater daily light exposure occurred on weekends compared to weekdays ($p < 0.05$), and greater physical activity occurred on weekdays compared to weekends ($p < 0.01$). Myopic children ($n = 41$, mean daily light exposure 915 +/- 519 lx) exhibited significantly lower average light exposure compared to 41 age- and gender-matched emmetropic children (1272 +/- 625 lx, $p < 0.01$). The amount of daily time spent in bright light conditions (>1000 lx) was also significantly greater in emmetropes (127 +/- 51 minutes) compared to myopes (91 +/- 44 minutes, $p < 0.001$). No significant differences were found

between the average daily physical activity levels of myopes and emmetropes (p > 0.05). CONCLUSIONS: Myopic children exhibit significantly lower daily light exposure, but no significant difference in physical activity compared to emmetropic children. This suggests the important factor involved in documented associations between myopia and outdoor activity is likely exposure to bright outdoor light rather than greater physical activity.

Real, Ruben G. L.; Dickhaus, Thorsten; Ludolph, Albert; Hautzinger, Martin; Kubler, Andrea (2014):

Well-being in amyotrophic lateral sclerosis: a pilot experience sampling study.

In: *Front Psychol* 5, S. 704. DOI: 10.3389/fpsyg.2014.00704.

Abstract:

OBJECTIVE: The aim of this longitudinal study was to identify predictors of instantaneous well-being in patients with amyotrophic lateral sclerosis (ALS). Based on flow theory well-being was expected to be highest when perceived demands and perceived control were in balance, and that thinking about the past would be a risk factor for rumination which would in turn reduce well-being. METHODS: Using the experience sampling method, data on current activities, associated aspects of perceived demands, control, and well-being were collected from 10 patients with ALS three times a day for two weeks. RESULTS: RESULTS show that perceived control was uniformly and positively associated with well-being, but that demands were only positively associated with well-being when they were perceived as controllable. Mediation analysis confirmed thinking about the past, but not thinking about the future, to be a risk factor for rumination and reduced well-being. DISCUSSION: Findings extend our knowledge of factors contributing to well-being in ALS as not only perceived control but also perceived demands can contribute to well-being. They further show that a focus on present experiences might contribute to increased well-being.

Ambulatory blood pressure monitoring-derived short-term blood pressure variability is increased in Cushing's syndrome.

In: *Endocrine. DOI:* 10.1007/s12020-014-0164-7.

Abstract:

Cushing's syndrome is associated with high cardiovascular morbility and mortality. Blood pressure (BP) variability within a 24-h period is increasingly recognized as an independent predictor of cardiovascular risk. The aim of our study was to investigate the short-term BP variability indices in Cushing's syndrome. Twenty-five patients with Cushing's syndrome (mean age 49 +/- 13 years, 4 males; 21 Cushing's disease and 4 adrenal adenoma patients) underwent 24-h ambulatory BP monitoring (ABPM) and evaluation of cardiovascular risk factors. Cushing patients were divided into 8 normotensive (NOR-CUSH) and 17 hypertensive (HYP-CUSH) patients and were compared with 20 normotensive (NOR-CTR) and 20 hypertensive (HYP-CTR) age-, sex-, and BMI-matched control subjects. Short-term BP variability was derived from ABPM and calculated as the following: (1) standard deviation (SD) of 24-h, daytime, and nighttime BP; (2) 24-h weighted SD of BP; and (3) average real variability (ARV), i.e., the average of the absolute differences between consecutive BP measurements over 24 h. In comparison with controls, patients with Cushing's syndrome, either normotensive or hypertensive, had higher 24-h and daytime SD of BP, as well as higher 24-h weighted SD and ARV of BP (P = 0.03 to P < 0.0001). No difference in metabolic parameters was observed between NOR-CTR and NOR-CUSH or between HYP-CTR and HYP-CUSH subgroups. ABPM-derived short-term BP variability is increased in Cushing's syndrome, independent of BP elevation. It may represent an additional cardiovascular risk factor in this disease. The role of excess cortisol in BP variability has to be further clarified.

Recio-Rodriguez, Jose I.; Martin-Cantera, Carlos; Gonzalez-Viejo, Natividad; Gomez-Arranz, Amparo; Arietaleanizbeascoa, Maria S.; Schmolling-Guinovart, Yolanda et al. (2014):

Effectiveness of a smartphone application for improving healthy lifestyles, a randomized clinical trial (EVIDENT II): study protocol.

In: *BMC Public Health* 14 (1), S. 254. DOI: 10.1186/1471-2458-14-254.

Abstract:

BACKGROUND: New technologies could facilitate changes in lifestyle and improve public health. However, no large randomized, controlled studies providing scientific evidence of the benefits of their use have been made. The aims of this study are to develop and validate a smartphone application, and to evaluate the effect of adding this tool to a standardized intervention

designed to improve adherence to the Mediterranean diet and to physical activity. An evaluation is also made of the effect of modifying habits upon vascular structure and function, and therefore on arterial aging. METHODS/DESIGN: A randomized, double-blind, multicenter, parallel group clinical trial will be carried out. A total of 1215 subjects under 70 years of age from the EVIDENT trial will be included. Counseling common to both groups (control and intervention) will be provided on adaptation to the Mediterranean diet and on physical activity. The intervention group moreover will receive training on the use of a smartphone application designed to promote a healthy diet and increased physical activity, and will use the application for three months. The main study endpoints will be the changes in physical activity, assessed by accelerometer and the 7-day Physical Activity Recall (PAR) interview, and adaptation to the Mediterranean diet, as evaluated by an adherence questionnaire and a food frequency questionnaire (FFQ). Evaluation also will be made of vascular structure and function based on central arterial pressure, the radial augmentation index, pulse velocity, the cardio-ankle vascular index, and carotid intima-media thickness. DISCUSSION: Confirmation that the new technologies are useful for promoting healthier lifestyles and that their effects are beneficial in terms of arterial aging will have important clinical implications, and may contribute to generalize their application in favor of improved population health. TRIAL REGISTRATION: Clinical Trials.gov Identifier: NCT02016014.

Reddy, Arun K.; Jogendra, Mather R. D.; Rosendorff, Clive (2014):

Blood pressure measurement in the geriatric population.

In: *Blood Press Monit* 19 (2), S. 59–63. DOI: 10.1097/MBP.0000000000000021.

Abstract:

As the population above 60 years of age is the fastest growing and hypertension is highly prevalent in this group, accurate blood pressure (BP) measurement in the elderly is a very important and widely applicable subject. As with any other population, an accurate measurement of BP is essential to plan therapy and this remains an important consideration in the elderly as well. There are some unique problems of BP measurement in the elderly, including drug-induced orthostatic hypotension, white-coat hypertension, and advanced atherosclerotic disease with stiff arteries. For clinical use, home blood pressure monitoring (HBPM), office measurement, and ambulatory blood pressure monitoring all play a role in patient management. In the office setting, aneroid devices, hybrid devices with electronic transducers, and oscillometric devices are available; all of these require frequent calibration, well-trained operators and technically sound execution. Because the white-coat effect is common in this group, there is a good case for the use of HBPM, which could also be used to detect orthostatic changes at home. Also, HBPM predicts cardiovascular events better than clinical BP, and is also useful in monitoring treatment. Ambulatory blood pressure monitoring provides the most precise assessment of BP over an extended period, but is more complex and expensive. Finally, the utility of noninvasive central arterial pressure through radial artery applanation tonometry, especially in patients with resistant hypertension and likely in the elderly because of advanced atherosclerotic disease and stiff arteries, may prove to be a useful tool to guide or modify drug therapy in the future and requires further study.

Redfield, Morgan T.; Cagle, John C.; Hafner, Brian J.; Sanders, Joan E. (2013):

Classifying prosthetic use via accelerometry in persons with transtibial amputations.

In: *J Rehabil Res Dev* 50 (9), S. 1201–1212. DOI: 10.1682/JRRD.2012.12.0233.

Abstract:

Knowledge of how persons with amputation use their prostheses and how this use changes over time may facilitate effective rehabilitation practices and enhance understanding of prosthesis functionality. Perpetual monitoring and classification of prosthesis use may also increase the health and quality of life for prosthetic users. Existing monitoring and classification systems are often limited in that they require the subject to manipulate the sensor (e.g., attach, remove, or reset a sensor), record data over relatively short time periods, and/or classify a limited number of activities and body postures of interest. In this study, a commercially available three-axis accelerometer (ActiLife ActiGraph GT3X+) was used to characterize the activities and body postures of individuals with transtibial amputation. Accelerometers were mounted on prosthetic pylons of 10 persons with transtibial amputation as they performed a preset routine of actions. Accelerometer data was postprocessed using a binary decision tree to identify when the prosthesis was being worn and to classify periods of use as movement (i.e., leg motion such as walking or stair climbing), standing (i.e., standing upright with limited leg motion), or sitting (i.e., seated with limited leg motion). Classifications were compared to visual observation by study researchers. The classifier achieved a mean +/- standard deviation accuracy of 96.6% +/- 3.0%.

Physical activity to prevent obesity in young children: cluster randomised controlled trial.

In: *BMJ* 333 (7577), S. 1041. DOI: 10.1136/bmj.38979.623773.55.

Abstract:

OBJECTIVE\r\nTo assess whether a physical activity intervention reduces body mass index in young children.\r\nDESIGN\r\nCluster randomised controlled single blinded trial over 12 months.\r\nSETTING\r\nThirty six nurseries in Glasgow, Scotland.\r\nPARTICIPANTS\r\n545 children in their preschool year, mean age 4.2 years (SD 0.2) at baseline.\r\nINTERVENTION\r\nEnhanced physical activity programme in nursery (three 30 minute sessions a week over 24 weeks) plus home based health education aimed at increasing physical activity through play and reducing sedentary behaviour.\r\nMAIN OUTCOME MEASURE\r\nBody mass index, expressed as a standard deviation score relative to UK 1990 reference data. Secondary measures were objectively measured physical activity and sedentary behaviour; fundamental movement skills; and evaluation of the process.\r\nRESULTS\r\nGroup allocation had no significant effect on the primary outcome measure at six and 12 months or on measures of physical activity and sedentary behaviour by accelerometry. Children in the intervention group had significantly higher performance in movement skills tests than control children at six month follow-up (P=0.0027; 95% confidence interval 0.3 to 1.3) after adjustment for sex and baseline performance.\r\nCONCLUSIONS\r\nPhysical activity can significantly improve motor skills but did not reduce body mass index in young children in this trial.\r\nTRIAL REGISTRATION\r\nCurrent Controlled Trials ISRCTN36363490.

Objective measurement of physical activity and sedentary behaviour: review with new data.

In: *Archives of disease in childhood* 93 (7), S. 614–619.

Abstract:

Objective methods are being used increasingly for the quantification of the amount of physical activity, intensity of physical activity and amount of sedentary behaviour in children. The accelerometer is currently the objective method of choice. In this review we address the advantages of objective measurement compared with more traditional subjective methods, notably the avoidance of bias, greater confidence in the amount of activity and sedentary behaviour measured, and improved ability to relate variation in physical activity and sedentary behaviour to variation in health outcomes. We also consider unresolved practical issues in paediatric accelerometry by critically reviewing the existing evidence and by providing new evidence.

Why researchers should think 'real-world': A conceptual rationale. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 3–21. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-001%26site%3dehost-live.

Abstract:

(from the chapter) Methods for studying daily life experiences have arrived. Daily life protocols are intended to "capture life as it is lived" (Bolger, Davis, & Rafaeli, 2003)—that is, to describe behavior as it occurs within its typical, spontaneous setting. By documenting the "particulars of life" (Allport, 1942), these methods provide extensively detailed data that can be used to examine the operation of social, psychological, and physiological processes within their natural contexts. A key premise of the daily life approach is that the contexts in which these processes unfold matter—in other words, that context influences behavior, and that proper understanding of behavior necessarily requires taking contextual factors into account. As the accessibility and popularity of daily life methods have increased, so too has researchers' ability grown in both range and complexity to ask and answer important questions about behavior. My goal in this chapter is to present the conceptual case for why researchers should consider adding daily life methods to their methodological toolbox. I begin by discussing the kind of information that daily life methods provide, highlighting ways in which they complement more traditional methods. Following this, the chapter reviews in turn three conceptual bases for daily life research: ecological validity, the value of field research, and the need to take context seriously. Next, I describe the role of daily life data in description and taxonomies, a step of theory building that in my opinion has been underemphasized in the behavioral sciences. The chapter concludes with a review of the place of daily life methods in research programs. An overarching goal of this chapter is to provide a context for the remainder of this handbook. My hope is

that greater appreciation of why these methods are valuable for substantive research will make the what and how of subsequent chapters more compelling. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Sequences of emotions in patients with borderline personality disorder.

In: *Acta Psychiatrica Scandinavica* 118 (1), S. 42–48.

Abstract:

OBJECTIVE:

To investigate sequences of emotions (temporal dependence of emotions) to identify specific patterns of borderline personality disorder (BPD).

METHOD:

The perceived emotions of 50 BPD patients and 50 healthy controls (HC) were monitored by using a hand-held computer system for a 24-h period in a daily life setting. Participants were prompted four times per hour to assess their current perceived emotions. Differences between BPD patients and HC in terms of activation, persistence and down-regulation of emotions were analyzed.

RESULTS:

Healthy controls in contrast to BPD patients more often activated joy and interest. BPD patients more often experienced persistence of anxiety and sadness. BPD patients more frequently switched from anxiety to sadness, from anxiety to anger and from sadness to anxiety. Anger was predominantly preceded by anxiety.

CONCLUSION:

Persistence of sadness and anxiety, as well as emotional oscillating between anxiety, sadness and anger are important aspects of the emotional dysregulation in BPD patients.

Reiterer, Veronika; Sauter, Cornelia; Klösch, Gerhard; Lalouschek, Wolfgang; Zeitlhofer, Josef (2008):

Actigraphy--a useful tool for motor activity monitoring in stroke patients.

In: *Eur Neurol* 60 (6), S. 285–291. DOI: 10.1159/000157882.

Abstract:

AIM\r\nThe aim of the present study was the evaluation of actigraphy as a tool to objectify the recovery process after motor paresis due to stroke.\r\nMETHODS\r\nThe motor activity of both arms of patients suffering from stroke was actigraphically recorded at four different time points during the course of rehabilitation: 24-36 h, 5-7 days, 3 months, and 6 months after stroke.\r\nRESULTS\r\nMotor activity monitored by wrist-worn actigraphs located at the impaired side revealed an increase in activity between the first two time points and the subsequent ones. Additionally, actigraphic recordings showed lower total motor activity at the impaired side as compared to the nonimpaired side. A significant positive correlation was found between the actigraphically recorded motor activity and the results of the Scandinavian Stroke scale, the Barthel Index, the Rankin Scale Score and with the Motoricity Index during the 1st week, which corresponds to the time when neurological deficits were most pronounced.\r\nCONCLUSION\r\nOur results suggest that actigraphy is a useful tool in the objective evaluation of motor activity after stroke. Moreover, actigraphy covers additional aspects that are not reflected by the usual stroke scales in a clinical situation.

Reitzel, Lorraine R.; Kendzor, Darla E.; Nguyen, Nga; Regan, Seann D.; Okuyemi, Kolawole S.; Castro, Yessenia et al. (2014):

Shelter Proximity and Affect among Homeless Smokers Making a Quit Attempt.

In: *Am J Health Behav* 38 (2), S. 161–169. DOI: 10.5993/AJHB.38.2.1.

Abstract:

OBJECTIVES: To explore the associations between shelter proximity and real-time affect during a specific smoking quit attempt among 22 homeless adults. METHODS: Affect was measured via 485 smartphone-based Ecological Momentary Assessments randomly administered during the weeks immediately before and after the quit day, and proximity to the shelter was measured via GPS. Adjusted linear mixed model regressions examined associations between shelter proximity and affect. RESULTS: Closer

proximity to the shelter was associated with greater negative affect only during the post-quit attempt week (p = .008). All participants relapsed to smoking by one week post-quit attempt. CONCLUSIONS: Among homeless smokers trying to quit, the shelter may be associated with unexpected negative affect/stress. Potential intervention applications are suggested.

Remacle, A.; Morsomme, D.; Finck, C. (2013):

Comparison of vocal loading parameters in kindergarten and elementary school teachers.

In: *J.Speech Lang Hear.Res.* (1092-4388 (Linking)). DOI: 10.1044/2013_JSLHR-S-12-0351.

Abstract:

PURPOSE: Although a global picture exists of teachers' voice demands in general, few studies have compared specific groups of teachers to determine whether some are more at risk than others. This study compared vocal loading of kindergarten and elementary school teachers; professional and non-professional vocal load was determined for both groups. METHOD: Twelve kindergarten and twenty elementary school female teachers without voice problems were monitored during one workweek using the Ambulatory Phonation Monitor. Vocal loading parameters analyzed were F0, SPL, time dose, distance dose and cycle dose. RESULTS: Comparisons between the groups showed significantly higher cycle dose and distance dose for kindergarten teachers than for elementary school teachers, in both professional and non-professional environments. Professional and non-professional voice use comparisons showed significant differences for all parameters, indicating that vocal load was higher in the professional environment for both groups. CONCLUSIONS: The higher vocal doses measured in kindergarten teachers suggest that particular attention should be paid to this specific group of teachers. Although non-professional vocal load is lower than professional vocal load, it is important to take both into account because of their cumulative effects

Rey-Lopez, J. P.; Ruiz, J. R.; Vicente-Rodriguez, G.; Gracia-Marco, L.; Manios, Y.; Sjostrom, M. et al. (2012):

Physical activity does not attenuate the obesity risk of TV viewing in youth.

In: *Pediatr.Obes.* (2047-6302 (Linking)). DOI: 10.1111/j.2047-6310.2011.00021.x.

Abstract:

OBJECTIVE: This study aimed to examine the association of television (TV) time, the frequency of meals while watching TV and the presence of TV set in the bedroom with total and abdominal obesity and to assess whether physical activity (PA) attenuates the obesity risk of TV viewing. METHODS: Cross-sectional data were obtained from 2200 adolescents (46% boys) from 10 European cities, The Healthy Lifestyle in Europe by Nutrition in Adolescence study, between 2006 and 2007. TV viewing, PA (by accelerometry) and body composition were measured. Binary logistic regression analyses were performed. RESULTS: Even adjusting by vigorous PA, TV in the bedroom (odds ratio [OR]: 1.33, 95% confidence interval [CI], 1.01-1.74) and >4 h d(-1) TV during week days (OR: 1.30, 95% CI, 1.02-1.67) (in boys) and eating every day with TV (OR: 1.18, 95% CI, 1.07-1.30) and >2 h d(-1) TV during weekend days (OR: 1.68, 95% CI, 1.25-2.26) (in girls) were significantly associated with total obesity. Likewise, in both sexes, having a TV set at bedroom was significantly associated with abdominal obesity. CONCLUSIONS: Adolescents spending excessive TV time are prone to obesity independently of their PA levels. Families should put TV sets out of adolescents' bedroom and keep TV sets off during meal times

Assessing the Quality and Usability of Smartphone Apps for Pain Self-Management.

In: *Pain Med. DOI:* 10.1111/pme.12327.

Abstract:

OBJECTIVE: To evaluate smartphone apps intended for self-management of pain using quality assessment criteria and usability testing with prospective users. DESIGN: 1) Survey and content analysis of available apps; and 2) individual usability study of two apps. SETTING: University of Leeds, United Kingdom. PARTICIPANTS: Forty-one participants (aged 19-59 years) with experience of chronic or recurrent pain episodes. METHODS: We undertook a survey, content analysis, and quality appraisal of all currently available mobile phone apps for self-management of pain. Two apps were then selected and assessed with usability testing. RESULTS: Twelve apps met the inclusion criteria. The quality assessment revealed wide variation in their clinical content, interface design, and usability to support self-management of pain. Very little user or clinician involvement was identified in the development of the apps. From the usability testing, participants stated a preference for an interface design employing a lighter color scheme and particular text font. Although very few participants were aware of pain-reporting apps prior to participation,

many would consider use in the future. CONCLUSIONS: Variation in app quality and a lack of user and clinician engagement in development were found across the pain apps in this research. Usability testing identified a range of user preferences. Although useful information was obtained, it would be beneficial to involve users earlier in the process of development, as well as establishing ways to merge end user requirements with evidence-based content, to provide high-quality and usable apps for self-management of pain.

High sodium intake in women with metabolic syndrome.

In: *Korean Circ J* 44 (1), S. 30–36. DOI: 10.4070/kcj.2014.44.1.30.

Abstract:

BACKGROUND AND OBJECTIVES: Metabolic syndrome and high sodium intake are associated with frequent cardiovascular events. Few studies have estimated sodium intake in subjects with metabolic syndrome by 24-hour urine sodium excretion. We evaluated sodium intake in individuals with metabolic syndrome. SUBJECTS AND METHODS: Participants were recruited by random selection and through advertisement. Twenty four-hour urine collection, ambulatory blood pressure measurements, and blood test were performed. Sodium intake was estimated by 24-hour urine sodium excretion. Participants receiving antihypertensive medications were excluded from analysis. RESULTS: Among the 463 participants recruited, subjects with metabolic syndrome had higher levels of 24-hour urine sodium excretion than subjects without metabolic syndrome (p=0.0001). There was a significant relationship between the number of metabolic syndrome factors and 24-hour urine sodium excretion (p=0.001). The proportion of subjects with metabolic syndrome was increased across the tertile groups of 24-hour urine sodium excretion (p<0.0001). The association of high sodium intake and metabolic syndrome was significant only among women. Among the factors related to metabolic syndrome, body mass index had an independent association with 24-hour urine sodium excretion (p<0.0001). CONCLUSION: Women with metabolic syndrome exhibited significantly higher sodium intake, suggesting that dietary education to reduce sodium consumption should be emphasized for women with metabolic syndrome.

Richmond, M. J.; Mermelstein, R. J.; Wakschlag, L. S. (2012):

Direct Observations of Parenting and Real-Time Negative Affect Among Adolescent Smokers and Nonsmokers.

In: *J Clin.Child Adolesc.Psychol.* (1537-4416 (Linking)). DOI: 10.1080/15374416.2012.738452.

Abstract:

This longitudinal study examined how observations of parental general communication style and control with their adolescents predicted changes in negative affect over time for adolescent smokers and nonsmokers. Participants were 9th- and 10th-grade adolescents (N = 111; 56.8% female) who had all experimented with cigarettes and were thus at risk for continued smoking and escalation; 36% of these adolescents (n = 40) had smoked in the past month at baseline and were considered smokers in the present analyses. Adolescents participated separately with mothers and fathers in observed parent-adolescent problem-solving discussions to assess parenting at baseline. Adolescent negative affect was assessed at baseline, 6 months, and 24 months via ecological momentary assessment. Among both smoking and nonsmoking adolescents, escalating negative affect significantly increased risk for future smoking. Higher quality maternal and paternal communication predicted a decline in negative affect over 1.5 years for adolescent smokers but was not related to negative affect for nonsmokers. Controlling maternal, but not paternal, parenting predicted escalation in negative affect for all adolescents. Findings suggest that reducing negative affect among experimenting youth can reduce risk for smoking escalation. Therefore, family-based prevention efforts for adolescent smoking escalation might consider parental general communication style and control as intervention targets. However, adolescent smoking status and parent gender may moderate these effects

Riddoch, Chris J.; Leary, Sam D.; Ness, Andy R.; Blair, Steven N.; Deere, Kevin; Mattocks, Calum et al. (2009):

Prospective associations between objective measures of physical activity and fat mass in 12-14 year old children: the Avon Longitudinal Study of Parents and Children (ALSPAC).

In: *BMJ* 339, S. b4544. DOI: 10.1136/bmj.b4544.

Abstract:

OBJECTIVE\r\nTo investigate associations between physical activity at age 12 and subsequent adiposity at age 14.\r\nDESIGN\r\nProspective birth cohort study with data collected between 2003 and 2007.\r\nSETTING\r\nOriginal recruitment in 1991-2 of 14,541 pregnant women living in the former County of Avon (United Kingdom).\r\nPARTICIPANTS\r\nAt age 12, 11,952 children were invited to attend the research clinic. Of these, 7159 attended, and 4150 (1964 boys, 2186 girls) provided sufficient data on exposure, outcome, and confounding variables.\r\nMAIN OUTCOME MEASURE\r\nFat mass at age 14, measured by dual emission x ray absorptiometry, associated with physical activity at age 12, measured by accelerometry.\r\nRESULTS\r\nProspective associations of fat mass at age 14 (outcome) with physical activity at age 12 (exposure) were strong for both total activity (accelerometer counts/min) and for daily amount of moderate-vigorous physical activity (min/day). An extra 15 minutes of moderate-vigorous physical activity per day at age 12 was associated with lower fat mass at age 14 in boys (by 11.9% (95% confidence interval 9.5% to 14.3%)) and girls (by 9.8% (6.7% to 12.8%)). The proportion of physical activity due to moderate-vigorous physical activity was between 20% and 30% in boys and girls at the two ages.\r\nCONCLUSIONS\r\nHigher levels of physical activity, in particular activity of moderate to higher intensities, are prospectively associated with lower levels of fat mass in early adolescence. Interventions to raise levels of physical activity in children are likely to be important in the fight against obesity.

Ridgers, Nicola D.; Graves, Lee E. F.; Foweather, Lawrence; Stratton, Gareth (2010):

Examining influences on boys' and girls' physical activity patterns: the a-class project.

In: *Pediatric Exercise Science* 22 (4), S. 638–650.

Abstract:

Understanding children's physical activity (PA) patterns and the factors that may influence PA are important for developing interventions within this population. One hundred and ten children aged 9-10 years from 8 schools had their PA patterns assessed over 7 days. Physiological and self-report data were also collected. Multilevel analyses revealed that cardiorespiratory fitness was a consistent, significant and positive predictor of weekday and weekend PA, while the availability of home sedentary activities was a significant but negative predictor of PA. Since a range of variables were associated with PA levels, intervention developers should be cognizant of variables that may influence children's activity.

Ridgers, Nicola D.; Salmon, Jo; Ridley, Kate; O'Connel, Eoin; Arundell, Lauren; Timperio, Anna (2012):

Agreement between activPAL and ActiGraph for assessing children's sedentary time.

In: *Int J Behav Nutr Phys Act* 9. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31461-001%26site%3dehost-live;nicky.ridgers@deakin.edu.au.

Abstract:

BACKGROUND:

Accelerometers have been used to determine the amount of time that children spend sedentary. However, as time spent sitting may be detrimental to health, research is needed to examine whether accelerometer sedentary cut-points reflect the amount of time children spend sitting. The aim of this study was to: a) examine agreement between ActiGraph (AG) cut-points for sedentary time and objectively-assessed periods of free-living sitting and sitting plus standing time using the activPAL (aP); and b) identify cut-points to determine time spent sitting and sitting plus standing.

METHODS:

Forty-eight children (54% boys) aged 8-12 years wore a waist-mounted AG and thigh-mounted aP for two consecutive school days (9-3:30 pm). AG data were analyzed using 17 cut-points between 50-850 counts·min-1 in 50 counts·min-1 increments to determine sedentary time during class-time, break time and school hours. Sitting and sitting plus standing time were obtained from the aP for these periods. Limits of agreement were computed to evaluate bias between AG50 to AG850 sedentary time and sitting and sitting plus standing time. Receiver Operator Characteristic (ROC) analyses identified AG cut-points that maximized sensitivity and specificity for sitting and sitting plus standing time.

RESULTS:

The smallest mean bias between aP sitting time and AG sedentary time was AG150 for class time (3.8 minutes), AG50 for break time (-0.8 minutes), and AG100 for school hours (-5.2 minutes). For sitting plus standing time, the smallest bias was observed for AG850. ROC analyses revealed an optimal cut-point of 96 counts·min-1 (AUC = 0.75) for sitting time, which had acceptable sensitivity (71.7%) and specificity (67.8%). No optimal cut-point was obtained for sitting plus standing (AUC = 0.51).

CONCLUSIONS:

Estimates of free-living sitting time in children during school hours can be obtained using an AG cut-point of 100 counts·min-1. Higher sedentary cut-points may capture both sitting and standing time.

Ridgers, Nicola D.; Stratton, Gareth; Fairclough, Stuart J.; Twisk, Jos W. R. (2007):

Long-term effects of a playground markings and physical structures on children's recess physical activity levels.

In: *Prev Med* 44 (5), S. 393–397.

Abstract:

OBJECTIVE:

The aim of the study was to investigate the impact of a playground redesign intervention across time on children's recess physical activity levels using combined physical activity measures and to evaluate the potential influence of covariates on the intervention effect.

METHOD:

Fifteen schools located in areas of high deprivation in one large city in England each received 20,000 pounds through a national 10 million pounds Sporting Playgrounds Initiative to redesign the playground environment based on a multicolored zonal design. Eleven schools served as matched socioeconomic controls. Physical activity levels during recess were quantified using heart rate telemetry and accelerometry at baseline, 6 weeks and 6 months following the playground redesign intervention. Data were collected between July 2003 and January 2005 and analyzed using multilevel modeling.

RESULTS:

Statistically significant intervention effects were found across time for moderate-to-vigorous and vigorous physical activity assessed using both heart rate and accelerometry.

CONCLUSIONS:

The results suggest that a playground redesign, which utilizes multicolor playground markings and physical structures, is a suitable stimulus for increasing children's school recess physical activity levels.

Ridgers, Nicola D.; Tóth, Miklós; Uvacsek, Martina (2009):

Physical activity levels of Hungarian children during school recess.

In: *Prev Med* 49 (5), S. 410–412. DOI: 10.1016/j.ypmed.2009.08.008.

Abstract:

OBJECTIVE\r\nThe purpose of this study was to examine physical activity levels and patterns of physical activity across daily school recess periods, and the contribution of recess to daily physical activity.\r\nMETHOD\r\nNinety-eight children (61% boys) from three schools in Hungary had their physical activity quantified using uni-axial accelerometry every 5 s for three consecutive school days (Wednesday to Friday). The proportion of time spent in sedentary, light, moderate-to-vigorous, and vigorous physical activity during 5 daily school recess periods was determined using existing age-appropriate cut-points. The relative contribution of recess to daily moderate-to-vigorous physical activity was also determined. Data were collected between May and October 2008.\r\nRESULTS\r\nBoys engaged in significantly more light (30.6+/-5.2%; 27.7+/-5.1%), moderate-to-vigorous (24.9+/-8.9%; 17.5+/-5.2%) and vigorous physical activity (7.6+/-4.7%; 4.3+/-2.9%) than girls during recess. Girls (54.8+/-8.1%) engaged in more sedentary activity than boys (44.5+/-10.2%). Physical activity levels were generally similar across multiple recess periods. Recess contributed more moderate-to-vigorous physical activity towards weekday physical activity for boys (13.1%) than girls (10.8%).\r\nCONCLUSIONS\r\nSince sedentary activity accounted for the largest proportion of recess, interventions may be needed across all recess periods to promote physical activity during the school day.

Riediger, Michaela; Wrzus, Cornelia; Wagner, Gert G. (2014):

Happiness is pleasant, or is it? Implicit representations of affect valence are associated with contrahedonic motivation and mixed affect in daily life.

In: *Emotion* 14 (5), S. 950–961. DOI: 10.1037/t03782-000.

Abstract:

People typically want to feel good. At times, however, they seek to maintain or enhance negative affect or to dampen positive affect. The prevalence of such contrahedonic motivation has been related to simultaneous experiences of positive and negative (i.e., mixed) affect. We investigated the role that implicit mental representations of affect valence may play in this regard in a study with N = 400 participants aged 11–88 years. Results demonstrated the age-fairness and reliability of the affect-valence Implicit Association Test, a newly developed implicit measure of interindividual differences in mental representations of affect valence. The older participants were, the more distinctively they implicitly associated happiness with pleasantness and/or unhappiness with unpleasantness. Participants furthermore carried mobile phones as assessment instruments with them for 3 weeks while pursuing their daily routines. The phones prompted participants on average 54 times to report their momentary affective experience and affect-regulation motivation. Contrahedonic motivation and mixed affect were most prevalent among adolescents and least prevalent among older adults, and thus showed a similar pattern of age differences as the affect-valence Implicit Association Test. Furthermore, the more distinctive participants' implicit associations of happiness with pleasantness, and/or unhappiness with unpleasantness, the less likely participants were to report contrahedonic motivation and mixed affect in their daily lives. These findings contribute to a refined understanding of the mixed-affect perspective on contrahedonic motivation by demonstrating the respective role of implicit affect-valence representations. Rittig, Søren; Matthiesen, Thorsten B.; Pedersen, Erling B.; Djurhuus, Jens C. (2006):

Circadian variation of angiotensin II and aldosterone in nocturnal enuresis: relationship to arterial blood pressure and urine output.

In: *The Journal of urology* 176 (2), S. 774–780.

Abstract:

PURPOSE:

We investigated the circadian rhythm of solute excretion and regulating hormones as well as blood pressure in patients with monosymptomatic nocturnal enuresis.

MATERIALS AND METHODS:

We included 15 patients with a mean age +/- SE of 13.4 +/- 0.9 years who had monosymptomatic nocturnal enuresis with at least 3 wet nights weekly and a control group of 10 healthy children with a similar age and sex distribution. During inpatient circadian studies urine was collected during 6 periods and blood was drawn at 7 time points during 24 hours. Heart rate and blood pressure was recorded with an ambulatory blood pressure monitor every 30 to 60 minutes.

RESULTS:

The total patient group excreted a significantly larger nocturnal urine volume than controls ($p < 0.01$). Five patients had marked nocturnal polyuria (nocturnal urine volume greater than the mean in the control group +2 SD), whereas urine output in the remaining patients without polyuria were similar to controls. Nocturnal polyuria was caused mainly by increased nocturnal solute excretion, especially Na. Serum aldosterone and plasma angiotensin II showed a marked circadian rhythm in normal children with a nocturnal increase concomitant with a significant decrease in mean arterial blood pressure during sleep. In contrast, the group of patients with nocturnal polyuria showed a lack of circadian rhythm in all excretion variables as well as an attenuated rhythm in plasma angiotensin II and mean arterial blood pressure. Interestingly this group had normal circadian rhythms of the circadian rhythm markers plasma cortisol and heart rate.

CONCLUSIONS:

The study suggests that an abnormally large nocturnal excretion of Na caused by selectively attenuated circadian rhythms of Na regulating hormones might be an important pathogenic factor in monosymptomatic nocturnal enuresis.

Robbins, Megan L.; Mehl, Matthias R.; Holleran, Shannon E.; Kasle, Shelley (2011):

Naturalistically observed sighing and depression in rheumatoid arthritis patients: a preliminary study.

In: *Health Psychol* 30 (1), S. 129.

Abstract:

OBJECTIVE:

This study tested the degree to which naturalistically observed sighing in daily life is a behavioral indicator of depression and reported physical symptoms (i.e., experienced pain and flare days) in rheumatoid arthritis (RA) patients.

DESIGN:

Thirteen RA patients wore the Electronically Activated Recorder (EAR), an observational ambulatory assessment tool, for two weekends (Friday through Sunday) approximately one month apart. The EAR periodically recorded snippets of ambient sounds from participants' momentary environments (50 s every 18 min). Sighs were coded from the sampled ambient sounds.

MAIN OUTCOME MEASURES:

Depression was assessed with the Center for Epidemiological Studies Depression Scale and the Beck Depression Inventory. Pain during the past month was assessed with a 10-cm visual-analog scale, and number of flare days during the prior 6 months was reported.

RESULTS:

Sighing was significantly and strongly related to patients' levels of depression and nonsignificantly and less strongly related to their reported pain and number of flare days.

CONCLUSION:

The findings suggest that sighing can serve as an observable marker of depression in RA patients. Because the sample size was small, the findings should be considered preliminary.

Robertson, Brandon M.; Piasecki, Thomas M.; Slutske, Wendy S.; Wood, Phillip K.; Sher, Kenneth J.; Shiffman, Saul; Heath, Andrew C. (2012):

Validity of the Hangover Symptoms Scale: Evidence from an electronic diary study.

In: *Alcoholism: Clinical and Experimental Research* 36 (1), S. 171–177. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00176-020&site=ehost-live;piaseckit@missouri.edu.

Abstract:

Background: The Hangover Symptoms Scale (HSS) assesses the frequency of 13 symptoms experienced after drinking in the past year. Cross-sectional analyses in college drinkers showed preliminary evidence for the validity of the HSS (Slutske et al., 2003). The current investigation extended this work by examining the construct validity of the HSS in an ecological momentary assessment investigation. Methods: Frequent drinkers (N = 404) carried electronic diaries to track their daily experiences over 3 weeks. Each morning, the diary assessed prior-night drinking behaviors, the presence of current hangover, and intensity of current headache and nausea. Results: Adjusting for sex and body mass, the HSS significantly predicted diary endorsement of hangover (OR = 2.11, 95% CI = 1.78 to 2.49, p < 0.001). Participants who endorsed the HSS headache and nausea items were especially likely to report the elevations of corresponding symptoms in diary records made the morning after drinking. HSS scores incrementally predicted hangover when the number of drinks consumed in the episode was covaried but did not moderate the relationship between the number of drinks and diary hangover reports. Conclusions: The HSS appears to be a valid tool for hangover research. Higher HSS scores identify individuals who complain of "real world" hangovers and who may be especially likely to display particular symptoms after a night of drinking. Past hangovers predicted future hangovers, suggesting hangovers do not necessarily discourage or inhibit future drinking, at least across the several-week time interval studied here. There is a need to develop and evaluate complementary measures that can more directly index individual differences in hangover susceptibility in survey designs. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Robinson, E.; Higgs, S.; Daley, A. J.; Jolly, K.; Lycett, D.; Lewis, A.; Aveyard, P. (2013):

Development and feasibility testing of a smart phone based attentive eating intervention.

In: *BMC Public Health* 13 (1471-2458 (Linking)), S. 639. DOI: 10.1186/1471-2458-13-639.

Abstract:

BACKGROUND: Attentive eating means eating devoid of distraction and increasing awareness and memory for food being consumed. Encouraging individuals to eat more attentively could help reduce calorie intake, as a strong evidence base suggests that memory and awareness of food being consumed substantially influence energy intake. METHODS: The development and feasibility testing of a smartphone based attentive eating intervention is reported. Informed by models of behavioral change, a smartphone application was developed. Feasibility was tested in twelve overweight and obese volunteers, sampled from university staff. Participants used the application during a four week trial and semi-structured interviews were conducted to

assess acceptability and to identify barriers to usage. We also recorded adherence by downloading application usage data from participants' phones at the end of the trial. RESULTS: Adherence data indicated that participants used the application regularly. Participants also felt the application was easy to use and lost weight during the trial. Thematic analysis indicated that participants felt that the application raised their awareness of what they were eating. Analysis also indicated barriers to using a smartphone application to change dietary behavior. CONCLUSIONS: An attentive eating based intervention using smartphone technology is feasible and testing of its effectiveness for dietary change and weight loss is warranted

Robinson, Fiona; Jones, Catriona (2014):

Women's engagement with mobile device applications in pregnancy and childbirth.

In: *Pract Midwife* 17 (1), S. 23–25.

Abstract:

Childbearing women are increasingly engaging with social media and technology. The use of apps for pregnancy and childbirth advice is a new approach to maternity provision, and has potential to impact upon midwifery. Apps are ideally placed to provide opportunities for women to access information; however, there are concerns about the quality of mobile app data in relation to evidence based midwifery. This discussion paper presents a general overview of the use of apps as an information resource, and provides a platform for debate about their position in midwifery care.

Robinson, Katie; Kennedy, Norelee; Harmon, Dominic (2012):

The flow experiences of people with chronic pain.

In: *OTJR: Occupation, Participation and Health* 32 (3), S. 104–112. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-19292-007&site=ehost-live;katie.robinson@ul.ie.

Abstract:

This electronic momentary assessment study explored the relationship between flow and pain intensity and examined whether flow is an optimal experience for people with chronic pain. Adults with chronic pain (n = 30) were signaled randomly seven times daily during 1 week to respond to a flow questionnaire via personal digital assistant. The participants responded to 718 questionnaires from 1,447 beeps (response rate = 49.6%). Results indicated that participants were most commonly at home, doing self-care activities, with family or alone. Participants experienced flow 34.9%, apathy 44.6%, relaxation 11.6%, and anxiety 8.9% of the sampled time. Participants' mean concentration, self-esteem, motivation, and potency scores were highest in flow compared to the other three states. Separate one-way between-groups analyses of variance comparing concentration ($F(3) = 11.85$; $p < .001$), self-esteem ($F(3) = 11.98$; $p < .001$), motivation ($F(3) = 29.29$; $p < .001$), positive affect ($F(3) = 2.89$; $p = .035$), potency ($F(3) = 19.88$; $p < .001$), and pain intensity ($F(3) = 1.39$; $p = .245$) scores across the four states showed a significant overall effect on all comparisons except pain intensity and positive affect. Robinson, Michael D.; Moeller, Sara K.; Buchholz, Maria M.; Boyd, Ryan L.; Troop-Gordon, Wendy (2012):

The regulatory benefits of high levels of affect perception accuracy: A process analysis of reactions to stressors in daily life.

In: *Emotion* 12 (4), S. 785–795. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-17909-001&site=ehost-live;Michael.D.Robinson@ndsu.edu.

Abstract:

Individuals attuned to affective signals from the environment may possess an advantage in the emotion-regulation realm. In two studies (total n = 151), individual differences in affective perception accuracy were assessed in an objective, performance-based manner. Subsequently, the same individuals completed daily diary protocols in which daily stressor levels were reported as well as problematic states shown to be stress-reactive in previous studies. In both studies, individual differences in affect perception accuracy interacted with daily stressor levels to predict the problematic outcomes. Daily stressors precipitated problematic reactions—whether depressive feelings (Study 1) or somatic symptoms (Study 2)—at low levels of affect perception accuracy, but did not do so at high levels of affect perception accuracy. The findings support a regulatory view of such perceptual abilities.

Implications for understanding emotion regulation processes, emotional intelligence, and individual differences in reactivity are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Robustillo Cortes, Maria de Las Aguas; Cantudo Cuenca, Maria Rosa; Morillo Verdugo, Ramon; Calvo Cidoncha, Elena (2014):

High Quantity but Limited Quality in Healthcare Applications Intended for HIV-Infected Patients.

In: *Telemed J E Health. DOI:* 10.1089/tmj.2013.0262.

Abstract:

Abstract Objective: The aim of this study was to evaluate, through the creation of a specific questionnaire, the information quality in mobile applicatons (apps) aimed at human immunodeficiency virus (HIV)-infected patients. We also established a quality rating and identified the main strengths and weaknesses of this kind of health app. Materials and Methods: Smartphone apps specifically related to HIV/acquired immunodeficiency syndrome (AIDS) were searched. We conducted a key word search with the terms "HIV," "AIDS," and "acquired immune deficiency syndrome" in the Apple (Cupertino, CA) App Store and the Android Google (Mountain View, CA) Play Store. A questionnaire was developed based on the different quality recommendations for health apps up to December 2012. The recommendations consulted were as follows: the Happtique Health App Certification Program, the Food and Drug Administration (Mobile Medical Applications), and recommendations for the design, use, and evaluation of health apps of the Agency of Health Quality in Andalusia. A group of 17 experts assessed the importance of the different sections by using a Delphi method. Results: In total, 41 health apps were analyzed. Only one app (2.4%), called inPractice HIV, approached class A. The remaining were classed as follows: 2 (4.9%) class B, 1 (2.4%) class C, 5 (12.2%) class D and E, and 27 (65.9%) class F (not exceeding minimum criteria). The design and the relevance were highlighted among the strengths. The main areas for improvement are provision of services and confidentiality in addition to privacy policies. Conclusions: The quality of the revised apps is limited. Only one app complied with the excellence criteria, and over 50% of the apps did not exceed minimum quality standards. The worst rated aspects were political advertising and logical security.

Robusto, K. M.; Trost, S. G. (2012):

Comparison of three generations of ActiGraph activity monitors in children and adolescents.

In: *J.Sports Sci.* 30 (13), S. 1429–1435. DOI: 10.1080/02640414.2012.710761.

Abstract:

In this study, we evaluated agreement among three generations of ActiGraph accelerometers in children and adolescents. Twenty-nine participants (mean age = 14.2 +/- 3.0 years) completed two laboratory-based activity sessions, each lasting 60 min. During each session, participants concurrently wore three different models of the ActiGraph accelerometers (GT1M, GT3X, GT3X+). Agreement among the three models for vertical axis counts, vector magnitude counts, and time spent in moderate-to-vigorous physical exercise (MVPA) was evaluated by calculating intraclass correlation coefficients and Bland-Altman plots. The intraclass correlation coefficient for total vertical axis counts, total vector magnitude counts, and estimated MVPA was 0.994 (95% CI = 0.989-0.996), 0.981 (95% CI = 0.969-0.989), and 0.996 (95% CI = 0.989-0.998), respectively. Inter-monitor differences for total vertical axis and vector magnitude counts ranged from 0.3% to 1.5%, while inter-monitor differences for estimated MVPA were equal to or close to zero. On the basis of these findings, we conclude that there is strong agreement between the GT1M, GT3X, and GT3X+ activity monitors, thus making it acceptable for researchers and practitioners to use different ActiGraph models within a given study

Robyn RM Gershon, MT, MHS, DrPH, Monika Pogorzelska, MPH, Kristine A Qureshi, RN, DNSc, Patricia W Stone, PhD, Allison N Canton, BA, Stephanie M Samar, BA, Leah J Westra, BA, Marc R Damsky, MPH, and Martin Sherman, PhD (2013):

Including the home as a care setting.

In: *Hosp Health Netw* 87 (12), S. 20.

Abstract:

Introduction: Home health care is the fastest growing sector in the health care industry, with an anticipated growth of 66 percent over the next 10 years and with over 7 million patients served each year. With the increasing acuteness of care provided in home health care and the increasing number of frail elderly that make up this patient population, it is important to identify risk factors

that affect patient health and safety in this setting. Methods: A convenience sample of 1,561 home health aides, attendants, and personal care workers completed a risk assessment survey. Items addressed personal, patient, and home characteristics and health hazards. All activities had prior Institutional Review Board approval. Preliminary Results: Ninety-five percent of home health care workers (HHCWs) were female with an average of 8 years experience. The majority of clients were elderly, with a smaller percentage of adult (26 percent) and pediatric (7 percent) cases. HHCWs reported the following exposures at their clients' homes: cockroaches (33 percent), cigarette smoke (30 percent), vermin (23 percent), irritating chemicals (17 percent), and peeling paint (15 percent). The following conditions were also described: clutter (17 percent), temperature extremes (9 percent), unsanitary (12 percent) and unsafe (6 percent) conditions in the home, neighborhood violence/crime (11 percent), and aggressive pets (6 percent). Two percent of respondents reported the presence of guns in the home. Additionally, 12 percent of HHCWs reported signs of abuse of their clients. Conclusion: Both HHCWs and home care patients appear to be at potential risk due to a variety of health hazards/exposures in the clients' homes. Given the growing population of both HHCWs and recipients, it is important to document this risk as an important first step in prevention and management.

Roche, Veronique Pasquale; Mohamad-Djafari, Ali; Innominato, Pasquale Fabio; Karaboue, Abdoulaye; Gorbach, Alexander; Levi, Francis Albert (2014):

Thoracic surface temperature rhythms as circadian biomarkers for cancer chronotherapy.

In: *Chronobiol Int* 31 (3), S. 409–420. DOI: 10.3109/07420528.2013.864301.

Abstract:

The disruption of the temperature circadian rhythm has been associated with cancer progression, while its amplification resulted in cancer inhibition in experimental tumor models. The current study investigated the relevance of skin surface temperature rhythms as biomarkers of the Circadian Timing System (CTS) in order to optimize chronotherapy timing in individual cancer patients. Baseline skin surface temperature at four sites and wrist accelerations were measured every minute for 4 days in 16 patients with metastatic gastro-intestinal cancer before chronotherapy administration. Temperature and rest-activity were recorded, respectively, with wireless skin surface temperature patches (Respironics, Phillips) and an actigraph (Ambulatory Monitoring). Both variables were further monitored in 10 of these patients during and after a 4-day course of a fixed chronotherapy protocol. Collected at baseline, during and after therapy longitudinal data sets were processed using Fast Fourier Transform Cosinor and Linear Discriminant Analyses methods. A circadian rhythm was statistically validated with a period of 24 h ($p < 0.05$) for 49/61 temperature time series (80.3%), and 15/16 rest-activity patterns (93.7%) at baseline. However, individual circadian amplitudes varied from 0.04 degrees C to 2.86 degrees C for skin surface temperature (median, 0.72 degrees C), and from 16.6 to 146.1 acc/min for rest-activity (median, 88.9 acc/min). Thirty-nine pairs of baseline temperature and rest-activity time series (75%) were correlated ($r > |0.7|$; $p < 0.05$). Individual circadian acrophases at baseline were scattered from 15:18 to 6:05 for skin surface temperature, and from 12:19 to 15:18 for rest-activity, with respective median values of 01:10 (25-75% quartiles, 22:35-3:07) and 14:12 (13:14-14:31). The circadian patterns in skin surface temperature and rest-activity persisted or were amplified during and after fixed chronotherapy delivery for 5/10 patients. In contrast, transient or sustained disruption of these biomarkers was found for the five other patients, as indicated by the lack of any statistically significant dominant period in the circadian range. No consistent correlation ($r < |0.7|$, $p >/= 0.05$) was found between paired rest-activity and temperature time series during fixed chronotherapy delivery. In conclusion, large inter-patient differences in circadian amplitudes and acrophases of skin surface temperature were demonstrated for the first time in cancer patients, despite rather similar rest-activity acrophases. The patient-dependent coupling between both CTS biomarkers, and its possible alteration on a fixed chronotherapy protocol, support the concept of personalized cancer chronotherapy.

Röcke, Christina; Li, Shu-Chen; Smith, Jacqui (2009):

Intraindividual variability in positive and negative affect over 45 days: do older adults fluctuate less than young adults?

In: *Psychology and Aging* 24 (4), S. 863–878. DOI: 10.1037/a0016276.

Abstract:

Opposing scenarios about age-related increases and decreases in intraindividual variability are found in the literature: Whereas accumulating evidence indicates that cognitive functioning is characterized by an age-related increase of short-term variability, age-related decreases in variability could be expected in affective states on the basis of theories of emotion regulation and self development. We examined age differences in intraindividual variability of positive affect (PA) and negative affect (NA) and in contingencies among daily affect, daily stress, and daily events using up to 45 daily assessments of 18 young (20-30 years) and 19 older (70-80 years) adults. Whereas age groups differed little in average affect levels, older adults showed significantly less variability in PA and NA than young adults. Age differences accounted for greater variance in variability than personality factors. Multilevel modeling indicated that for young but not older adults, PA was higher (lower) on days with a positive (negative) event,

and NA was lower on days with a positive event. There were no age differences in daily affect reactivity to appraised stress severity.

Rodell, Jessica B.; Judge, Timothy A. (2009):

Can \"good\" stressors spark \"bad\" behaviors? The mediating role of emotions in links of challenge and hindrance stressors with citizenship and counterproductive behaviors.

In: *J Appl Psychol* 94 (6), S. 1438–1451. DOI: 10.1037/a0016752.

Abstract:

The authors combined affective events theory (H. M. Weiss & Cropanzano, 1996) and the transactional stress model (R. S. Lazarus & Folkman, 1984) to build and test a model specifying the dynamic, emotion-based relationships among challenge and hindrance stressors and citizenship and counterproductive behaviors. The study employed an experience sampling methodology. Results showed that challenge stressors had offsetting indirect links with citizenship behaviors through attentiveness and anxiety and a positive indirect effect on counterproductive behaviors through anxiety. Hindrance stressors had a negative indirect effect on citizenship behaviors through anxiety and a positive indirect effect on counterproductive behaviors through anxiety and anger. Finally, multilevel moderating effects showed that the relationship between hindrance stressors and anger varied according to employees' levels of neuroticism.

Roelofs, Jeffrey; Peters, Madelon L.; Patijn, Jacob; Schouten, Erik G. W.; Vlaeyen, Johan W. S. (2006):

An electronic diary assessment of the effects of distraction and attentional focusing on pain intensity in chronic low back pain patients.

In: *British Journal of Health Psychology* 11 (Pt 4), S. 595–606. DOI: 10.1348/135910705X74819.

Abstract:

OBJECTIVE\r\nThe present study examined the effects of a manipulation of attention to pain (i.e. attentional focusing vs. distraction) on pain intensity in daily life of patients with chronic low back pain. It was hypothesized that attentional focusing would lead to decreased pain intensity in high pain fearful individuals, whereas distraction from pain would be associated with decreased pain intensity in low pain fearful individuals.\r\nDESIGN\r\nAn experience sampling methodology was used to examine the effects of a manipulation of attention to pain on pain intensity in daily life of pain patients.\r\nMETHODS\r\nA total number of 38 patients with chronic low back pain participated in this study and carried a palmtop computer for 2 weeks. During this period, patients were 'beeped' 8 times a day to complete diary questions. On certain days, instructions to either attend to or distract from pain were given.\r\nRESULTS\r\nMulti-level analyses showed that attentional focusing was not associated with decreased pain intensity in high pain fearful individuals and that distraction did not lead to decreased pain intensity in low pain fearful individuals. The manipulations in isolation neither influenced pain intensity. The manipulation check was generally weak.\r\nCONCLUSION\r\nA manipulation of attention to pain in daily life of patients with chronic low back pain proved difficult to accomplish. As the manipulation check was generally unsuccessful, no clear inferences about the underlying theory can be made. Future research within the field of pain treatments (e.g. in vivo exposure) might benefit greatly from electronic diary assessments studies.

Roetenberg, Daniel; Baten, Chris; Veltink, Peter H. (2007):

Estimating body segment orientation by applying inertial and magnetic sensing near ferromagnetic materials.

In: *Neural Systems and Rehabilitation Engineering, IEEE Transactions on* 15 (3), S. 469–471.

Abstract:

Inertial and magnetic sensors are very suitable for ambulatory monitoring of human posture and movements. However, ferromagnetic materials near the sensor disturb the local magnetic field and, therefore, the orientation estimation. A Kalman-based fusion algorithm was used to obtain dynamic orientations and to minimize the effect of magnetic disturbances. This paper compares the orientation output of the sensor fusion using three-dimensional inertial and magnetic sensors against a laboratory bound opto-kinetic system (Vicon) in a simulated work environment. With the tested methods, the difference between the optical reference system and the output of the algorithm was 2.6 degrees root mean square (rms) when no metal was near the

sensor module. Near a large metal object instant errors up to 50 degrees were measured when no compensation was applied. Using a magnetic disturbance model, the error reduced significantly to 3.6 degrees rms.

Roetenberg, Daniel; Slycke, Per J.; Veltink, Peter H. (2007):

Ambulatory position and orientation tracking fusing magnetic and inertial sensing.

In: *Biomedical Engineering, IEEE Transactions on* 54 (5), S. 883–890.

Abstract:

This paper presents the design and testing of a portable magnetic system combined with miniature inertial sensors for ambulatory 6 degrees of freedom (DOF) human motion tracking. The magnetic system consists of three orthogonal coils, the source, fixed to the body and 3-D magnetic sensors, fixed to remote body segments, which measure the fields generated by the source. Based on the measured signals, a processor calculates the relative positions and orientations between source and sensor. Magnetic actuation requires a substantial amount of energy which limits the update rate with a set of batteries. Moreover, the magnetic field can easily be disturbed by ferromagnetic materials or other sources. Inertial sensors can be sampled at high rates, require only little energy and do not suffer from magnetic interferences. However, accelerometers and gyroscopes can only measure changes in position and orientation and suffer from integration drift. By combing measurements from both systems in a complementary Kalman filter structure, an optimal solution for position and orientation estimates is obtained. The magnetic system provides 6 DOF measurements at a relatively low update rate while the inertial sensors track the changes position and orientation in between the magnetic updates. The implemented system is tested against a lab-bound camera tracking system for several functional body movements. The accuracy was about 5 mm for position and 3 degrees for orientation measurements. Errors were higher during movements with high velocities due to relative movement between source and sensor within one cycle of magnetic actuation.

Rofail, Lydia Makarie; Wong, Keith K. H.; Unger, Gunnar; Marks, Guy B.; Grunstein, Ronald R. (2010):

The utility of single-channel nasal airflow pressure transducer in the diagnosis of OSA at home.

In: *Sleep* 33 (8), S. 1097.

Abstract:

RATIONALE:

Given the high prevalence of obstructive sleep apnea (OSA) and the demand on polysomnography (PSG), there is a need for low cost accurate simple diagnostic modalities that can be easily deployed in primary care to improve access to diagnosis.

STUDY OBJECTIVES:

The aim was to examine the utility of single-channel nasal airflow monitoring using a pressure transducer at home in patients with suspected OSA.

DESIGN:

Cross-sectional study

SETTING:

Laboratory and home

PARTICIPANTS:

The study was conducted in two populations. Consecutive patients with suspected OSA were recruited from the sleep disorders clinic at a tertiary referral center and from 6 local metropolitan primary care centers.

INTERVENTIONS:

All patients answered questionnaires and had laboratory PSG. Nasal airflow was monitored for 3 consecutive nights at home in random order either before or after PSG.

RESULTS:

Atotal of 193 patients participated (105 sleep clinic patients and 88 from primary care). The mean bias PSG apnea hypopnea index (AHI) minus nasal flow respiratory disturbance index (NF RDI) was -4.9 events per hour with limits of agreement (2 SD) of 27.8. NF RDI monitored over 3 nights had high accuracy for diagnosing both severe OSA (defined as PSG AHI > 30 events per

hour) with area under the receiver operating characteristic curve (AUC) 0.92 (95% confidence interval (CI) 0.88-0.96) and any OSA (PSG AHI > 5), AUC 0.87 (95% CI 0.80-0.94).

CONCLUSIONS:

Single-channel nasal airflow can be implemented as an accurate diagnostic tool for OSA at home in both primary care and sleep clinic populations.

Rofey, Dana L.; Hull, Ethan E.; Phillips, Jennifer; Vogt, Kristen; Silk, Jennifer S.; Dahl, Ronald E. (2010):

Utilizing Ecological Momentary Assessment in pediatric obesity to quantify behavior, emotion, and sleep.

In: *Obesity (Silver Spring)* 18 (6), S. 1270–1272. DOI: 10.1038/oby.2009.483.

Abstract:

This study examined the feasibility of using Ecological Momentary Assessment (EMA) to examine important domains relevant to interregulatory health processes in overweight adolescent females in their natural environments. Participants were 20 overweight adolescent females engaged in a cognitive-behavioral and motivational interviewing intervention aimed at weight loss and improving mood (11-19 years old, 80% white, 15% African American, mean BMI = 39). During this EMA protocol, participants were asked to report their physical activity (PA), nutrition, mood, and sleep during 14 cellular phone calls over three extended weekends (Thursday to Monday). Simultaneously, participants wore an actigraph (armband and watch communicator) that provided instantaneous PA feedback (steps taken and kilocalories) and sleep parameters (duration and efficiency). EMA compliance rates for the armband and phone calls were 74.7 +/- 0.3% and 64.2 +/- 0.3%, respectively. Data from the armband and phone calls are presented to illustrate the depth of information acquired by utilizing this innovative methodology.

Romero-Canyas, Rainer; Downey, Geraldine; Berenson, Kathy; Ayduk, Ozlem; Kang, N. Jan (2010):

Rejection sensitivity and the rejection-hostility link in romantic relationships.

In: *J Personality* 78 (1), S. 119–148. DOI: 10.1111/j.1467-6494.2009.00611.x.

Abstract:

Rejection sensitivity is the disposition to anxiously expect, readily perceive, and intensely react to rejection. In response to perceived social exclusion, highly rejection sensitive people react with increased hostile feelings toward others and are more likely to show reactive aggression than less rejection sensitive people in the same situation. This paper summarizes work on rejection sensitivity that has provided evidence for the link between anxious expectations of rejection and hostility after rejection. We review evidence that rejection sensitivity functions as a defensive motivational system. Thus, we link rejection sensitivity to attentional and perceptual processes that underlie the processing of social information. A range of experimental and diary studies shows that perceiving rejection triggers hostility and aggressive behavior in rejection sensitive people. We review studies that show that this hostility and reactive aggression can perpetuate a vicious cycle by eliciting rejection from those who rejection sensitive people value most. Finally, we summarize recent work suggesting that this cycle can be interrupted with generalized self-regulatory skills and the experience of positive, supportive relationships.

Rönkä, Anna; Malinen, Kaisa; Kinnunen, Ulla; Tolvanen, Asko; Lämsä, Tiina (2010):

Capturing daily family dynamics via text messages: development of the mobile diary.

In: *Community, Work & Family* 13 (1), S. 5–21.

Abstract:

In this paper we introduce a new tool, the mobile phone, for use in diary research. We demonstrate, with reference to two family studies conducted in Finland, how daily family dynamics can be captured by using the mobile diary. In both studies family members sent text messages (SMSs) in answer to structured diary questions three times a day over a one-week period. The participants kept also paper-and-pencil diaries. Two mobile diary items measuring mood (stressfulness and feelings of competence) both at home and at work are reported here as examples. For both items we found statistically significant daily and weekly variation as well as individual fluctuation. The data gathered by the mobile diary were congruent but not identical with the data gathered by the paper-and-pencil diary. The mobile phone method of data collection facilitated participants' answers at the agreed times and the participants reported that answering was easy and did not take too much time. The main limitation is the lack of space for answers; therefore, the few questions that are used have to be reliable and valid.

Rose, M.; Bjorner, J. B.; Fischer, F.; Anatchkova, M.; Gandek, B.; Klapp, B. F.; Ware, J. E. (2012):

Computerized adaptive testing--ready for ambulatory monitoring?

In: *Psychosom.Med.* 74 (4), S. 338–348. DOI: 10.1097/PSY.0b013e3182547392.

Abstract:

BACKGROUND: Computerized adaptive tests (CATs) have abundant theoretical advantages over established static instruments, which could improve ambulatory monitoring of patient-reported outcomes (PROs). However, an empirical demonstration of their practical benefits is warranted. METHODS: We reviewed the literature and evaluated existing data to discuss the potential of CATs for use in ambulatory monitoring outside clinical facilities. RESULTS: Computerized adaptive tests are not being used for ambulatory monitoring, but initial results from their use in health care research allow for discussion of some issues relevant to ambulatory care. Evidence shows that CATs can capture the most relevant health outcomes as well as established static tools, with substantially decreased respondent burden. They can be more precise than static tools of similar length and can reduce floor and ceiling effects. Computerized adaptive tests can reliably measure a construct over time with different items, which yields the potential of introducing item exposure control in ambulatory monitoring. Studies have shown that CATs can be at least as valid as well-designed static tools in group comparisons, but further investigation is needed to determine whether psychometric advantages lead to increased responsiveness of CATs. CONCLUSIONS: Ambulatory monitoring of PROs demands short, yet very precise measurements, which can be repeated up to many times a day. Computerized adaptive tests may address several present shortcomings in ambulatory monitoring of PROs efficiently. However, most CAT developments have primarily focused on psychometric improvements. To use the full potential of CATs for ambulatory monitoring purposes, content must also be carefully considered

Rosen, P. J.; Epstein, J. N.; Van, Orden G. (2013):

I know it when I quantify it: ecological momentary assessment and recurrence quantification analysis of emotion dysregulation in children with ADHD.

In: *Atten.Defic.Hyperact.Disord.* (1866-6116 (Linking)). DOI: 10.1007/s12402-013-0101-2.

Abstract:

Two studies examined the feasibility, utility, and validity of Ecological Momentary Assessment (EMA) and Recurrence Quantification Analysis (RQA) in assessing emotion dysregulation in children with Attention-Deficit/Hyperactivity Disorder (ADHD). In Study 1, 11 parents of children with ADHD ages 8-11 completed EMA-based ratings of their children's mood three times daily for 28 days (84 ratings total) and questionnaires regarding their children's emotion dysregulation. RQA was used to quantify the temporal patterning of dysregulation of the children's mood. In Study 2, five children ages 8-11 completed EMA-based ratings of their mood three times daily for 28 days. Results supported the feasibility and validity of the parent report EMA protocol, with greater intensity, variability, and persistent patterning of variability associated with greater emotion dysregulation. Results did not support the validity of the child report protocol, as children were less likely to complete ratings when emotionally distressed and demonstrated substantial response bias

Rosen, P. J.; Factor, P. I. (2012):

Emotional Impulsivity and Emotional and Behavioral Difficulties Among Children With ADHD: An Ecological Momentary Assessment Study.

In: *J Atten.Disord.* (1087-0547 (Linking)). DOI: 10.1177/1087054712463064.

Abstract:

OBJECTIVE:

Children with ADHD often demonstrate impulsive shifts in emotion, characterized by sudden and intense shifts in affect. This study examined the effects of emotional impulsivity over time on the emotional and behavioral functioning of children with ADHD using ecological momentary assessment (EMA).

METHOD:

Twenty-seven 8- to 12-year-old children with ADHD, and their parents, completed baseline measures of the children's emotional and behavioral functioning. Parents and children then completed an EMA protocol, whereby they each rated the child's affect three times daily for 28 days.

RESULTS:

Hierarchical regression analyses strongly supported the relation of greater EMA-derived emotional impulsivity to children's increased emotional and behavioral difficulties. These effects were evident across reporters and were maintained after controlling for baseline emotion dysregulation.

CONCLUSION:

Overall, this study demonstrated the utility of EMA-based assessments and suggested that emotional impulsivity may play an important role in the emotional and behavioral functioning of children with ADHD.

Rosenbaum, D.; Brandes, M.; Hardes, J.; Gosheger, G.; Rödl, R. (2008):

Physical activity levels after limb salvage surgery are not related to clinical scores—objective activity assessment in 22 patients after malignant bone tumor treatment with modular prostheses.

In: *Journal of surgical oncology* 98 (2), S. 97–100.

Abstract:

BACKGROUND:

The aim of the present study was to objectively assess the physical activity levels of patients after tumor prosthesis implantation with two objective measurement devices.

METHODS:

The DynaPort ADL monitor permitted up to 24 hr monitoring of lower-extremity physical activities in daily life with respect to posture and locomotion. The step activity monitor (SAM) was worn for a whole week to collect the daily number of gait cycles. The devices were worn during the waking hours by 22 patients with knee prostheses after wide tumor resection.

RESULTS:

In the MSTS and TESS scores the patients achieved over 80% of the maximum score indicating a good clinical outcome. The most prominent activity was sitting which accounted for 54 +/- 18% of the recorded time, followed by standing (27 +/- 16%), locomotion (10 +/- 6%), and lying (8 +/- 6%). During locomotion, the average walking activity accumulated to 4,786 +/- 1,770 step cycles per day (range 2,045-8,135) corresponding to a yearly 1.75 million steps. There was no significant correlation between clinical scores and step count measures.

CONCLUSIONS:

Even though this activity level was lower than for a group of healthy adults it was comparable to the activity level for other patients, for example, with hip arthroplasty as reported in the literature.

Rosenkranz, Richard R.; Welk, Gregory J.; Hastmann, Tanis J.; Dzewaltowski, David A. (2011):

Psychosocial and demographic correlates of objectively measured physical activity in structured and unstructured after-school recreation sessions.

In: *Journal of Science and Medicine in Sport* 14 (4), S. 306–311. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-12851-009&site=ehost-live;r.rosenkranz@uws.edu.au.

Abstract:

Most studies of psychosocial and demographic correlates of physical activity (PA) have examined relationships across various types of physical and social environments, rather than within a specific environmental behavior setting. The objective of this study was to investigate correlates of PA in structured and unstructured after-school recreation sessions. This study is cross-sectional. School records, questionnaires, and anthropometry were used to obtain demographic and psychosocial variables. Third and fourth-grade children (n=230) from seven schools wore Actigraph GT1M accelerometers up to six times per year during after-school programming. Accelerometer data were processed to determine percentage of time in moderate-to-vigorous PA (T scores, reflective of an individual child's PA level relative to group mean, were computed for each session and averaged across sessions). Pearson correlations, point-biserial correlations, and mixed-model analyses were used to determine significant associations with PA for each session type (structured and unstructured). For structured sessions, gender, PA barriers self-efficacy, and PA enjoyment were significantly related to PA. For unstructured sessions, only gender was related to PA. Despite equivalent opportunities to participate in active recreation, boys were more active than girls, and children varied in PA

level partly due to psychosocial factors. Our results showed that PA self-efficacy and enjoyment explained variability in structured PA sessions. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Interactive diary for diabetes: A useful and easy-to-use new telemedicine system to support the decision-making process in type 1 diabetes.

In: *Diabetes technology & therapeutics* 11 (1), S. 19–24. DOI: 10.1089/dia.2008.0020.

Abstract:

BACKGROUND\r\nWidespread use of carbohydrate (CHO) counting is limited by its complex educational needs, but a telemedicine system could simplify the patients' training.\r\nMETHODS\r\nThe Diabetes Interactive Diary (DID) was set up on patients' mobile phones and allowed to record the blood glucose values and quantify the total CHO intake during a meal, by choosing the specific food and the amount ingested from a list of pictures. It also suggested the most appropriate insulin bolus in relation to the patient's CHO/insulin ratio. Data were sent to the physician by Short Message Service (also known as text message). Two pilot studies were carried out to investigate the feasibility and acceptability of the system and its effectiveness in improving metabolic control.\r\nRESULTS\r\nIn the first study, 50 patients were involved in a survey with questionnaires administered before and 12 weeks after the start of the DID. The system was considered by almost all the patients as easy to use and very helpful. CHO counting and insulin bolus calculation were ranked as the most useful functions. In the second study, 41 consecutive patients using DID under routine clinical practice conditions were evaluated after a median of 9 months of follow-up. DID was associated with a nonstatistically significant reduction in fasting blood glucose (FBG), postprandial glucose (PPG), and hemoglobin A1c levels. FBG and PPG coefficient of variation (CV) values were significantly reduced: FBG-CV decreased by 6.7% (95% confidence interval -11.9, -1.6; P = 0.02), while PPG-CV decreased by 11.5% (95% confidence interval -19.3, -3.7; P = 0.01). No patients reported serious hypoglycemic episodes requiring medical intervention.\r\nCONCLUSIONS\r\nDID can represent a useful, safe, and easy-to-use tool to help the patient with type 1 diabetes promote dietary freedom. Adjustment of insulin doses according to CHO intake allowed the reduction of glucose variability, increasingly recognized as an important, independent risk factor for cardiovascular events.

Rotariu, C.; Costin, H. (2013):

Remote respiration monitoring system for sleep apnea detection.

In: *Rev Med Chir Soc Med Nat Iasi* 117 (1), S. 268–274.

Abstract:

Sleep is a dynamic physiological process, its primary function being the restoration of the central nervous system. Because sleep disorders affect a significant part of the population the dynamic long term monitoring of human respiration plays a very important role in diagnosis and treatment. MATERIAL AND METHODS: We describe a remote monitoring system designed for in-hospital or at-home detection with a high degree of accuracy of sleep-related disorders in patients experiencing episodes of obstructive sleep apnea. Patient's respiratory rate is continuously measured by using wireless devices and then transfered to a central monitoring station via a wireless sensor network. The central monitoring station runs a respiration monitoring application that receives the patient's respiratory rate from the network and activates an alert upon detection of a sleep apnea episode. RESULTS: A user-friendly graphical user interface was designed for the respiration monitoring application that displays patient's respiratory rates and sleep apnea alerts. A prototype of the system has been developed, implemented and tested. CONCLUSIONS: The described system allows persons with respiratory diseases or elderly to be monitored at their homes, as an alternative to medical supervision in hospitals.

Rotenberg, Sivan; McGrath, Jennifer J. (2014):

Sampling compliance for cortisol upon awakening in children and adolescents.

In: *Psychoneuroendocrinology* 40, S. 69–75. DOI: 10.1016/j.psyneuen.2013.10.002.

Abstract:

Compliance with awakening salivary sampling is important for precise measurement of the diurnal cortisol profile. During childhood and adolescence, developmental factors influence sampling upon awakening (awake0) due to school routine, sleep/wake patterns, and age related cortisol changes. In the present study, children and adolescents' sampling compliance of awakening cortisol was evaluated using accelerometry. Children and adolescents (N=201; 45.3% female; 8-18 years; Mage=12.68

years, SD=2.03) participating in the Healthy Heart Project collected saliva samples, wore a tri-axle accelerometer, and completed demographic questionnaires. Intra-class correlations derived to examine awake0 sampling compliance indicated children and adolescents were highly compliant (ICC=.98). In children, a delay in awake0 sampling was associated with a steeper diurnal slope (beta=-.23, p=.037) and greater awake0 cortisol (beta=.24, p=.024); this was not observed in adolescents. In summary, children and adolescents are compliant with awakening salivary sampling. Sampling delay, particularly in children, and time of awakening influenced measures of the diurnal cortisol profile. These findings inform future studies assessing the diurnal cortisol profile in children and adolescents.

Who provides accelerometry data? Correlates of adherence to wearing an accelerometry motion sensor: the 2008 Health Survey for England.

In: *J.Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:22398686.

Abstract:

BACKGROUND: Use of objective physical activity measures is rising. We investigated the representativeness of survey participants who wore an accelerometer. METHODS: 4,273 adults aged 16+ from a cross-sectional survey of a random, nationally-representative general population sample in England in 2008 were categorised as: provided sufficient accelerometry data (4-7 valid days (10+ hrs/d), n=1,724); less than that (n=237); or declined (n=302). Multinomial logistic regression identified demographic, socio-economic, health, lifestyle, and biological correlates of participants in these latter two groups, compared with those who provided sufficient accelerometry data (4+ valid days). RESULTS: Those in the random sub-sample offered the accelerometer were older and more likely to be retired and to report having a longstanding limiting illness than the rest of the adult HSE participants. Compared with those providing sufficient accelerometery data, those wearing the accelerometer less were younger, less likely to be in paid employment, and more likely to be a current smoker. Those who declined to wear an accelerometer did not differ significantly from those who wore it for sufficient time. CONCLUSIONS: We found response bias in wearing the accelerometers for sufficient time, but refusers did not differ from those providing sufficient data. Differences should be acknowledged by data users

Roth, Walter R.; Vilardaga, Roger; Wolfe, Nathanael; Bricker, Jonathan B.; McDonell, Michael G. (2014):

Practical considerations in the design and development of smartphone apps for behavior change.

In: *J Contextual Behav Sci* 3 (4), S. 269–272. DOI: 10.1016/j.jcbs.2014.08.006.

Abstract:

The fast adoption of smartphone applications (apps) by behavioral scientists pose a new host of opportunities as well as knowledge and interdisciplinary challenges. Therefore, this brief report will discuss the lessons we have learned during the development and testing of smartphone apps for behavior change, and provide the reader with guidance and recommendations about this design and development process. We hope that the guidance and perspectives presented in this brief report will empower behavioral scientists to test the efficacy of smartphone apps for behavior change, further advance the contextual behavioral etiology of behavioral disorders and help move the field towards personalized behavior change technologies.

Rothney, Megan P.; Apker, Gregory A.; Song, Yanna; Chen, Kong Y. (2008):

Comparing the performance of three generations of ActiGraph accelerometers.

In: *Journal of applied physiology (Bethesda, Md. : 1985)* 105 (4), S. 1091–1097. DOI: 10.1152/japplphysiol.90641.2008.

Abstract:

ActiGraph accelerometers are a useful tool for objective assessment of physical activity in clinical and epidemiological studies. Several generations of ActiGraph are being used; however, little work has been done to verify that measurements are consistent across generations. This study employed mechanical oscillations to characterize the dynamic response and intermonitor variability of three generations of ActiGraph monitors, from the oldest 7164 (n = 13), 71256 (n = 12), to the newest GT1M (n = 12). The response due to independent radius (22.1-60.4 mm) and frequency (25-250 rpm) changes were measured, as well as intermonitor variability within each generation. The 7164 and 71256 have similar relationships between activity counts and radius (P = 0.229) but were significantly different from the GT1M (P < 0.001). The frequency responses were nonlinear in all three

generations. Although the response curve shapes were similar, the differences between generations at various frequencies were significant ($P < 0.017$), especially in the extremes of the measurement range. Intermonitor variability was markedly reduced in the GT1M compared with the 7164 and 71256. Other measurement differences between generations include decreased peak counts and decreased sensitivity in low-frequency detection in the GT1M. The results of this study revealed an improvement of the intermonitor variability by the GT1M monitor. However, the reduced sensitivity in low-count ranges in the GT1M may not be well suited for monitoring sedentary or light-intensity movements. Furthermore, the algorithms for energy expenditure predictions developed using older 7164 monitors may need to be modified for the GT1M.

Ambulatory assessment of 3D ground reaction force using plantar pressure distribution.

In: *Gait Posture* 32 (3), S. 311–316.

Abstract:

This study aimed to use the plantar pressure insole for estimating the three-dimensional ground reaction force (GRF) as well as the frictional torque (T(F)) during walking. Eleven subjects, six healthy and five patients with ankle disease participated in the study while wearing pressure insoles during several walking trials on a force-plate. The plantar pressure distribution was analyzed and 10 principal components of 24 regional pressure values with the stance time percentage (STP) were considered for GRF and T(F) estimation. Both linear and non-linear approximators were used for estimating the GRF and T(F) based on two learning strategies using intra-subject and inter-subjects data. The RMS error and the correlation coefficient between the approximators and the actual patterns obtained from force-plate were calculated. Our results showed better performance for non-linear approximation especially when the STP was considered as input. The least errors were observed for vertical force (4%) and anterior-posterior force (7.3%), while the medial-lateral force (11.3%) and frictional torque (14.7%) had higher errors. The result obtained for the patients showed higher error; nevertheless, when the data of the same patient were used for learning, the results were improved and in general slight differences with healthy subjects were observed. In conclusion, this study showed that ambulatory pressure insole with data normalization, an optimal choice of inputs and a well-trained nonlinear mapping function can estimate efficiently the three-dimensional ground reaction force and frictional torque in consecutive gait cycle without requiring a force-plate.

Rovine, Michael J.; Lo, Lawrence L. (2012):

Foundational issues in intraindividual longitudinal analysis. In: Brett Laursen, Todd D. Little und Noel A. Card (Hg.): Handbook of developmental research methods.

New York, NY US: Guilford Press, S. 313–332. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-07988-019%26site%3dehost-live.

Abstract:

(from the chapter) Single-subject and person-specific approaches to the modeling of developmental processes are becoming more central in the description of complex and time-varying processes. The availability of time series data (intensive data collected on each individual) through diaries, personal data assistants, and "smartphone" devices through measures of physiological characteristics (EKG, fMRI, heart rate, blood pressure, etc.); and by other means have brought time series approaches into the domain of the developmental sciences (Molenaar, 1994). Time series approaches, including Box-Jenkins type autoregressive integrated moving average (ARIMA) models (Box & Jenkins, 1970), multivariate vector autoregressive models (Luktepohl, 2005), P-technique factor models and dynamic factor models (Molenaar, 1985; Wood & Brown, 1994), and state-space models (Molenaar, 1994), among others, have been appearing more often in the developmental literature. Both time domain (Box & Jenkins, 1970) and frequency domain (Jenkins & Watts, 1968) approaches developed for engineering, econometric, and medical applications are now becoming important tools in the social sciences. As with the switch to any new set of methods, a certain amount of reluctance and misunderstanding exists. In this chapter we wish to discuss issues involved in these important approaches. Evaluating reactivity to ecological momentary assessment during smoking cessation.

In: *Experimental and Clinical Psychopharmacology* 15 (4), S. 382.

Abstract:

Ecological momentary assessment (EMA) consists of assessing phenomena in real time in the natural environment. EMA allows for more fine-grained analyses of addictive behavior and minimizes threats to internal validity, such as recall biases and errors. However, because of the intensive monitoring involved in EMA, measurement reactivity is a concern. To test whether EMA with palmtop personal computers induces reactivity, the authors compared smoking-related outcomes between smokers using EMA and those not using EMA during a quit attempt. The use of no-EMA control groups has been rare in reactivity investigations to date. The EMA protocol included event-contingent assessments (smoking episodes, urge episodes) and random assessments. Outcomes included biologically confirmed abstinence and self-report measures of withdrawal, self-efficacy, motivation, affect, and temptations. Participants were smokers motivated to quit (N = 96). They were randomized to 1 of 3 groups: EMA for the week preceding a planned quit date, EMA for the week following the quit date, and no EMA. Abstinence rates did not differ between the groups at Day 7 or at Day 28 postcessation. For the 20 subscales assessed at each of 3 assessment times, there were significant differences between participants with and without EMA experience for 3 subscales at the 1st of 3 assessment times, and significant differences for 3 different subscales at the 3rd assessment time. These differences suggest some reactivity to EMA, although the inconsistent pattern across time indicates that further research is needed to definitively conclude that EMA induces reactivity.

Rowlands, Alex V.; Fraysse, Francois; Catt, Mike; Stiles, Victoria H.; Stanley, Rebecca M.; Eston, Roger G.; Olds, Tim S. (2014):

Comparability of Measured Acceleration from Accelerometry-Based Activity Monitors.

In: *Med Sci Sports Exerc. DOI:* 10.1249/MSS.0000000000000394.

Abstract:

BACKGROUND: Accelerometers that provide triaxial measured acceleration data are now available. However, equivalence of output between brands cannot be assumed and testing is necessary to determine whether features of the acceleration signal are interchangeable. PURPOSE: To establish the equivalence of output between two brands of monitor in a laboratory and in a free-living environment. METHODS: Part 1: Thirty-eight adults performed nine laboratory-based activities while wearing an ActiGraph GT3X+ and GENEActiv at the hip. Part 2: Fifty-eight 10-12 y old children wore a GT3X+ and GENEActiv at the hip for seven days in a free-living setting. RESULTS: Part 1: The magnitude of time-domain features from the GENEActiv was greater than from the GT3X+. However, frequency domain features compared well, with perfect agreement of the dominant frequency for 97-100% of participants for most activities. Part 2: Mean daily acceleration measured by the two brands was correlated ($r=0.93$, $p<0.001$, respectively), but the magnitude was ~15% lower for the GT3X+ than the GENEActiv at the hip. CONCLUSION: Frequency-domain-based classification algorithms should be transferable between monitors and it should be possible to apply time-domain-based classification algorithms developed for one device to the other, by applying an affine conversion on the measured acceleration values. The strong relationship between accelerations measured by the two brands suggests habitual activity level and activity patterns assessed by the GENE and GT3X+ may compare well if analysed appropriately.

Rowlands, Ann V.; Pilgrim, Emma L.; Eston, Roger G. (2008):

Patterns of habitual activity across weekdays and weekend days in 9–11-year-old children.

In: *Prev Med* 46 (4), S. 317–324.

Abstract:

OBJECTIVE:

To characterize the pattern of activity in boys and girls across weekdays and weekend days.

METHODS:

Physical activity was recorded every 2 s by uniaxial accelerometry in 84 children, aged 9-11 years, for up to four weekdays and two weekend days. Activity bouts (>or= 4 s and >or= 5 min) greater than light (>or= LIGHT), moderate (>or= MOD) and vigorous (>or= VIG) intensity were recorded. The study took place in the South-West of England in 2007.

RESULTS:

The mean duration of activity bouts decreased as intensity increased from 11.0+/-1.3 s for >or= LIGHT activity to 6.1+/-1.0 s for >or= VIG activity. The frequency, duration and intensity of bouts were greater in boys than girls, and the frequency and duration of bouts were greater on weekdays than weekend days. Girls accumulated more activity sporadically than boys, whereas boys accumulated more activity in >or= 5-min bouts.

CONCLUSION:

Sex differences and weekday/weekend differences in activity were largely due to the intensity of the most frequent bouts of activity and frequency of the most intense bouts. Information regarding the pattern of children's habitual activity can be used to inform activity interventions and assess the aspects of the activity pattern that are related to health.

Rozenblyum, Evelyn V.; Mistry, Niraj; Cellucci, Tania; Martimianakis, Tina; Laxer, Ronald M. (2014):

A144: Resident's Guide to Rheumatology Guide Mobile Application: An International Needs Assessment.

In: *Arthritis Rheumatol* 66 Suppl 11, S. S187. DOI: 10.1002/art.38565.

Abstract:

BACKGROUND/PURPOSE: "A Resident's Guide To Pediatric Rheumatology" (the Guide) is a widely accepted resource for pediatric rheumatologists and trainees. In preliminary assessments, uptake of the Guide was broader than intended and it was used by trainees to help with clinical decision-making, learning and teaching. Users of the Guide suggested that it be developed into a mobile application (app) The Technology Acceptance Model (TAM) provides a framework to assess the perceived usefulness and ease of use of a tool to predict future acceptance and use. OBJECTIVES: To determine the International demand amongst pediatric professionals and current trainees for a mobile app format of the Guide. To determine user preferred features, functions, and format to be included in a mobile app using the TAM. METHODS: An electronic survey was developed and distributed to pediatric residents at SickKids hospital and to both faculty and trainee members of the international Pediatric Rheumatology list server. The survey included respondent demographics, perceived usefulness, perceived ease of use, and behavioural intention to use the app based on the TAM. Data were analyzed using descriptive statistics. RESULTS: The survey was distributed to 75 pediatric residents and 1132 members of the Pediatric Rheumatology listserver and 135 (12% response rate) completed the survey. The majority of respondents were rheumatologists (53%), while the remainder consisted of Fellows (17%), Pediatric Residents (16%), and other allied health professionals (5%). 93% owned a smartphone and 58% owned a tablet. Most had medically related apps (75%) compared to e-books (38%), but had similar use for each-Mone to several times per week for 1-15 minutes each time on average. The most useful features of an app would be clinical pictures (e.g. skin rashes), radiology images (e.g. joint x-rays), and definitions of key terms. Least useful features were games and multiple-choice questions. Additional features included a searchable index and links to journal articles. Looking at the TAM, the vast majority of respondents thought that the mobile app would enhance trainees' learning and teaching effectiveness. Greater than 80% of respondents consistently supported its perceived ease of use. 55% stated that they were likely to use the app often. 86% felt it was important for the app to be developed. If the app was not available for free, a majority (43%) of respondents were willing to pay for the app with a most willing to pay up to $5.00, and 10% willing to pay up to $10 for access to the app. CONCLUSION: Development of the Guide app was well supported with adding features such as clinical photographs, radiology images, definitions and searchable index. TAM showed the intention to use the app in the future will be most determined by the perceived ease of use which was consistently high in the survey. Interestingly, users were willing to pay for the app if it was not free. Future steps include a qualitative study ultilizing focus groups to assess the perceived functionality, usability, facilitators and barriers in using the Guide app prototype to create the most targeted, user friendly app.

Rozov-Ung, Inna; Mreyoud, Amjad; Moore, John; Wilding, Gregory E.; Khawam, Elias; Lackner, Jeffrey M. et al. (2014):

Detection of drug effects on gastric emptying and contractility using a wireless motility capsule.

In: *BMC Gastroenterol* 14, S. 2. DOI: 10.1186/1471-230X-14-2.

Abstract:

BACKGROUND: A wireless motility capsule is a new method for ambulatory assessment of transit times and motility throughout the gastrointestinal tract. The objective of this study was to evaluate the ability of a wireless motility capsule to detect drug effects on gastric emptying time (GET) and gastric contractility. METHODS: 15 healthy adults were administered in random order saline, erythromycin IV 150 mg, or morphine IV 0.05 mg/kg BW. Subjects ate a standard meal after each infusion, and subsequently ingested the motility capsule. Data were recorded for 8 hours, and the results were analyzed using the manufacturer's software. RESULTS: GET was significantly faster after erythromycin than either saline or morphine. Morphine tended to delay emptying of the capsule compared to saline. There was a trend toward a greater frequency of gastric contractions with erythromycin and a reduced frequency of gastric contractions with morphine that did not reach statistical significance. CONCLUSIONS: A wireless motility capsule successfully detected acceleration of gastric emptying induced by erythromycin, and retardation of gastric motility caused by morphine. These results indicate that a wireless motility capsule is a promising technique to assess pharmacologic effects on gastric transit and contractility and aid in development of drugs for gastric motor disorders.

Rubin, Daniela A.; Wilson, Kathleen S.; Wiersma, Lenny D.; Weiss, Jie W.; Rose, Debra J. (2014):

Rationale and design of active play @ home: a parent-led physical activity program for children with and without disability.

In: *BMC Pediatr* 14, S. 41. DOI: 10.1186/1471-2431-14-41.

Abstract:

BACKGROUND: Compared to other children, those with disability have additional challenges to being physically active. Prader-Willi Syndrome is a genetic form of childhood obesity that is characterized by hypotonia, growth hormone deficiency, behavioral, and cognitive disability. In children, the low prevalence of this syndrome (1 in 10,000 to 15,000 live births) makes group-based physical activity interventions difficult. In contrast, the home environment presents a natural venue to establish a physical activity routine for this population. This manuscript describes the design of a parent-led physical activity intervention incorporating playground and interactive console-based games to increase physical activity participation in youth with and without Prader-Willi Syndrome. METHODS/DESIGN: The study participants will be 115 youth ages 8-15 y (45 with the syndrome and 70 without the syndrome but categorized as obese). The study will use a parallel design with the control group receiving the intervention after serving as control. Participants will be expected to complete a physical activity curriculum 4 days a week for 6 months including playground games 2 days a week and interactive console games 2 days a week. Parents will be trained at baseline and then provided with a curriculum and equipment to guide their implementation of the program. Tips related to scheduling and coping with barriers to daily program implementation will be provided. Throughout, parents will be contacted by phone once a week (weeks 1-4) and then every other week to receive support in between visits. Measurements of children and parents will be obtained at baseline, 12 weeks, and at the end (week 24) of the intervention. Children main outcomes include physical activity (accelerometry), body composition (dual x-ray absorptiometry), motor proficiency (Bruininks-Oseretsky Test of Motor Proficiency), quality of life and physical activity self-efficacy (questionnaires). Intervention compliance will be monitored using mail-in daily self-report checklists. DISCUSSION: This parent-guided physical activity intervention aims to increase physical activity by using a curriculum that builds physical activity related self-confidence through the development and/or enhancement of motor skill competency. Ultimately, helping children develop these skills as well as joy in being physically active will translate into sustained behavior change. TRIAL REGISTRATION: Current Controlled Trial: NCT02058342.

Ruiz, Pedro J. Garcia; Bernardos, Vicenta Sanchez (2008):

Evaluation of ActiTrac®(ambulatory activity monitor) in Parkinson's Disease.

In: *J Neurol Sci* 270 (1), S. 67–69.

Abstract:

At present, the evaluation of Parkinson's Disease (PD) relies mainly on Unified Parkinson's Disease Rating Scale (UPDRS). Other objective measures have been proposed, including functional studies, timed tests and ambulatory activity monitors (AAM). We carried out a prospective study to analyze the utility and correlation of the AAM: ActiTrac with UPDRS scores and timed tests in patients with PD. We studied 28 patients with idiopathic PD (age: 62 +/- 11 years; duration of illness: 7.7 +/- 4.4 years; clinical stage 2.3 +/- 0.39). Motor evaluation included UPDRS and five timed tests: Purdue Pegboard test and those proposed in CAPIT protocol, pronation-supination (PS), finger dexterity (FD), movement between two points (MTP) and walking test (WT). Clinical evaluation was performed in off condition, at 9 a.m., (12h off their medication). Finally, ActiTrac was placed on the wrist (more affected side) continuously for at least 72h. ActiTrac activity was correlated (Spearman) with total UPDRS (r: - 0.53, p < 0.005) and motor UPDRS (r:- 0.46, p: 0.01); UPDRS rigidity subscore (r:- 0.52, p < 0.01); UPDRS bradykinesia subscore (r:- 0.48; p:0.01); FD (r: - 0.47 p: 0.01), WT (r: - 0.49, p < 0.01) and Purdue test (r:0.54; p < 0.01). ActiTrac seems to be a reasonably accurate method to evaluate motor activity in PD.

Ruiz, Jonatan R.; Labayen, Idoia; Ortega, Francisco B.; Moreno, Luis A.; Rodriguez, Gerardo; Breidenassel, Christina et al. (2014):

Physical activity, sedentary time, and liver enzymes in adolescents: the HELENA study.

In: *Pediatr Res. DOI:* 10.1038/pr.2014.26.

Abstract:

Background:To examine the association between physical activity (PA) and liver enzyme levels in adolescents from nine European countries.Methods:The study comprised 718 adolescents (397 girls). PA was measured by accelerometry and expressed as total PA (counts/min), and time (min/d) engaged in moderate to vigorous intensity PA (MVPA). Time spent sedentary was also objectively measured. We measured serum levels of alanine aspartate aminostrasferase (AST), alanine aminostransferase (ALT), and gamma-glutamyltrasnferase (GGT), and the AST/ALT ratio was computed.Results:There was an association between MVPA and AST and AST/ALT (age, sex, and center-adjusted beta = 0.096, 95% confidence interval (CI):

0.016 to 0.118; and beta = 0.090, 95% CI: 0.006 to 0.112, respectively). Meeting the PA recommendations (60 min/d of MVPA) was significantly associated with higher AST and AST/ALT, which persisted after further adjusting for sedentary time and waist circumference. Sedentary time was not associated with any of the studied liver enzyme levels.Conclusion:Meeting the current PA recommendations of 60 min/d of MVPA is associated with higher levels of AST and AST/ALT regardless of time spent sedentary as well as total and central body fat in European adolescents.Pediatric Research (2014); doi:10.1038/pr.2014.26.

Ruiz, Jonatan R.; Rizzo, Nico S.; Hurtig-Wennlöf, Anita; Ortega, Francisco B.; Wärnberg, Julia; Sjöström, Michael (2006):

Relations of total physical activity and intensity to fitness and fatness in children: the European Youth Heart Study.

In: *Am J Clin Nutr* 84 (2), S. 299–303.

Abstract:

BACKGROUND:

It is unclear how the amount and intensity of physical activity (PA) are associated with cardiovascular fitness (CVF) and body fatness in children.

OBJECTIVE:

We aimed to examine the associations of total PA and intensity levels to CVF and fatness in children.

DESIGN:

A cross-sectional study of 780 children aged 9-10 y from Sweden and Estonia was conducted. PA was measured by accelerometry and was expressed as min/d of total PA, moderate PA, and vigorous PA. CVF was measured with a maximal ergometer bike test and was expressed as W/kg. Body fat was derived from the sum of 5 skinfold-thickness measurements. Multiple regression analysis was used to determine the degree to which variance in CVF and body fat was explained by PA, after control for age, sex, and study location.

RESULTS:

Lower body fat was significantly associated with higher levels of vigorous PA, but not with moderate or total PA. Those children who engaged in >40 min vigorous PA/d had lower body fat than did those who engaged in 10-18 min vigorous PA/d. Total PA, moderate PA, and vigorous PA were positively associated with CVF. Those children who engaged in >40 min vigorous PA/d had higher CVF than did those who accumulated <18 min vigorous PA/d.

CONCLUSIONS:

The results suggest that PA of vigorous intensity may have a greater effect on preventing obesity in children than does PA of lower intensity, whereas both total and at least moderate to vigorous PA may improve children's CVF.

Ruiz-Fernandez, Daniel; Marin-Alonso, Oscar; Soriano-Paya, Antonio; Garcia-Perez, Joaquin D. (2014):

eFisioTrack: a telerehabilitation environment based on motion recognition using accelerometry.

In: *ScientificWorldJournal* 2014, S. 495391. DOI: 10.1155/2014/495391.

Abstract:

The growing demand for physical rehabilitation processes can result in the rising of costs and waiting lists, becoming a threat to healthcare services' sustainability. Telerehabilitation solutions can help in this issue by discharging patients from points of care while improving their adherence to treatment. Sensing devices are used to collect data so that the physiotherapists can monitor and evaluate the patients' activity in the scheduled sessions. This paper presents a software platform that aims to meet the needs of the rehabilitation experts and the patients along a physical rehabilitation plan, allowing its use in outpatient scenarios. It is meant to be low-cost and easy-to-use, improving patients and experts experience. We show the satisfactory results already obtained from its use, in terms of the accuracy evaluating the exercises, and the degree of users' acceptance. We conclude that this platform is suitable and technically feasible to carry out rehabilitation plans outside the point of care.

Daily life functioning of community-dwelling elderly couples: an investigation of the feasibility and validity of Ecological Momentary Assessment.

In: *Int J Methods Psychiatr Res. DOI:* 10.1002/mpr.1425.

Abstract:

Although ambulatory data collection techniques have been used in elderly populations, their feasibility and validity amongst elderly individuals with cognitive impairment and amongst couples remains unexplored. The main objective of this study is to examine the validity of Ecological Momentary Assessment (EMA) in elderly persons with or without cognitive impairment and their spouses. The sample included 58 retired farmers (mean 77.3 years, standard deviation [SD] 5.5) with or without cognitive impairment, recruited within a French cohort and 60 spouses (mean 73.4 years, SD 6.9). The presence of cognitive impairment determining by a panel of specialized neurologists permitted to define two groups: "The Cognitive Impairment Group" and "The Control Group". EMA procedures consisted of repeated telephone interviews five times per day during four days for each spouse. Our results demonstrate the validity of EMA procedures through a 92.1% level of compliance, the absence of fatigue effects, and the lack of evidence for major reactivity to the methods. However, the specificity of our sample may explain the acceptance (42%) and response (75%) rates and may reduce the generalizability of the results to the general population of elderly individuals. Finally, the validation of such techniques may contribute to future research examining community-dwelling elderly individuals and their spouses. Copyright (c) 2013 John Wiley & Sons, Ltd.

Rump, Keiran May (2012):

Affective experiences in adolescents with autism: An EMA study.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 72 (11-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-99100-030&site=ehost-live.

Abstract:

Clinical consensus and a limited number of empirical studies indicate that the understanding, awareness, and expression of personal emotional experiences are atypical in individuals with autism; however, the exact nature and magnitude of the atypicality is unclear. The purpose of the current study was to gain a better understanding of how individuals with autism understand and describe their own emotional experiences. This study measured affective awareness and understanding in both the laboratory setting, and in the individual's natural environment using ecological momentary assessment. Nineteen individuals with autism (11-17 years old) and 19 typically developing controls, matched on age and IQ, completed an in-lab task asking them to describe causes of their emotions in addition to self-report measures of depression, anxiety, social skills, and alexithymia. Their parents completed corresponding parent-report forms. Following the lab visit, participants were contacted via cell phone for 14 consecutive days and were asked to rate a subset of emotions from the PANAS-C. Corresponding parent reports were collected for a random subset of these days. Results indicated that on the lab-based measure, the individuals with autism, in contrast to controls, had significantly more difficulty describing appropriate causal contexts for their self-conscious emotions. When reporting on their daily levels of affect, the individuals with autism, in contrast to controls, reported higher intensity negative affect and more lability in positive and negative affect. In comparison to parent report, there was some suggestion that the individuals with autism, but not controls, were underreporting the intensity of their negative affect. For both groups, intensity and lability of negative affect were related to self-reported depression symptoms, but not to parent reports of child depression or self- or parent-reported anxiety symptoms. In addition, no measures of affective awareness and understanding were related to child or parent reported social skills. The current findings suggest that in adolescence, the manner in which individuals with autism understand, experience, and report on their emotional experiences differs from their typically developing peers in subtle yet notable ways. Potential mechanisms underlying these differences are discussed, and a number of future directions are suggested. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

A smartphone ecological momentary assessment/intervention "app" for collecting real-time data and promoting self-awareness.

In: *PLoS One* 8 (8), S. e71325. DOI: 10.1371/journal.pone.0071325.

Abstract:

We have designed a flexible ecological momentary assessment/intervention smartphone (EMA/EMI) "app". We examine the utility of this app for collecting real-time data, and assessing intra-subject variability, by using it to assess how freshman undergraduates spend their time. We also explore whether its use can promote greater self-awareness. Participants were

randomly divided into an experimental group, who used the app, and a control group, who did not. We used the app to collect both randomized in-the-moment data as well as end-of-day data to assess time use. Using a posttest survey we asked participants questions about how they spent time throughout the school semester. We also asked the experimental group about their experience with the app. Among other findings, 80.49% participants indicated that they became more aware of how they spent their time using the app. Corroborating this report, among the experimental group, end-of-semester self-assessment of time spent wasted, and time spent using electronics recreationally, predicted semester GPA at a strength comparable to high school GPA and ACT score (two of the best single predictors for first semester college GPA), but had no correlation among controls. We discuss the advantages and limitations of using apps, such as ours, for EMA and/or EMI

Rusby, J. C.; Westling, E.; Crowley, R.; Light, J. M. (2012):

Concurrent and Predictive Associations Between Early Adolescent Perceptions of Peer Affiliates and Mood States Collected in Real Time via Ecological Momentary Assessment Methodology.

In: *Psychol.Assess.* (1040-3590 (Linking)). DOI: 10.1037/a0030393.

Abstract:

This study uses ecological momentary assessment (EMA) to simultaneously capture youths' perceptions of peer affiliates and social contexts to determine their association with youths' current and future mood states. A sample of 82 seventh grade students (36 at risk for developing or escalating rule breaking and substance use and 46 randomly selected) from 4 schools participated. Using EMA methodology, we had students report their peer affiliations, perceptions of peer affiliates, moods, activities, location, and behaviors during their free time. Data from 3 assessment waves were collected; each wave consisted of 27 randomly prompted assessments during a week. Youths spent a large portion of their free time watching television, on the computer, or playing video games. Being "out and about" increased over the school year, whereas adult supervision decreased, showing an increase in potentially risky situations. Happiness was associated with affiliating with peers who were perceived to be popular. Negative moods were associated with affiliating with peers by whom they were teased or treated meanly. Multilevel models found that both levels and lability of negative moods (i.e., sadness, anxiety) were predicted by risk status and affiliation with peers who tease them. Compared with boys, girls who affiliated more with peers who teased them and were classified as at risk had more extreme negative moods and negative mood lability. EMA methodology has demonstrated the ways in which salient intrapersonal and peer processes are associated over time, which can inform efforts to prevent the development and escalation of behavior problems, substance use, and mood disorders in adolescence. A step-wise approach to find a valid and feasible method to detect non-adherence to tuberculosis drugs.

Abstract:

A step-wise approach to identify valid and feasible methods to detect non-adherence to tuberculosis drugs was evaluated in a prospective study among pulmonary tuberculosis patients in an outpatient clinic in Indonesia. First, adherence was measured by self-reporting with the standardized Morisky questionnaire, physician assessment, pill-count, visit attendance, diary and an electronic medication event monitoring system (MEMS). Next, validity of single methods was assessed against MEMS as gold standard. Feasibility of methods was then judged by physicians in the field. Finally, when valid and feasible methods were combined, it appeared that self-reporting by a questionnaire plus physician assessment could identify all non-adherent patients. It is recommended to use a systematic approach to develop a valid and locally feasible combination of methods to detect non-adherence to TB drugs.

A real-time assessment of work stress in physicians and nurses.

In: *Health Psychol* 28 (2), S. 194–200. DOI: 10.1037/a0013145.

Abstract:

OBJECTIVE\r\nThis study adapted ecological momentary assessment methods to: (a) examine differences in work stress between nurses and physicians, and (b) to study relationships between work stress, work activity patterns, and sleep.\r\nDESIGN\r\nA total of 185 physicians and 119 nurses (206 women, 98 men) working in four teaching hospitals participated in an observational study of work stress.\r\nMAIN OUTCOME MEASURES\r\nParticipants carried handheld computers that randomly prompted them for work activity, patient load, and work stress information.\r\nRESULTS\r\nParticipants completed more than 9,500 random interval surveys during the study (an average of 30.8 surveys per person-week). Approximately 85% of all surveys were completed in full (73.3%) or partially (11.6%). Emotional stress scores among physicians were nearly 50% higher (26.9[19.0]) than those of nurses (18.1[14.9], r[302] = .37, p < .001). Direct and indirect care activities were associated with higher stress reports by both clinician groups (rs[159] = .14-.26, ps < .01). Sleep quality and quantity were predictors of work stress scores (ps < .05). Finally, higher work stress and lower sleep quality were also associated with poorer memory performance (r[302] = -.12, .17, ps < 05).\r\nCONCLUSIONS\r\nThe findings identify patterns of work stress in relationship to work activities, sleep habits, and provider differences that may be used to assist ongoing hospital work reform efforts.

Is a failure to recognize an increase in food intake a key to understanding insulin-induced weight gain?

In: *Diabetes Care* 31 (3), S. 448–450.

Abstract:

The present study aimed to assess the contribution of energy intake to positive energy balance and weight gain with insulin therapy. Changes in energy intake (self-report and weighed food intake), dietary behavior (auto-questionnaires), resting energy expenditure (REE) (indirect calorimetry), physical activity (accelerometry), and glucosuria were monitored over the first 6 months of insulin therapy in 46 diabetic adults. No change in REE, activity, or glucosuria could explain weight gain in the type 1 (4.1 +/- 0.6 kg, P < 0.0001) or type 2 (1.8 +/- 0.8 kg, P = 0.02) diabetic groups. An increase in energy intake provides the most likely explanation for weight gain with insulin. However, it is not being recognized because of significant underestimation of self-reported food intake, which appears to be associated with increased dietary restraint.

Sabia, Severine; van Hees, Vincent T.; Shipley, Martin J.; Trenell, Michael I.; Hagger-Johnson, Gareth; Elbaz, Alexis et al. (2014):

Association between questionnaire- and accelerometer-assessed physical activity: the role of sociodemographic factors.

In: *Am J Epidemiol* 179 (6), S. 781–790. DOI: 10.1093/aje/kwt330.

Abstract:

The correlation between objective and self-reported measures of physical activity varies between studies. We examined this association and whether it differed by demographic factors or socioeconomic status (SES). Data were from 3,975 Whitehall II (United Kingdom, 2012-2013) participants aged 60-83 years, who completed a physical activity questionnaire and wore an accelerometer on their wrist for 9 days. There was a moderate correlation between questionnaire- and accelerometer-assessed physical activity (Spearman's r = 0.33, 95% confidence interval: 0.30, 0.36). The correlations were higher in high-SES groups than in low-SES groups (P 's = 0.02), as defined by education (r = 0.38 vs. r = 0.30) or occupational position (r = 0.37 vs. r = 0.29), but did not differ by age, sex, or marital status. Of the self-reported physical activity, 68.3% came from mild activities, 25% from moderate activities, and only 6.7% from vigorous activities, but their correlations with accelerometer-assessed total physical activity were comparable (range of r 's, 0.21-0.25). Self-reported physical activity from more energetic activities was more strongly associated with accelerometer data (for sports, r = 0.22; for gardening, r = 0.16; for housework, r = 0.09). High-SES persons reported more energetic activities, producing stronger accelerometer associations in these groups. Future studies should identify the aspects of physical activity that are most critical for health; this involves better understanding of the instruments being used.

Feasibility and Utility of Experience Sampling to Assess Alcohol Consumption Among Older Adults.

In: *J Appl Gerontol. DOI:* 10.1177/0733464813519009.

Abstract:

In the literature on alcohol use and aging, drinking has often been conceptualized as a means of coping with negative feelings, such as stress, yet much of the literature on older adults and drinking has utilized cross-sectional or other data ill-suited for exploring dynamic processes. Experience sampling methods have the ability to measure and analyze dynamic processes in real time, such as relations between alcohol use and mood states. Nonetheless, these approaches are intensive and may burden respondents. Therefore, this study evaluated the feasibility, acceptability, and validity of a modified daily diary to measure alcohol use and explored alternate methods of collecting diary data. Findings suggest that a modified diary was acceptable and not burdensome. Respondents were reluctant to consider technology (e.g., cellphone)-based means of data collection. Measures of alcohol use showed little within-person variation suggesting that for those who drink at all, drinking is a daily habit.

Context-aware personal navigation using embedded sensor fusion in smartphones.

In: *Sensors (Basel)* 14 (4), S. 5742–5767. DOI: 10.3390/s140405742.

Abstract:

Context-awareness is an interesting topic in mobile navigation scenarios where the context of the application is highly dynamic. Using context-aware computing, navigation services consider the situation of user, not only in the design process, but in real time while the device is in use. The basic idea is that mobile navigation services can provide different services based on different contexts-where contexts are related to the user's activity and the device placement. Context-aware systems are concerned with the following challenges which are addressed in this paper: context acquisition, context understanding, and context-aware application adaptation. The proposed approach in this paper is using low-cost sensors in a multi-level fusion scheme to improve the accuracy and robustness of context-aware navigation system. The experimental results demonstrate the capabilities of the context-aware Personal Navigation Systems (PNS) for outdoor personal navigation using a smartphone.

Influence of room heating on ambulatory blood pressure in winter: a randomised controlled study.

In: *J Epidemiol.Community Health* (0143-005X (Linking)). DOI: 10.1136/jech-2012-201883.

Abstract:

BACKGROUND: Previous studies have proposed that higher blood pressure (BP) in winter is an important cause of increased mortality from cardiovascular disease during the winter. Some observational and physiological studies have shown that cold exposure increases BP, but evidence from a randomised controlled study assessing the effectiveness of intensive room heating for lowering BP was lacking. OBJECTIVES: The present study aimed to determine whether intensive room heating in winter decreases ambulatory BP as compared with weak room heating resulting in a 10 degrees C lower target room temperature when sufficient clothing and bedclothes are available. METHODS: We conducted a parallel group, assessor blinded, simple randomised controlled study with 1:1 allocation among 146 healthy participants in Japan from November 2009 to March 2010. Ambulatory BP was measured while the participants stayed in single experimental rooms from 21:00 to 8:00. During the session, participants could adjust the amount of clothing and bedclothes as required. Compared with the weak room heating group (mean temperature+/-SD: 13.9+/-3.3 degrees C), systolic morning BP (mean BP 2 h after getting out of bed) of the intensive room heating group (24.2+/-1.7 degrees C) was significantly lower by 5.8 mm Hg (95% CI 2.4 to 9.3). Sleep-trough morning BP surges (morning BP minus lowest night-time BP) in the intensive room heating group were significantly suppressed to about two thirds of the values in the weak room heating group (14.3 vs 21.9 mm Hg; $p<0.01$). CONCLUSIONS: Intensive room heating decreased morning BP and the morning BP surge in winter

Assessment of primary healthcare professionals' management of hypertensive patients with riser pattern.

In: *Eur J Cardiovasc Nurs. DOI:* 10.1177/1474515113518856.

Abstract:

Background:Ambulatory blood pressure monitoring (ABPM) was implemented in our primary care setting four years ago. Since then, 450 ABPMs have been performed and 69 riser subjects identified. The riser pattern is an independent risk factor for both incidence of cardiovascular events and their associated mortality.Objective:The purpose of this study was to assess the amount of control of essential hypertension (EH) among riser patients and to evaluate how our health professionals manage therapeutic changes in riser individuals.Materials and methodology:This retrospective study involved 34,289 inhabitants served in a centre in the Barcelona metropolitan area. EH individuals (450) were recruited and ABPM was performed following guidelines of the MAPAPRES (www.cardiorisc.com/MP/index_MP.asp).Results:Good control of blood pressure was observed in 46% of dipper and non-dipper subjects but only 35% of riser subjects had blood pressures within good control ranges. The measured cardiovascular risk was either high or very high in 35% of riser individuals. Changes in medication were introduced in riser patients with both good and poor blood pressure control. A second follow-up ABPM was done in only 27% of the riser individuals. In these subjects, therapeutic changes successfully modified ABPM patterns in 87% of cases.Conclusions:Therapeutic changes in riser patients were introduced when these subjects were poorly controlled and these changes were highly effective. Additional ABPM to confirm the effectiveness of therapeutic changes was only performed in some individuals. Thus, for management of riser patients, more specific training of health professionals is needed.

Sakai, M.; Okuyama, Y.; Wei, D. (2012):

Separation of EEG and ECG components based on wavelet shrinkage and variable cosine window.

In: *J.Med.Eng Technol.* 36 (2), S. 135–143. DOI: 10.3109/03091902.2011.645947.

Abstract:

During ambulatory monitoring, it is sometimes required to record an electroencephalogram (EEG) and an electrocardiogram (ECG) simultaneously. It would be ideal if both EEG and ECG could be obtained with one measurement. Here, we introduce an algorithm that combines the wavelet shrinkage and variable cosine window operation to separate the EEG and ECG components from an EEG signal recorded with a noncephalic reference (NCR). Evaluation using simulated data and actual measured data showed that accurate frequency analysis of EEG and an R-R detection-based heart rate analysis were feasible with our proposed algorithm, which improved the signal-averaging based algorithm so that ECG components containing ectopic beats can be applied

Sakai, Motoki; Wei, Daming (2009):

Separation of electrocardiographic and encephalographic components based on signal averaging and wavelet shrinkage techniques.

In: *Computers in biology and medicine* 39 (7), S. 620–629. DOI: 10.1016/j.compbiomed.2009.04.009.

Abstract:

During ambulatory monitoring, it is often required to record the electroencephalogram (EEG) and the electrocardiogram (ECG) simultaneously. It would be ideal if both EEG and ECG can be obtained with one measurement. We introduce an algorithm combining the wavelet shrinkage and signal averaging techniques to extract the EEG and ECG components from an EEG lead signal to a noncephalic reference (NCR). The evaluation using simulation data and measured data showed that the normalized power spectrum unvaried in all frequency bands for the EEG components, and the sensitivity and specificity of R-wave detection for the ECG component were nearly 100%.

Panic disorder and locomotor activity.

In: *BioPsychoSocial Medicine* 2, S. 23.

Abstract:

Background

Panic disorder is one of the anxiety disorders, and anxiety is associated with some locomotor activity changes such as "restlessness". However, there have been few studies on locomotor activity in panic disorder using actigraphy, although many studies on other psychiatric disorders have been reported using actigraphy. Therefore, the aim of the present study was to investigate the relationship between panic disorder and locomotor activity pattern using a wrist-worn activity monitor. In addition, an ecological momentary assessment technique was used to record panic attacks in natural settings.

Methods

Sixteen patients with panic disorder were asked to wear a watch-type computer as an electronic diary for recording panic attacks for two weeks. In addition, locomotor activity was measured and recorded continuously in an accelerometer equipped in the watch-type computer. Locomotor activity data were analyzed using double cosinor analysis to calculate mesor and the amplitude and acrophase of each of the circadian rhythm and 12-hour harmonic component. Correlations between panic disorder symptoms and locomotor activity were investigated.

Results

There were significant positive correlations between the frequency of panic attacks and mesor calculated from double cosinor analysis of locomotor activity (r = 0.55) and between HAM-A scores and mesor calculated from double cosinor analysis of locomotor activity (r = 0.62).

Conclusion

Panic disorder patients with more panic attacks and more anxiety have greater objectively assessed locomotor activity, which may reflect the "restlessness" of anxiety disorders.

A case of transient ischemic attack of hemodynamic origin induced by postprandial hypotension.

In: *Rinsho Shinkeigaku* 54 (2), S. 162–165.

Abstract:

An 82-year-old man had a transient ischemic attack (TIA) with symptoms of consciousness disturbance and right hemiparesis while resting in a sitting position after breakfast. His symptoms improved around 1 h after onset when he lied in a supine position and received intravenous hydration. Duplex carotid ultrasonography revealed severe stenosis of the left common carotid artery. A decrease in the brain perfusion reserve was confirmed by acetazolamide-stress brain perfusion scintigraphy. Moreover, ambulatory blood pressure monitoring revealed a reduction in systolic blood pressure below 90 mmHg after each meal, indicating postprandial hypotension (PPH). The PPH was improved by oral administration of alpha-glucosidase inhibitor without any subsequent recurrences of TIA. The patient was diagnosed with TIA of hemodynamic origin that was induced by PPH and exhibited severe carotid stenosis. PPH is common in elderly people, and it should be recognized as a significant trigger for ischemic cerebrovascular disease.

Saladini, F.; Benetti, E.; Malipiero, G.; Casiglia, E.; Palatini, P. (2012):

Does home blood pressure allow for a better assessment of the white-coat effect than ambulatory blood pressure?

In: *J Hypertens* 30 (11), S. 2118–2124. DOI: 10.1097/HJH.0b013e3283589ee6.

Abstract:

BACKGROUND: The difference between clinic and ambulatory blood pressure (BP) is a poor estimate of the true white-coat effect (WCE) measured with beat-to-beat recording. METHOD: We investigated whether the difference between clinic and home BP (home WCE) was a better estimate of true WCE than ambulatory WCE. In 73 young hypertensives, ambulatory WCE was calculated as the difference between clinic BP and the mean of two 24-h BP recordings, and home WCE as the difference

between clinic and home BP (HBP) measured over 6 months. All individuals underwent beat-to-beat BP monitoring with the Finometer. During the recording, a white-coat test (true WCE) and a public speaking test were performed. RESULTS: Ambulatory WCE correlated with home WCE (P < 0.001 for systolic and diastolic BPs). However, both surrogate WCEs were unrelated to true WCE (P = 0.93/0.36 and P = 0.11/0.36, respectively). True WCE correlated with the BP reaction to public speaking (P < 0.001/P < 0.001), whereas both surrogate WCEs were unrelated to the BP response to this test (all P > 0.21). Individuals were divided into two groups according to whether BP response to the doctor's visit was above (WCH+) or below (WCH-) the median. WCH+ patients had similar clinic and ambulatory BPs to WCH- but showed a higher BP response to public speaking. CONCLUSION: As previously observed for ambulatory WCE, home WCE does not reflect the true BP reaction to doctor's visit. BP response to psychosocial stressors is increased in individuals with hyperreactivity to doctor's measurement but not in individuals with white-coat hypertension identified with either ambulatory or HBP measurement

Salamon, Reda; Johnson, Elizabeth I.; Swendsen, Joel (2011):

Daily life mechanisms of stress spillover among early adolescents experiencing academic difficulty.

In: *European Journal of Psychology of Education* 26 (4), S. 453–463. DOI: 10.1037/t06497-000;

Abstract:

Research has suggested that academic stress may “spillover” into other life domains and have negative psychological or social consequences for children and adolescents outside of school settings, but relatively few investigations have examined mediators and moderators of spillover. The current study explored the mediating role of state affect and the moderating roles of prior academic performance and mood disturbances on spillover in a sample of 131 French adolescents. Participants completed clinical measures of anxiety and depression and participated in a 7-day ambulatory monitoring phase that involved multiple daily assessments of mood, behaviors, and activities. Spillover was observed for family events and subsequent school-related events, as well as between family and leisure events. These associations remained significant when controlling for immediate mood responses, suggesting that state affect does not play a salient mediating role. There was no evidence that spillover was moderated by academic difficulty, anxiety, depression, or gender. Results are discussed in terms of the role that emotional processes may play in spillover phenomena as well as the reciprocal influence that academic and non-academic events may exert each other. Ambulatory monitoring of physical activities in patients with Parkinson's disease.

In: *Biomedical Engineering, IEEE Transactions on* 54 (12), S. 2296–2299.

Abstract:

A new ambulatory method of monitoring physical activities in Parkinson's disease (PD) patients is proposed based on a portable data-logger with three body-fixed inertial sensors. A group of ten PD patients treated with subthalamic nucleus deep brain stimulation (STN-DBS) and ten normal control subjects followed a protocol of typical daily activities and the whole period of the measurement was recorded by video. Walking periods were recognized using two sensors on shanks and lying periods were detected using a sensor on trunk. By calculating kinematics features of the trunk movements during the transitions between sitting and standing postures and using a statistical classifier, sit-to-stand (SiSt) and stand-to-sit (StSi) transitions were detected and separated from other body movements. Finally, a fuzzy classifier used this information to detect periods of sitting and standing. The proposed method showed a high sensitivity and specificity for the detection of basic body postures allocations: sitting, standing, lying, and walking periods, both in PD patients and healthy subjects. We found significant differences in parameters related to SiSt and StSi transitions between PD patients and controls and also between PD patients with and without STN-DBS turned on. We concluded that our method provides a simple, accurate, and effective means to objectively quantify physical activities in both normal and PD patients and may prove useful to assess the level of motor functions in the latter.

Salarian, Arash; Russmann, Heike; Wider, Christian; Burkhard, Pierre R.; Vingerhoets, Françios J. G.; Aminian, Kamiar (2007):

Quantification of tremor and bradykinesia in Parkinson's disease using a novel ambulatory monitoring system.

In: *Biomedical Engineering, IEEE Transactions on* 54 (2), S. 313–322.

Abstract:

An ambulatory system for quantification of tremor and bradykinesia in patients with Parkinson's disease (PD) is presented. To record movements of the upper extremities, a sensing units which included miniature gyroscopes, has been fixed to each of the forearms. An algorithm to detect and quantify tremor and another algorithm to quantify bradykinesia have been proposed and validated. Two clinical studies have been performed. In the first study, 10 PD patients and 10 control subjects participated in a 45-min protocol of 17 typical daily activities. The algorithm for tremor detection showed an overall sensitivity of 99.5% and a specificity of 94.2% in comparison to a video reference. The estimated tremor amplitude showed a high correlation to the Unified Parkinson's Disease Rating Scale (UPDRS) tremor subscore (e.g., $r = 0.87$, $p < 0.001$ for the roll axis). There was a high and significant correlation between the estimated bradykinesia related parameters estimated for the whole period of measurement and respective UPDRS subscore (e.g., $r = -0.83$, $p < 0.001$ for the roll axis). In the second study, movements of upper extremities of 11 PD patients were recorded for periods of 3-5 hr. The patients were moving freely during the measurements. The effects of selection of window size used to calculate tremor and bradykinesia related parameters on the correlation between UPDRS and these parameters were studied. By selecting a window similar to the period of the first study, similar correlations were obtained. Moreover, one of the bradykinesia related parameters showed significant correlation ($r = -0.74$, $p < 0.01$) to UPDRS with window sizes as short as 5 min. Our study provides evidence that objective, accurate and simultaneous assessment of tremor and bradykinesia can be achieved in free moving PD patients during their daily activities.

Salazar, Antonio J.; Silva, Ana S.; Silva, Claudia; Borges, Carla M.; Correia, Miguel V.; Santos, Rubim S.; Vilas-Boas, Joao P. (2014):

Low-cost wearable data acquisition for stroke rehabilitation: a proof-of-concept study on accelerometry for functional task assessment.

In: *Top Stroke Rehabil* 21 (1), S. 12–22. DOI: 10.1310/tsr2101-12.

Abstract:

BACKGROUND: An increasingly aging society and consequently rising number of patients with poststroke-related neurological dysfunctions are forcing the rehabilitation field to adapt to ever-growing demands. Although clinical reasoning within rehabilitation is dependent on patient movement performance analysis, current strategies for monitoring rehabilitation progress are based on subjective time-consuming assessment scales, not often applied. Therefore, a need exists for efficient nonsubjective monitoring methods. Wearable monitoring devices are rapidly becoming a recognized option in rehabilitation for quantitative measures. Developments in sensors, embedded technology, and smart textile are driving rehabilitation to adopt an objective, seamless, efficient, and cost-effective delivery system. This study aims to assist physiotherapists' clinical reasoning process through the incorporation of accelerometers as part of an electronic data acquisition system. METHODS: A simple, low-cost, wearable device for poststroke rehabilitation progress monitoring was developed based on commercially available inertial sensors. Accelerometry data acquisition was performed for 4 first-time poststroke patients during a reach-press-return task. RESULTS: Preliminary studies revealed acceleration profiles of stroke patients through which it is possible to quantitatively assess the functional movement, identify compensatory strategies, and help define proper movement. CONCLUSION: An inertial data acquisition system was designed and developed as a low-cost option for monitoring rehabilitation. The device seeks to ease the data-gathering process by physiotherapists to complement current practices with accelerometry profiles and aid the development of quantifiable methodologies and protocols.

Salinas, Jennifer J.; Hilfinger Messias, Deanne K.; Morales-Campos, Daisy; Parra-Medina, Deborah (2014):

English language proficiency and physical activity among Mexican-origin women in South Texas and South Carolina.

In: *J Health Care Poor Underserved* 25 (1), S. 357–375. DOI: 10.1353/hpu.2014.0033.

Abstract:

OBJECTIVES: To examine the relationship between English language proficiency (ELP), physical activity, and physical activity-related psychosocial measures (i.e., exercise self-efficacy, exercise social support, perceptions of environmental supports) among Mexican-origin women in South Carolina and Texas. DESIGN: Adjusted robust regression and interaction modeling to evaluate baseline questionnaire data on self-reported ELP with CHAMPS leisure-time moderate-to-vigorous physical activity (MVPA), accelerometry data, Physical Activity Self-Efficacy, Physical Activity Social Support, and Environmental Support for Physical Activity in 118 Mexican-origin women. RESULTS: The adjusted regression revealed a significant association between ELP and perceived physical activity self-efficacy (beta = 234.2, $p = .004$), but not with physical activity social support. In South Carolina, CHAMPS leisure-time MVPA (411.4 versus 114.3 minutes, $p < .05$) was significantly different between women in the high ELP quartile and those in the very low quartile. Among high ELP Mexican-origin women, participants in Texas reported significantly higher MVPA measured by accelerometry ($p = .042$) than those in South Carolina. CONCLUSION: Our findings indicate that ELP was associated with physical activity and that contextual factors may also play a role.

Salles, Gil F.; Cardoso, Claudia R. L.; Muxfeldt, Elizabeth S. (2008):

Prognostic influence of office and ambulatory blood pressures in resistant hypertension.

In: *Archives of internal medicine* 168 (21), S. 2340–2346.

Abstract:

BACKGROUND:

The prognostic value of office and ambulatory blood pressures (BPs) in patients with resistant hypertension is uncertain.

METHODS:

This prospective study investigates the importance of office and ambulatory BPs as predictors of cardiovascular morbidity and mortality. At baseline, 556 resistant hypertensive patients underwent clinical-laboratory and 24-hour ambulatory BP monitoring examinations. Primary end points were a composite of fatal and nonfatal cardiovascular events and all-cause and cardiovascular mortalities. Multiple Cox regression was used to assess associations between BP and subsequent end points.

RESULTS:

After median follow-up of 4.8 years, 109 patients (19.6%) reached the primary end point, and 70 all-cause deaths (12.6%) occurred (46 had cardiovascular causes). After adjustment for age, sex, body mass index, diabetes mellitus, smoking, physical inactivity, dyslipidemia, previous cardiovascular diseases, serum creatinine level, and number of antihypertensive drugs in use, no office BP showed any prognostic value. After further adjustment for office BP, higher mean ambulatory BPs were independent predictors of the composite end point. The hazard ratios associated with a 1-SD increment in daytime and nighttime systolic BP were 1.26 (95% confidence interval, 1.04-1.53) and 1.38 (1.13-1.68), respectively; the corresponding values for diastolic BP were 1.31 (1.05-1.63) and 1.36 (1.10-1.69). Ambulatory systolic and diastolic BP were equivalent predictors, and both were better than pulse pressure; nighttime BP was superior to daytime BP. For all-cause mortality, only the ambulatory BP monitoring diagnosis of true resistant hypertension was an independent predictor.

CONCLUSION:

Higher ambulatory BP predicts cardiovascular morbidity and mortality in resistant hypertensive patients, whereas office BP has no prognostic value.

Salvador, R.; Watson, T. J.; Herbella, F.; Dubecz, A.; Polomsky, M.; Jones, C. E. et al. (2009):

Association of gastroesophageal reflux and O2 desaturation: a novel study of simultaneous 24-h MII-pH and continuous pulse oximetry.

In: *Journal of gastrointestinal surgery : official journal of the Society for Surgery of the Alimentary Tract* 13 (5), S. 854–861. DOI: 10.1007/s11605-009-0815-9.

Abstract:

BACKGROUND\r\nProof of the relationship between gastroesophageal reflux disease (GERD) and respiratory symptoms remains a challenge. Our aim was to determine the association between reflux events and O(2) desaturation in GERD patients with primary respiratory symptoms (RS) compared to those with primary esophageal symptoms (ES) using ambulatory monitoring systems.\r\nMETHODS\r\nOne thousand eight hundred fifty-one reflux episodes were detected by multichannel intraluminal impedance (MII)-pH testing in 30 patients with symptoms of GERD (20 RS, ten ES.) All patients underwent simultaneous 24-h MII-pH and continuous O(2) saturation monitoring via pulse oximetry. Reflux-associated desaturation events were determined by correlating synchronized 24-h esophageal pH and/or impedance and O(2) desaturation.\r\nRESULTS\r\nOne thousand one hundred seventeen reflux events occurred in patients with RS and 734 in those with ES. Nearly 60% of these 1,851 reflux events were associated with O(2) desaturation. Markedly more events were associated with O(2) desaturation in patients with RS (74.5%, 832/1,117) than in patients with ES (30.4%, 223/734, $p < 0.0001$). The difference in reflux desaturation association was more profound with proximal reflux--80.3% with RS vs. 29.4% with ES ($p < 0.0001$).\r\nCONCLUSIONS\r\nA remarkably high prevalence of O(2) desaturation associated with gastroesophageal reflux was noted in patients with RS. Given further study, simultaneous combined esophageal reflux and O(2) saturation monitoring may prove a useful diagnostic tool in this difficult group of patients.

An evaluation of mobile health application tools.

In: *JMIR Mhealth Uhealth* 2 (2), S. e19. DOI: 10.2196/mhealth.3088.

Abstract:

BACKGROUND: The rapid growth in the number of mobile health applications could have profound significance in the prevention of disease or in the treatment of patients with chronic disease such as diabetes. OBJECTIVE: The objective of this study was to describe the characteristics of the most common mobile health care applications available in the Apple iTunes marketplace. METHODS: We undertook a descriptive analysis of a sample of applications in the "health and wellness" category of the Apple iTunes Store. We characterized each application in terms of its health factor and primary method of user engagement. The main outcome measures of the analysis were price, health factors, and methods of user engagement. RESULTS: Among the 400 applications that met the inclusion criteria, the mean price of the most frequently downloaded paid applications was US $2.24 (SD $1.30), and the mean price of the most currently available paid applications was US $2.27 (SD $1.60). Fitness/training applications were the most popular (43.5%, 174/400). The next two most common categories were health resource (15.0%, 60/400) and diet/caloric intake (14.3%, 57/400). Applications in the health resource category constituted 5.5% (22/400) of the applications reviewed. Self-monitoring was the most common primary user engagement method (74.8%, 299/400). A total of 20.8% (83/400) of the applications used two or more user engagement approaches, with self-monitoring and progress tracking being the most frequent. CONCLUSIONS: Most of the popular mobile health applications focus on fitness and self-monitoring. The approaches to user engagement utilized by these applications are limited and present an opportunity to improve the effectiveness of the technology.

Samuels, Tiana Y.; Raedeke, Thomas D.; Mahar, Matthew T.; Karvinen, Kristina H.; Dubose, Katrina D. (2011):

A randomized controlled trial of continuous activity, short bouts, and a 10,000 step guideline in inactive adults.

In: *Prev Med* 52 (2), S. 120–125.

Abstract:

OBJECTIVE:

Although several studies have examined the effect of accumulated bouts on health outcomes, the impact of recommending short bouts on activity-related behavior in health promotion efforts has received minimal investigation.

METHOD:

During this 5-week study in 2007-2008, 43 university employees (8 male, 35 female) in the Southeastern United States were randomly assigned to a group recommended to achieve (a) 10,000 steps (10K), (b) 30-minutes (30 min) of continuous physical activity, or (c) 30-minutes of activity in bouts of at least 10 minutes (bouts).

RESULTS AND CONCLUSIONS:

Repeated measures ANOVA revealed that the 10K group showed the largest increase in step counts whereas the bouts group showed the smallest change over the intervention period, p=0.01. Condition differences were most pronounced on days in which participants met their activity recommendation. Accelerometer results revealed that the 10K (d=1.1) and 30 min groups (d=0.89) showed large increases in minutes of moderate to vigorous activity (MVPA), whereas the bouts group showed minimal change (d=0.11). Although activity recommendations did not differentially affect self-efficacy, participants from all conditions showed decreased self-efficacy across the intervention (p=0.02), highlighting the need to develop strategies to increase self-efficacy in activity promotion efforts.

Sanchez, Diana T.; Garcia, Julie A. (2009):

When race matters: racially stigmatized others and perceiving race as a biological construction affect biracial people's daily well-being.

In: *Pers Soc Psychol Bull* 35 (9), S. 1154–1164. DOI: 10.1177/0146167209337628.

Abstract:

Stigmatized group members experience greater well-being in the presence of similar others, which may be driven by the perception that similar others value their shared stigmatized identities (i.e., high public regard). Using experience sampling methodology, this hypothesis is tested with biracial people (29 Asian/White, 23 Black/ White, and 26 Latino/White biracial participants). This study proposes that the greater percentage of stigmatized similar others in one's daily context would predict greater daily well-being for biracial people through higher public regard, but only if biracial people believe that race has biological meaning. These findings add to a growing, but limited, literature on biracial individuals. These findings are situated within the broader literature on stigma and similar others, as well as new theories regarding the consequences of believing race has biological meaning.

Daily life evidence of environment-incongruent emotion in schizophrenia.

In: *Psychiatry Res. DOI:* 10.1016/j.psychres.2014.07.041.

Abstract:

Researchers have recently hypothesized that negative emotion in positive situations may be one mechanism for understanding emotion dysfunction in schizophrenia. Using ecological momentary assessment, we examined the relationship between emotion experience and environmental context in the daily lives of participants with and without schizophrenia. Participants with (n=47) and without schizophrenia (n=41) were provided a cellular telephone and called four times a day for one week. During each call participants rated their emotion experiences, described their current activities, and rated enjoyment from those activities. In line with previous research, participants with schizophrenia reported higher negative emotion overall relative to participants without schizophrenia, but equivalent levels of positive emotion and activity enjoyment. In line with the environment-incongruent negative emotion hypothesis, participants with schizophrenia evidenced a weaker relationship between reported enjoyment of current activities and current negative emotion compared to participants without schizophrenia. In addition, lower neurocognition predicted this weak relationship between negative emotion and context in the schizophrenia group. These findings provide ecologically valid support for environment-incongruent negative emotion in schizophrenia, and suggest that people with schizophrenia with more impaired neurocognition may have more difficulties regulating negative emotion.

Sanders, Taren; Cliff, Dylan P.; Lonsdale, Chris (2014):

Measuring adolescent boys' physical activity: bout length and the influence of accelerometer epoch length.

In: *PLoS One* 9 (3), S. e92040. DOI: 10.1371/journal.pone.0092040.

Abstract:

OBJECTIVES: Accurate, objective measurement is important for understanding adolescents' physical activity (PA) behaviour. When using accelerometry to objectively measure PA, a decision must be made regarding how frequently data is recorded (i.e., epoch length). The purpose of this study was to examine i) PA bout length, and ii) the effect of variations in accelerometer epoch length on PA estimates during physical education (PE) and leisure time in adolescent boys. DESIGN: Cross-sectional study. METHODS: Year 9 boys (N = 133; mean age +/-SD = 14.36+/-0.48 years) wore accelerometers during two PE lessons, and for a period of seven consecutive days. Data were reintegrated from 1s into longer periods of 2, 5, 10, 30, and 60 seconds. ANOVAs were used to test for differences in PA estimates between epochs in leisure time and PE. RESULTS: The mean length of vigorous PA (VPA) bouts was 3.5+/-2.0 seconds for PE and 2.5+/-1.7 seconds for leisure time, and mean length of moderate PA (MPA) bouts was 2.3+/-0.5 seconds for PE and 2.9+/-0.5 seconds for leisure time. During PE, estimates of MVPA, MPA, and light PA (LPA) increased as epoch increased from 1 second to 60 seconds, while VPA and sedentary behaviour estimates decreased. During leisure time, estimates of all PA intensities decreased as epoch increased from 1 second to 60 seconds, with the exception of sedentary behaviour, which increased as epoch length increased. CONCLUSION: The context in which PA occurs can influence PA bout length measurement and the effect of variations in epoch length on PA estimates. Researchers measuring PA with accelerometry should be conscious of the possible influence of context on PA estimates.

Sandland, Carolyn J.; Morgan, Mike D. L.; Singh, Sally J. (2008):

Patterns of domestic activity and ambulatory oxygen usage in COPD.

In: *CHEST Journal* 134 (4), S. 753–760.

Abstract:

BACKGROUND:

The aim of this study was to examine patterns of domestic activity and ambulatory oxygen usage in patients with COPD in their domestic environment.

METHODS:

Twenty patients (14 men; mean age, 73.4 years [SD, 6.8 years]; FEV1, 1.0 L [SD, 0.5 L]) with stable COPD were recruited after completing a 7-week pulmonary rehabilitation program. Patients were either hypoxic at rest or had desaturation during exercise. Patients were randomized to an 8-week, double-blind, placebo-controlled trial of cylinder oxygen vs cylinder air. Total domestic physical activity and health-related quality of life (HRQL) measures were recorded before and after intervention.

RESULTS:

There were no significant changes in domestic activity or HRQL measures after the intervention for either cylinder oxygen or cylinder air, except for a worsening of the Chronic Respiratory Questionnaire dyspnea domain on cylinder air. There was a significant increase in mean duration (minutes per day) of cylinder use ($p < 0.05$) between weeks 1 vs 7 and weeks 1 vs 8 for the oxygen group. However, when comparing the two groups together, there were no between-group differences in cylinder use or time spent outside the home. Over the 8 weeks the majority of patients were using the cylinders in the home rather than outside, however, the number of times patients reported using the cylinders outside the home increased over the 8 weeks for the oxygen group.

CONCLUSION:

In the short term, ambulatory oxygen therapy is not associated with improvements in physical activity, HRQL, or time spent away from home. However, the use of cylinder oxygen increased over the 8 weeks compared to cylinder air. Patients need time to learn how to use oxygen, and ambulatory oxygen appears to enhance activities rather than increase them.

Sandroff, Brian M.; Riskin, Barry J.; Agiovlasitis, Stamatis; Motl, Robert W. (2014):

Accelerometer cut-points derived during over-ground walking in persons with mild, moderate, and severe multiple sclerosis.

In: *J Neurol Sci. DOI:* 10.1016/j.jns.2014.02.024.

Abstract:

BACKGROUND: There has been increased interest in objectively quantifying time spent in moderate-to-vigorous physical activity (MVPA) using accelerometry as an outcome among persons with multiple sclerosis (MS). This requires development of a cut-point for interpreting the rate of accelerometer output based on its association with energy expenditure during physical activity. OBJECTIVE: The current study measured activity counts from a waist-worn accelerometer and energy expenditure based on indirect calorimetry during three speeds of over-ground walking for deriving cut-points for interpreting accelerometer output in persons with mild, moderate, and severe MS disability. METHODS: 54 participants with MS initially completed a neurological examination for generation of an EDSS score. Participants were then fitted with an ActiGraph model GT3X+ accelerometer and a Cosmed portable metabolic system, and completed three, 6-minute walk (6 MW) tests that were interspersed with 10-15min of rest. The first 6 MW was undertaken at a comfortable walking speed (CWS), and the two remaining 6 MW tests were undertaken above (faster walking speed) or below (slower walking speed) the participant's CWS in a counterbalanced order. RESULTS: The linear association between activity counts per minute and energy expenditure did not differ between persons with mild and moderate MS disability, but it was significantly different among persons with severe disability. This resulted in disability-specific cut-points for MVPA of 1980 and 1185 counts per minute for groups with mild/moderate disability and severe disability, respectively. CONCLUSIONS: We believe that this research will facilitate a better understanding of time spent in MVPA across a broad range of MS disability.

Sano, W.; Nakamura, T.; Yoshiuchi, K.; Kitajima, T.; Tsuchiya, A.; Esaki, Y. et al. (2012):

Enhanced persistency of resting and active periods of locomotor activity in schizophrenia.

In: *PLoS One* 7 (8), S. e43539. DOI: 10.1371/journal.pone.0043539.

Abstract:

Patients with schizophrenia frequently exhibit behavioral abnormalities associated with its pathological symptoms. Therefore, a quantitative evaluation of behavioral dynamics could contribute to objective diagnoses of schizophrenia. However, such an approach has not been fully established because of the absence of quantitative biobehavioral measures. Recently, we studied the dynamical properties of locomotor activity, specifically how resting and active periods are interwoven in daily life. We discovered universal statistical laws ("behavioral organization") and their alterations in patients with major depressive disorder. In this study, we evaluated behavioral organization of schizophrenic patients (n = 19) and healthy subjects (n = 11) using locomotor activity data, acquired by actigraphy, to investigate whether the laws could provide objective and quantitative measures for a possible diagnosis and assessment of symptoms. Specifically, we evaluated the cumulative distributions of resting and active periods, defined as the periods with physical activity counts successively below and above a predefined threshold, respectively. Here we report alterations in the laws governing resting and active periods; resting periods obeyed a power-law cumulative distribution with significantly lower parameter values (power-law scaling exponents), whereas active periods followed a stretched exponential distribution with significantly lower parameter values (stretching exponents), in patients. Our findings indicate enhanced persistency of both lower and higher locomotor activity periods in patients with schizophrenia, probably reflecting schizophrenic pathophysiology

Ecological Momentary Assessment in Borderline Personality Disorder: A Review of Recent Findings and Methodological Challenges.

In: *J Pers.Disord.* (0885-579X (Linking)). DOI: 10.1521/pedi_2012_26_067.

Abstract:

The use of Ecological Momentary Assessment (EMA) has led to increased insight into borderline personality disorder (BPD) symptoms, especially regarding affective instability. EMA is characterized by a series of repeated assessments of current affective, behavioral, and contextual experiences or physiological processes while participants engage in normal daily activities. EMA has several advantages. It enables researchers to avoid biased recollection, to investigate within-person processes, and to enhance real-life generalizability. This review is dedicated to four main objectives: (1) to discuss the characteristics of EMA in studying BPD symptomatology; (2) to provide an extensive overview of EMA findings in BPD structured into findings regarding DSM-IV criteria and findings regarding emotional dysregulation as stated in the biosocial theory of Linehan; (3) to discuss challenges of EMA and to give recommendations for the proper use of it; and (4) to highlight prospects and promising applications that should be addressed

Santhanam, Gopal; Linderman, Michael D.; Gilja, Vikash; Afshar, Afsheen; Ryu, Stephen; Meng, Teresa H.; Shenoy, Krishna V. (2007):

HermesB: a continuous neural recording system for freely behaving primates.

In: *Biomedical Engineering, IEEE Transactions on* 54 (11), S. 2037–2050.

Abstract:

Chronically implanted electrode arrays have enabled a broad range of advances in basic electrophysiology and neural prosthetics. Those successes motivate new experiments, particularly, the development of prototype implantable prosthetic processors for continuous use in freely behaving subjects, both monkeys and humans. However, traditional experimental techniques require the subject to be restrained, limiting both the types and duration of experiments. In this paper, we present a dual-channel, battery-powered neural recording system with an integrated three-axis accelerometer for use with chronically implanted electrode arrays in freely behaving primates. The recording system called HermesB, is self-contained, autonomous, programmable, and capable of recording broadband neural (sampled at 30 kS/s) and acceleration data to a removable compact flash card for up to 48 h. We have collected long-duration data sets with HermesB from an adult macaque monkey which provide insight into time scales and free behaviors inaccessible under traditional experiments. Variations in action potential shape and root-mean square (RMS) noise are observed across a range of time scales. The peak-to-peak voltage of action potentials varied by up to 30% over a 24-h period including step changes in waveform amplitude (up to 25%) coincident with high acceleration movements of the head. These initial results suggest that spike-sorting algorithms can no longer assume stable neural signals and will need to transition to adaptive signal processing methodologies to maximize performance. During physically active periods (defined by head-mounted accelerometer), significantly reduced 5-25-Hz local field potential (LFP) power and increased firing rate variability were observed. Using a threshold fit to LFP power, 93% of 403 5-min recording blocks were correctly classified as active or inactive, potentially providing an efficient tool for identifying different behavioral contexts in prosthetic applications. These results demonstrate the utility of the HermesB system and motivate using this type of system to advance neural prosthetics and electrophysiological experiments.

Santos, R.; Mota, J.; Okely, A. D.; Pratt, M.; Moreira, C.; Coelho-E-Silva Mj et al. (2013):

The independent associations of sedentary behaviour and physical activity on cardiorespiratory fitness.

In: *Br.J Sports Med* (0306-3674 (Linking)). DOI: 10.1136/bjsports-2012-091610.

Abstract:

BACKGROUND: During childhood and adolescence, both physical activity (PA) and sedentary behaviour seem to influence cardiorespiratory fitness (CRF); however, the combined association of PA and sedentary behaviour remains to be understood. We analysed the combined association of objectively measured sedentary behaviour and moderate-to-vigorous intensity PA (MVPA) on CRF in Portuguese children and adolescents. METHODS: The sample comprised 2506 Portuguese healthy children and adolescents aged 10-18 years, from a cross-sectional school-based study (2008). PA and sedentary behaviour were assessed with accelerometry. Participants were classified as meeting current PA guidelines for youth versus not meeting, and as low versus high sedentary (according to the median value of sedentary time/day by age and gender), and then grouped as follows: Low active-high sedentary; low active-low sedentary; high active-high sedentary; high active-low sedentary. CRF was assessed with

the FITNESSGRAM 20 m shuttle-run test. Binary logistic regression models were constructed to verify the relationship between high CRF and the combined influence of MVPA/sedentary behaviour, adjusting for age, gender, body mass index and accelerometer wear time. RESULTS: Participants classified as high active/low sedentary (OR=1.81; 95% CI 1.21 to 2.69), as well as those classified as low active/low sedentary (OR=1.27; 95% CI 1.01 to 1.61) were more likely to be fit, compared with those from the low-active/high-sedentary group. CONCLUSION: MVPA and sedentary behaviour may act independently in their relation with CRF, and that MVPA levels may not overcome the deleterious influence of high-sedentary time in maximising CRF

Santos-Silva, Rogerio; Sartori, Denis E.; Truksinas, Viviane; Truksinas, Eveli; Alonso, Fabiana F F D; Tufik, Sergio; Bittencourt, Lia R. A. (2009):

Validation of a Portable Monitoring System for the Diagnosis of Obstructive Sleep Apnea Syndrome.

In: *Sleep* 32 (5), S. 629–636. DOI: 10.1016/j.jamcollsurg.2006[PII].

Abstract:

STUDY OBJECTIVE:: To evaluate if a portable monitor could accurately measure the apnea-hypopnea index (AHI) in patients with a suspicion of obstructive sleep apnea (OSA). DESIGN:: Prospective and randomized. SETTING:: Sleep laboratory. PARTICIPANTS:: 80 participants: 70 patients with clinical OSA suspicion and 10 subjects without suspicion of OSA. INTERVENTIONS:: N/A MEASUREMENTS AND RESULTS:: Three-order randomized evaluations were performed: (1) STD (Stardust II) used at the participants' home (STD home), (2) STD used simultaneously with PSG in the sleep lab (STD+PSG lab), and (3) PSG performed without the STD (PSG lab). Four AHI values were generated and analyzed: (a) STD home; (b) STD from STD+PSG lab; (c) PSG from STD+PSG (named PSG+STD lab); and (d) PSG lab. Two technicians, blinded to study details, performed the analyses of all evaluations. There was a strong correlation between AHI from the STD and PSG recordings for all 4 AHI values (all correlations above 0.87). Sensitivity, specificity, and positive and negative predictive values at AHI cut-off values of 5, 15, and 30 events/hour were calculated. AHI values from the PSG lab and PSG+STD lab were compared to STD home and STD+PSG lab and showed the best results when STD and PSG were performed simultaneously. In all analyses, the area under ROC curve was at least 0.90. With multiple comparisons, diagnostic agreement was between 91% and 75%. The Bland Altman analyses showed strong agreement between AHI values from the STD and PSG recordings, especially when comparing the AHI from simultaneous STD and PSG recordings. CONCLUSION:: These data suggest that the STD is accurate in confirming the diagnosis of OSA where there is a suspicion of the disorder. Better agreement occurred during simultaneous recordings. CITATION:: Santos-Silva R; Sartori DE; Truksinas V; Truksinas E; Alonso FFFD; TufikS; Bittencourt LRA. Validation of a portable monitoring system for the diagnosis of obstructive sleep apnea syndrome. SLEEP 2009;32(5):629-639.

Persistence of social signatures in human communication.

In: *Proc Natl Acad Sci U S A* 111 (3), S. 942–947. DOI: 10.1073/pnas.1308540110.

Abstract:

The social network maintained by a focal individual, or ego, is intrinsically dynamic and typically exhibits some turnover in membership over time as personal circumstances change. However, the consequences of such changes on the distribution of an ego's network ties are not well understood. Here we use a unique 18-mo dataset that combines mobile phone calls and survey data to track changes in the ego networks and communication patterns of students making the transition from school to university or work. Our analysis reveals that individuals display a distinctive and robust social signature, captured by how interactions are distributed across different alters. Notably, for a given ego, these social signatures tend to persist over time, despite considerable turnover in the identity of alters in the ego network. Thus, as new network members are added, some old network members either are replaced or receive fewer calls, preserving the overall distribution of calls across network members. This is likely to reflect the consequences of finite resources such as the time available for communication, the cognitive and emotional effort required to sustain close relationships, and the ability to make emotional investments.

Sardella, Chiara; Urbani, Claudio; Lombardi, Martina; Nuzzo, Alessandro; Manetti, Luca; Lupi, Isabella et al. (2014):

The Beneficial Effect Of Acromegaly Control On Blood Pressure Values In Normotensive Patients.

In: *Clin Endocrinol (Oxf). DOI:* 10.1111/cen.12455.

Abstract:

OBJECTIVE: Control of acromegaly may ameliorate blood pressure (BP) in hypertensive patients. We evaluated the impact of acromegaly control on BP values of normotensive acromegalics. DESIGN: Retrospective cohort study. PATIENTS: Fifty-eight naive patients with acromegaly (39 F; age range, 30-69 years), including 28 normotensive (NT) and 30 hypertensive (HT) subjects, participated in the study. MEASUREMENTS: Blood pressure was measured by clinical measurement and 24-hr ambulatory monitoring at diagnosis and after 24 months of medical therapy for acromegaly. RESULTS: Acromegaly was controlled by medical therapy in 15 NT and 17 HT patients at 24 months. In the NT group, systolic (SBP) or diastolic (DBP) BP significantly increased (all $p < 0.005$) when acromegaly was uncontrolled, but did not change when the disease was controlled. Changes in SBP and DPB were also significantly different between uncontrolled and controlled NT patients. At 24 months, clinical hypertension was detected only in uncontrolled NT patients (46% vs. 0%, $p < 0.001$), whereas ambulatory hypertension was found in 38% of uncontrolled and in 7% of controlled NT subjects ($p = 0.035$). In the HT group, ambulatory SBP increased in patients with uncontrolled acromegaly (24-hr SBP $p = 0.046$, day SBP $p = 0.005$, night SBP $p = 0.005$), whereas ambulatory DBP decreased in subjects with controlled disease (24-hr DBP $p = 0.008$, day DBP $p = 0.026$). CONCLUSIONS: Control of acromegaly has a beneficial effect on BP regulation either in HT or NT subjects; in the latter it may prevent progression towards hypertension.

Sartori, Raffaela D. G.; Marelli, Marco; Garavaglia, Paolo; Castelli, Lucia; Busin, Silvano; Delle Fave, Antonella (2014):

The assessment of patients' quality of experience: autonomy level and perceived challenges.

In: *Rehabil Psychol* 59 (3), S. 267–277. DOI: 10.1037/a0036519.

Abstract:

PURPOSE/OBJECTIVE: Motor rehabilitation programs in hospital aim at promoting patients' highest attainable recovery of body functions and capabilities. Well-being is predominantly identified with physical autonomy, yet the psychological dimensions of rehabilitation are often overlooked. RESEARCH METHOD/DESIGN: To partially fill this gap, the quality of daily experience reported by 50 adult participants hospitalized in an Italian rehabilitation unit was investigated. Data were gathered through Experience Sampling Method, (ESM), providing repeated real-time assessments of the experience associated with daily activities. Before analysis, participants were divided into 3 groups, according to their low, moderate, or high levels of autonomy assessed through Barthel Index. RESULTS: Participants predominantly associated rehabilitation activities with optimal experience, characterized by high concentration, engagement, control of the situation, and by the perception of high challenges matched with adequate personal skills. During personal care and leisure-the most frequent daily activities-participants reported instead low challenging experiences of apathy and boredom. During social interactions perceived high challenges prevailed. Multilevel analysis showed that the type of activity performed was a significant predictor of participants' quality of experience, and the level of autonomy had a modest impact on it. CONCLUSIONS/IMPLICATIONS: Results highlighted the potential added value of rehabilitation tasks as opportunities to promote patients' well-being. The predominantly negative experiences associated with the other daily activities point instead to the need for changes in hospital organization in order to more effectively promote patients' autonomy and resource mobilization.

The Assessment of Patients' Quality of Experience: Autonomy Level and Perceived Challenges.

In: *Rehabilitation Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-26962-001%26site%3dehost-live.

Abstract:

Purpose/Objective: Motor rehabilitation programs in hospital aim at promoting patients' highest attainable recovery of body functions and capabilities. Well-being is predominantly identified with physical autonomy, yet the psychological dimensions of rehabilitation are often overlooked. Research Method/Design: To partially fill this gap, the quality of daily experience reported by 50 adult participants hospitalized in an Italian rehabilitation unit was investigated. Data were gathered through Experience Sampling Method, (ESM), providing repeated real-time assessments of the experience associated with daily activities. Before analysis, participants were divided into 3 groups, according to their low, moderate, or high levels of autonomy assessed through Barthel Index. Results: Participants predominantly associated rehabilitation activities with optimal experience, characterized by high concentration, engagement, control of the situation, and by the perception of high challenges matched with adequate personal skills. During personal care and leisure—the most frequent daily activities—participants reported instead low challenging experiences of apathy and boredom. During social interactions perceived high challenges prevailed. Multilevel

analysis showed that the type of activity performed was a significant predictor of participants' quality of experience, and the level of autonomy had a modest impact on it. Conclusions/Implications: Results highlighted the potential added value of rehabilitation tasks as opportunities to promote patients' well-being. The predominantly negative experiences associated with the other daily activities point instead to the need for changes in hospital organization in order to more effectively promote patients' autonomy and resource mobilization. Aldosterone-to-renin ratio and nocturnal blood pressure decline assessed by self-measurement of blood pressure at home: the Ohasama Study.

In: *Clin Exp Hypertens* 36 (2), S. 108–114. DOI: 10.3109/10641963.2014.892121.

Abstract:

Abstract Based on ambulatory blood pressure (BP) monitoring, the aldosterone-to-renin ratio (ARR) has been reported to be associated with a diminished nocturnal decline in BP, generally referred to as a "non-dipping" pattern. The objective of this cross-sectional study was to investigate the association between ARR and the non-dipping pattern based on home BP measurements. This study included 177 participants >/=55 years from the general population of Ohasama (mean age: 67.2 years; 74.6% women); no patient was receiving antihypertensive treatment. The median plasma renin activity (PRA), plasma aldosterone concentration (PAC) and ARR were 0.8 ng/mL/h, 8.1 ng/dL and 9.7 ng/dL per ng/mL/h, respectively. Each 1 SD increase in log-transformed (ln) ARR was significantly associated with the prevalence of the non-dipping pattern after adjustments for possible confounding factors including home morning systolic BP (odds ratio, 1.45; p = 0.049). However, no significant associations of PRA or PAC with the non-dipping pattern were observed (p >/= 0.2). When participants were divided into four groups according to median levels of home morning and night-time systolic BPs, the group with a higher home morning systolic BP (>/=128.4 mmHg) with a higher home night-time systolic BP (>/=114.4 mmHg) had the greatest ARR levels (ANCOVA p = 0.01). These results support the hypothesis that relative aldosterone excess may be related to a non-dipping pattern in a general population and suggest that a non-dipping pattern can be accurately observed by home BP measurements.

Maternal Prenatal Felt Security and Infant Health at Birth Interact to Predict Infant Fussing and Crying at 12 Months Postpartum.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-56005-001%26site%3dehost-live.

Abstract:

Infants born with medical problems are at risk for less optimal developmental outcomes. This may be, in part, because neonatal medical problems are associated with maternal distress, which may adversely impact infants. However, the reserve capacity model suggests that an individual's bank of psychosocial resources buffers the adverse effects of later-encountered stressors. This prospective longitudinal study examined whether preexisting maternal psychosocial resources, conceptualized as felt security in close relationships, moderate the association between neonatal medical problems and infant fussing and crying 12 months postpartum. Maternal felt security was measured by assessing its indicators in 5,092 pregnant women. At birth, infants were classified as healthy or having a medical problem. At 12 months, experience sampling was used to assess daily maternal reports of fussing and crying in 135 mothers of infants who were healthy or had medical problems at birth. Confirmatory factor analyses revealed that attachment, relationship quality, self-esteem, and social support can be conceptualized as indicators of a single felt security factor. Multiple regression analyses revealed that prenatal maternal felt security interacts with infant health at birth to predict fussing and crying at 12 months. Among infants born with medical problems, higher felt security predicted decreased fussing and crying. Maternal felt security assessed before birth dampens the association between neonatal medical problems and subsequent infant behavior. This supports the hypothesis that psychosocial resources in reserve can be called upon in the face of a stressor to reduce its adverse effects on the self or others. Sayk, Friedhelm; Teckentrup, Christina; Becker, Christoph; Heutling, Dennis; Wellhöner, Peter; Lehnert, Hendrik; Dodt, Christoph (2010):

Effects of selective slow-wave sleep deprivation on nocturnal blood pressure dipping and daytime blood pressure regulation.

In: *American journal of physiology. Regulatory, integrative and comparative physiology* 298 (1), S. R191-7. DOI: 10.1152/ajpregu.00368.2009.

Abstract:

Nocturnal blood pressure (BP) decline or \"dipping\" is an active, central, nervously governed process, which is important for BP regulation during daytime. It is, however, not known whether the sleep process itself or, more specifically, slow-wave sleep (SWS) is important for normal dipping. Therefore, in the present study, healthy subjects (6 females, 5 males) were selectively deprived of SWS by EEG-guided acoustic arousals. BP and heart rate (HR) were monitored during experimental nights and the following day. Additionally, nocturnal catecholamine excretion was determined, and morning baroreflex function was assessed by microneurographic measurements of muscle sympathetic nerve activity (MSNA) and heart rate variability (HRV). Data were compared with a crossover condition of undisturbed sleep. SWS was successfully deprived leading to significantly attenuated mean arterial BP dipping during the first half ($P < 0.05$), but not during the rapid-eye-movement-dominated second half of total sleep; however, dipping still evolved even in the absence of SWS. No differences were found for nighttime catecholamine excretion. Moreover, daytime resting and ambulatory BP and HR were not altered, and morning MSNA and HRV did not differ significantly, indicating that baroreflex-mediated sympathoneural BP regulation was not affected by the preceding SWS deprivation. We conclude that in healthy humans the magnitude of nocturnal BP dipping is significantly affected by sleep depth. Deprivation of SWS during one night does not modulate the morning threshold and sensitivity of the vascular and cardiac baroreflex and does not alter ambulatory BP during daytime.

Sbarra, David A.; Ferrer, Emilio (2006):

The structure and process of emotional experience following nonmarital relationship dissolution: dynamic factor analyses of love, anger, and sadness.

In: *Emotion* 6 (2), S. 224–238. DOI: 10.1037/1528-3542.6.2.224.

Abstract:

Dynamic factor analysis was used to examine the structure and process of daily emotions in a sample of young adults following a romantic breakup. Participants completed a daily diary for 4 weeks reporting on their love/longing for their ex-partner, anger, and sadness. Using a lag-1 process factor analysis model, results revealed that love/longing, sadness, and anger could be reliably distinguished as separate but correlated mood states in a trivariate model. Four emotional dynamics (amplification, reversing, persistence, and cooccurrence) were operationalized and investigated. Differences in these dynamics were observed on the basis of overall adjustment to the separation and attachment styles. Findings are discussed in terms of attachment and contemporary emotion theories, as well as the need to operationalize time-based affective processes.

Long-term telemonitoring of mobility trends of elderly people using SMS messaging.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 10 (2), S. 412–413.

Abstract:

A telemonitoring system, based on short message service (SMS), has been developed to remotely monitor the long-term mobility levels of elderly people in their natural environment. Mobility is measured by an accelerometer-based portable unit, worn by each monitored subject. Mobility level summaries are transmitted hourly, as an SMS message, directly from the portable unit to a remote server for long-term analysis. Each subject's mobility levels are monitored using custom-designed mobility alert software, and the appropriate medical personnel are alerted by SMS if the subject's mobility levels decrease.

Establishing Wrist-Based Cutpoints for the Actical Accelerometer in Elementary School Aged Children.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23493290.

Abstract:

BACKGROUND: The wrist has become a standard location for accelerometry (ACC) data collection, primarily to optimize compliance, yet interpreting wrist ACC data is limited due to a lack of calibration studies. This study aimed to establish cutpoints for a wrist-mounted Actical accelerometer in 6-11 year-old children using two methods. METHODS: Metabolic and ACC data (15 sec epoch) were collected during 8 activities in 22 children ages 6-11. Linear regression (LR) and Receiver Operator Characteristics (ROC) were used to examine the relationship between METs and ACC counts. Cutpoints were established at <1.5, 1.5-3, 3-6 and >/=6 METs for sedentary, light, moderate and vigorous activity, respectively. Cutpoints were applied to a large, multi-day sample of children (n=269) to examine differences in cutpoints on minutes of moderate-vigorous PA (MVPA). RESULTS: LR and ROC yielded moderate cutpoints of 574 and 388, respectively. When applied to the large sample, LR and ROC cutpoints resulted in an estimated 83 and 140 minutes of daily MVPA, respectively. CONCLUSIONS: We have established wrist-mounted Actical cutpoints for children using two methods. The differences in cutpoints and their effect on estimates of MVPA in an independent sample highlight challenges associated with establishing cutpoints, suggesting that standardized calibration procedures be developed

Schafer, A.; Vagedes, J. (2012):

How accurate is pulse rate variability as an estimate of heart rate variability?: A review on studies comparing photoplethysmographic technology with an electrocardiogram.

In: *Int.J Cardiol.* (0167-5273 (Linking)). DOI: 10.1016/j.ijcard.2012.03.119.

Abstract:

BACKGROUND: The usefulness of heart rate variability (HRV) as a clinical research and diagnostic tool has been verified in numerous studies. The gold standard technique comprises analyzing time series of RR intervals from an electrocardiographic signal. However, some authors have used pulse cycle intervals instead of RR intervals, as they can be determined from a pulse wave (e.g. a photoplethysmographic) signal. This option is often called pulse rate variability (PRV), and utilizing it could expand the serviceability of pulse oximeters or simplify ambulatory monitoring of HRV. METHODS: We review studies investigating the accuracy of PRV as an estimate of HRV, regardless of the underlying technology (photoplethysmography, continuous blood pressure monitoring or Finapresi, impedance plethysmography). RESULTS/CONCLUSIONS: Results speak in favor of sufficient accuracy when subjects are at rest, although many studies suggest that short-term variability is somewhat overestimated by PRV, which reflects coupling effects between respiration and the cardiovascular system. Physical activity and some mental stressors seem to impair the agreement of PRV and HRV, often to an inacceptable extent. Findings regarding the position of the sensor or the detection algorithm are not conclusive. Generally, quantitative conclusions are impeded by the fact that results of different studies are mostly incommensurable due to diverse experimental settings and/or methods of analysis

Use of mental health telemetry to enhance identification and predictive value of early changes during augmentation treatment of major depression.

In: *J.Clin.Psychopharmacol.* 33 (6), S. 775–781. DOI: 10.1097/JCP.0b013e31829e8359.

Abstract:

Standard clinical trial methodology in depression does not allow for careful examination of early changes in symptom intensity. The purpose of this study was to use daily "Mental Health Telemetry" (MHT) to prospectively record change in depressive and anxiety symptoms for depressed patients receiving augmentation treatment, and determine the extent and predictive capacity of early changes. We report results of a 6-week, open-label study of the addition of quetiapine XR (range, 50-300 mg) for adult patients (n = 26) with major depressive disorder who were nonresponsive to antidepressant treatment. In addition to regular study visits, all participants completed daily, wirelessly transmitted self-report ratings of symptoms on a Smartphone. Daily and 3-day moving average mean scores were calculated, and associations between early symptom change and eventual response to treatment were determined. Improvement in depressive and anxiety symptoms was identified as early as day 1 of treatment. Of the total decline in depression severity over 6 weeks, 9% was present at day 1, 28% at day 2, 39% at days 3 and 4, 65% at day 7, and 80% at day 10. Self-report rating of early improvement (>/=20%) in depressive symptoms at day 7 significantly predicted

responder status at week 6 (P = 0.03). Clinician-rated depressive and anxiety symptoms only became significantly associated with responder status at day 14. In conclusion, very early changes in depressive symptoms were identified using MHT, early changes accounted for most of total change, and MHT-recorded improvement as early as day 7 significantly predicted response to treatment at study end point

Middle and High School Students' Exposure to Alcohol- and Smoking-Related Media: A Pilot Study Using Ecological Momentary Assessment.

In: *Psychology of Addictive Behaviors*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-20766-001%26site%3dehost-live.

Abstract:

The goals of this study were to assess the feasibility of using Ecological Momentary Assessment (EMA) to measure adolescents' exposure to alcohol and smoking-related media. A sample of 20 middle and high school students completed a 2-week EMA protocol in which they monitored exposures to alcohol and smoking-related media. Results showed that adolescents were highly compliant with the study protocol. A total of 255 exposures to alcohol (67%) and smoking (33%) were captured, representing an average of 8.50 (SD = 5.82) alcohol-related media exposures and 4.25 (SD = 3.67) smoking-related media exposures per participant, during the study period. Exposures tended to occur in the afternoon (52% alcohol; 54% smoking), at point of sale (44% alcohol; 65% smoking), and on days leading up to the weekend (57% alcohol; 57% smoking). Exposures were also likely in the presence of family (69% alcohol; 56% smoking). Overall, results of this small pilot provide preliminary evidence that EMA is a useful tool for tracking and characterizing middle and high school students' real-world exposures to alcohol- and smoking-related media. Future studies may suggest mechanisms by which media exposures lead to youth uptake of drinking and smoking behaviors. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Schasfoort, Fabiënne C.; Formanoy, Margriet A. G.; Bussmann, Johannes B. J.; Peters, Jeroen W. B.; Tibboel, Dick; Stam, Henk J. (2008):

Objective and continuous measurement of peripheral motor indicators of pain in hospitalized infants: a feasibility study.

In: *Pain* 137 (2), S. 323–331. DOI: 10.1016/j.pain.2007.09.011.

Abstract:

Measurement of pain in pre-verbal infants is complex. Until now, pain behavior has mainly been assessed intermittently using observational tools. Therefore, we determined the feasibility of long-term, objective and continuous measurement of peripheral motor parameters through body-fixed sensors to discriminate between pain and no pain in hospitalized pre-verbal infants. Two pain modes were studied: for procedural pain 10 measurements were performed before, during and after routine heel lances in 9 infants (age range infants: 5-175 days), and for post-operative pain 14 infants (age range 45-400 days) were measured for prolonged periods (mean 7h) using the validated COMFORT-behavior scale as reference method. Several peripheral motor parameters were studied: three body part activity parameters derived from acceleration sensors attached to one arm and both legs, and two muscle activity parameters derived from electromyographic (EMG) sensors attached to wrist flexor and extensor muscles. Results showed that the accelerometry-based parameters legs activity and overall extremity activity (i.e. mean of arm and legs) were significantly higher during heel lance than before or after lance (p0.001), whereas arm activity accelerometry data and wrist muscle activity EMG data showed no significant change. For the post-operative pain measurements, relationships were found between accelerometry-based overall extremity activity and COMFORT-behavior ($r=0.76$, $p<0.001$), and between EMG-based wrist flexor activity and COMFORT-behavior ($r=0.55$, $p<0.001$, for a subgroup of 7 infants). We conclude that long-term, objective and continuous measurement of peripheral motor parameters is feasible, has high potential, and is promising to assess pain in pre-verbal hospitalized infants.

Scheers, T.; Philippaerts, R.; Lefevre, J. (2012):

Assessment of physical activity and inactivity in multiple domains of daily life: a comparison between a zomputerized questionnaire and the SenseWear Armband complemented with an electronic diary.

In: *Int.J Behav.Nutr.Phys.Act.* 9 (1), S. 71. DOI: 10.1186/1479-5868-9-71.

Abstract:

ABSTRACT: BACKGROUND: Although differences between paper-and-pencil questionnaires and accelerometers have been reported for overall physical activity and time spent in moderate and vigorous activity, few studies have looked at domain-specific behavior. This study compared estimates of domainspecific physical (in)activity obtained with the Flemish physical activity computerized questionnaire (FPACQ) with those obtained from a combination of the SenseWear Armband and an electronic diary. Furthermore, it was investigated whether the correspondence between the two methods varied with gender and age METHODS: Data were obtained from 442 Flemish adults (41.4+/-9.8 years). Physical activity was questioned with the FPACQ and measured for seven consecutive days using the SenseWear Armband together with an electronic activity diary (SWD). Analogous variables were calculated from the FPACQ and SWD. Mean differences and associations between FPACQ and SWD outcomes were examined with paired t-tests and Pearson correlations. The BlandAltman method was used to assess the level of agreement between the two methods. Main effects and interaction of gender and age groups (20-34; 35-49; 50-64 years) on differences between FPACQ and SWD outcomes were analyzed using two-way ANOVAs. RESULTS: All parameters of the FPACQ were significantly correlated with SWD assessments (r = 0.21 to 0.65). Reported activity was significantly different from SWD-obtained values for all parameters, except screen time. Physical activity level, total energy expenditure and time spent in vigorous activities were significantly higher (+0.14 MET, +25.09 EThours.week-1and +1.66 hours.week-1, respectively), and moderate activities and sedentary behavior significantly lower (-5.20 and -25.01 hours.week-1, respectively) with the FPACQ compared to SWD. Time and energy expenditure of job activities and active transport were significantly higher, while household chores, motorized transport, eating and sleeping were significantly lower with the FPACQ. Time spent in sports was lower (-0.54 hours.week-1), but energy expenditure higher (+4.18 METhours.week-1) with the FPACQ. The correspondence between methods varied with gender and age, but results differed according to the intensity and domain of activity. CONCLUSIONS: Despite the moderate correlations, significant differences between the two methods were found. In general, physical activity was higher and sedentary behavior lower as calculated from the FPACQ compared to SWD

Scheers, T.; Philippaerts, R.; Lefevre, J. (2013):

Objectively-determined intensity- and domain-specific physical activity and sedentary behavior in relation to percent body fat.

In: *Clin.Nutr.* 32 (6), S. 999–1006. DOI: 10.1016/j.clnu.2013.03.014.

Abstract:

BACKGROUND & AIMS: This study examined the independent and joint associations of overall, intensity-specific and domain-specific physical activity and sedentary behavior with bioelectrical impedance-determined percent body fat. METHODS: Physical activity was measured in 442 Flemish adults (41.4 +/- 9.8 years) using the SenseWear Armband and an electronic diary. Two-way analyses of covariance investigated the interaction of physical activity and sedentary behavior with percent body fat. Multiple linear regression analyses, adjusted for potential confounders, examined the associations of intensity-specific and domain-specific physical activity and sedentary behavior with percent body fat. RESULTS: Results showed a significant main effect for physical activity in both genders and for sedentary behavior in women, but no interaction effects. Light activity was positively (beta = 0.41 for men and 0.43 for women) and moderate (beta = -0.64 and -0.41), vigorous (beta = -0.21 and -0.24) and moderate-to-vigorous physical activity (MVPA) inversely associated with percent body fat, independent of sedentary time. Regarding domain-specific physical activity, significant associations were present for occupation, leisure time and household chores, irrespective of sedentary time. The positive associations between body fat and total and domain-specific sedentary behavior diminished after MVPA was controlled for. CONCLUSIONS: MVPA during leisure time, occupation and household chores may be essential to prevent fat gain

Scheibe, S.; English, T.; Tsai, J. L.; Carstensen, L. L. (2012):

Striving to Feel Good: Ideal Affect, Actual Affect, and Their Correspondence Across Adulthood.

In: *Psychol.Aging* (0882-7974 (Linking)). DOI: 10.1037/a0030561.

Abstract:

The experience of positive affect is essential for healthy functioning and quality of life. Although there is a great deal of research on ways in which people regulate negative states, little is known about the regulation of positive states. In the present study we examined age differences in the types of positive states people strive to experience and the correspondence between their desired and actual experiences. Adults aged 18-93 years of age described their ideal positive affect states. Then, using experience-sampling over a 7-day period, they reported their actual positive affect experiences. Two types of positive affect were assessed: low-arousal (calm, peaceful, relaxed) and high-arousal (excited, proud). Young participants valued both types of positive affect equally. Older participants, however, showed increasingly clear preferences for low-arousal over high-arousal positive affect. Older adults reached both types of positive affective goals more often than younger adults (indicated by a smaller discrepancy between actual and ideal affect). Moreover, meeting ideal levels of positive low-arousal affect (though not positive high-arousal affect) was associated with individuals' physical health, over and above levels of actual affect. Findings underscore the importance of considering age differences in emotion-regulatory goals related to positive experience. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Schepers, H. Martin; Koopman, Hfjm; Veltink, Peter H. (2007):

Ambulatory assessment of ankle and foot dynamics.

In: *Biomedical Engineering, IEEE Transactions on* 54 (5), S. 895–902.

Abstract:

Ground reaction force (GRF) measurement is important in the analysis of human body movements. The main drawback of the existing measurement systems is the restriction to a laboratory environment. This paper proposes an ambulatory system for assessing the dynamics of ankle and foot, which integrates the measurement of the GRF with the measurement of human body movement. The GRF and the center of pressure (CoP) are measured using two six-degrees-of-freedom force sensors mounted beneath the shoe. The movement of foot and lower leg is measured using three miniature inertial sensors, two rigidly attached to the shoe and one on the lower leg. The proposed system is validated using a force plate and an optical position measurement system as a reference. The results show good correspondence between both measurement systems, except for the ankle power estimation. The root mean square (RMS) difference of the magnitude of the GRF over 10 evaluated trials was (0.012 plusmn 0.001) N/N (mean plusmn standard deviation), being (1.1 plusmn 0.1)% of the maximal GRF magnitude. It should be noted that the forces, moments, and powers are normalized with respect to body weight. The CoP estimation using both methods shows good correspondence, as indicated by the RMS difference of (5.1 plusmn 0.7) mm, corresponding to (1.7 plusmn 0.3)% of the length of the shoe. The RMS difference between the magnitudes of the heel position estimates was calculated as (18 plusmn 6) mm, being (1.4 plusmn 0.5)% of the maximal magnitude. The ankle moment RMS difference was (0.004 plusmn 0.001) Nm/N, being (2.3 plusmn 0.5)% of the maximal magnitude. Finally, the RMS difference of the estimated power at the ankle was (0.02 plusmn 0.005) W/N, being (14 plusmn 5)% of the maximal power. This power difference is caused by an inaccurate estimation of the angular velocities using the optical reference measurement system, which is due to considering the foot as a single segment. The ambulatory system considers separa- e heel and forefoot segments, thus allowing an additional foot moment and power to be estimated. Based on the results of this research, it is concluded that the combination of the instrumented shoe and inertial sensing is a promising tool for the assessment of the dynamics of foot and ankle in an ambulatory setting

Scherbaum, Charles A.; Meade, Adam W. (2013):

New directions for measurement in management research.

In: *International Journal of Management Reviews* 15 (2), S. 132–148. DOI: 10.1037/t03782-000;

Abstract:

Despite its importance, measurement has received less attention in the management sciences than it deserves. Currently, there is an over-reliance on a narrow set of methods of measuring cognitive, affective, motivational, attitudinal and individual difference constructs that are often of interest in behavioural management research. The authors argue that there is a need to expand the scope of the measurement methods commonly employed by management researchers and that a greater diversity of measurement methods would benefit the field by contributing to theory development and the pursuit of new areas of research. The goals of this review are twofold: (1) to increase awareness among management researchers of the alternative measurement methods that can capture many of the cognitive, affective, motivational, attitudinal and individual difference constructs of interest; (2) to critically evaluate how these methods can and should be used, with a focus on both the strengths and limitations of each method. This review focuses on three classes of measures: physiological and biological measures; experience-sampling measures; and implicit measures. These measures have had a tremendous impact on the research and theories of other fields such as marketing and economics, despite still being in their infancy. The authors believe that these three classes of measures have the potential to impact the nature and scope of management research and theory as well. Schlotz, Wolff; Schulz, Peter; Hellhammer, Juliane; Stone, Arthur A.; Hellhammer, Dirk H. (2006):

Trait anxiety moderates the impact of performance pressure on salivary cortisol in everyday life.

In: *Psychoneuroendocrinology* 31 (4), S. 459–472. DOI: 10.1016/j.psyneuen.2005.11.003.

Abstract:

Stress and negative affective states are associated with cortisol in everyday life. However, it remains unclear what types of stressors and which affective states yield these associations, and the effect of trait anxiety is unknown. This study investigates the associations of specific task-related stressors and negative affective states in everyday life with salivary cortisol, and explores the mediating and moderating role of state negative affect and trait anxiety, respectively. Salivary cortisol, subjective stress, and state negative affect were measured three times a day on 2 days in 71 participants in everyday life, using a handheld computer to collect self-reports and time stamps and an electronic device to monitor saliva sampling compliance. Stress measures comprised the experience of performance pressure and failure during daily tasks; measures of negative affect comprised worn-out, tense, unhappy, and angry. Effects were tested using multilevel fixed-occasion models. Momentary performance under pressure was related to higher momentary cortisol measures, while mean task failure was related to lower daily cortisol concentrations. The association of performance pressure with cortisol varied between subjects, and this variation was explained by trait anxiety, yielding stronger associations in participants scoring high on trait anxiety. No evidence was found for a mediating role of state negative affect. These results describe the well-documented associations of everyday stressors and affect with salivary cortisol more precisely, suggesting that performance pressure is a significant condition related to short-term changes in cortisol. Subjects scoring high on trait anxiety seem to process stress-relevant information in a way that amplifies the association of performance pressure with reactions of the hypothalamus-pituitary-adrenal axis.

Schmidt, Michael D.; Cleland, Verity J.; Shaw, Kelly; Dwyer, Terence; Venn, Alison J. (2009):

Cardiometabolic risk in younger and older adults across an index of ambulatory activity.

In: *Am J Prev Med* 37 (4), S. 278–284. DOI: 10.1016/j.amepre.2009.05.020.

Abstract:

BACKGROUND\r\nPedometers are increasingly being used to assess population levels of physical activity and as motivational tools for individuals to increase their physical activity. To maximize their utility, a framework for classifying pedometer-determined activity into meaningful health-related categories is needed.\r\nPURPOSE\r\nThis study investigated whether a pedometer step index proposed by Tudor-Locke and Bassett can effectively group younger and older adults according to cardiometabolic health status.\r\nMETHODS\r\nAnalyses (conducted in 2008) used cross-sectional data from the Childhood Determinants of Adult Health study (1793 adults aged 26-36 years; collected 2004-2006) and from the Tasmanian Older Adult Cohort study (1014 adults aged 50-80 years; collected 2002-2006). Participants wore a pedometer for 7 days and the prevalence of cardiometabolic health indicators, including the metabolic syndrome, elevated Pathobiological Determinants of Atherosclerosis in Youth risk scores, and elevated Framingham risk scores, was examined across the following step categories: sedentary (< 5000); low-active (5000-7499); somewhat active (7500-9999); active (10,000-12,499); and high-active (> or = 12,500).\r\nRESULTS\r\nWith the exception of younger men, individuals achieving > or = 5000 steps had a substantially lower prevalence of adverse cardiometabolic health indicators than those obtaining fewer steps. Differences in the prevalence of adverse indicators were generally modest across higher steps-per-day categories. However, younger men and women in the high-active category had a substantially lower prevalence of some adverse health indicators.\r\nCONCLUSIONS\r\nIn general, the proposed index for classifying pedometer activity effectively distinguishes cardiometabolic health risk. Pedometers may be a useful tool for objectively identifying inactive individuals at greatest risk for poor cardiometabolic health.

Schnall, R.; Okoniewski, A.; Tiase, V.; Low, A.; Rodriguez, M.; Kaplan, S. (2013):

Using text messaging to assess adolescents' health information needs: an ecological momentary assessment.

In: *J Med Internet Res* 15 (3), S. e54. DOI: 10.2196/jmir.2395.

Abstract:

BACKGROUND: Use of mobile technology has made a huge impact on communication, access, and information/resource delivery to adolescents. Mobile technology is frequently used by adolescents. OBJECTIVE: The purpose of this study was to understand the health information needs of adolescents in the context of their everyday lives and to assess how they meet their information needs. METHODS: We gave 60 adolescents smartphones with unlimited text messaging and data for 30 days. Each smartphone had applications related to asthma, obesity, human immunodeficiency virus, and diet preinstalled on the phone. We

sent text messages 3 times per week and asked the following questions: (1) What questions did you have about your health today? (2) Where did you look for an answer (mobile device, mobile application, online, friend, book, or parent)? (3) Was your question answered and how? (4) Anything else? RESULTS: Our participants ranged from 13-18 years of age, 37 (62%) participants were male and 22 (37%) were female. Of the 60 participants, 71% (42/60) participants identified themselves as Hispanic and 77% (46/60) were frequent users of mobile devices. We had a 90% (1935/2150) response rate to our text messages. Participants sent a total of 1935 text messages in response to the ecological momentary assessment questions. Adolescents sent a total of 421 text messages related to a health information needs, and 516 text messages related to the source of information to the answers of their questions, which were related to parents, friends, online, mobile apps, teachers, or coaches. CONCLUSIONS: Text messaging technology is a useful tool for assessing adolescents' health behavior in real-time. Adolescents are willing to use text messaging to report their health information. Findings from this study contribute to the evidence base on addressing the health information needs of adolescents. In particular, attention should be paid to issues related to diet and exercise. These findings may be the harbinger for future obesity prevention programs for adolescents

Schneiders, Josien; Nicolson, Nancy A.; Berkhof, Johannes; Feron, Frans J.; van Os, Jim; Devries, Marten W. (2006):

Mood reactivity to daily negative events in early adolescence: relationship to risk for psychopathology.

In: *Developmental Psychology* 42 (3), S. 543–554. DOI: 10.1037/0012-1649.42.3.543.

Abstract:

Emotional responses to negative daily experiences in young adolescents may provide important clues to the development of psychopathology, but research is lacking. This study assessed momentary mood reactivity to daily events as a function of risk profile in a school sample, ages 11-14. High-risk (HR, n=25) and low-risk (LR, n=106) subgroups completed frequent self-reports of mood and events for 5 days. HR adolescents reported more negative events involving family and peers. Multilevel modeling results showed that negative events, especially if stressful, were associated with increased negative and decreased positive affects, with heightened responses in HR adolescents. HR adolescents with greater stress over the last 3 months showed additional increases in depressed mood following negative events. Altered reactivity to and dysfunctional appraisals of daily events may link adolescent risk profiles to later mental health problems.

Schoebi, Dominik (2008):

The coregulation of daily affect in marital relationships.

In: *Journal of Family Psychology* 22 (4), S. 595.

Abstract:

This study examined whether changes in individuals' affective states are associated with their partners' affect when spouses come together in daily life after having spent time apart while pursuing individual activities, as well as whether such associations are moderated by individual differences in interpersonal insecurity and perspective taking. For 7 consecutive days, spouses from 166 married couples reported their affect 6 times per day on 2 dimensions, hard affect (angry-calm) and soft affect (sad/depressed-upbeat/content). Within-couple analyses indicated that spouses' changes in hard affect covaried, particularly when they scored high on interpersonal insecurity. Moreover, husbands' changes in soft affect covaried with their wives' soft affect when the husbands scored high on perspective taking. The results emphasize the interconnectedness of spouses' feelings when they reunite, and they identify key individual difference variables that strengthen interpersonal transmission of emotion in close relationships.

Schoenthaler, Antoinette M.; Schwartz, Joseph; Cassells, Andrea; Tobin, Jonathan N.; Brondolo, Elizabeth (2010):

Daily interpersonal conflict predicts masked hypertension in an urban sample.

In: *Am J Hypertens* 23 (10), S. 1082–1088.

Abstract:

BACKGROUND:

Masked hypertension (MH) is a risk factor for cardiovascular and cerebrovascular diseases. However, little is known about the effect of psychosocial stressors on MH.

METHODS:

Daily interpersonal conflict was examined as a predictor of elevated ambulatory blood pressure (ABP) in a community sample of 240 unmedicated black and Latino(a) adults (63% women; mean age 36 years) who had optimal office blood pressure (BP) readings (≤120/80 mm Hg). Electronic diaries were used to assess daily interpersonal conflict (i.e., perceptions of being treated unfairly/harassed during social interactions). Participants rated the degree to which they experienced each interaction as unfair or harassing on a scale of 1-100. Systolic and diastolic ABP (SysABP and DiaABP, respectively) were collected using a validated 24-h ABP monitor. Participants were classified as having marked MH (MMH) if the average of all readings obtained yielded SysABP: ≥135 mm Hg or DiaABP: ≥85 mm Hg. Logistic regression was used to examine whether daily interpersonal conflict is an independent predictor of MMH.

RESULTS:

This form of MMH (i.e., optimal office BP plus elevated ABP) was present in 21% of participants (n = 50). Those with MMH (vs. without) were significantly more likely to be men (P < 0.001). Daily harassment and unfair treatment scores were significant predictors of MMH group status (P < 0.05). Participants with harassment scores >30 were significantly more likely to be in the MMH group.

CONCLUSION:

MH may be a concern, even for patients with optimal office BP. Evaluating exposure to psychosocial stressors, including routine levels of interpersonal conflict may help to identify those patients who might benefit from further clinical follow-up.

Schomer, Donald L. (2006):

Ambulatory EEG telemetry: how good is it?

In: *Journal of clinical neurophysiology* 23 (4), S. 294–305.

Abstract:

When someone asks the question, how good is ambulatory EEG telemetry, there is no correct answer. There are many manufacturers of ambulatory EEG technology. Each device has its own strengths and weaknesses. What one is really interested in when one asks such a question needs to be defined in terms of expectations and technical capabilities for the piece of equipment under discussion. Systems exist or can be easily modified to be as sophisticated as the best of the inpatient units. However, is that level of sophistication needed for the ambulatory based recordings? Again, the answer to that is dependent on the ordering physician's expectations. Below is a discussion of the different clinical expectations that are frequently encountered and the needed requirements for an ambulatory system to properly address them.

Schott, Timm Cornelius; Ludwig, Bjorn (2014):

Microelectronic wear-time documentation of removable orthodontic devices detects heterogeneous wear behavior and individualizes treatment planning.

In: *Am J Orthod Dentofacial Orthop* 146 (2), S. 155–160. DOI: 10.1016/j.ajodo.2014.04.020.

Abstract:

INTRODUCTION: The aim of this study was to investigate whether microelectronic wear-time documentation can contribute to individualized orthodontic management. METHODS: The wear times and behaviors of 281 patients undergoing orthodontic treatment with removable appliances were quantified and analyzed using the TheraMon microelectronic system (Sales Agency Gschladt, Hargelsberg, Austria) over a 6-month treatment period. RESULTS: The 281 study participants wore their removable appliances for a median of 9.0 hours per day, compared with the 12 to 15 hours per day prescribed. Wear behavior was variable and heterogeneous in patients with almost identical median wear times, with fluctuating and numerous zero wear-time periods observed. CONCLUSIONS: Both the duration of daily wear time and the wear behavior need to be considered to individualize the prescription for wear time; this is made possible with microelectronic wear-time documentation. Individual prescription changes based on the wear-time documentation can be arranged with patients in a shared decision-making process to achieve effective and successful treatment progress.

Schrama, Thijs (2009):

A wireless portable physiology recorder for psychophysiology research based on a personal digital assistant.

In: *Behavior Research Methods* 41 (3), S. 827–832. DOI: 10.3758/BRM.41.3.827.

Abstract:

Psychophysiology research is increasingly relying on portable instruments that can assess physiological responses during real-life situations at locations outside of research labs, such as at school, home, work, and outdoors. In this article, I report on the feasibility of a personal digital assistant-based portable physiology recording system with online signal graphing and wireless digital telemetry for psychophysiology research. I demonstrate that such a system can measure electrocardiogram and electrodermal activity and send this data over a wireless communication link to a PC. It enables users to inspect the integrity of the acquired signals on the portable device and on a PC base station, and it allows users to place time markers for online data analysis.

Schreiber-Gregory, D. N.; Lavender, J. M.; Engel, S. G.; Wonderlich, S. A.; Crosby, R. D.; Peterson, C. B. et al. (2013):

Examining duration of binge eating episodes in binge eating disorder.

In: *Int.J Eat.Disord.* (0276-3478 (Linking)). DOI: 10.1002/eat.22164.

Abstract:

OBJECTIVE: The primary goal of this article is to examine and clarify characteristics of binge eating in individuals with binge eating disorder (BED), particularly the duration of binge eating episodes, as well as potential differences between individuals with shorter compared to longer binge eating episodes. METHOD: Two studies exploring binge eating characteristics in BED were conducted. Study 1 examined differences in clinical variables among individuals (N = 139) with BED who reported a short (<2 h) versus long (>/=2 h) average binge duration. Study 2 utilized an ecological momentary assessment design to examine the duration and temporal pattern of binge eating episodes in the natural environment in a separate sample of nine women with BED. RESULTS: Participants in Study 1 who were classified as having long duration binge eating episodes displayed greater symptoms of depression and lower self-esteem, but did not differ on other measures of eating disorder symptoms, compared to those with short duration binge eating episodes. In Study 2, the average binge episode duration was approximately 42 min, and binge eating episodes were most common during the early afternoon and evening hours, as well as more common on weekdays versus weekends. DISCUSSION: Past research on binge episode characteristics, particularly duration, has been limited to studies of binge eating episodes in bulimia nervosa. This study contributes to the existing literature on characteristics of binge eating in BED. (c) 2013 Wiley Periodicals, Inc. (Int J Eat Disord 2013)

Schubert, Christian (2008):

Research on psychosomatic complexity: another example of the usefulness of diaries for symptoms research.

In: *Journal of Psychosomatic Research* 64 (2), S. 237–238. DOI: 10.1016/j.jpsychores.2007.11.002.

Abstract:

I read the Burton et al. [1] review on the usefulness of electronic diaries for symptoms research with great interest. The authors concluded from the comparison of 32 papers that electronic diaries are both acceptable to users and sufficiently accurate for research purposes. However, in their list of issues still to be resolved with electronic diaries, I miss the point that electronic diary studies—supposed to answer questions too complex for simpler designs—have not yet identified truly complex psychosomatic phenomena such as feedback mechanisms and dynamic networks [2].

Schulz, Marc S.; Waldinger, Robert J. (2010):

Capturing the elusive: Studying emotion processes in couple relationships.

Abstract:

In this chapter, we describe our efforts to study emotion processes in couple interactions using multiple approaches and multiple windows of observation. We begin by briefly embedding these efforts in the larger context of research and theory on

emotion processes in couples. We then discuss modern theories of emotion and note the challenges that these theories present for investigators. Finally, we review approaches to addressing major challenges in emotion research using examples from the field and from our own studies of couple interactions. These challenges include how to study emotion in ecologically valid situations; how to capture fleeting emotional experiences, including associated cognitive and motivational elements; how to reliably and sensitively assess emotion expression; and how to track and integrate multiple aspects of emotion (e.g., physiology, subjective feeling states, observed expression) as they unfold over time.

Schutte, A. E.; Schutte, R.; Smith, W.; Huisman, H. W.; Mels, C. M. C.; Malan, L. et al. (2014):

Compromised bioavailable IGF-1 of black men relates favourably to ambulatory blood pressure: The SABPA study.

In: *Atherosclerosis* 233 (1), S. 139–144. DOI: 10.1016/j.atherosclerosis.2013.12.025.

Abstract:

OBJECTIVES: Insulin-like growth factor-1 (IGF-1) has potent endothelial-protective, anti-platelet and anti-thrombotic activities, and also exerts mitogenic and proliferatory actions on vascular smooth muscle cells. Conflicting reports exist regarding the role of IGF-1 in vascular protection and atherogenesis. We therefore investigated the relationships of ambulatory blood pressure (BP) and carotid intima-media thickness (cIMT) with a range of components of the IGF-1 axis in a bi-ethnic population. METHODS: We included black (N = 86) and white (N = 101) men and measured growth hormone, total IGF-1, insulin-like growth factor binding protein-3 (IGFBP-3), and pregnancy-associated plasma protein-A (PAPP-A) levels. RESULTS: Ambulatory BP was almost 10 mmHg higher in black men (137/88 mmHg versus 128/80 mmHg; both $p < 0.001$), accompanied by an adverse profile of the IGF-axis for all measured components (all $p < 0.01$), including reduced bioavailable IGF-1 (IGF-1/IGFBP-3; $p = 0.006$) and tissue IGF-1 accessibility index as represented by IGF-1.PAPP-A/IGFBP-3 ($p < 0.001$). Single, partial and multiple regression analyses confirmed an independent inverse association between ambulatory systolic BP and bioavailable IGF-1 in black men ($R(2) = 0.24$; beta = -0.22; $p = 0.035$). cIMT was similar in the ethnic groups ($p = 0.34$), and was negatively associated with bioavailable IGF-1 in white men ($R(2) = 0.42$; beta = -0.17; $p = 0.039$) prior to adjustment for gamma-glutamyl transferase ($R(2) = 0.45$; beta = -0.10; $p = 0.25$). CONCLUSION: Ambulatory systolic BP is inversely related to bioavailable IGF-1 in black men who displayed low IGF-1 concentrations. An inverse relation was found between cIMT and IGF-1 in white men, which disappeared after correction for gamma-glutamyl transferase - opposing reports of a detrimental role of IGF-1 in the early stages of atherogenesis.

Schuz, Natalie; Ferguson, Stuart G. (2014):

Australian Smokers' and Nonsmokers' Exposure to Antismoking Warnings in Day-to-Day Life: A Pilot Study.

In: *Nicotine Tob Res. DOI:* 10.1093/ntr/ntu253.

Abstract:

INTRODUCTION: Smokers and nonsmokers can encounter a variety of antismoking messages in their everyday life. Antismoking warnings often involve fear appeals to which particularly smokers may react in a defensive manner by avoiding or derogating the messages, or downplaying their personal risk. However, previous studies testing the effects of antismoking warnings have either been retrospective or lab-based, thus introducing potential recall biases and yielding limited ecological validity. We used ecological momentary assessment (EMA) to give an overview on the number, type, and locations where individuals encounter such messages and to examine their immediate reactions. METHODS: In an EMA study, 33 smokers and 37 never-smokers logged every encounter with antismoking warnings during 2.5 weeks (1,237 participant days of monitoring). After randomly selected encounters, several markers of defensiveness were assessed. RESULTS: On average, nonsmokers reported noticing significantly fewer warnings than smokers (M = 0.49/day vs. M = 2.14/day). Both groups saw the majority of warnings on cigarette packages. Smokers reported a significantly higher level of message derogation and a significantly lower level of message acceptance than nonsmokers. There were no differences in feelings of vulnerability between smokers and nonsmokers upon encountering the warnings. CONCLUSIONS: The overall number of encounters with antismoking warnings in people's everyday life is relatively low, particularly among smokers. Smokers are likely to avoid messages and respond defensively, thus limiting their potential effectiveness.

Schuz, N.; Walters, J. A.; Frandsen, M.; Bower, J.; Ferguson, S. G. (2013):

Compliance With an EMA Monitoring Protocol and Its Relationship With Participant and Smoking Characteristics.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt142.

Abstract:

INTRODUCTION: Arguably, the greatest advantage of ecological momentary assessment (EMA) studies is that data are collected repeatedly in real-time and real-world situations, which reduces recall and situational biases and thus improves the accuracy and validity of the data collected. However, the validity of EMA data is contingent upon compliance rates. If participant characteristics are related to missing data, analyses should control for these factors, or they should be targeted in EMA training sessions. This study evaluates the impact of demographic and smoking-related participant characteristics on compliance to an EMA smoking study protocol. METHODS: Prequit day data were taken from the control arm of an ongoing randomized controlled trial of a smoking-cessation program. After training, N = 119 participants were asked to carry a mobile device with them at all times for ~6 days and log every cigarette they smoked in addition to completing randomly scheduled assessments. Different types of compliance were assessed: the percentage of completed random prompts (signal-contingent compliance), the percentage of logged cigarettes per day compared to a timeline follow-back measure, and the correlation between logged cigarettes and a carbon monoxide assessment 2hr later (both event-contingent compliance). RESULTS: Overall compliance rates were 78.48% for event-contingent and 72.17% for signal-contingent compliance. None of the demographic or smoking-related participant characteristics predicted signal-contingent compliance; however, female participants showed higher event-contingent compliance than male participants, and Caucasian participants showed higher event-contingent compliance than non-Caucasian participants. CONCLUSIONS: Compliance did not depend on smoking-related characteristics. EMA is a valid method to assess smoking behavior in real-time and real-world settings

Schwerdtfeger, Andreas R.; Schienle, Anne; Leutgeb, Verena; Rathner, Eva-Maria (2014):

Does cardiac reactivity in the laboratory predict ambulatory heart rate? Baseline counts.

In: *Psychophysiology* 51 (6), S. 565–572. DOI: 10.1111/psyp.12199.

Abstract:

Cardiovascular reactivity to laboratory stress might predict cardiovascular load in everyday life. However, previous research throws doubt on this hypothesis. This study examined associations between heart rate (HR) to a public speaking task and ambulatory HR throughout a day. Electrocardiogram, bodily movement, and psychosocial variables (affect, context) were recorded in 111 individuals. Ambulatory HR was positively associated with both positive and negative affect. Baseline HR in the laboratory significantly predicted ambulatory HR, but HR reactivity did not. The interaction of momentary negative affect and cardiac reactivity in the laboratory was also not significant. However, a significant interaction of baseline HR and reactivity indicated that, when baseline was high, there was a positive relation between HR reactivity and ambulatory HR. Findings suggest that baseline has to be considered when aiming to predict cardiovascular load in everyday life.

Age differences in emotional responses to daily stress: The role of timing, severity, and global perceived stress.

In: *Psychology and Aging* 28 (4), S. 1076–1087. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-44002-013%26site%3dehost-live;sbs26@psu.edu.

Abstract:

Research on age differences in emotional responses to daily stress has produced inconsistent findings. Guided by recent theoretical advances in aging theory (S. T. Charles, 2010, Strength and vulnerability integration: A model of emotional well-being across adulthood, Psychological Bulletin, Vol. 136, pp. 1068–1091) that emphasize the importance of context for predicting when and how age is related to affective well-being, the current study examined age differences in emotional responses to everyday stressors. The present study examined how three contextual features (e.g., timing of exposure, stressor severity, global perceived stress [GPS]) moderate age differences in emotional experience in an ecological momentary assessment study of adults (N = 190) aged 18–81 years. Results indicated that older adults' negative affect (NA) was less affected by exposure to recent stressors than younger adults, but that there were no age differences in the effects of stressor exposure 3–6 hr afterward. Higher levels of GPS predicted amplified NA responses to daily stress, and controlling for GPS eliminated age differences in NA responses to stressors. No age differences in NA responses as a function of stressor severity were observed. In contrast, older age was

associated with less of a decrease in PA when exposed to recent stressors or with more severe recent stressors. There were no age differences in the effect of previous stressor exposure or severity on PA, or any interactions between momentary or previous stress and GPS on PA. Together, these results support the notion that chronic stress plays a central role in emotional experience in daily life. We discuss the implications of these results for emotion theories of aging. Scott, Stacey B.; Sliwinski, Martin J.; Mogle, Jacqueline A.; Almeida, David M. (2014):

Age, stress, and emotional complexity: Results from two studies of daily experiences.

In: *Psychol Aging* 29 (3), S. 577–587. DOI: 10.1037/a0037282.

Abstract:

Experiencing positive and negative emotions together (i.e., co-occurrence) has been described as a marker of positive adaptation during stress and a strength of socioemotional aging. Using data from daily diary (N = 2,022; ages 33-84) and ecological momentary assessment (N = 190; ages 20-80) studies, we evaluate the utility of a common operationalization of co-occurrence, the within-person correlation between positive affect (PA) and negative affect (NA). Then we test competing predictions regarding when co-occurrence will be observed and whether age differences will be present. Results indicate that the correlation is not an informative indicator of co-occurrence. Although correlations were stronger and more negative when stressors occurred (typically interpreted as lower co-occurrence), objective counts of emotion reports indicated that positive and negative emotions were 3 to 4 times more likely to co-occur when stressors were reported. This suggests that co-occurrence reflects the extent to which negative emotions intrude on typically positive emotional states, rather than the extent to which people maintain positive emotions during stress. The variances of both PA and NA increased at stressor reports, indicating that individuals reported a broader not narrower range of emotion during stress. Finally, older age was associated with less variability in NA and a lower likelihood of co-occurring positive and negative emotions. In sum, these findings cast doubt on the utility of the PA-NA correlation as an index of emotional co-occurrence, and question notion that greater emotional co-occurrence represents either a typical or adaptive emotional state in adults. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

MyHealthAssistant: An Event-driven Middleware for Multiple Medical Applications on a Smartphone-mediated Body Sensor Network.

In: *IEEE J Biomed Health Inform. DOI:* 10.1109/JBHI.2014.2326604.

Abstract:

An ever-growing range of wireless sensors for medical monitoring has shown that there is significant interest in monitoring patients in their everyday surroundings. It however remains a challenge to merge information from several wireless sensors and applications are commonly built from scratch. This paper presents a middleware targeted for medical applications on smartphone-like platforms that relies on an event-based design to enable flexible coupling with changing sets of wireless sensor units, while posing only a minor overhead on the resources and battery capacity of the interconnected devices. We illustrate the requirements for such middleware with three different healthcare applications that were deployed with our middleware solution, and characterize the performance with energy consumption, overhead caused for the smartphone, and processing time under real-world circumstances. Results show that with sensingintensive applications our solution only minimally impacts the phone's resources, with an added CPU utilization of 3% and a memory usage under 7 MB. Furthermore, for a minimum message delivery ratio of 99.9%, up to 12 sensor readings per second are guaranteed to be handled, regardless of the number of applications using our middleware.

Seekins, Tom; Ipsen, Catherine; Arnold, Nancy L. (2007):

Using ecological momentary assessment to measure participation: A preliminary study.

In: *Rehabilitation Psychology* 52 (3), S. 319.

Abstract:

Purpose/Objective: Participation is emerging as the gold standard of outcome measurement in disability and rehabilitation, but there are few methods for measuring it. This article describes the development of a dynamic measure of participation that uses the International Classification of Functioning, Disability and Health as the framework for measure development and ecological momentary assessment (EMA) as the data collection methodology. Research Method/Design: Researchers programmed

personal data assistants to prompt 5 residents of a rural community to report their location, activity, social contact, environmental barriers and facilitators, secondary conditions, and ratings of community connectedness and fulfillment. Results: Overall, 5 participants reported data on 1,352 engagements over 7 weeks. Participants reported greater community connectedness and fulfillment when they spent time with others, were not home, and were not experiencing barriers or secondary conditions. Conclusions/Implications: EMA measures and methodology are 1 step in answering questions about participation within the ecological framework of disability. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Segura-Jimenez, Victor; Munguia-Izquierdo, Diego; Camiletti-Moiron, Daniel; Alvarez-Gallardo, Inmaculada C.; Ortega, Francisco B.; Ruiz, Jonatan R.; Delgado-Fernandez, Manuel (2013):

Comparison of the International Physical Activity Questionnaire (IPAQ) with a multi-sensor armband accelerometer in women with fibromyalgia: the al-Andalus project.

In: *Clin Exp Rheumatol* 31 (6 Suppl 79), S. S94-101.

Abstract:

OBJECTIVES: To compare levels of physical activity (PA) assessed by the International Physical Activity Questionnaire (IPAQ) with PA measured with the SenseWear Pro Armband (SWA) in women with fibromyalgia, and to assess the test-retest reliability of the IPAQ. METHODS: The study comprised a total of 183 women with fibromyalgia aged 51.1+/-8.2 years. Participants wore the SWA for 9 consecutive days and filled in the IPAQ twice (separated by a 9-day interval). Total PA, time spent on moderate and vigorous intensity PA, and sitting time assessed by the IPAQ and the SWA (n=123) were compared. RESULTS: Time spent on PA at different intensities (total, moderate and vigorous) was higher and sedentary time was lower when assessed by the IPAQ compared with the SWA (all p<0.001). Differences between the IPAQ and the SWA increased as the minutes per day in the IPAQ increased. The Bland-Altman plots showed no agreement between the IPAQ and the SWA. There was no association between the IPAQ and the SWA in any of the variables studied, except for walking domain from the IPAQ and moderate PA from the SWA (rp=0.19, p=0.03). Test-retest systematic differences were found for total PA score, moderate and vigorous intensity, working and domestic domains (all p<0.05). The ICCs for those domains without systematic differences (sitting, vehicle, walking, active transport time and leisure domains) ranged from 0.52 to 0.71). CONCLUSIONS: The IPAQ differs from objectively measured PA and presents limitations to classify different categories of PA based on SWA data. Moreover, the IPAQ is not a reliable tool to assess PA in women with fibromyalgia.

Sejdić, Ervin; Steele, Catriona M.; Chau, Tom (2010):

A procedure for denoising dual-axis swallowing accelerometry signals.

In: *Physiol Meas* 31 (1), S. N1-9. DOI: 10.1088/0967-3334/31/1/N01.

Abstract:

Dual-axis swallowing accelerometry is an emerging tool for the assessment of dysphagia (swallowing difficulties). These signals however can be very noisy as a result of physiological and motion artifacts. In this note, we propose a novel scheme for denoising those signals, i.e. a computationally efficient search for the optimal denoising threshold within a reduced wavelet subspace. To determine a viable subspace, the algorithm relies on the minimum value of the estimated upper bound for the reconstruction error. A numerical analysis of the proposed scheme using synthetic test signals demonstrated that the proposed scheme is computationally more efficient than minimum noiseless description length (MNDL)-based denoising. It also yields smaller reconstruction errors than MNDL, SURE and Donoho denoising methods. When applied to dual-axis swallowing accelerometry signals, the proposed scheme exhibits improved performance for dry, wet and wet chin tuck swallows. These results are important for the further development of medical devices based on dual-axis swallowing accelerometry signals.

Selby, Edward Andrew (2012):

A real-time evaluation of emotional cascades in borderline personality disorder.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (2-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-99160-552%26site%3dehost-live.

Abstract:

Borderline personality disorder (BPD) is characterized by intensity and sensitivity of negative emotion (emotion dysregulation) as well as various dysregulated behaviors, including self-injury, suicide attempts, binge eating, and substance use. The emotional

cascade model of BPD (Selby & Joiner, 2009) suggests that the turbulent emotional experience of those with BPD is the result of emotional cascades, vicious cycles of increasing rumination and negative emotion. Dysregulated behaviors, then, may serve as potent methods of distraction from rumination due to the salient physical sensations these behaviors provide (e.g., pain from self-injury). Although this model has received correlational and experimental support (Selby et al., 2009), additional research on the real-time processes of rumination and emotion, and how they relate to dysregulated behaviors, is needed. The following study used experience sampling methodology wherein individuals endorsing recent behavioral dysregulation (some with diagnoses of BPD) were signaled randomly 5 times each day for two weeks using palm pilots, at which times they recorded their thought processes, emotional experience, recent interpersonal events and dysregulated behaviors. Participants completed a total of 3,118 scheduled random assessments over monitoring. Using various forms of hierarchical linear modeling, the results of the study supported the Emotional Cascade Model using real-world data. Importantly, the data indicated that high levels of rumination have an exponential effect on predicting future engagement in dysregulated behaviors, especially for those with BPD. The results of this study provide important support for the emotional cascade model and suggest that it is a theory with important clinical implications. Selby, E. A.; Doyle, P.; Crosby, R. D.; Wonderlich, S. A.; Engel, S. G.; Mitchell, J. D.; Le, Grange D. (2012):

Momentary emotion surrounding bulimic behaviors in women with bulimia nervosa and borderline personality disorder.

In: *J Psychiatr.Res* 46 (11), S. 1492–1500. DOI: 10.1016/j.jpsychires.2012.08.014.

Abstract:

BACKGROUND: Bulimia nervosa (BN) and borderline personality disorder (BPD) are disorders that involve emotion dysregulation, for negative emotion in particular, as well as impulsive behaviors beyond binge eating and vomiting. Given these similarities in psychopathology, it is not surprising that those with BN also present with BPD in approximately one third of cases. Improved understanding of similarities and differences in the experience of negative and positive emotion could aid in the development of treatments specifically tailored to the needs of these disorders. METHODS: In this study, we examined Ecological Momentary Assessment (EMA) data from 133 women diagnosed with BN, 25 of whom also exhibited diagnostic levels of BPD. Emotions and behaviors were assessed daily, with multiple random and event-contingent signals to complete questionnaires on portable digital devices, for a period of two weeks. RESULTS: Results indicated that the BPD group experienced higher negative emotional variability on bulimic event days. Both groups also demonstrated increasing negative emotion and decreasing positive emotion pre- binge eating and vomiting, with levels of negative emotion decreasing and positive emotion increasing after, for both behaviors. CONCLUSIONS: In terms of group differences, additive effects were found for the BN comorbid with BPD group, who demonstrated greater negative emotional variability, on bulimic event days, and also had higher overall levels of negative emotion pre- and post-binge eating. Those with BN only, however, displayed increasing trajectories of positive emotion before and after binge eating and after vomiting, indicating a potential emotional dampening effect of BPD

Emotional cascades and self-injury: Investigating instability of rumination and negative emotion.

In: *Journal of Clinical Psychology* 69 (12), S. 1213–1227. DOI: 10.1037/t18597-000;

Abstract:

Objective: Nonsuicidal self-injury (NSSI) is a public health concern and risk factor for suicide. The Emotional Cascade Model (ECM) proposes that NSSI partially functions as a distraction from cascades of negative affect and rumination. The purpose of this study was to examine the roles of trait rumination, and momentary instability of rumination and negative emotion, in NSSI. Method: Experience sampling methods were used to monitor thoughts, emotions, and behaviors in 47 individuals reporting dysregulated behaviors including NSSI. Instability indices were generated for rumination and negative emotion using the momentary assessments. Results: Twenty-five episodes of NSSI were reported during monitoring. Trait rumination prospectively predicted NSSI episodes, and the instability indices interacted to predict NSSI. Conclusions: Consistent with the ECM, the interaction between rumination instability and negative affect instability during monitoring significantly predicted NSSI, with the strongest effects occurring for sadness and rumination about past. These findings may enhance conceptualization and treatment of patients with NSSI. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Selby, Edward A.; Nock, Matthew K.; Kranzler, Amy (2014):

How does self-injury feel? Examining automatic positive reinforcement in adolescent self-injurers with experience sampling.

In: *Psychiatry Res* 215 (2), S. 417–423. DOI: 10.1016/j.psychres.2013.12.005.

Abstract:

One of the most frequently reported, yet understudied, motivations for non-suicidal self-injury (NSSI) involves automatic positive reinforcement (APR), wherein sensations arising from NSSI reinforce and promote the behavior. The current study used experience sampling methodology with a clinical sample of self-injuring adolescents (N=30) over a 2-week period during which the adolescents reported NSSI behaviors, and rated if an APR motivation was present, and if so whether that motivation pertained to feeling "pain," "stimulation," or "satisfaction." Over 50% of the sample reported at least one instance of NSSI for APR reasons. No significant differences were found on demographic factors or psychiatric comorbidity for those with and without an APR motivation. However, those with an APR motivation reported elevated NSSI thoughts, longer duration of those thoughts, and more NSSI behaviors. They also reported more alcohol use thoughts, alcohol use, impulsive spending, and binge eating. The most commonly reported sensation following NSSI for APR was "satisfaction." However those endorsing feeling pain reported the most NSSI behaviors. These findings provide new information about the APR motivations for NSSI and shed light on the different sensations felt.

What Dreams May Come: Emotional Cascades and Nightmares in Borderline Personality Disorder.

In: *Dreaming*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-08154-001%26site%3dehost-live.

Abstract:

People diagnosed with borderline personality disorder (BPD) have been found to have a number of sleep problems, including frequent and distressing nightmares. The experience of nightmares is likely to worsen emotion dysregulation and decrease coping abilities the subsequent day, making it an important issue for clinicians to address. One recent theoretical model of BPD psychopathology, the Emotional Cascade Model (ECM), may shed light on this phenomenon by characterizing nightmares as the experience of emotional cascades that occur during sleep. A model is presented in which these cascades may carry over from a stressful day and lead to elevated cognitive activity during sleep, as well as nightmare-like phenomena. To test this model we used experience sampling from 47 participants exhibiting dysregulated behaviors—16 of them diagnosed with BPD. Negative emotion, rumination, and number of nightmares were assessed daily across two consecutive weeks. Analyses indicated that the BPD group experienced more frequent nightmares, that BPD diagnosis interacted with baseline trait rumination to prospectively predict number of nightmares reported during monitoring, and daily experience of emotional cascades predicted subsequent number of nightly nightmares. These findings held after controlling for key covariates, including sleep quality and diagnoses of depression and posttraumatic stress disorder. Important clinical interventions consistent with the ECM conceptualization of nightmares are proposed, including the potential for management of daily rumination and negative emotion, imagery rescripting for recurrent or anxiously anticipated nightmares, and potential prescription of prazosin (an alpha1-adrenergic antagonist) for the reduction of nightmares in this group. Selya, Arielle S.; Updegrove, Nicole; Rose, Jennifer S.; Dierker, Lisa; Tan, Xianming; Hedeker, Donald et al. (2015):

Nicotine-dependence-varying effects of smoking events on momentary mood changes among adolescents.

In: *Addict Behav* 41, S. 65–71. DOI: 10.1016/j.addbeh.2014.09.028.

Abstract:

INTRODUCTION: Theories of nicotine addiction emphasize the initial role of positive reinforcement in the development of regular smoking behavior, and the role of negative reinforcement at later stages. These theories are tested here by examining the effects of amount smoked per smoking event on smoking-related mood changes, and how nicotine dependence (ND) moderates this effect. The current study examines these questions within a sample of light adolescent smokers drawn from the metropolitan Chicago area (N=151, 55.6% female, mean 17.7years). INSTRUMENTS: Ecological momentary assessment data were

collected via handheld computers, and additional variables were drawn from a traditional questionnaire. METHODS: Effects of the amount smoked per event on changes in positive affect (PA) and negative affect (NA) after vs. before smoking were examined, while controlling for subject-averaged amount smoked, age, gender, and day of week. ND-varying effects were examined using varying effect models to elucidate their change across levels of ND. RESULTS: The effect of the amount smoked per event was significantly associated with an increase in PA among adolescents with low-to-moderate levels of ND, and was not significant at high ND. Conversely, the effect of the amount smoked was significantly associated with a decrease in NA only for adolescents with low levels of ND. CONCLUSIONS: These findings support the role of positive reinforcement in early stages of dependent smoking, but do not support the role of negative reinforcement beyond early stages of smoking. Other potential contributing factors to the relationship between smoking behavior and PA/NA change are discussed.

Senso, Meghan M.; Anderson, Christopher P.; Crain, A. Lauren; Sherwood, Nancy E.; Martinson, Brian C. (2014):

Self-reported Activity and Accelerometry in 2 Behavior-maintenance Trials.

In: *Am J Health Behav* 38 (2), S. 254–264. DOI: 10.5993/AJHB.38.2.11.

Abstract:

OBJECTIVES: To compare between accelerometry (MVPA-A) and self-reported activity (MVPA-SR) in activity-maintenance (Keep Active Minnesota; KAM) and weight loss-maintenance (Keep It Off; KIO) trials. METHODS: Linear regression estimated moderation of study, treatment, or time on MVPA-A and MVPA-SR associations. RESULTS: MVPA-A was similar between studies (KAM 119 minutes, KIO 112 minutes, p = .555), whereas MVPA-SR differed significantly (KAM 350 minutes, KIO 87 minutes, p < .0001). Only study moderated correla-tion between MVPA-A and MVPA-SR. MVPA-SR better predicted MVPA-A in KIO relative to KAM (p = .023). CONCLUSIONS: Results suggest that self-presentation bias may influence validity of self-report in intervention studies with activity as a primary outcome. Researchers should select self-report to assess activity dimensions that objective measures capture poorly.

Seo, Myeong-Gu; Bartunek, Jean M.; Barrett, Lisa Feldman (2010):

The role of affective experience in work motivation: Test of a conceptual model.

In: *J. Organiz. Behav.* 31 (7), S. 951–968.

Abstract:

The purpose of this paper was to contribute to understanding of the crucial role of emotion in work motivation by testing a conceptual model developed by Seo, Barrett, and Bartunek (2004) that predicted the impacts of core affect on three behavioral outcomes of work motivation, generative-defensive orientation, effort, and persistence. We tested the model using an Internet-based investment simulation combined with an experience sampling procedure. Consistent with the predictions of the model, pleasantness was positively related to all three of the predicted indices. For the most part, these effects occurred indirectly via its relationships with expectancy, valence, and progress judgment components. Also as predicted by the model, activation was directly and positively related to effort.

Sepp&#65533;L&#65533;, Piia; Mauno, Saija; Kinnunen, Marja Liisa; Feldt, Taru; Juuti, Tanja; Tolvanen, Asko; Rusko, Heikki (2012):

Is work engagement related to healthy cardiac autonomic activity? Evidence from a field study among Finnish women workers.

In: *The Journal of Positive Psychology* 7 (2), S. 95–106. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-07208-002&site=ehost-live;piia.seppala@ttl.fi.

Abstract:

The present study investigated whether work engagement is related to and can explain healthy cardiac autonomic activity as indicated by decreased heart rate (HR; i.e., sympathetic and parasympathetic activity) and increased high-frequency power (HFP) of heart rate variability (i.e., parasympathetic activity). A total of 30 healthy Finnish female cleaning workers underwent an ambulatory monitoring period of two nights and two regular workdays, and mean values of work period HR and HFP were utilized as dependent variables. Correlations revealed that work engagement was, as hypothesized, negatively related to HR and positively to HFP. Furthermore, in hierarchical linear regression analysis, work engagement accounted for an additional 19% of the variance explained in HFP, independent of individual baseline, age, Body Mass Index, physical fitness, and medication. However, the explanation rate for HR did not reach statistical significance. The findings suggest that work engagement is

associated with healthy, adaptable cardiac autonomic activity, particularly increased parasympathetic activity. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Serre, F.; Fatseas, M.; Debrabant, R.; Alexandre, J. M.; Auriacombe, M.; Swendsen, J. (2012):

Ecological momentary assessment in alcohol, tobacco, cannabis and opiate dependence: A comparison of feasibility and validity.

In: *Drug Alcohol Depend* (0376-8716 (Linking)). DOI: 10.1016/j.drugalcdep.2012.04.025.

Abstract:

BACKGROUND: Despite growing use of computerized ambulatory monitoring in substance dependence research, little is known about the comparative feasibility and validity of these novel methods by substance type. This study compares the feasibility and validity of computerized ambulatory monitoring in outpatients seeking treatment for alcohol, tobacco, cannabis or opiate dependence. METHODS: A total of 109 participants were recruited from an outpatient treatment center and completed standard clinical instruments followed by 2 weeks of computerized ambulatory monitoring of daily life experiences and substance use. RESULTS: Individuals with cannabis dependence had the lowest rates of study acceptance (31%) as well as compliance with the repeated electronic interviews (79.9%), while those with tobacco dependence had the highest rates (62% and 91.0%, respectively). Concurrent validity was found between scores from standard clinical instruments and similar constructs assessed in daily life, with no difference by substance group. While no fatigue effects were detected, change in some variables was observed as a function of time in the study. CONCLUSIONS: Computerized ambulatory protocols are feasible and provide valid data in individuals with diverse forms of dependence, but compliance to repeated sampling methodology may vary by substance type

Setodji, C. M.; Martino, S. C.; Scharf, D. M.; Shadel, W. G. (2012):

Friends Moderate the Effects of Pro-Smoking Media on College Students' Intentions to Smoke.

In: *Psychol.Addict.Behav.* (0893-164X (Linking)). DOI: 10.1037/a0028895.

Abstract:

Exposure to prosmoking media (e.g., smoking in movies, advertising in magazines) contributes to smoking in young people. However, the extent to which the impact of exposure depends on the social context in which those exposures occur has not been investigated. This study used ecological momentary assessment to examine the moderating role of social context in the relationship between college students' exposure to prosmoking media and their smoking refusal self-efficacy and intention to smoke. College students (n = 134) carried handheld computers for 21 days, recording their exposure to all forms of prosmoking media during the assessment period. They also responded to three investigator-initiated control prompts (programmed to occur randomly) each day of the assessment. After each exposure to prosmoking media and after each control prompt, participants answered questions about smoking refusal self-efficacy and their intentions to smoke; they also indicated whether they were with friends, with family, with a romantic partner, or alone (i.e., their social context). When participants were with friends, prosmoking media exposures were associated with stronger smoking intentions and lower smoking refusal self-efficacy; these associations were not present when participants were alone. Being with family members or with a romantic partner did not moderate the impact of prosmoking media exposure on either dependent variable. These results suggest a new role for peers in the development of youth smoking. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Setodji, Claude M.; Martino, Steven C.; Scharf, Deborah M.; Shadel, William G. (2014):

Quantifying the persistence of pro-smoking media effects on college students' smoking risk.

In: *Journal of Adolescent Health* 54 (4), S. 474–480. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-11041-007%26site%3dehost-live.

Abstract:

Purpose: To quantify the persistence of pro-smoking media exposure effects on college students' intentions to smoke and smoking refusal self-efficacy. Method: A total of 134 college students (ages 18–24 years) were enrolled in an ecological momentary assessment study in which they carried handheld data collection devices for 3 weeks and reported their exposures to

pro-smoking media as they occurred in the real world. Smoking intentions and smoking refusal self-efficacy were assessed after each exposure to pro-smoking media and at random prompts during each day of the 3-week assessment period. A generalized additive model was used to determine how long the effect of an exposure to pro-smoking media persisted. Results: The effect of pro-smoking media exposures persisted for 7 days. After exposure, smoking intentions immediately increased (.56; 95% confidence interval [CI]: [.26, .87]) and then steadily decreased (−.12; 95% CI: [−.19, −.05]) each day for 7 days, while smoking refusal self-efficacy immediately decreased (−.42; 95% CI: [−.75, −.10]) and then steadily increased (.09; 95% CI: [.02, .16]) each day for 7 days. Daily changes occurring after 7 days were not statistically significant, suggesting that smoking intentions and refusal self-efficacy had stabilized and were no longer affected by pro-smoking media exposure. Conclusions: Exposures to pro-smoking media may have strong implications for emerging young adults smoking risk as the impact of an individual exposure appears to persist for at least a week. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Severo, Mateus Dornelles; Leiria, Liana Farias; Ledur, Priscila Dos Santos; Becker, Alexandre Dalpiaz; Aguiar, Fernanda Musa; Massierer, Daniela et al. (2014):

Association between erectile dysfunction and echocardiographic variables of ventricular hypertrophy and diastolic function in hypertensive patients with type 2 diabetes mellitus: A cross-sectional study.

In: *J Diabetes. DOI:* 10.1111/1753-0407.12133.

Abstract:

BACKGROUND: This study was conducted among individuals with diabetes and hypertension in order to assess the prevalence of erectile dysfunction (ED) and the association between ED and cardiovascular risk variables such as echocardiographic changes. METHODS: We evaluated 114 men with type 2 diabetes mellitus and hypertension. ED was assessed by International Index of Erectile Function (IIEF-5) score. Clinical and laboratory variables were evaluated, including C-reactive protein (CRP), ambulatory blood pressure monitoring (ABPM), ankle brachial index (ABI) and transthoracic echocardiography. Comparisons between patients with ED (IIEF-5 < 22) and without ED (IIEF-5 >/= 22) were performed. RESULTS: Patients were 56.8 +/- 5.7 years-old, systolic and diastolic blood pressure were 150.7 +/- 19.5 mmHg and 85.4 +/- 11.4 mmHg, respectively, and HbA1c was 8.0 +/- 1.7%. The majority (74.6%) of patients had ED. Levels of CRP, ABPM values and ABI were similar between men with and without ED. Echocardiography variables related to cardiac chamber diameters, left ventricular hypertrophy and diastolic function were similar between groups, except there was a slight lower left ventricular ejection fraction in men with ED (64.9 +/- 7.3 vs 68.1 +/- 3.9%, P = 0.004). CONCLUSIONS: In high cardiovascular risk hypertensive individuals with type 2 diabetes, ED is highly prevalent as expected, but its presence is associated with neither echocardiographic variables, nor other cardiovascular risk factors.

Factors associated with probability of personal digital assistant-based dietary self-monitoring in those with type 2 diabetes.

In: *Journal of Behavioral Medicine* 33 (4), S. 315–325.

Abstract:

Knowledge of factors associated with the use of technology could inform the design of technology-based behavioral interventions. This study examined modifiable and nonmodifiable factors associated with technology-based self-monitoring. 123 participants with type 2 diabetes self-monitored diet using a personal digital assistant in a 6-month behavioral intervention. Multinomial logistic regression was used to examine probability of nonadherent and suboptimally adherent behavior relative to adherent behavior. Sociodemographic characteristics were not associated with probability of self-monitoring. Probability of adherence generally was greater in the weeks preceding no group session, and lower in the weeks following no group session or following skipped sessions. Non-modifiable factors suggested by the literature to be associated with poorer access to technology (lower income, older age, minority race, and lower education) were not associated with probability of self-monitoring in this population.

Shaban, Heba A.; Abou El-Nasr, Mohamad; Buehrer, R. Michael (2010):

Toward a highly accurate ambulatory system for clinical gait analysis via UWB radios.

In: *IEEE transactions on information technology in biomedicine : a publication of the IEEE Engineering in Medicine and Biology Society* 14 (2), S. 284–291. DOI: 10.1109/TITB.2009.2037619.

Abstract:

In this paper, we propose and investigate a low-cost and low-complexity wireless ambulatory human locomotion tracking system that provides a high ranging accuracy (intersensor distance) suitable for the assessment of clinical gait analysis using wearable ultra wideband (UWB) transceivers. The system design and transceiver performance are presented in additive-white-gaussian noise and realistic channels, using industry accepted channel models for body area networks. The proposed system is theoretically capable of providing a ranging accuracy of 0.11 cm error at distances equivalent to interarker distances, at an 18 dB SNR in realistic on-body UWB channels. Based on real measurements, it provides the target ranging accuracy at an SNR = 20 dB. The achievable accuracy is ten times better than the accuracy reported in the literature for the intermarker-distance measurement. This makes it suitable for use in clinical gait analysis, and for the characterization and assessment of unstable mobility diseases, such as Parkinson's disease.

Shadel, W. G.; Martino, S. C.; Setodji, C.; Scharf, D. (2012):

Momentary Effects of Exposure to Prosmoking Media on College Students' Future Smoking Risk.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0027291.

Abstract:

Objective: This study used ecological momentary assessment to examine acute changes in college students' future smoking risk as a function of their exposure to prosmoking media (e.g., smoking in movies, paid advertising, point-of-sale displays). Method: A sample of 135 college students ("ever" and "never" smokers) carried handheld computers for 21 days, recording their exposures to all forms of prosmoking media during the assessment period. They also responded to three investigator-initiated control prompts during each day of the assessment period (i.e., programmed to occur randomly). After each prosmoking media exposure and after each random control prompt they answered questions that measured their risk of future smoking. Responses between prosmoking media encounters were compared (within subjects) to responses made during random control prompts. Results: Compliance with the study protocol was high, with participants responding to over 83% of all random prompts. Participants recorded nearly three encounters with prosmoking media each week. Results of linear mixed modeling indicated that all participants had higher future smoking risk following exposure to prosmoking media compared with control prompts ($p < .05$); this pattern of response did not differ between ever and never smokers ($p = .769$). Additional modeling of the variances around participants' risk of future smoking revealed that the response of never smokers to prosmoking media was significantly more variable than the response of ever smokers. Conclusion: Exposure to prosmoking media is associated with acute changes in future smoking risk, and never smokers and ever smokers respond differently to these exposures. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Shadel, William G.; Martino, Steven C.; Setodji, Claude; Scharf, Deborah (2013):

Exposure to pro-smoking media in college students: Does type of media channel differentially contribute to smoking risk?

In: *Annals of Behavioral Medicine* 45 (3), S. 387–392. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-15639-015%26site%3dehost-live;shadel@rand.org.

Abstract:

Background: There are almost no data on whether the different channels through which pro-smoking media appear (i.e., point-of-sale advertising, movie smoking) differently influence smoking. Purpose: This study used ecological momentary assessment to examine whether differences in smoking risk were observed for exposures to different pro-smoking media channels. Methods: College students (n = 134) carried smartphones for 21 days, recording their exposures to pro-smoking media and the media channels for that exposure and responding to three randomly issued control prompts per day. Participants answered questions about their future smoking risk after each pro-smoking media exposure and random prompt. Results: Participants had elevated future smoking risk following exposure to pro-smoking media at point of sale ($p < 0.001$); smoking risk at times of exposure to smoking in movies did not differ from risk measured during control prompts ($p = 0.78$). Conclusions: There is merit to examining

the relative contribution of different pro-smoking media channels to smoking behavior. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Shadur, Julia M.; Hussong, Andrea M. (2014):

Friendship intimacy, close friend drug use, and self-medication in adolescence.

In: *Journal of Social and Personal Relationships* 31 (8), S. 997–1018. DOI: 10.1037/t05466-000;

Abstract:

The current study tested between-person hypotheses that global negative affect, friendship intimacy, and close friend drug use predict increased substance use, and the within-person hypothesis that friendship intimacy and close friend substance use moderate the temporal relationship between daily negative affect and subsequent substance use (i.e., self-medication). Experience sampling methodology captured daily variations in mood and substance use, and multilevel modeling techniques were used to parse between- versus within-person effects. Findings supported between-person hypotheses that greater negative affect and lower friendship intimacy predicted greater substance use, and a consistent trend indicated that friendship intimacy and close friend drug use interact to predict substance use overall (though not for self-medication). Risk and protective mechanisms indicate that the effect of friendship intimacy on adolescent use depends on close friend drug use. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Shalev-Goldman, Einat; McGuire, K. Ashlee; Ross, Robert (2014):

Waist circumference and cardiorespiratory fitness are independently associated with glucose tolerance and insulin resistance in obese women.

In: *Appl Physiol Nutr Metab* 39 (3), S. 358–362. DOI: 10.1139/apnm-2013-0160.

Abstract:

The purpose of this study was to determine the independent associations between physical activity (PA), cardiorespiratory fitness (CRF), abdominal obesity and insulin action in obese women. We studied 141 abdominally obese women (waist circumference (WC): 106.4 +/- 10.2 cm). PA duration (min/day) and intensity (counts/min) were obtained by accelerometry. CRF was measured using a treadmill. WC was measured at the iliac crest; abdominal adiposity was measured by magnetic resonance imaging. Glucose and insulin measures were obtained during a 75-g, 2-h glucose tolerance test. The homeostasis model of assessment iHOMA2-IS was used to estimate insulin sensitivity. PA duration and intensity were not associated with glucose or insulin metabolism ($p > 0.05$). However, moderate-to-vigorous PA (MVPA) duration was associated with fasting insulin and iHOMA2-IS ($p < 0.01$). CRF was associated with fasting insulin and iHOMA2-IS ($r = 0.27$, $p </= 0.01$), whereas WC was associated with fasting insulin ($r = 0.50$, $p < 0.01$) and iHOMA2-IS ($r = -0.52$, $p </= 0.01$). Following adjustment for CRF, MVPA, and age, WC remained associated with fasting glucose, insulin, 2-h glucose and iHOMA2-IS ($r = -0.44$, $p </= 0.01$). CRF was associated with fasting glucose as well as 1- and 2-h glucose ($r = 0.24$, $p < 0.01$) after adjusting for WC, MVPA, and age. MVPA was not associated with glucose or insulin measures after control for CRF and WC ($p > 0.05$). Mediation analysis revealed that CRF and WC combined mediated the relationship between MVPA and both glucose tolerance and insulin resistance ($p < 0.05$). In conclusion, among abdominally obese women, WC and CRF are independently associated with measures of glucose tolerance and insulin resistance and mediate the association between MVPA and insulin resistance.

Sharp, Darren B.; Allman-Farinelli, Margaret (2014):

Feasibility and validity of mobile phones to assess dietary intake.

In: *Nutrition* 30 (11-12), S. 1257–1266. DOI: 10.1016/j.nut.2014.02.020.

Abstract:

Current limitations of conventional dietary assessment methods restrict the establishment of diet-disease relationships and efficacy of dietary interventions. Technology, in particular the use of mobile phones, may help resolve methodologic limitations, in turn improving the validity of dietary assessment and research and associated findings. This review aims to evaluate the validity, feasibility, and acceptability of dietary assessment methods that have been deployed on mobile phone platforms. In August 2013, electronic databases for health sciences were searched for English, peer-reviewed, full-text articles, published from January 1, 2001 onward; and accompanied by a hand search of available relevant publications from universities and government bodies. Studies were not limited by design, length, setting, or population group. Of 194 articles, 12 met eligibility criteria: mobile phone as the dietary recording platform and validation of energy and/or macronutrient intake against another dietary or

biological reference method. Four dietary recoding methods had been validated on mobile phone platforms: electronic food diary, food photograph-assisted self-administered, 24 h recall, food photograph analysis by trained dietitians, and automated food photograph analysis. All mobile phone dietary assessment methods showed similar, but not superior, validity or reliability when compared with conventional methods. Participants' satisfaction and preferences for mobile phone dietary assessment methods were higher than those for conventional methods, indicating the need for further research. Validity testing in larger and more diverse populations, over longer durations is required to evaluate the efficacy of these methods in dietary research.

Quantifying the return of headache in triptan-treated migraineurs: an observational study.

In: *Cephalalgia* 30 (7), S. 838–846.

Abstract:

To improve understanding of secondary treatment failure in migraine patients, we evaluated 'headache return' as a novel endpoint to assess returning headaches according to their severity, expanding on current standard assessments of overall recurrence or relapse rates, in a six-month observational study of triptan-treated migraineurs. A total of 359 patients (91% female; mean age, 42.5 years) recorded data for 2168 headaches in electronic diaries. Two-thirds of headaches responded to triptan treatment (improved-to-mild or no pain two hours post-dose); 34% of headaches had a pain-free response. By 48 hours post-dose, 19% of all responding headaches returned; 24% of headaches achieving a pain-free response returned, predominantly to mild pain. More severe baseline headache, short duration since diagnosis of migraine, and female gender were associated with increased likelihood of headache return. Treatment satisfaction declined with increasing severity of headache return, demonstrating the value of assessing headache return by severity to fully evaluate its impact.

Handheld computers for data entry: high tech has its problems too.

In: *Trials* 8 (5), S. 2.

Abstract:

BACKGROUND:

The use of handheld computers in medicine has increased in the last decade, they are now used in a variety of clinical settings. There is an underlying assumption that electronic data capture is more accurate that paper-based data methods have been rarely tested. This report documents a study to compare the accuracy of hand held computer data capture versus more traditional paper-based methods.

METHODS:

Clinical nurses involved in a randomised controlled trial collected patient information on a hand held computer in parallel with a paper-based data form. Both sets of data were entered into an access database and the hand held computer data compared to the paper-based data for discrepancies.

RESULTS:

Error rates from the handheld computers were 67.5 error per 1000 fields, compared to the accepted error rate of 10 per 10,000 field for paper-based double data entry. Error rates were highest in field containing a default value.

CONCLUSION:

While popular with staff, unacceptable high error rates occurred with hand held computers. Training and ongoing monitoring are needed if hand held computers are to be used for clinical data collection.

Feeling (Mis)Understood and Intergroup Friendships in Interracial Interactions.

In: *Pers Soc Psychol Bull. DOI:* 10.1177/0146167214538459.

Abstract:

The present research investigated whether having out-group friends serves as a buffer for feeling misunderstood in interracial interactions. Across three experience sampling studies, we found that among ethnic minorities who have few White friends or are not interacting with White friends, daily interracial interactions are associated with feeling less understood. By contrast, we found that among ethnic minorities who have more White friends or are interacting with White friends, the relationship between daily interracial interactions and feeling understood is not significant. We did not find similar results for Whites; that is, having ethnic minority friends did not play a role in the relationship between daily interracial interactions and feeling understood. Together, these studies demonstrate the beneficial effects of intergroup friendships for ethnic minorities.

Shernoff, David J. (2010):

Engagement in after-school programs as a predictor of social competence and academic performance.

In: *American journal of community psychology* 45 (3-4), S. 325–337. DOI: 10.1007/s10464-010-9314-0.

Abstract:

Using the experience sampling method, this study examined two questions related to outcomes associated with after-school programming. First, does the quality of experience in after-school programs mediate the effect of program participation on social competence and academic performance? Second, among program participants, is the difference in quality of experience when in programs versus other settings after school related to higher social competence and academic performance? Middle school students (N = 196) attending eight programs in three Midwestern states reported a total of 4,970 randomly sampled experiences in and out of after-school programs during 1 week in the fall and spring of the 2001-2002 academic year. Engagement during after-school hours partially mediated the relationship between participation in after-school programs and social competence. In addition, relative perceptions of engagement, challenge, and importance when in after-school programs compared to elsewhere after school predicted higher English and math grades. Results suggest that the quality of experiences in after-school programs may be a more important factor than quantity of experiences (i.e., dosage) in predicting positive academic outcomes.

Flow: Flow and optimal learning environments. In: Jeffrey J. Froh und Acacia C. Parks (Hg.): Activities for teaching positive psychology: A guide for instructors.

Washington, DC US: American Psychological Association, S. 109–115. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-22248-018%26site%3dehost-live.

Abstract:

(from the chapter) Flow is a peak experiential state of focused concentration and elevated enjoyment during intrinsically interesting activities. The experience of flow is further characterized by deep absorption, the perception of being in control, loss of self-consciousness, and a distorted perception of time (usually time seems to fly). It is suggested that students first obtain instruction in the basic concept and theory of flow through readings, presentations, or discussions before initiating the activity described in this chapter (suggested readings are provided). In this activity, students participate in the leading methodology used to research flow (the experience sampling method) by tracking and graphing their subjective experiences when signaled in a variety of instructional activities throughout an instructional unit on flow and engagement in learning. A new approach to physical activity maintenance: Rationale, design, and baseline data from the Keep Active Minnesota trial.

In: *BMC geriatrics* 8 (1), S. 17.

Abstract:

BACKGROUND:

Since many individuals who initiate physical activity programs are highly likely to return to a sedentary lifestyle, innovative strategies to efforts to increase the number of physically active older adults who successfully maintain beneficial levels of PA for a substantial length of time are needed.

METHODS/DESIGN:

The Keep Active Minnesota Trial is a randomized controlled trial of an interactive phone- and mail-based intervention to help 50-70 year old adults who have recently increased their physical activity level, maintain that activity level over a 24-month period in comparison to usual care. Baseline, 6, 12, and 24 month measurement occurred via phone surveys with kilocalories expended per week in total and moderate-to-vigorous physical activity (CHAMPS Questionnaire) as the primary outcome measures. Secondary outcomes include hypothesized mediators of physical activity change (e.g., physical activity enjoyment, self-efficacy, physical activity self-concept), body mass index, and depression. Seven day accelerometry data were collected on a sub-sample of participants at baseline and 24-month follow-up.

DISCUSSION:

The Keep Active Minnesota study offers an innovative approach to the perennial problem of physical activity relapse; by focusing explicitly on physical activity maintenance, the intervention holds considerable promise for modifying the typical relapse curve. Moreover, if shown to be efficacious, the use of phone- and mail-based intervention delivery offers potential for widespread dissemination.

Developmental validation of a point-of-care, salivary α-amylase biosensor.

In: *Psychoneuroendocrinology* 36 (2), S. 193–199.

Abstract:

The translation of salivary alpha-amylase (sAA) to the ambulatory assessment of stress hinges on the development of technologies capable of speedy and accurate reporting of sAA levels. Here, we describe the developmental validation and usability testing of a point-of-care, colorimetric, sAA biosensor. A disposable test strip allows for streamlined sample collection and a corresponding hand-held reader with integrated analytic capabilities permits rapid analysis and reporting of sAA levels. Bioanalytical validation utilizing saliva samples from 20 normal subjects indicates that, within the biosensor's linear range (10-230 U/ml), its accuracy (R(2)=0.989), precision (CV<9%), and measurement repeatability (range -3.1% to +3.1%) approach more elaborate laboratory-based, clinical analyzers. The truncated sampling-reporting cycle (<1 min) and the excellent performance characteristics of the biosensor has the potential to take sAA analysis out of the realm of dedicated, centralized laboratories and facilitate future sAA biomarker qualification studies.

Shiffman, Saul (2009):

Ecological momentary assessment (EMA) in studies of substance use.

In: *Psychological Assessment* 21 (4), S. 486–497. DOI: 10.1037/a0017074.

Abstract:

Ecological momentary assessment (EMA) is particularly suitable for studying substance use, because use is episodic and thought to be related to mood and context. This article reviews EMA methods in substance use research, focusing on tobacco and alcohol use and relapse, where EMA has been most applied. Common EMA designs combine event-based reports of substance use with time-based assessments. Approaches to data organization and analysis have been very diverse, particularly regarding their treatment of time. Compliance with signaled assessments is often high. Compliance with recording of substance use appears good but is harder to validate. Treatment applications of EMA are emerging. EMA captures substance use patterns not measured by questionnaires or retrospective data and holds promise for substance use research.

Shiffman, Saul (2009):

How many cigarettes did you smoke? Assessing cigarette consumption by global report, Time-Line Follow-Back, and ecological momentary assessment.

In: *Health Psychol* 28 (5), S. 519–526. DOI: 10.1037/a0015197.

Abstract:

OBJECTIVE\r\nThis study evaluated and compared several methods of assessing daily cigarette consumption.\r\nDESIGN\r\nComparison of measures of daily cigarette consumption from several sources, from 232 smokers entering a smoking cessation program.\r\nMAIN OUTCOME MEASURES\r\nGlobal reports of average smoking, Time-Line Follow-Back (TLFB) recall for the week preceding the study (premonitoring TLFB), 2 weeks' cigarette recordings using electronic diaries and ecological momentary assessment (EMA), and TLFB recall of smoking during EMA (monitored TLFB).\r\nRESULTS\r\nGlobal reports and premonitoring TLFB showed severe digit bias: six times as many values as expected were rounded at 10. Monitored TLFB also showed substantial digit bias (four times). EMA data showed none. EMA averaged 2.6 cigarettes lower than monitored TLFB, but exceeded TLFB on 32% of days. Across days, EMA and TLFB only correlated 0.29. Daily variations in TLFB did not correlate with variations in carbon monoxide (CO) measures taken on 3 days, but EMA measures did; among participants whose CO varied, r = .69. CO correlated with EMA cigarettes recorded in the preceding 2 hours, suggesting timely recording of cigarettes.\r\nCONCLUSION\r\nTLFB measures are limited for precise assessment of cigarette consumption. EMA measures appear to be useful for tracking smoking, and likely other health-relevant events.

Conceptualizing Analyses of Ecological Momentary Assessment Data.

In: *Nicotine.Tob.Res.* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt195.

Abstract:

Ecological Momentary Assessment (EMA) methods, which involve collection of real-time data in subjects' real-world environments, are particularly well suited to studying tobacco use. Analyzing EMA datasets can be challenging, as the datasets include a large and varied number of observations per subject and are relatively unstructured. This paper suggests that time is typically a key organizing principle in EMA data, and that conceptualizing the data as a timeline of events, behaviors, and experiences can help define analytic approaches. EMA datasets lend themselves to answering a diverse array of research questions, and the research question must drive how data are arranged for analysis, and the kinds of statistical models that are applied. The paper illustrates this with brief examples of diverse analyses applied to answer different questions from an EMA study of tobacco use and relapse

Prediction of lapse from associations between smoking and situational antecedents assessed by ecological momentary assessment.

In: *Drug Alcohol Depend* 91 (2), S. 159–168.

Abstract:

Smoking is associated with particular moods and activities, but it is not known whether there are individual differences in these associations and whether these differences are associated with success in smoking cessation. We assessed such associations using ecological momentary assessment: real-world, real-time data, collected by palm-top computer. Two hundred and fourteen smokers participating in a smoking cessation study provided data during ad lib smoking at baseline. Participants recorded moods and activities each time they smoked and, for comparison, at randomly selected non-smoking occasions. Situational associations with smoking were captured by examining the associations between smoking and antecedents considered relevant to lapse risk: negative affect (NA), arousal, socializing with others, the presence of others smoking, and consumption of coffee and alcohol. The associations varied across participants, confirming individual differences in situational smoking associations. Survival analyses revealed that only the NA pattern predicted first lapse. The effect was only seen in EMA assessments of NA smoking, and was not captured by questionnaire measures of negative affect smoking, which did not predict lapse risk. Moreover, the effect was not mediated by nicotine dependence.

Shiffman, Saul; Dunbar, Michael S.; Li, Xiaoxue; Scholl, Sarah M.; Tindle, Hilary A.; Anderson, Stewart J.; Ferguson, Stuart G. (2014):

Craving in Intermittent and Daily Smokers During Ad Libitum Smoking.

In: *Nicotine Tob Res. DOI:* 10.1093/ntr/ntu023.

Abstract:

INTRODUCTION: This study aimed to assess average and peak craving intensity among nondaily intermittent smokers (ITS), in smoking episodes and when not smoking, compared to that of daily smokers (DS). METHODS: Two hundred and twelve ITS and 194 DS monitored their smoking and craving for 3 weeks using Ecological Momentary Assessment methods. Craving was assessed (0-100 scale) when subjects lit a cigarette and at random times when not smoking; 48,469 observations were analyzed using generalized estimating equations. RESULTS: ITS experienced craving, including intense craving; their 95th percentile intensity averaged 77.7+/-22.5 out of 100 (higher among DS: 89.1+/-14.5). ITS reported lower craving than DS, both when smoking and when not smoking. In both groups, craving was less intense when not smoking (DS: 71.1+/-20.7 vs. 59.83+/-21.97; ITS: 59.91+/-23.03 vs. 26.63+/-19.87), but the difference was significantly greater among ITS. Among ITS, the probability of smoking rose continuously as craving increased over the full range of the scale. In contrast, among DS, the probability of smoking rose until the midpoint of the scale, after which the relationship flattened. Findings were mostly similar for ITS with and without a history of past daily smoking. CONCLUSIONS: ITS do experience craving, including intense craving. The relationship between craving and smoking is stronger among ITS because DS experience moderate craving even between cigarettes. In contrast, ITS appear to experience craving in limited situations associated with smoking, suggesting that their craving and smoking may be driven by transient cues rather than endogenous needs.

Shiffman, Saul; Dunbar, Michael S.; Li, Xiaoxue; Scholl, Sarah M.; Tindle, Hilary A.; Anderson, Stewart J.; Ferguson, Stuart G. (2014):

Smoking patterns and stimulus control in intermittent and daily smokers.

In: *PLoS One* 9 (3), S. e89911. DOI: 10.1371/journal.pone.0089911.

Abstract:

Intermittent smokers (ITS) - who smoke less than daily - comprise an increasing proportion of adult smokers. Their smoking patterns challenge theoretical models of smoking motivation, which emphasize regular and frequent smoking to maintain nicotine levels and avoid withdrawal, but yet have gone largely unexamined. We characterized smoking patterns among 212 ITS (smoking 4-27 days per month) compared to 194 daily smokers (DS; smoking 5-30 cigarettes daily) who monitored situational antecedents of smoking using ecological momentary assessment. Subjects recorded each cigarette on an electronic diary, and situational variables were assessed in a random subset (n = 21,539 smoking episodes); parallel assessments were obtained by beeping subjects at random when they were not smoking (n = 26,930 non-smoking occasions). Compared to DS, ITS' smoking was more strongly associated with being away from home, being in a bar, drinking alcohol, socializing, being with friends and acquaintances, and when others were smoking. Mood had only modest effects in either group. DS' and ITS' smoking were substantially and equally suppressed by smoking restrictions, although ITS more often cited self-imposed restrictions. ITS' smoking was consistently more associated with environmental cues and contexts, especially those associated with positive or "indulgent" smoking situations. Stimulus control may be an important influence in maintaining smoking and making quitting difficult among ITS.

Shiffman, Saul; Ferguson, Stuart G. (2008):

The effect of a nicotine patch on cigarette craving over the course of the day: results from two randomized clinical trials.

In: *Current Medical Research and Opinion®* 24 (10), S. 2795–2804.

Abstract:

OBJECTIVES:

The objective of this analysis was to assess the efficacy of a 21 mg/24-h nicotine patch for the reduction of craving throughout the waking day, compared both to placebo, and to a 15 mg/16-h patch differing pharmacokinetic profile over the day. The primary end-point was craving during the evening hours, because previous research suggested that smoking relapse was particularly likely at that time.

RESEARCH DESIGN AND METHODS:

Data were drawn from two similar randomized clinical trials among nicotine-dependent smokers who were quitting smoking: Study 1 compared the 21 mg/24-h patch to a placebo patch, while Study 2 compared the 21 mg/24-h patch to a 15 mg/16-h nicotine patch. In both studies, subjects (Study 1: n = 102; Study 2: n = 244) were prompted by an electronic diary to rate their craving multiple times per day during a 1 week baseline period, and for up to 2 weeks after quitting. For analysis, the day was divided into five blocks: morning (up to 10:59 a.m.), mid-day (11:00 a.m.-1:59 p.m.), afternoon (2:00 p.m.-4:59 p.m.), evening (5:00 p.m.-8:59 p.m.), and late night (9:00 p.m. onwards). The individual craving ratings were divided into three intervals based on time since quitting: Days 1-3, 4-7, and 8-14.

RESULTS:

The 21 mg/24-h nicotine patch resulted in significantly lower craving during all post-quit intervals, at each time of day, both compared to placebo (Study 1), and compared to the 15 mg/16-h nicotine patch (Study 2). Study 2 saw a significant treatment by interval interaction: in later time intervals, the difference in craving experience between 24- and 16-h patch conditions shrunk--while remaining significantly different--as overall levels of craving experienced by subjects in the two groups dropped. Adverse events reported in both studies tended to be mild and transient, consistent with the well characterized adverse event profile of nicotine patches.

CONCLUSIONS:

Study 1 demonstrated that a 21 mg/24-h patch was effective in reducing craving throughout the day, including the evening period when relapse risk is heightened. A further study comparing the 21 mg/24-h patch to a 15 mg/16-h nicotine patch found that craving was significantly lower at all times of day for smokers using the 21 mg/24-h patch. The studies were limited in that craving was only monitored for the first 2 weeks of quitting (when craving is most prominent), and cannot elucidate the impact of patch use on craving outside of this time. Also, there was substantial attrition of the sample over time, partly due to relapse in all conditions.

Shiffman, S.; Ferguson, S. G.; Dunbar, M. S.; Scholl, S. M. (2012):

Tobacco Dependence Among Intermittent Smokers.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/nts097.

Abstract:

INTRODUCTION: Intermittent smokers (ITS) are an increasingly prevalent segment of smokers, yet it is unknown whether or how dependence severity may vary across ITS. METHODS: Participants were 217 ITS (70 never daily ITS [NITS], 138 converted ITS [CITS], and 9 unknown), who smoked 4-27 days per month, and 197 daily smokers (DS), recruited for a study on smoking patterns. Participants completed questionnaires on dependence (time to first cigarette after waking, Fagerstrom Test of Nicotine Dependence [FTND], Nicotine Dependence Syndrome Scale [NDSS], Wisconsin Inventory of Smoking Dependence Motives [WISDM], and Hooked on Nicotine Checklist [HONC]) and recorded each cigarette in real time over 3 weeks using Ecological Momentary Assessment. Logistic regression assessed differences in dependence between groups (DS vs. ITS; CITS vs. NITS), and least squares regression examined associations between dependence and smoking behavior (mean, maximum cigarettes per day; proportion of days smoked; longest period of abstinence) within ITS. RESULTS: As expected, DS were significantly more dependent than ITS: FTND, NDSS, and WISDM discriminated between ITS and DS with greater than 90% accuracy. Similarly, among ITS, NITS demonstrated lower dependence than CITS. Within ITS, dependence measures also correlated with observed smoking rate and duration of abstinence.Conclusions:The study confirmed that DS are more dependent than ITS and that CITS are more dependent than NITS. Importantly, ITS exhibit features of dependence, and there is meaningful variation in dependence within ITS, suggesting that some aspects of dependence may appear with very infrequent smoking. Future work should examine implications for ITS' potential progression to daily smoking and cessation outcome

Shiffman, Saul; Gwaltney, Chad J. (2008):

Does heightened affect make smoking cues more salient?

In: *Journal of Abnormal Psychology* 117 (3), S. 618.

Abstract:

Negative affect (NA) states are robustly related to relapse. However, the mechanisms for this relationship are not well understood. Whereas most models have proposed that NA directly promotes lapsing, some models suggest that NA may promote lapses indirectly by increasing reactivity to smoking cues. This hypothesis was tested in secondary analyses of a study in which 248 smokers used ecological momentary assessment to self-monitor affective valence, smoking cues, and lapses during an attempt to quit smoking. The smoking cues the authors examined were others' smoking and consumption of alcohol or coffee. The odds of lapsing when exposed to smoking cues were compared across conditions of positive affect, neutral affect, and NA. Consistent main effects of affective valence were seen but not the hypothesized interaction. Indeed, analyses showed that the effect of cues was typically diminished under conditions of NA. No evidence was found to support the hypothesis that smoking cues and lapsing are more closely linked under NA conditions.

Shiffman, Saul; Kirchner, Thomas R. (2009):

Cigarette-by-cigarette satisfaction during ad libitum smoking.

In: *Journal of Abnormal Psychology* 118 (2), S. 348–359. DOI: 10.1037/a0015620.

Abstract:

Smoking is thought to produce immediate reinforcement, and subjective satisfaction with smoking is thought to influence subsequent smoking. The authors used ecological momentary assessment (A. A. Stone & S. Shiffman, 1994) to assess cigarette-by-cigarette smoking satisfaction in 394 heavy smokers who subsequently attempted to quit. Across 14,882 cigarettes rated, satisfaction averaged 7.06 (0-10 scale), but with considerable variation across cigarettes and individuals. Women and African American smokers reported higher satisfaction. More satisfied smokers were more likely to lapse after quitting (HR = 1.1, $p < .03$), whereas less satisfied smokers derived greater benefit from patch treatment to help them achieve abstinence (HR = 1.23, $p < .001$). Cigarettes smoked in positive moods were more satisfying, correcting for mood at the time of rating. The best predictor of subsequent smoking satisfaction was the intensity of craving prior to smoking. Understanding subjective smoking satisfaction provides insight into sources of reinforcement for smoking.

Shiffman, Saul; Patten, Christi; Gwaltney, Chad; Paty, Jean; Gnys, Maryann; Kassel, Jon et al. (2006):

Natural history of nicotine withdrawal.

In: *Addiction* 101 (12), S. 1822–1832. DOI: 10.1111/j.1360-0443.2006.01635.x.

Abstract:

AIMS\r\nTo examine the natural history of nicotine withdrawal and individual differences associated with withdrawal duration and severity.\r\nDESIGN AND SETTING\r\nProspective study of withdrawal symptoms among smokers who quit for at least 24 hours. Participants used Ecological Momentary Assessment to monitor symptoms in their natural environment using an Electronic Diary (ED).\r\nPARTICIPANTS\r\nA total of 214 cigarette smokers (59% female, 92% Caucasian).\r\nINTERVENTION\r\nAll participants received a clinic-based, behavioral, group cessation intervention. Severity and duration of withdrawal was not addressed explicitly in treatment.\r\nMEASUREMENTS\r\nParticipants were 'beeped' by the ED approximately five times/day to complete affect assessments (negative affect, arousal, attention disturbance, restlessness), and daily assessments of sleep disturbance (at waking) and of cognitive performance (each evening) for a week prior to quitting and for up to 21 days after quitting. Withdrawal was considered resolved when withdrawal scores returned to baseline levels for at least 2 consecutive days.\r\nFINDINGS\r\nAll symptoms returned to baseline levels within 10 days of quitting. All variables except arousal and sleep disturbance showed change over time. No robust predictors of individual differences in withdrawal responses emerged.\r\nCONCLUSIONS\r\nThe time-course of withdrawal may be shorter than previously reported. The natural history of nicotine withdrawal may have implications for theories of withdrawal and smoking relapse and for smoking cessation treatment.

Shiffman, Saul; Paty, Jean (2006):

Smoking patterns and dependence: contrasting chippers and heavy smokers.

In: *Journal of Abnormal Psychology* 115 (3), S. 509.

Abstract:

The authors used ecological momentary assessment to contrast smoking patterns among chippers (CHs; n = 26)--smokers who smoke despite an apparent absence of tobacco dependence--with those seen in heavy smokers (HSs; n = 28). Smoking and nonsmoking settings (activity, mood, etc.) were assessed by means of electronic diary. CHs were not social smokers; like HSs, they smoked half their cigarettes while alone. When smoking, CHs' urge levels equaled those of HSs; between cigarettes, CHs had few urges, whereas HSs reported moderate urges. CHs' smoking was particularly associated with indulgent activities: relaxation, socializing, eating, and drinking alcohol. Outside of these indulgent settings, CHs' (but not HSs') smoking was associated with negative affect. In idiographic analyses, CHs' smoking was under much stronger stimulus control than was that of HSs. The authors propose that the disappearance of stimulus control over use is a characteristic of dependence.

Shiffman, Saul; Scharf, Deborah M.; Shadel, William G.; Gwaltney, Chad J.; Dang, Qianyu; Paton, Stephanie M.; Clark, Duncan B. (2006):

Analyzing milestones in smoking cessation: illustration in a nicotine patch trial in adult smokers.

In: *Journal of Consulting and Clinical Psychology* 74 (2), S. 276–285. DOI: 10.1037/0022-006X.74.2.276.

Abstract:

Tests of addiction treatments seldom reveal where treatment exercises its effect (i.e., promoting initial abstinence, preventing lapses, and/or impeding progression from lapse to relapse). The authors illustrate analyses distinguishing effects on these milestones in a randomized trial of high-dose nicotine patch (35 mg; n = 188) versus placebo (n = 136) in adult smokers, who used electronic diaries to monitor smoking in real time during 5 weeks of treatment. High-dose patch promoted initial abstinence (hazard ratio [HR] = 1.3) and decreased the risk of lapsing among those who achieved abstinence (HR = 1.6). The biggest effect of treatment was to prevent progression to relapse among those who had lapsed (HR = 7.1). Analysis of effects by milestones may enhance understanding of cessation treatments and their mechanisms of action.

Shimbo, Daichi; Kuruvilla, Sujith; Haas, Donald; Pickering, Thomas G.; Schwartz, Joseph E.; Gerin, William (2009):

Preventing misdiagnosis of ambulatory hypertension: algorithm using office and home blood pressures.

In: *J Hypertens* 27 (9), S. 1775–1783. DOI: 10.1097/HJH.0b013e32832db8b9.

Abstract:

OBJECTIVES\r\nAn algorithm for making a differential diagnosis between sustained and white coat hypertension (WCH) has been proposed - patients with office hypertension undergo home blood pressure monitoring (HBPM) and those with normal HBP levels undergo ambulatory blood pressure monitoring (ABPM). We tested whether incorporating an upper office blood pressure (OBP) cut-off in the algorithm, higher than the traditional 140/90 mmHg, reduces the need for HBPM and ABPM.\r\nMETHODS\r\nTwo hundred twenty-nine normotensive and untreated mildly hypertensive participants (mean age 52.5 +/- 14.6 years, 54% female participants) underwent OBP measurements, HBPM, and 24-h ABPM. Using the algorithm, sensitivity, specificity, and positive and negative predictive values (PPV, NPV) for sustained hypertension and WCH were assessed. We then modified the algorithm utilizing a systolic and diastolic OBP cut-off at a specificity of 95% for ambulatory hypertension - those with office hypertension but OBP levels below the upper cut-off underwent HBPM and subsequent ABPM, if appropriate.\r\nRESULTS\r\nUsing the original algorithm, sensitivity and PPV for sustained hypertension were 100% and 93.8%, respectively. Despite a specificity of 44.4%, NPV was 100%. These values correspond to specificity, NPV, sensitivity, and PPV for WCH, respectively. Using the modified algorithm, the diagnostic accuracy for sustained hypertension and WCH did not change. However, far fewer participants needed HBPM (29 vs. 84) and ABPM (8 vs. 15).\r\nCONCLUSION\r\nIn this sample, the original and modified algorithms are excellent at diagnosing sustained hypertension and WCH. However, the latter requires far fewer participants to undergo HBPM and ABPM. These findings have important implications for the cost-effective diagnosis of sustained hypertension and WCH.

Shimbo, Daichi; Pickering, Thomas G.; Spruill, Tanya M.; Abraham, Dennis; Schwartz, Joseph E.; Gerin, William (2007):

Relative utility of home, ambulatory, and office blood pressures in the prediction of end-organ damage.

In: *Am J Hypertens* 20 (5), S. 476–482.

Abstract:

BACKGROUND:

Home blood pressure (HBP) monitoring plays an increasingly important role in the diagnosis and treatment of hypertension. We evaluated the independent value of HBP compared with ambulatory blood pressure (ABP) and office blood pressure (OBP) in the prediction of cardiovascular end-organ damage in normotensive subjects and untreated patients with mild hypertension.

METHODS:

One hundred sixty-three subjects underwent measurements of OBP, HBP, ABP, and echocardiography. A physician using a mercury-column sphygmomanometer performed three OBP measurements. The ABP was recorded using a noninvasive ambulatory monitor (mean, 35.4 awake readings per subject). Participants took HBP readings with an automatic, oscillometric

device over a 10-week period (mean, 277.9 readings per subject). The left-ventricular mass index (LVMI) was calculated from measurements obtained from two-dimensionally guided M-mode or linear tracings on echocardiography.

RESULTS:

For systolic and diastolic blood pressures (SBP/DBP), the correlation coefficients of the LVMI with OBP, awake ABP, and HBP were 0.29/0.27, 0.41/0.26, and 0.47/0.35, respectively (all P < .01). In a multivariate regression analysis in which age, sex, body mass index, OBP, awake ABP, and HBP were included, only age, sex, and HBP were significant predictors of LVMI. When only the first 12 home readings were used, the superiority of HBP was no longer evident.

CONCLUSIONS:

In contrast to OBP and ABP, HBP measurements, when averaged over a 10-week period, are independently related to LVMI. The HBP adds prognostic information over and above OBP and ABP in the prediction of cardiovascular end-organ damage, but this relationship appears to depend on the number of readings taken.

Unconstrained snoring detection using a smartphone during ordinary sleep.

In: *Biomed Eng Online* 13, S. 116. DOI: 10.1186/1475-925X-13-116.

Abstract:

BACKGROUND: Snoring can be a representative symptom of a sleep disorder, and thus snoring detection is quite important to improving the quality of an individual's daily life. The purpose of this research is to develop an unconstrained snoring detection technique that can be integrated into a smartphone application. In contrast with previous studies, we developed a practical technique for snoring detection during ordinary sleep by using the built-in sound recording system of a smartphone, and the recording was carried out in a standard private bedroom. METHOD: The experimental protocol was designed to include a variety of actions that frequently produce noise (including coughing, playing music, talking, rining an alarm, opening/closing doors, running a fan, playing the radio, and walking) in order to accurately recreate the actual circumstances during sleep. The sound data were recorded for 10 individuals during actual sleep. In total, 44 snoring data sets and 75 noise datasets were acquired. The algorithm uses formant analysis to examine sound features according to the frequency and magnitude. Then, a quadratic classifier is used to distinguish snoring from non-snoring noises. Ten-fold cross validation was used to evaluate the developed snoring detection methods, and validation was repeated 100 times randomly to improve statistical effectiveness. RESULTS: The overall results showed that the proposed method is competitive with those from previous research. The proposed method presented 95.07% accuracy, 98.58% sensitivity, 94.62% specificity, and 70.38% positive predictivity. CONCLUSION: Though there was a relatively high false positive rate, the results show the possibility for ubiquitous personal snoring detection through a smartphone application that takes into account data from normally occurring noises without training using preexisting data.

Teledermatology consultation using a smartphone multimedia messaging service for common skin diseases in the Korean army: a clinical evaluation of its diagnostic accuracy.

In: *J Telemed Telecare* 20 (2), S. 70–74. DOI: 10.1177/1357633X14524151.

Abstract:

We evaluated the diagnostic accuracy of teleconsultations for skin diseases common in the army using a smartphone multimedia messaging service (MMS). Images of skin lesions were obtained from 100 army patients using digital cameras built into smartphones. Three remotely located dermatologists received the dermatology images and associated clinical information via the MMS. The teledermatologists' diagnoses were compared with those obtained from face-to-face examinations. The three most common diagnoses made at the dermatology clinics were eczema, viral warts and fungal infections. The mean diagnostic agreement between face-to-face and teledermatology consultations was 71% (SD 2). The mean kappa coefficient was 0.73 (SD 0.06) for the three most common diagnostic categories. The mean values for sensitivity were 78% (SD 0), 88% (SD 21) and 61% (SD 11) for eczema, viral warts and fungal infections, respectively, and the specificity values were above 90% for these skin diseases. Teledermatology consultation using smartphones is simple. Although diagnoses using telemedicine do not perfectly match diagnoses from face-to-face consultations the diagnostic accuracy using smartphones is superior to that of clinicians who are not specialized in dermatology.

Real-Time Assessment of Nurse Work Environment and Stress.

In: *Journal for healthcare quality* 33 (1), S. 39–48.

Abstract:

Ecological momentary assessment methods were used to examine real-time relationships between work environment factors and stress in a sample of 119 registered nurses (RNs) in acute and critical care settings of three hospitals. The RNs carried handheld computers for 1 week of work shifts and were randomly surveyed within 90-min intervals to self-report work activity, perceived workload, and stress. Mixed effects linear regression analyses were completed to predict the stress score in the sample. The number of patients assigned significantly predicted stress; the greater the number of assigned patients, the higher the reported stress ($p<.01$). Age, gender, adult versus pediatric facility type, familiarity with patients, and proportion of direct care tasks were not significant predictors of stress. Further research is needed to link work environment factors and stress with errors among nurses.

Modeling Nonlinear Time-Dependent Treatment Effects: An Application of the Generalized Time-Varying Effect Model (TVEM).

In: *Journal of Consulting and Clinical Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-44749-001%26site%3dehost-live.

Abstract:

Objective: The goal of this article is to introduce to social and behavioral scientists the generalized time-varying effect model (TVEM), a semiparametric approach for investigating time-varying effects of a treatment. The method is best suited for data collected intensively over time (e.g., experience sampling or ecological momentary assessments) and addresses questions pertaining to effects of treatment changing dynamically with time. Thus, of interest is the description of timing, magnitude, and (nonlinear) patterns of the effect. Method: Our presentation focuses on practical aspects of the model. A step-by-step demonstration is presented in the context of an empirical study designed to evaluate effects of surgical treatment on quality of life among early stage lung cancer patients during posthospitalization recovery (N = 59; 61% female, M age = 66.1 years). Frequency and level of distress associated with physical symptoms were assessed twice daily over a 2-week period, providing a total of 1,544 momentary assessments. Results: Traditional analyses (analysis of covariance [ANCOVA], repeated-measures ANCOVA, and multilevel modeling) yielded findings of no group differences. In contrast, generalized TVEM identified a pattern of the effect that varied in time and magnitude. Group differences manifested after Day 4. Conclusions: Generalized TVEM is a flexible statistical approach that offers insight into the complexity of treatment effects and allows modeling of nonnormal outcomes. The practical demonstration, shared syntax, and availability of a free set of macros aim to encourage researchers to apply TVEM to complex data and stimulate important scientific discoveries. Shockley, K. M.; Allen, T. D. (2013):

Episodic work-family conflict, cardiovascular indicators, and social support: an experience sampling approach.

In: *J Occup.Health Psychol.* 18 (3), S. 262–275. DOI: 10.1037/a0033137.

Abstract:

Work-family conflict, a prevalent stressor in today's workforce, has been linked to several detrimental consequences for the individual, including physical health. The present study extends this area of research by examining episodic work-family conflict in relation to objectively measured cardiovascular health indicators (systolic and diastolic blood pressure and heart rate) using an experience sampling methodology. The results suggested that the occurrence of an episode of work interference with family conflict is linked to a subsequent increase in heart rate but not blood pressure; however, the relationship between episodes of family interference with work conflict and both systolic and diastolic blood pressure is moderated by perceptions of family-supportive supervision. No evidence was found for the moderating role of work-supportive family. Further theoretical and practical implications are discussed

Shrier, Lydia A.; Scherer, Emily Blood (2014):

It depends on when you ask: Motives for using marijuana assessed before versus after a marijuana use event.

In: *Addict Behav* 39 (12), S. 1759–1765. DOI: 10.1016/j.addbeh.2014.07.018.

Abstract:

BACKGROUND: Marijuana use motives are typically evaluated retrospectively using measures that summarize or generalize across episodes of use, which may compromise validity. Using Ecological Momentary Assessment data, we examined the main reason for a specific marijuana use event measured both prospectively and retrospectively. We then determined reason types, event characteristics, and user characteristics that predicted change in reason. METHODS: Thirty-six medical outpatients age 15 to 24 years who used marijuana two times a week or more used a handheld computer to select their main reason for use from the five categories of the Marijuana Motives Measure (Simons, Correia, & Carey, 1998) just before and after each time they used marijuana over two weeks (n=263 events with before/after reason). The reasons were examined individually and according to dimensions identified in motivational models of substance use (positive/negative, internal/external). RESULTS: The reason assessed before use changed to a different reason after use for 20% of events: 10% of events for pleasure; 21%, to cope; 35%, to be more social; 55%, to expand my mind; and 100%, to conform. In the multivariable model, external and expansion reasons each predicted change in reason for use ($p<0.0001$ and $p=0.001$, respectively). Youth were also more likely to change their reason if older ($p=0.04$), if male ($p=0.02$), and with weekend use ($p=0.002$). CONCLUSION: Retrospective assessments of event-specific motives for marijuana use may be unreliable and therefore invalid for a substantial minority of events, particularly if use is for external or expansion reasons.

A momentary sampling study of the affective experience following coital events in adolescents.

In: *Journal of Adolescent Health* 40 (4), S. 357-e1.

Abstract:

PURPOSE:

To describe the affective experience following sexual intercourse among sexually active adolescents. We hypothesized that these youth would experience more positive and less negative affects following sexual intercourse than at other times in their daily lives.

METHODS:

Approximately every 3 waking hours, sexually active adolescents aged 15-21 years used a handheld computer to report current affect and recent sexual intercourse in response to random signals. Participants also completed a report after sexual intercourse. Affect was determined by eight states, as well as composite variables for positive and negative affect. Generalized estimating equations compared affect on reports that did and did not include sexual intercourse. Each model included average affect, affect variability (standard deviation), and significant interactions with the occurrence of sexual intercourse. Based on their distribution, outcome variables were modeled as presence/absence of affect.

RESULTS:

Sixty-seven youth completed 1385 random and 392 event reports. There were 266 unique coital reports (median 2.6/participant/week); 94% were with a main partner and 49% involved condom use. Youth were more likely to report positive affect and less likely to report negative affect when they were also reporting recent sexual intercourse, as compared to noncoital reports. In multivariate analyses, participants had greater odds of reporting well being and alertness and lower odds of reporting stress and anger following sexual intercourse compared to other times.

CONCLUSIONS:

Adolescents report improvement in specific positive and negative affective states following sexual intercourse. Determining how feeling more positive and less negative after sexual intercourse may motivate or reinforce sexual intercourse will be important in understanding adolescent sexual behavior.

The FDA's role in the development of medical mobile applications.

In: *Clin Pharmacol Ther* 95 (5), S. 485–488. DOI: 10.1038/clpt.2014.45.

Abstract:

The use of mobile apps is revolutionizing health-care delivery and has the potential to transform health care by allowing doctors to diagnose patients with potentially life-threatening conditions outside traditional health-care settings, as well as helping consumers manage their own health and wellness and gain access to useful information when and where they need it.

Sievert, L. L. (2013):

Subjective and objective measures of hot flashes.

In: *Am J Hum.Biol.* 25 (5), S. 573–580. DOI: 10.1002/ajhb.22415.

Abstract:

Up to 75% of women in the US report having experienced hot flashes during the menopausal transition. The purpose of this review is to describe the physiology of hot flashes, and the ways in which hot flashes have been examined by subjective report and by objective measurement. Hot flashes occur because of an activation of the heat dissipation response, possibly triggered by a hypothalamic mechanism within the context of declining estrogen levels. There is cross-population variation in the frequency of self-reported hot flashes, although cross-study comparisons are problematic because of incompatibilities in study design. Diaries are a good way to collect information on the time and severity of hot flashes, and body diagrams allow researchers to study the pattern of heat and sweating. Hot flashes can be objectively measured by increases in heart rate, finger blood flow, respiratory exchange ratio, skin temperature, and core body temperature. Sternal skin conductance is the method most highly correlated with subjective hot flash report. In a laboratory, concordance between subjective report and sternal skin conductance can approach 100%. Ambulatory monitoring allows for the tracking of hot flashes during a woman's daily routine or sleep; however, concordance is much lower with ambulatory, compared to laboratory, monitoring. The study of hot flashes at menopause provides a model for the study of any experience that can be assessed by both self-report and biometric measurement. Am. J. Hum. Biol., 25:573-580, 2013. Sievert, Lynnette L.; Reza, Angela; Mills, Phoebe; Morrison, Lynn; Rahberg, Nichole; Goodloe, Amber et al. (2010):

Diurnal rhythm and concordance between objective and subjective hot flashes: the Hilo Women's Health Study.

In: *Menopause (New York, N.Y.)* 17 (3), S. 471–479. DOI: 10.1097/gme.0b013e3181cbb3c6.

Abstract:

OBJECTIVE\r\nThe aims of this study were to test for a diurnal pattern in hot flashes in a multiethnic population living in a hot, humid environment and to examine the rates of concordance between objective and subjective measures of hot flashes using ambulatory and laboratory measures.\r\nMETHODS\r\nStudy participants aged 45 to 55 years were recruited from the general population of Hilo, HI. Women wore a Biolog hot flash monitor (UFI, Morro Bay, CA), kept a diary for 24 hours, and also participated in 3-hour laboratory measures (n = 199). Diurnal patterns were assessed using polynomial regression. For each woman, objectively recorded hot flashes that matched subjective experience were treated as true-positive readings. Subjective hot flashes were considered the standard for computing false-positive and false-negative readings. True-positive, false-positive, and false-negative readings were compared across ethnic groups by chi analyses.\r\nRESULTS\r\nFrequencies of sternal, nuchal, and subjective hot flashes peaked at 1500 +/- 1 hours with no difference by ethnicity. Laboratory results supported the pattern seen in ambulatory monitoring. Sternal and nuchal monitoring showed the same frequency of true-positive measures, but nonsternal electrodes picked up more false-positive readings. Laboratory monitoring showed very low frequencies of false negatives. There were no ethnic differences in the frequency of true-positive or false-positive measures. Women of European descent were more likely to report hot flashes that were not objectively demonstrated (false-negative measures).\r\nCONCLUSIONS\r\nThe diurnal pattern and peak in hot flash occurrence in the hot humid environment of Hilo were similar to results from more temperate environments. Lack of variation in sternal versus nonsternal measures and in true-positive measures across ethnicities suggests no appreciable effect of population variation in sweating patterns.

Der Einsatz von Ecological Momentary Assessment bei Patienten mit pathologischem Kaufverhalten.

In: *Psychotherapie, Psychosomatik, medizinische Psychologie* 58 (12), S. 454–461. DOI: 10.1055/s-2007-986352.

Abstract:

Although compulsive buying is a disorder that has begun to receive attention from researchers in recent years, relatively little is known about the relationship between compulsive buying, mood, and daily stressful events. In our pilot study ecological momentary assessment (EMA) was used to examine the described relationships for the first time. 26 patients, who met criteria for compulsive buying, self-monitored their pathological behaviour, their momentary mood and the occurrence of stressful events four times a day on a handheld computer for a period of two weeks. On days with excessive buying behaviour patients reported significantly more daily stressful events compared to days without pathological buying. Before the buying episode patients recorded significantly more positive emotions. The most common consequence of compulsive buying was a significant decrease of positive affects. Thus the results of the current study suggest that mood states and daily stressful events are associated with compulsive buying behaviour. Although mood got worse immediately after excessive buying, this negative consequence did not reduce the frequency of pathological behaviour. This could implicate a high presence-orientation and impulsivity of the patients.

Pupillary reactivity to emotional information in child and adolescent depression: links to clinical and ecological measures.

In: *American Journal of Psychiatry* 164 (12), S. 1873–1880.

Abstract:

Objective: Pupil dilation provides a quantitative index of the temporal pattern of brain reactivity to emotional stimuli. Previous reports indicate that depressed adults show sustained pupil dilation to emotional words, but this phenomenon has not been investigated in children. This study investigated pupil dilation in children with depression and examined how differences in pupillary responses to emotional stimuli correlate with self-rated emotional experiences in participants' natural environments in everyday life. Method: Participants were 20 children with major depressive disorder and 22 comparison children ages 8–17. Pupil dilation was measured during a valence identification task. Participants also rated positive and negative affect in their natural environments as part of an ecological momentary assessment protocol. Results: Children showed greater pupil dilation to

negative words than to neutral or positive words. Children with major depression had diminished late pupil dilation relative to comparison children 9–12 sec after a negative word was presented. Diminished late pupil dilation to negative words was associated with greater severity of depression and with higher levels of negative affect and lower levels of positive affect in the natural environment. Conclusions: Depressed children exhibit a dynamic change in cognitive-affective resources devoted to processing negative emotional words, with more dramatic decreases than in comparison children after a negative word is initially processed, a pattern that differs markedly from that observed in depressed adults. Diminished late pupil dilation in children with major depression could be a marker for problems in emotional reactivity and/or regulation associated with pediatric depression.

Peer acceptance and rejection through the eyes of youth: Pupillary, eyetracking and ecological data from the Chatroom Interact Task.

In: *Social Cognitive and Affective Neuroscience* 7 (1), S. 93–105. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00562-009&site=ehost-live;silkj@upmc.edu.

Abstract:

We developed an ecologically valid virtual peer interaction paradigm—the Chatroom Interact Task in which 60 pre-adolescents and adolescents (ages 9–17 years) were led to believe that they were interacting with other youth in a simulated internet chatroom. Youth received rejection and acceptance feedback from virtual peers. Findings revealed increased pupil dilation, an index of increased activity in cognitive and affective processing regions of the brain, to rejection compared to acceptance trials, which was greater for older youth. Data from a cell-phone Ecological Momentary Assessment (EMA) protocol completed following the task indicated that increased pupillary reactivity to rejection trials was associated with lower feelings of social connectedness with peers in daily life. Eyetracking analyses revealed attentional biases toward acceptance feedback and away from rejection feedback. Biases toward acceptance feedback were stronger for older youth. Avoidance of rejection feedback was strongest among youth with increased pupillary reactivity to rejection, even in the seconds leading up to and following rejection feedback. These findings suggest that adolescents are sensitive to rejection feedback and seek to anticipate and avoid attending to rejection stimuli. Furthermore, the salience of social rejection and acceptance feedback appears to increase during adolescence. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Silva, Pedro; Lott, Ryan; Mota, Jorge; Welk, Greg (2014):

Direct and indirect effects of social support on youth physical activity behavior.

In: *Pediatr Exerc Sci* 26 (1), S. 86–94. DOI: 10.1123/pes.2012-0207.

Abstract:

Social support (SS) from parents and peers are key reinforcing factors in the Youth Physical Activity Promotion (YPAP) model. This study aims to identify the relative contribution of parental and peer SS on youth participation in moderate to vigorous physical activity (MVPA). Participants included 203 high school students (n = 125 girls; mean age 14.99 +/- 1.55 years). MVPA was assessed by accelerometry. SS influences were evaluated using a well-established scale. Structural equation modeling measured (AMOS, Version 19) the relative fit of the YPAP models using both parental and peer SS. Parental SS had significant associations with both predisposing factors, enjoyment (beta = .62, $p < .01$), and self-efficacy (beta= .32, $p < .01$), as well a direct effect on MVPA (beta = .30, $p < .01$). Peer SS had direct effect on MVPA (beta = .33, $p < .05$), also significantly influenced levels of enjoyment (beta = .47, $p < .01$) and self-efficacy (beta = .67, $p < .01$). In both models self-efficacy mediated the influence on MVPA. The direct effects for parents and peers were similar. This demonstrates that both parental and peer social support exert a strong influence on adolescent MVPA.

Human activity classification with inertial sensors.

In: *Stud Health Technol Inform* 200, S. 101–104.

Abstract:

Monitoring human physical activity has become an important research area and is essential to evaluate the degree of functional performance and general level of activity of a person. The discrimination of daily living activities can be implemented with

machine learning techniques. A public dataset provided during the European Symposium on Artificial Neural Networks 2013, with time and frequency domain features extracted from raw signals of the smartphone inertial sensors, was used to implement and evaluate an activity classifier. Using a decision tree classifier, an accuracy of 86% was achieved for the classification of walk, climb stairs, stand, sit, and lay down. The results obtained suggest that the smartphone's inertial sensors could be used for an accurate physical activity classification even with real-time requirements.

Everyday creativity in daily life: An experience-sampling study of “little c” creativity.

In: *Psychology of Aesthetics, Creativity, and the Arts* 8 (2), S. 183–188. DOI: 10.1037/t05569-000;

Abstract:

Richards proposed that everyday creativity—creative actions that are common among ordinary people in daily life, such as drawing, making recipes, writing, and any activity done with the purpose of being creative—both fosters and reflects psychological health. To explore when people are more likely to do something creative during the day, and to see who tends to act more creatively, we conducted a week-long experience-sampling study with a sample of young adults. Throughout the day, people’s actions and feelings were randomly sampled, with an emphasis on whether people were doing something creative. Consistent with the notion of everyday creativity as a psychological strength, within-person models showed that people who reported feeling happy and active were more likely to be doing something creative at the time. Between-person models found that openness to experience and conscientiousness had large effects on whether people spent their time on creative pursuits. Neither negative states (e.g., momentary feelings of anger, stress, and self-consciousness) nor traits (e.g., neuroticism) significantly predicted creative activity. The findings support Richards’s theorizing about everyday creative behavior as a cause and effect of positive psychological processes, and they illustrate the value of experience sampling for uncovering what creativity looks like in people’s idiosyncratic environments. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Silvia, P. J.; Kwapil, T. R.; Walsh, M. A.; Myin-Germeys, I. (2013):

Planned missing-data designs in experience-sampling research: Monte Carlo simulations of efficient designs for assessing within-person constructs.

In: *Behav.Res Methods* (1554-351X (Linking)). DOI: 10.3758/s13428-013-0353-y.

Abstract:

Experience-sampling research involves trade-offs between the number of questions asked per signal, the number of signals per day, and the number of days. By combining planned missing-data designs and multilevel latent variable modeling, we show how to reduce the items per signal without reducing the number of items. After illustrating different designs using real data, we present two Monte Carlo studies that explored the performance of planned missing-data designs across different within-person and between-person sample sizes and across different patterns of response rates. The missing-data designs yielded unbiased parameter estimates but slightly higher standard errors. With realistic sample sizes, even designs with extensive missingness performed well, so these methods are promising additions to an experience-sampler's toolbox

Increasing overall physical activity and aerobic fitness is associated with improvements in metabolic risk: cohort analysis of the ProActive trial.

In: *Diabetologia* 51 (5), S. 787–794.

Abstract:

Aims/hypothesis

Our aim was to examine the association between change in physical activity energy expenditure (PAEE), total body movement (counts per day) and aerobic fitness (maximum oxygen consumption [equation M1]) over 1 year and metabolic risk among individuals with a family history of diabetes.

Methods

Three hundred and sixty-five offspring of people with type 2 diabetes underwent measurement of energy expenditure (PAEE measured using the flex heart rate method), total body movement (daily activity counts from accelerometry data), equation M2

predicted from a submaximal graded treadmill exercise test and anthropometric and metabolic status at baseline and 1 year (n = 321) in the ProActive trial. Clustered metabolic risk was calculated by summing standardised values for waist circumference, fasting triacylglycerol, insulin and glucose, blood pressure and the inverse of HDL-cholesterol. Linear regression was used to quantify the association between changes in PAEE, total body movement and fitness and clustered metabolic risk at follow-up.

Results

Participants increased their activity by 0.01 units PAEE kJ kg−1 day−1 over 1 year. Total body movement increased by an average of 9,848 counts per day. Change in total body movement (β = −0.066, p = 0.004) and fitness (β = −0.056, p = 0.003) was associated with clustered metabolic risk at follow-up, independently of age, sex, smoking status, socioeconomic status and baseline metabolic score.

Conclusions/interpretation

Small increases in activity and fitness were associated with a reduction in clustered metabolic risk in this cohort of carefully characterised at-risk individuals. Further research to quantify the reduction in risk of type 2 diabetes associated with feasible changes in these variables should inform preventive interventions.

Personal health records: mobile biosensors and smartphones for developing countries.

In: *Stud.Health Technol.Inform.* 182 (0926-9630 (Linking)), S. 125–132. Online verfügbar unter PM:23138087.

Abstract:

A target of telehealth is to maintain or improve the health of people outside the normal healthcare infrastructure. A modern paradigm in healthcare, and one which fits perfectly with telehealth, is "person self-monitoring", and this fits with the concept of "personal health record" (PHR). One factor in maintaining health is to monitor physiological parameters; this is of course especially important in people with chronic maladies such as diabetes or heart disease. Parameters to be monitored include blood pressure, pulse rate, temperature, weight, blood glucose, oxygen saturation, electrocardiogram (ECG), etc. So one task within telehealth would be to help monitor an individual's physiological parameters outside of healthcare institutions and store the results in a PHR in a way which is available, comprehensible and beneficial to the individual concerned and to healthcare providers. To date many approaches to this problem have been fragmented - emphasizing only part of the problem - or proprietary and not freely verifiable. We describe a framework to approach this task; it emphasizes the implementation of standards for data acquisition, storage and transmission in order to maximize the compatibility among disparate components, e.g. various PHR systems. Data from mobile biosensors is collected on a smartphone using the IEEE 11073 standard where possible; the data can be stored in a PHR on the phone (using standard formats) or can be converted in real-time into more useful information in the PHR, which is based on the International Classification for Primary Care (ICPC2e). The phone PHR data or information can be uploaded to a central online PHR using either the Wi-Fi or GSM transmission protocol together with the Continuity of Care Record message format (CCR, ASTM E2369)

Simons, Jeffrey S.; Wills, Thomas A.; Neal, Dan J. (2014):

The Many Faces of Affect: A Multilevel Model of Drinking Frequency/Quantity and Alcohol Dependence Symptoms Among Young Adults.

In: *J Abnorm Psychol. DOI:* 10.1037/a0036926.

Abstract:

This research tested a multilevel structural equation model of associations between 3 aspects of affective functioning (state affect, trait affect, and affective lability) and 3 alcohol outcomes (likelihood of drinking, quantity on drinking days, and dependence symptoms) in a sample of 263 college students. Participants provided 49 days of experience sampling data over 1.3 years in a longitudinal burst design. Within-person results: At the daily level, positive affect was directly associated with greater likelihood and quantity of alcohol consumption. Daily negative affect was directly associated with higher consumption on drinking days and with higher dependence symptoms. Between-person direct effects: Affect lability was associated with higher trait negative, but not positive, affect. Trait positive affect was inversely associated with the proportion of drinking days, whereas negative affectivity predicted a greater proportion of drinking days. Affect lability exhibited a direct association with dependence symptoms. Between-person indirect effects: Trait positive affect was associated with fewer dependence symptoms via proportion of drinking days. Trait negative affect was associated with greater dependence symptoms via proportion of drinking days. The results distinguish relations of positive and negative affect to likelihood versus amount of drinking and state versus trait drinking outcomes, and highlight the importance of affect variability for predicting alcohol dependence symptoms.

Simpson, Tracy L.; Galloway, Christopher; Rosenthal, Christina F.; Bush, Kristen R.; McBride, Brittney; Kivlahan, Daniel R. (2011):

Daily telephone monitoring compared with retrospective recall of alcohol use among patients in early recovery.

In: *The American Journal on Addictions* 20 (1), S. 63–68.

Abstract:

Most studies comparing frequent self-monitoring protocols and retrospective assessments of alcohol use find good correspondence, but have excluded participants with significant comorbidity and/or social instability, and some have included abstainers. We evaluated the correspondence between measures of alcohol use based on daily interactive voice response (IVR) telephone monitoring and a 28-day modification of the Form-90 (Form-28). Participants were 25 outpatients with alcohol use disorder and significant PTSD symptomatology. Overall correlations between the IVR and Form-28 on days drinking and total standard drink units (SDUs) were strong for the entire sample and the subsample of drinkers (n = 7). Day-to-day correspondence between IVR and Form-28 was modest, but much stronger for the most recent week assessed than for the prior 3 weeks. Finally, the drinkers reported significantly greater total SDUs and heavy drinking days on the Form-28 than via IVR. The results indicate a need for further refinement of IVR methodology for treatment seeking populations as well as caution when retrospectively assessing drinking over time periods longer than a week among these individuals. (Am J Addict 2010;00:1–6)

Internet-based assessment and self-monitoring of problematic alcohol and drug use.

In: *Addict Behav* 35 (5), S. 464–470. DOI: 10.1016/j.addbeh.2009.12.021.

Abstract:

A Swedish web-based service (www.escreen.se) offers self-assessment and self-monitoring of alcohol and drug use via on-line screening with the Alcohol Use Disorders Identification Test (AUDIT) and the Drug Use Disorders Identification Test (DUDIT) as well as in-depth risk assessment using extended versions of both tests (Alcohol-E and DUDIT-E). Users receive individualized feedback concerning their alcohol and drug consumption and can follow their alcohol and drug use over time in personal diagrams and by writing in an electronic diary. This study describes user characteristics, service utilization patterns, and psychometric test properties for 2361 individuals who created a valid account over 20 months starting in February 2007. Problematic alcohol use according to AUDIT criteria was indicated for 67.4%, while 46.0% met DUDIT criteria for problematic drug use. Men and women accessed the service equally, with a mean age of 23 years. Internal consistency reliability figures were 0.90 for 1846 first-time AUDIT users and 0.97 for 1211 first-time DUDIT users; among 213 second-time AUDIT users reliability was 0.93, and 0.96 for 97 second-time DUDIT users. Internet-based alcohol and drug monitoring could function as a self-help tool or as a complement to substance abuse treatment.

Singh, B.; Russell, S. D.; Cheng, A. (2012):

Update on device technologies for monitoring heart failure.

In: *Curr.Treat.Options.Cardiovasc.Med.* 14 (5), S. 536–549. DOI: 10.1007/s11936-012-0192-7.

Abstract:

OPINION STATEMENT: Congestive heart failure (CHF) affects more than 5 million people in the United States and is one of the most common reasons for recurrent hospitalizations. Since the majority of admissions related to CHF are secondary to progressively worsening congestion, many clinicians are quick to initiate aggressive diuresis once early signs of impending heart failure develop. These signs are based in large measure on patient-reported symptoms. Unfortunately, recent trials have shown that traditional ambulatory monitoring of heart failure using patient symptoms or body weight do not reduce episodes of decompensated heart failure requiring hospitalization. This has led to great interest in developing monitoring systems that can detect impending episodes of CHF even prior to the development of symptoms. Some of the these systems utilize existing implantable cardioverter defibrillators and cardiac resynchronization therapy devices to monitor electrophysiologic parameters including the presence of ventricular arrhythmias, heart rate variability and even transthoracic impedances. Other more recent developments have focused on more invasive hemodynamic monitoring systems that can measure pressures in the right ventricle, pulmonary arteries and the left atrium. The data on the utility of such systems is limited but encouraging. While none of these systems are currently FDA approved, they have been applied in a number of clinical trials. This paper highlights the currently available monitoring systems for heart failure and reviews the evidence supporting its use

Sirard, John R.; Pate, Russell R. (2001):

Physical activity assessment in children and adolescents.

In: *Sports Med* 31 (6), S. 439–454.

Abstract:

Chronic disease risk factors, including a sedentary lifestyle, may be present even in young children, suggesting that early prevention programmes may be critical to reducing the rates of chronic disease. Accurate assessment of physical activity in children is necessary to identify current levels of activity and to assess the effectiveness of intervention programmes designed to increase physical activity. This article summarises the strengths and limitations of the methods used to evaluate physical activity in children and adolescents. MEDLINE searches and journal article citations were used to locate 59 articles that validated physical activity measurement methods in children and adolescents. Only those methods that were validated against a more stringent measure were included in the review.

Based on the definition of physical activity as any bodily movement resulting in energy expenditure (EE), direct observation of the individual's movement should be used as the gold standard for physical activity research. The doubly labelled water technique and indirect calorimetry can also be considered criterion measures for physical activity research, because they measure EE, a physiologic consequence closely associated with physical activity. Devices such as heart rate monitors, pedometers and accelerometers have become increasingly popular as measurement tools for physical activity. These devices reduce the subjectivity inherent in survey methods and can be used with large groups of individuals. Heart rate monitoring is sufficiently valid to use in creating broad physical activity categories (e.g. highly active, somewhat active, sedentary) but lacks the specificity needed to estimate physical activity in individuals. Laboratory and field validations of pedometers and accelerometers yield relatively high correlations using oxygen consumption (r = 0.62 to 0.93) or direct observation (r = 0.80 to 0.97) as criterion measures, although, they may not be able to capture all physical activity.

Physical activity has traditionally been measured with surveys and recall instruments. These techniques must be used cautiously in a paediatric population that has difficulty recalling such information. Still, some studies have reported 73.4% to 86.3% agreement between these instruments and direct observation. Future investigations of physical activity instruments should validate the novel instrument against a higher standard. Additional studies are needed to investigate the possibility of improving the accuracy ofmeasurement by combining 2 or more techniques. The accurate measurement of physical activity is critical for determining current levels of physical activity, monitoring compliance with physical activity guidelines, understanding the dose-response relationship between physical activity and health and determining the effectiveness of intervention programmes designed to improve physical activity.

Sisson, Susan B.; Camhi, Sarah M.; Tudor-Locke, Catrine; Johnson, William D.; Katzmarzyk, Peter T. (2012):

Characteristics of step-defined physical activity categories in U.S. adults.

In: *Am J Health Promot* 26 (3), S. 152–159. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-01535-004&site=ehost-live;susan-sisson@ouhsc.edu.

Abstract:

Purpose: Descriptive physical activity epidemiology of the U.S. population is critical for program development and resource allocation. The purpose of this project was to describe step-defined categories (as measured by accelerometer) of U.S. adults and to determine predictors of sedentary classification (<5000 steps/d). Design: The National Health and Nutrition Examination Survey (NHANES) is an annual, nationally representative survey used to determine the health status of the U.S. populace. Setting: In-home interviews and physical examination components of NHANES. Participants: Overall, 4372 eligible adults wore accelerometers in the 2005–2006 NHANES; 628 were excluded, which yielded 3744 adults (of which 46.8% were men). Measures: Steps per day; body mass index (BMI); demographic, household and behavioral variables. Analysis: Means and frequencies were calculated. Logistic regression was utilized to determine predictors of sedentary classification. Results: Overall, 36.1% were sedentary (i.e., <5000 steps/d); 47.6% were low to somewhat active (5000–9999 steps/d); 16.3% were active to highly active (≥10,000 steps/d). Advancing age (odds ratio [OR], 1.95; confidence intervals [CIs], 1.78, 2.13), higher BMI (OR, 1.40; CIs, 1.23, 1.59), female sex (OR, 1.86; CIs, 1.46, 2.36), African-American versus European-American ethnicity (OR, 1.36; CIs, 1.13, 1.65), household income versus ≥$45,000 (<$25,000: OR, 1.94; CIs, 1.40, 2.69; $25,000–$44,000: OR, 1.51; CIs, 1.23, 1.85), and current versus never smoker (OR, 1.53; CIs, 1.26, 1.86) variables had higher odds of sedentary classification. Usual daily occupational/domestic physical activity categories of standing/walking (OR, .51; CIs, .38, .69); lifting/climbing (OR, .26; CIs, .17, .38); and heavy loads/labor (OR, .16; CIs, .10, .26) had lower odds of sedentary classification than sitting. Conclusions: Over one-third of the U.S. population was classified as sedentary by accelerometer-determined steps per day, and several characteristics predicted sedentary classification. Sisson, Susan B.; Tudor-Locke, Catrine (2008):

Comparison of cyclists' and motorists' utilitarian physical activity at an urban university.

In: *Prev Med* 46 (1), S. 77–79.

Abstract:

OBJECTIVE:

Preliminary comparison of cyclists and motorists on: (1) distance lived from campus and, (2) the impact of transportation mode on physical activity.

METHODS:

A purposive sample of students (n=50; cyclists=26, motorists=24) living <5 miles from Arizona State University campus wore an accelerometer and completed a travel log for two on-campus days during fall 2005-spring 2006. Residence distance to campus was calculated by geocoded addresses (n=45; cyclists=23 vs. motorists=22). Final outcome variables were: distance lived from campus, accelerometer time moderate-to-vigorous physical activity, steps/day, total time moderate-to-vigorous physical activity (logged minutes cycling+accelerometer-derived moderate-to-vigorous physical activity), and minutes total active commuting (logged walking+cycling).

RESULTS:

Groups were significantly different for: distance lived from campus (cyclists=0.6+/-0.6 vs. motorists=2.0+/-1.1 miles; p<0.000); steps/day (cyclists=11,051+/-4295 vs. motorists=9174+/-3319; p=0.046); total time moderate-to-vigorous physical activity (cyclists=85.7+/-37.0 vs. motorists=50.3+/-23.8 minutes; p<0.001); minutes in motorized transport (cyclists=24.9+/-27.5 vs. motorists=61.6+/-32.9; p<0.001); and total active transport (cyclists=59.4+/-32.4 vs. motorists=29.5+/-20.0; p<0.001).

CONCLUSION:

Among students living within 5 miles of campus, cyclists lived relatively closer to campus, accumulated more minutes of physical activity, and spent more time in active transportation than students who used motorized means.

Everyday emotional experience of adults with attention deficit hyperactivity disorder: evidence for reactive and endogenous emotional lability.

In: *Psychol Med*, S. 1–13. DOI: 10.1017/S0033291714001032.

Abstract:

BACKGROUND: Emotional lability (EL), characterized by negative emotional traits and emotional instability, is frequently reported in children and adults with attention deficit hyperactivity disorder (ADHD). However, EL is primarily assessed using retrospective self-report, which is subject to reporting bias and does not consider the potential influence of positive and negative everyday experiences. METHOD: Ambulatory assessment was carried out in 41 men with ADHD without co-morbidity, current medication or substance abuse, and 47 healthy control participants. Reports of negative and positive emotions (irritability, frustration, anger, happiness, excitement) and the occurrence of bad and good events were completed eight times daily during a working week. Group differences in emotional intensity and instability were investigated using multilevel models, and explored in relation to bad and good events and the Affective Lability Scale - Short Form (ALS-SF), an EL questionnaire. RESULTS: The ADHD group reported significantly more frequent bad events, heightened intensity and instability of irritability and frustration, and greater intensity of anger. The results for positive emotions were equivocal or negative. Bad events significantly contributed to the intensity and instability of negative emotions, and showed a stronger influence in the ADHD group. However, covariation for their effect did not eliminate group differences. Small-to-moderate correlations were seen between intensity and instability of negative emotions and the ALS-SF. CONCLUSIONS: Adults with ADHD report heightened intensity and instability of negative emotions in daily life. The results suggest two components of EL in ADHD: a reactive component responsive to bad events and an endogenous component, independent of negative everyday events.

Skoglund, Per H.; Arpegard, Johannes; Ostergren, Jan; Svensson, Per (2014):

Amino-terminal pro-B-type natriuretic peptide and high-sensitivity C-reactive protein but not cystatin C predict cardiovascular events in male patients with peripheral artery disease independently of ambulatory pulse pressure.

In: *Am J Hypertens* 27 (3), S. 363–371. DOI: 10.1093/ajh/hpt278.

Abstract:

BACKGROUND: Patients with peripheral arterial disease (PAD) are at high risk for cardiovascular (CV) events. We have previously shown that ambulatory pulse pressure (APP) predicts CV events in PAD patients. The biomarkers amino-terminal pro-B-type natriuretic peptide (NT-proBNP), high-sensitivity C-reactive protein (hs-CRP), and cystatin C are related to a worse outcome in patients with CV disease, but their predictive values have not been studied in relation to APP. METHODS: Blood samples and 24-hour measurements of ambulatory blood pressure were examined in 98 men referred for PAD evaluation during 1998-2001. Patients were followed for a median of 71 months. The outcome variable was CV events defined as either CV mortality or any hospitalization for myocardial infarction, stroke, or coronary revascularization. The predictive values of log(NT-proBNP), log(hs-CRP), and log(cystatin C) alone and together with APP were assessed by multivariable Cox regression. Area under the curve (AUC) and net reclassification improvement (NRI) were calculated compared with a model containing other significant risk factors. RESULTS: During follow-up, 36 patients had at least 1 CV event. APP, log(NT-proBNP), and log(hs-CRP) all predicted CV events in univariable analysis, whereas log(cystatin C) did not. In multivariable analysis log(NT-proBNP) (hazard ratio (HR) = 1.62; 95% confidence interval (CI) = 1.05-2.51) and log(hs-CRP) (HR = 1.63; 95% CI = 1.19-2.24) predicted events independently of 24-hour PP. The combination of log(NT-proBNP), log(hs-CRP), and average day PP improved risk discrimination (AUC = 0.833 vs. 0.736; P < 0.05) and NRI (37%; P < 0.01) when added to other significant risk factors. CONCLUSIONS: NT-proBNP and hs-CRP predict CV events independently of APP and the combination of hs-CRP, NT-proBNP, and day PP improves risk discrimination in PAD patients.

Skoglund, P. H.; Ostergren, J.; Svensson, P. (2012):

Ambulatory pulse pressure predicts cardiovascular events in patients with peripheral arterial disease.

In: *Blood Press* (0803-7051 (Linking)). DOI: 10.3109/00365599.2012.676755.

Abstract:

Background. Patients with peripheral arterial disease (PAD) are at high risk of cardiovascular (CV) events and often have hypertension with a high pulse pressure (PP). We studied the prognostic value of ambulatory blood pressure (ABP) in PAD patients with special reference to PP. Methods. 98 consecutive males with PAD had 24-h ABP measurements. The mean age was 68 years and CV comorbidity was prevalent. The outcome variable was CV events defined as CV mortality or any hospitalization for myocardial infarction, stroke or coronary revascularization. The predictive value of ABP variables was assessed by Cox regression. 90 age-matched men free of CV disease served as controls. Results. During follow-up (median 71 months), 36 patients and seven controls had at least one CV event. In PAD patients, 24-h PP (hazard ratios, HR, 1.48 (95% confidence interval, CI, 1.14-1.92), p < 0.01) predicted CV events. Office PP did not predict events in PAD patients (HR 1.15 (0.97-1.38), ns). In multivariate analysis, 24-h PP (HR 1.48 (1.12-1.95), p < 0.01) remained a predictor of CV events. Conclusions. Ambulatory PP predicts CV events in patients with PAD. ABP measurement may be indicated for better risk stratification in PAD patients

Sladek, Michael R.; Doane, Leah D. (2014):

Daily diary reports of social connection, objective sleep, and the cortisol awakening response during adolescents' first year of college.

In: *Journal of Youth and Adolescence*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-57518-001%26site%3dehost-live.

Abstract:

Poor sleep and alterations in the stress-sensitive hypothalamic–pituitary–adrenal (HPA) axis may be mechanisms through which loneliness impacts adolescents' well-being. Few researchers have explored whether daily variation in experiences of social connection predict day-to-day variation in sleep and HPA axis activity among adolescents navigating the college context. Using daily diary reports of social connection, objective measures of sleep (actigraphy), and naturalistic salivary assessment, the present study examined within-person associations between first-year college students' social connection during the day and sleep that night, as well as diurnal cortisol activity the following day. The present study also explored trait-level loneliness as a moderator of these associations after adjusting for baseline loneliness assessed in high school. Seventy-one first-year college students (23 % male; M age = 18.85; 52 % non-Hispanic White) completed daily diary reports, wore a wrist-based accelerometer (actigraph watch), and provided saliva samples five times daily across three consecutive weekdays. The results from hierarchical linear models indicated that within-person increases in daily social connection were significantly associated with longer time spent in bed and more actual time asleep that night only for adolescents high on loneliness. Within-person increases in daily social connection were associated with a greater cortisol awakening response (CAR) the next day, regardless of trait loneliness. These findings illustrate that more daily social connection with others than usual may predict improved sleep quantity for lonely

adolescents and a physiological index of anticipating upcoming daily demands (CAR) in general. Future intervention programs might consider including strategies focused on enhancing daily social interactions among adolescents starting college, particularly for lonely adolescents. Physical Strain of Walking Relates to Activity Level in Adults With Cerebral Palsy.

In: *Arch.Phys.Med.Rehabil.* (0003-9993 (Linking)). DOI: 10.1016/j.apmr.2012.11.005.

Abstract:

OBJECTIVE: To gain insight into underlying mechanisms of inactive lifestyles among adults with spastic bilateral cerebral palsy (CP) with a focus on aerobic capacity, oxygen consumption, and physical strain during walking at preferred walking speed, as well as fatigue. DESIGN: Cross-sectional. SETTING: University hospital. PARTICIPANTS: Adults (N=36), aged 25 to 45 years, with spastic bilateral CP, walking with (n=6) or without (n=30) walking aids. INTERVENTIONS: Not applicable. MAIN OUTCOME MEASURES: Physical strain during walking was defined as oxygen uptake during walking, expressed as percentage of peak aerobic capacity. Participants with spastic bilateral CP walked their preferred walking speed while oxygen uptake was measured using a portable gas analyzer. Peak aerobic capacity was measured during maximal cycle ergometry. An accelerometry-based activity monitor measured total daily walking time. Regression analyses were performed to assess the relation between aerobic capacity, oxygen uptake, and physical strain of walking on the one hand and total daily walking time on the other hand. RESULTS: Neither aerobic capacity nor oxygen uptake during walking was related to total daily walking time ($r(2)=.29$, $P=.10$ and $r(2)=.27$, $P=.16$, respectively). Physical strain of walking at preferred walking speed was inversely related to total daily walking time ($r(2)=.44$, $P<.01$). CONCLUSIONS: Physical strain during walking is moderately related to total daily walking time, implying that people with high physical strain during walking at preferred walking speed likely walk less in daily life

Slaper, Michael R.; Conkol, Kimberly (2014):

mHealth tools for the pediatric patient-centered medical home.

In: *Pediatr Ann* 43 (2), S. e39-43. DOI: 10.3928/00904481-20140127-09.

Abstract:

The concept of the pediatric patient-centered medical home (PCMH) as a theory has been evolving since it was initially conceived more than 40 years ago. When the American Academy of Pediatrics' (AAP) Council on Pediatric Practice first wrote about this model, "medical home" was defined solely as the central location of a pediatric patient's medical records. Approximately two decades later, the AAP published its inaugural policy statement on this topic. Through this policy statement, the medical home was defined as a place where care for pediatric patients would be accessible, continuous, comprehensive, family-centered, coordinated, compassionate, and culturally effective. Although the lack of access to providers, especially in rural communities, may inhibit the adoption of the PCMH or chronic care models, technology has evolved to the point where many of the gaps in care can be bridged. mHealth, defined by the National Institutes of Health (NIH) as the use of mobile and wireless devices to improve health outcomes, health care services, and health research, can be one specific example of how technology can address these issues. One early study has shown that patients who use mHealth tools are more likely to adhere to self-monitoring requirements and, in turn, have significantly improved outcomes. A rapidly evolving and scalable mHealth technology that has the ability to address these issues are self-management mobile applications, or apps. It has been estimated that there are currently more than 40,000 health care-related apps available. Furthermore, use of these apps is growing, as more than 50% of smartphone users surveyed responded that they have used their device to gather health information, and almost 20% of this population has at least one health care app on their device.

Sliwinski, Martin J. (2011):

Approaches to modeling intraindividual and interindividual facets of change for developmental research. In: Karen L. Fingerman, Cynthia A. Berg, Jacqui Smith und Toni C. Antonucci (Hg.): Handbook of life-span development.

New York, NY US: Springer Publishing Co, S. 1–25. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-03366-001&site=ehost-live.

Abstract:

(from the chapter) The science of human development seeks to understand how individuals change on physical, cognitive, and social dimensions of functioning across the life span. Although many informative developmental studies have relied on cross-sectional comparisons among individuals of different ages, optimal designs for addressing developmental questions must involve the study of intraindividual change across time. In this chapter, I will discuss the conceptual underpinnings and methodological approaches for linking change processes that operate across different time scales. First, I will discuss important distinctions (i.e., variability vs. change, intraindividual vs. interindividual differences in change) in developmental methodology and how they map onto commonly used analytic approaches. Second, I will explore the utility of different research designs for studying both the intraindividual and interindividual facets of developmental change across different time scales (i.e., over the shortterm and long-term). Emphasis will be given to a relatively novel hybrid research design, the measurement burst. Most longitudinal designs consist of measuring behavior once every several months or years to detect long-term developmental trends. In contrast, measurement-burst designs consist of "bursts" of intensive (e.g., daily) measurements that are repeated over longer intervals (e.g., every several months). Thus, the measurement burst combines elements of intensive short-term measurement designs (e.g., microgenetic, daily diary, experience sampling) with more conventional longitudinal designs that focus on longerterm follow-up. For example, a researcher interested in developmental changes in emotion regulation might examine affective reactivity to daily stress and how characteristics such as personality and chronic stress exposure influence these changes. A measurement-burst approach to this problem could involve repeating a week-long daily diary study every few months to examine longer-term intraindividual changes in patterns of variability and covariation between affect and stress. This type of design affords researchers with the opportunity to pose and address a rich array of questions regarding processes of intraindividual variability and change that operate across very different time intervals. Sloane, Richard; Snyder, Denise Clutter; Demark-Wahnefried, Wendy; Lobach, David; Kraus, William E. (2009):

Comparing the 7-day physical activity recall with a triaxial accelerometer for measuring time in exercise.

In: *Med Sci Sports Exerc* 41 (6), S. 1334–1340. DOI: 10.1249/MSS.0b013e3181984fa8.

Abstract:

PURPOSE\r\nThe primary study aim was to evaluate associations of estimated weekly minutes of moderate-to-vigorous-intensity exercise from self-reports of the telephone-administered 7-Day Physical Activity Recall (7-Day PAR) with data captured by the RT3 triaxial accelerometer.\r\nMETHODS\r\nThis investigation was undertaken as part of the FRESH START study, a randomized clinical trial that tested an iteratively tailored diet and exercise mailed print intervention among newly diagnosed breast and prostate cancer survivors. A convenience sample of 139 medically eligible subjects living within a 60-mile radius of the study center provided both 7-Day PAR and accelerometer data at enrollment. Ultimately, substudy subjects (n = 115) were found eligible for the FRESH START study and randomized to one of two study treatment arms. Follow-up assessments at year 1 (n = 103) and year 2 (n = 99) provided both the 7-Day PAR and the accelerometer data.\r\nRESULTS\r\nThere was moderate agreement between the 7-Day PAR and the accelerometer with longitudinal serial correlation coefficients of 0.54 (baseline), 0.24 (year 1), and 0.53 (year 2), all P values <0.01, although the accelerometer estimates for weekly time in moderate-to-vigorous physical activity (PA) were much higher than those of the 7-Day PAR at all time points. The two methods were poorly correlated in assessing sensitivity to change from baseline to year 1 (rho = 0.11, P = 0.30). Using mixed models repeated-measures analysis, both methods exhibited similar nonsignificant treatment arm x time interaction P values (7-Day PAR = 0.22, accelerometer = 0.23).\r\nCONCLUSIONS\r\nThe correlations for three serial time points were in agreement with findings of other studies that compared self-reported time in exercise with PA captured by accelerometry. However, these methods capture somewhat different dimensions of PA and provide differing estimates of change over time.

Accelerometers and Internet for physical activity promotion in youth? Feasibility and effectiveness of a minimal intervention [ISRCTN93896459].

In: *Prev Med* 51 (1), S. 31–36. DOI: 10.1016/j.ypmed.2010.03.015.

Abstract:

OBJECTIVE\r\nTo evaluate the feasibility and effectiveness of a 3-month minimal physical activity (PA) intervention in adolescents.\r\nMETHODS\r\nA randomised controlled trial, including five secondary schools (n=87). In the 3-month intervention (Amsterdam, The Netherlands, 2005) adolescents were provided with a PAM accelerometer, coupled to a web-based tailored PA advice (PAM COACH). Measurements (i.e., PA, determinants of PA, aerobic fitness and anthropometrics) took place at baseline and at 3- and 8-month follow-up.\r\nRESULTS\r\nSixty-five percent of the participants in the intervention

group reported to have worn the PAM frequently and 56% of the PAM users uploaded their PAM scores to the PAM COACH at least once. We found significant differences between groups in favour of the intervention group in moderate intensity PA (MPA) for girls after 3 months (411 min/week; 95% CI: 1; 824; P=0.04) and in sedentary time for boys after 8 months (-1801 min/week; 95% CI: -3545; -57; P=0.04).\r\nCONCLUSIONS\r\nAlthough the process evaluation suggests that a substantial proportion of the participants did not regularly wear the PAM and did not upload information to the PAM COACH website, our findings suggest promising intervention effects on MPA among girls and sedentary time among boys.

Disagreement in physical activity assessed by accelerometer and self-report in subgroups of age, gender, education and weight status.

In: *Int J Behav Nutr Phys Act* 6. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-30460-001%26site%3dehost-live;w.vanmechelen@vumc.nl;jaap.seidell@falw.vu.nl;m.chinapaw@vumc.nl;jantine.schuit@rivm.nl;slootmaker@gmail.com.

Abstract:

Background

The purpose of this study is to compare self-reported time (by questionnaire) and objectively measured time (by accelerometer) spent on physical activity at moderate (MPA) and vigorous intensity (VPA) in subgroups of age, gender, education and weight status.

Methods

In total, 236 adolescents (aged 12–18) and 301 adults (aged 22–40), completed the questionnaire and wore an accelerometer for two weeks.

Results

Adolescents reported exceptionally more time spent on MPA (mean difference 596 ± 704 min/wk) and VPA (mean difference 178 ± 315 min/wk) than was assessed objectively by the accelerometer. Based on the questionnaire, high educated adolescents spent more time on MPA (205 min/wk, p = 0.002) and VPA (120 min/wk, p = 0.01) than low educated adolescents, but according to the accelerometer they spent less time on MPA (149 min/wk, p = 0.001) and VPA (47 min/wk, p = 0.001). Among adults there was moderate agreement between self-reported time and objectively measured time spent on MPA, but in general the reported time spent on MPA (mean difference 107 ± 334 min/wk) and VPA (mean difference 169 ± 250 min/wk) exceeded the time measured with the accelerometer. Overweight adults reported significantly more VPA (57 min/wk, p = 0.04) than normal weight adults, but this was not confirmed by the accelerometer data.

Conclusion

We observed large differences in time spent on MPA and VPA measured by questionnaire and accelerometer in adolescents but reasonably good agreement in adults. Differences between methods varied by gender, education and weight status. This finding raises serious questions about the use of questionnaires to quantify MPA and VPA in adolescents. There is a clear need in advanced valid assessments of PA in adolescents.

Smallwood, Jonathan; Schooler, Jonathan W.; Turk, David J.; Cunningham, Sheila J.; Burns, Phebe; MacRae, C. Neil (2011):

Self-reflection and the temporal focus of the wandering mind.

In: *Conscious Cogn* 20 (4), S. 1120–1126. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-24616-018&site=ehost-live;jonsmallwood2004@yahoo.com.

Abstract:

Current accounts suggest that self-referential thought serves a pivotal function in the human ability to simulate the future during mind-wandering. Using experience sampling, this hypothesis was tested in two studies that explored the extent to which self-reflection impacts both retrospection and prospection during mind-wandering. Study 1 demonstrated that a brief period of self-reflection yielded a prospective bias during mind-wandering such that participants' engaged more frequently in spontaneous future than past thought. In Study 2, individual differences in the strength of self-referential thought — as indexed by the memorial advantage for self rather than other-encoded items — was shown to vary with future thinking during mind-wandering. Together these results confirm that self-reflection is a core component of future thinking during mind-wandering

and provide novel evidence that a key function of the autobiographical memory system may be to mentally simulate events in the future. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

The effects of perceived discrimination on ambulatory blood pressure and affective responses to interpersonal stress modeled over 24 hours.

In: *Health Psychol* 29 (4), S. 403.

Abstract:

OBJECTIVE:

This research examined the impact of perceived discrimination on ambulatory blood pressure (ABP) and daily level affect during social interaction.

DESIGN:

For 24 hrs, adult Black and White participants wore an ABP monitor and completed palm pilot diary entries about their social interactions.

MAIN OUTCOME MEASURES:

Mean level and time-trend trajectories of blood pressure and heart rate were examined as well as mean level measures of positive and negative affect after stressful and nonstressful social interactions.

RESULTS:

Analyses showed that, after controlling for important covariates, perceived discrimination predicted the slopes of both wake and nocturnal ABP responses, with those who reported more discrimination having steeper daytime trajectories for systolic and diastolic blood pressure and less nighttime dipping in heart rate over time as compared to those who had reported relatively infrequent discrimination. High levels of perceived discrimination were also related to positive and negative affective responses after stressful encounters.

CONCLUSIONS:

These results suggest that, regardless of race, perceived discrimination is related to cardiovascular and affective responses that may increase vulnerability to pathogenic processes.

Keeping secrets from parents: daily variations among poor, urban adolescents.

In: *Journal of Adolescence* 33 (2), S. 321–331. DOI: 10.1016/j.adolescence.2009.04.003.

Abstract:

Daily variations in secrecy with mothers and fathers were examined in 108 poor, urban, diverse middle adolescents (M=15.16 years, SD=0.89). Adolescents completed online diaries over 14 days assessing secrecy from parents about school, personal, and multifaceted activities (e.g., staying out late), and bad behavior. Three-level hierarchical linear models indicated that there were significant daily fluctuations in adolescents' secrecy with mothers and that adolescents kept more secrets from mothers about personal than other activities. Secrecy with mothers also was associated with greater involvement in problem behavior. For both mothers and fathers, secrecy on the current day was associated with greater secrecy on the previous day and with poorer overall relationships (as aggregated across study days) with that parent. Thus, for mothers, secrecy appeared to be associated with both stable factors and daily variations, whereas for fathers, secrecy was associated primarily with stable factors. The results provide a detailed picture of secrecy in diverse adolescents' everyday lives.

Evaluative threat and ambulatory blood pressure: Cardiovascular effects of social stress in daily experience.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0026947.

Abstract:

Objective: Physiological effects of social evaluation are central in models of psychosocial influences on physical health. Experimental manipulations of evaluative threat evoke substantial cardiovascular and neuroendocrine responses in laboratory studies, but only preliminary evidence is available regarding naturally occurring evaluative threats in daily life. In such nonexperimental ambulatory studies, it is essential to distinguish effects of evaluative threat from related constructs known to alter stress, such as ability perceptions and concerns about appearance. Methods: 94 married, working couples (mean age 29.2 years) completed a 1-day (8 a.m. to 10 p.m.) ambulatory blood pressure protocol with random interval-contingent measurements using a Suntech monitor and Palm Pilot-based measures of control variables and momentary experiences of social-evaluative threat, concerns about appearance, and perceived ability. Results: In hierarchical analyses for couples and multiple measurement occasions (Proc Mixed; SAS) and controlling individual differences (BMI, age, income) and potential confounds (e.g., posture, activity), higher reports of social-evaluative threat were associated with higher concurrent systolic (estimate = .87, SE = .34) and diastolic blood pressure (estimate = 1.06; SE = .26), both $p < .02$. Effects of social-evaluative threat remained significant when perceived ability and appearance concerns were controlled. Conclusions: Naturally occurring social-evaluative threat during daily activity is associated with increased systolic and diastolic blood pressure. Given associations between ambulatory blood pressure and risk of cardiovascular disease, the findings support conceptual models of threats to the social self as a potentially important influence on physical health. Mispredictions and misrecollections: challenges for subjective outcome measurement.

In: *Disability and rehabilitation* 30 (6), S. 418–424.

Abstract:

PURPOSE:

To review research from the behavioral sciences that demonstrates how predictions of future events--and memories of past events--are often systematically biased.

METHOD:

Description of how these biases present challenges for subjective outcome measurement in rehabilitation settings, and for measuring health utility.

RESULTS:

Two new techniques for outcome measurement that have been specifically designed to resist these biases Ecological Momentary Assessment and the Day Reconstruction Method are successful.

CONCLUSION:

We propose that these techniques could be adopted for measuring rehabilitation outcomes.

Acoustic cough—reflux associations in chronic cough: potential triggers and mechanisms.

In: *Gastroenterology* 139 (3), S. 754–762.

Abstract:

Background & Aims

Central sensitization is thought to play a role in chronic cough and might explain the temporal association between cough and gastroesophageal reflux (GOR) in patients in whom non-GOR causes have been excluded. Using our novel simultaneous acoustic cough recording and impedance/pH monitoring technique, we aimed to explore this further by assessing such temporal associations and their relationship to the acidity, duration, and proximal extent of reflux and the presence of erosive disease and cough reflex sensitivity in unselected patients (ie, including non-GOR causes) with chronic cough.

Methods

Twenty-four hour ambulatory acoustic cough monitoring with simultaneous impedance/pH recording was carried out in 71 unselected patients with chronic cough, aged 51–64 years (47 female). In addition, all patients underwent cough reflex sensitivity testing to citric acid, and 66 patients underwent gastroscopy. Temporal associations between cough and reflux were expressed using the symptom association probability.

Results

Seventy percent of patients exhibited temporal associations, with 48% having a positive symptom association probability (SAPR-C) for cough preceded by reflux (mainly distal), 56% a positive symptom association probability (SAPC-R (2 min)) for reflux preceded by cough, and 32% both. Moreover, SAPR-C positive patients had a more sensitive cough reflex (P = .03) but similar esophageal reflux exposure and erosive disease, together with similar prevalence of extraesophageal causes of cough compared with SAPR-C negative patients. Reflux immediately following cough was rare.

Conclusions

Cough temporally associates with reflux irrespective of proposed diagnoses, may be self-perpetuating in some patients, and is likely to be driven by central processes.

Smith, Meredith Y.; Depue, Judith D.; Rini, Christine (2007):

Computerized Decision-Support Systems for Chronic Pain Management in Primary Care.

In: *Pain Medicine* 8 (s3), S. S155-S166.

Abstract:

Objective. Computerized decision-support systems (CDSSs) can offer clinical guidance, as well as promote doctor–patient collaboration and patient self-care. As such, they have great potential for improving chronic pain management, particularly in the primary care setting, where physicians often lack sufficient pain-specific clinical expertise and communication skills. The objective of this study was to examine the use of CDSSs in chronic pain management, and to review the evidence for their feasibility and effectiveness.

Design. A review of the available literature using search terms associated with computerized decision-support and chronic pain management. Major databases searched included: MEDLINE, CINAHL, PsychINFO, HealthSTAR, EMBASE, Cochrane Library, Computer and Information Systems Abstracts, and Electronics and Communications Abstracts. Descriptive and evaluative studies were included.

Results. Nine studies describing eight CDSSs met study inclusion criteria. With but two exceptions, CDSSs were specific to a pain-related condition(s). All were designed to assist clinicians to manage pain medically. Aside from pain status, input specifications differed markedly. Evaluative studies were exclusively feasibility studies and varied widely in design and level of description. All were nonexperimental; most were methodologically weak. Two primary care studies were reported. Patient and clinician acceptability ratings of CDSSs ranged from moderate to high. Due to insufficient data, definitive conclusions concerning the impact of CDSSs on provider performance and patient outcomes were not possible.

Conclusion. Research on CDSSs in chronic pain management is limited. The effects of CDSSs on provider and patient outcomes remain understudied, and their potential to improve doctor–patient collaboration and self-care largely untested.

Smith, B.; Harms, W. D.; Burres, S.; Korda, H.; Rosen, H.; Davis, J. (2012):

Enhancing behavioral health treatment and crisis management through mobile ecological momentary assessment and SMS messaging.

In: *Health Informatics.J* 18 (4), S. 294–308. DOI: 10.1177/1460458212445349.

Abstract:

Many veterans returning from service in Afghanistan or Iraq suffer from post-traumatic stress disorder or mild traumatic brain injury. Treating these conditions can be challenging because of high rates of relapse and associated memory impairments. We report on a pilot study that assessed the utility of mobile health (mHealth) technologies, including personal digital assistant-based ecological momentary assessment and two-way interactive text (SMS) messaging, for providing treatment feedback to clinicians, encouraging and motivating veterans throughout treatment, and monitoring participants for relapse after treatment discharge. The results of the pilot suggest that mHealth technologies are feasible adjuncts to traditional mental treatment in the veteran population. Additional work is needed to establish the degree of clinical and economic value

Smith, Lindsey P.; Hua, Jenna; Seto, Edmund; Du, Shufa; Zang, Jiajie; Zou, Shurong et al. (2014):

Development and validity of a 3-day smartphone assisted 24-hour recall to assess beverage consumption in a Chinese population: a randomized cross-over study.

In: *Asia Pac J Clin Nutr* 23 (4), S. 678–690. DOI: 10.6133/apjcn.2014.23.4.10.

Abstract:

This paper addresses the need for diet assessment methods that capture the rapidly changing beverage consumption patterns in China. The objective of this study was to develop a 3-day smartphone-assisted 24-hour recall to improve the quantification of beverage intake amongst young Chinese adults (n=110) and validate, in a small subset (n=34), the extent to which the written record and smartphone-assisted recalls adequately estimated total fluid intake, using 24-hour urine samples. The smartphone-assisted method showed improved validity compared with the written record-assisted method, when comparing reported total fluid intake to total urine volume. However, participants reported consuming fewer beverages on the smartphone-assisted method compared with the written record-assisted method, primarily due to decreased consumption of traditional zero-energy beverages (i.e. water, tea) in the smartphone-assisted method. It is unclear why participants reported fewer beverages in the smartphone-assisted method than the written record -assisted method. One possibility is that participants found the smartphone method too cumbersome, and responded by decreasing beverage intake. These results suggest that smartphone-assisted 24-hour recalls perform comparably but do not appear to substantially improve beverage quantification compared with the current written record-based approach. In addition, we piloted a beverage screener to identify consumers of episodically consumed SSBs. As expected, a substantially higher proportion of consumers reported consuming SSBs on the beverage screener compared with either recall type, suggesting that a beverage screener may be useful in characterizing consumption of episodically consumed beverages in China's dynamic food and beverage landscape.

Daily assessment of pain in adults with sickle cell disease.

In: *Ann Intern Med* 148 (2), S. 94–101.

Abstract:

BACKGROUND:

Researchers of sickle cell disease have traditionally used health care utilization as a proxy for pain and underlying vaso-occlusion. However, utilization may not completely reflect the amount of self-reported pain or acute, painful episodes (crises).

OBJECTIVE:

To examine the prevalence of self-reported pain and the relationship among pain, crises, and utilization in adults with sickle cell disease.

DESIGN:

Prospective cohort study.

SETTING:

Academic and community practices in Virginia.

PATIENTS:

232 patients age 16 years or older with sickle cell disease.

MEASUREMENTS:

Patients completed a daily diary for up to 6 months, recording their maximum pain (on a scale of 0 to 9); whether they were in a crisis (crisis day); and whether they used hospital, emergency, or unscheduled ambulatory care for pain on the previous day (utilization day). Summary measures included both simple proportions and adjusted probabilities (for repeated measures within patients) of pain days, crisis days, and utilization days, as well as mean pain intensity.

RESULTS:

Pain (with or without crisis or utilization of care) was reported on 54.5% of 31 017 analyzed patient-days (adjusted probability, 56%). Crises without utilization were reported on 12.7% of days and utilization on only 3.5% (unadjusted). In total, 29.3% of patients reported pain in greater than 95% of diary days, whereas only 14.2% reported pain in 5% or fewer diary days (adjusted). The frequency of home opiate use varied and independently predicted pain, crises, and utilization. Mean pain intensity on crisis days, noncrisis pain days, and total pain days increased as the percentage of pain days increased ($P < 0.001$). Intensity was

significantly higher on utilization days (P < 0.001). However, utilization was not an independent predictor of crisis, after controlling for pain intensity.

LIMITATIONS:

The study was done in a single state. Patients did not always send in their diaries.

CONCLUSION:

Pain in adults with sickle cell disease is the rule rather than the exception and is far more prevalent and severe than previous large-scale studies have portrayed. It is mostly managed at home; therefore, its prevalence is probably underestimated by health care providers, resulting in misclassification, distorted communication, and undertreatment.

Smyth, N.; Clow, A.; Thorn, L.; Hucklebridge, F.; Evans, P. (2013):

Delays of 5-15min between awakening and the start of saliva sampling matter in assessment of the cortisol awakening response.

In: *Psychoneuroendocrinology* (0306-4530 (Linking)). DOI: 10.1016/j.psyneuen.2012.12.013.

Abstract:

Linking psychosocial measures to the cortisol awakening response (CAR) demands accurate saliva sampling times. Monitoring adherence to the saliva sampling protocol requires electronic monitoring of both awakening and sampling times since self-reported times are inaccurate. Delays greater than 15min between awakening and commencement of saliva sampling reduce CAR magnitude. Less delay has been judged tolerable but remains unexplored for different magnitude measures, and for timing of the CAR peak. Study 1: Fifty healthy females (21+/-4 years) were instructed to collect saliva on four days at 0, 15, 30 and 45min post-awakening (samples 1-4). Both self-reported awakening and sampling times were electronically monitored using actigraphy and track caps. Self-reported awakening was later than actigraph estimated awakening (median difference of 4min). Estimates of CAR magnitude were significantly greater on non-adherent days (delay of 5-15min) compared to adherent days (delay<5min). On non-adherent compared to adherent days cortisol on average peaked earlier, at sample 3 rather than at sample 4. Study 2: Accurately timed cortisol values were obtained in an intensive investigation of 10 participants who collected saliva on 2 days every 5min for 30min post-awakening. Cortisol did not significantly increase until 10min post-awakening, suggesting a time lag may be typical between awakening and observation of a cortisol increase. We conclude that moderate delays between awakening and collection of saliva samples previously considered tolerable result in erroneous estimation of CAR magnitude and timing of the peak. These results are attributed to an approximate 10min time lag between awakening and the start of the cortisol rise. The absence of this latent period in calculations leads to overestimation of the CAR magnitude on moderately non-adherent sampling days. These findings, if more universally generalizable, will further theoretical understanding of the physiology of the CAR, but are methodologically challenging for researchers since self-reported awakening times are not accurate enough to override the concerns raised. However accurate electronic measurement of adherence to protocol would enable sampling delays to be taken into account in computing CAR estimates

Health psychology. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 569–584. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-032%26site%3dehost-live.

Abstract:

(from the chapter) There is a long history of the study and practice of mind-body medicine (see Harrington, 2009). Speaking broadly, this area of enquiry attempts to study the interplay of social, behavioral, psychological, and biological factors that influence health (Smyth & Stone, 2003). Such research is conducted at many "levels" and includes basic biological and physiological processes, as well as behavioral, social, psychological, cultural, and other factors. We use the term health psychology, although there are many other cognate disciplines and related nomenclatures (behavioral medicine, medical sociology, psychosomatic medicine, etc.). Our goal in this chapter is to provide an overview of how research methods for studying daily life can be applied within the field of health psychology. We begin with a discussion of the specific advantages and challenges researchers might experience when using these methods in the field. We then provide an overview of the various ways in which daily assessment methods, particularly ecological momentary assessment (EMA), can be and have been used to address research questions in health psychology. Finally we conclude with a discussion of the innovative uses of daily

assessment and intervention methods, particularly as advances in technology continue, as well as some future directions of the field. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Examining the effects of perceived social support on momentary mood and symptom reports in asthma and arthritis patients.

In: *Psychology & Health* 29 (7), S. 813–831. DOI: 10.1037/t29468-000.

Abstract:

Objective: Social support has been linked to beneficial effects on health directly (main effect) and as a buffer to stress. Most research, however, has examined these relationships using global and retrospective assessments of health and stress, which may be subject to recall biases. This study used ambulatory ecological momentary assessment (EMA) methods to test the main and stress-buffering effects of social support on the daily health and well-being of asthma and rheumatoid arthritis (RA) patients.Design: Community volunteers with asthma (n = 97) or RA (n = 31) responded to EMA prompts five times daily for one week.Main outcomes: Baseline perceived social support was obtained, and then, participants reported mood, stress and symptoms using EMA. Multilevel mixed-modeling examined whether social support predicted mood and symptoms directly or via stress-reducing effects.Results: Supporting a main effect, more perceived social support predicted decreased negative mood and stress severity. Supporting a stress-buffering effect, more perceived social support resulted in fewer reported symptoms when stress was present.Conclusion: Results suggest perceived social support directly relates to better ambulatory status and dynamically buffers individuals against the negative effects of stressors, and highlight the importance of studying social support across different temporal and contextual levels. Snell, Carolyn (2012):

A daily phone diary procedure to assess behavioral engagement in the treatment of adolescent anxiety and depressive disorders.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 73 (5-B). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-99220-093%26site%3dehost-live.

Abstract:

Anxiety and depressive disorders are common conditions for adolescents and are associated with significant impairments in functioning. Cognitive behavior therapy (CBT) is an effective treatment modality for these youth, and the behavioral components of CBT protocols, in particular, are thought to be one of the active mechanisms through which positive symptom changes are produced. However, few procedures are available to measure the behavioral changes taking place in adolescents' daily lives as they make therapeutic progress. This study examined adolescents' "behavioral engagement" throughout treatment, a construct defined as time spent in social, athletic and academic activities. Behavioral engagement was measured using the Daily Phone Diary (DPD), a validated measure of daily activities utilized in the child health literature, which employs the principles of

Ecological Momentary Assessment (EMA). Twenty-four adolescents reported each activity they engaged in throughout the day, in chronological order, over the past 24 hours. Participants were diverse in their ages, ethnicities, socioeconomic statuses and internalizing disorder diagnoses. Activities were reported during phone calls scheduled before, during, and after treatment using a transdiagnostic formulation of CBT and, for a randomized subset of the sample (N=8), both before and following a Waitlist comparison condition. Results indicated that "behavioral engagement" is a construct that is measurable and that daily phone diaries are an acceptable method of data collection for this population. Based on theoretical and empirical literature, three key categories of activities on the DPD comprised behavioral engagement: (1) Time spent socially engaged with others; (2) Time spent on any physical or athletic activity; and (3) Time doing homework. Results supported good inter-rater reliability and potentially reasonable test-retest reliability; data collection via the DPD was feasible and acceptable in this context. Tests of convergent validity with other measures of anxiety and depressive symptoms suggested that prior to treatment, more time spent in some activity categories was associated with more internalizing symptoms for those with anxiety disorders only, but fewer internalizing symptoms for those with depression as well as anxiety. Tests of convergent validity with other measures of weekly mood were promising. Future studies will explore alternate definitions of behavioral engagement, examine this construct in a larger sample that has completed a full course of CBT, and explore this construct's potential role as a mediator of clinical improvement. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

Snir, Raphael; Zohar, Dov (2008):

Workaholism as Discretionary Time Investment at Work: An Experience-Sampling Study.

In: *Applied Psychology* 57 (1), S. 109–127.

Abstract:

Adopting an operational definition of workaholism as discretionary investment of considerable time at work, the purpose of the present study was to test hypotheses regarding the cognitive aspect of workaholism, as well as the positive and negative/addictive views of this construct. The study employed an experience-sampling method (ESM), using a sample of 65 full-time employees who completed the ESM forms at four random times during the day for one week. Results indicated that workaholism was associated with continued cognitive engagement with work, accompanied by a preference for work over leisure activity and higher positive affect during work activity than during leisure activity. No significant differences were found between workaholics and non-workaholics with regard to the likelihood of performing work-related activities during leisure activity, or in the levels of physical discomfort and negative affect during the weekend. These results highlight the utility of an operational framework for studying the variety of workaholism correlates. Theoretical and applied implications are discussed.

A partir d'une définition opérationnelle de l'addiction au travail comme étant un investissement sans contrôle d'un temps considérable consacré au travail, cette recherche s'est donné comme objectif de mettre à l'épreuve des hypothèses relatives à la dimension cognitive de l'addiction au travail, ainsi que les aspects positifs et négatifs (addictifs) de ce concept. Cette recherche a exploité la méthode de l'échantillonnage des expériences (ESM) à partir d'un échantillon composé de 65 salariés à plein-temps qui ont rempli la feuille de recueil des données quatre fois par jour au hasard pendant une semaine. Les résultats ont montré que l'addiction au travail était liée à un engagement cognitif permanent vis-à-vis du travail, associéà une plus forte attirance pour le travail que pour les loisirs et à un état affectif plus fortement positif lors du travail qu'à l'occasion des activités de loisirs. On n'a pas trouvé de différences significatives entre les drogués du travail et les autres en ce qui concerne la probabilité de réaliser des activités relevant du travail pendant les loisirs, ou dans le niveau d'inconfort physique et le poids des affects négatifs pendant le week-end. Ces résultats montrent l'utilité d'un schéma opérationnel dans l'étude de la diversité des phénomènes reliés à l'addiction au travail. Les implications théoriques et pratiques sont examinées.

Snook, Erin M.; Motl, Robert W.; Gliottoni, Rachael C. (2009):

The effect of walking mobility on the measurement of physical activity using accelerometry in multiple sclerosis.

In: *Clinical Rehabilitation* 23 (3), S. 248–258.

Abstract:

Objective: To examine whether accelerometry provides a measure of physical activity, walking ability or both in a sample of individuals with multiple sclerosis. The secondary purpose was to examine the validity of physical activity measures in people with multiple sclerosis who have ambulatory impairments.

Participants: Forty-two individuals with multiple sclerosis without ambulatory impairment (Expanded Disability Status Scale (EDSS) score ≤ 4.5) and 32 individuals with multiple sclerosis with ambulatory impairment (EDSS ≥5.0).

Method: Participants completed the Multiple Sclerosis Walking Scale-12 and Performance Scales, wore an accelerometer for seven days, and completed the Godin Leisure-Time Exercise Questionnaire and short-form of the International Physical Activity Questionnaire.

Results: There were significant differences between groups on scores from the five measures. There were large correlations between the accelerometer counts with scores from both the self-report measures of physical activity and the self-report measures of walking mobility in the overall sample. There were large correlations between scores from both measures of physical activity in the overall sample and the subsample with ambulatory impairment.

Conclusion: Our data suggest that accelerometers are measuring both physical activity and walking mobility in individuals with multiple sclerosis, whereas self-report measures are measuring physical activity in individuals with multiple sclerosis, including those with ambulatory impairment.

Detecting improvements in acute psychotic symptoms using experience sampling methodology.

In: *Psychiatry Res*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-24916-001%26site%3dehost-live.

Abstract:

This study aimed to explore the feasibility and validity of using experience sampling methodology (ESM, or ecological momentary assessment or mobile device signaling) to measure temporal changes and fluctuations in psychotic symptoms in patients with acute psychosis at the start of antipsychotic treatment. Twenty-six in-patients with delusions were assessed within 2 weeks of starting antipsychotic treatment using ESM on a personal digital assistant (PDA), seven times a day for 14 consecutive days. They were also interviewed at baseline, 1 week and 2 weeks after using standardized symptom measures. Sixteen patients (61.5%) completed at least one-third of the entries, with a compliance rate of 70.7%. Responses to the ESM items were internally consistent. At baseline, ESM and clinical ratings converged on suspiciousness and images, but not on voices and most of the delusion dimensions. Conducting ESM with patients in an acute episode was found to be feasible and internally valid. There is some divergence in symptom data obtained by ESM and standard symptom interviews, but ESM captures rich information about change that may not be represented by observer ratings. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Changes in delusions in the early phase of antipsychotic treatment - An experience sampling study.

In: *Psychiatry Res* 215 (3), S. 568–573. DOI: 10.1016/j.psychres.2013.12.033.

Abstract:

It has been suggested that different aspects of delusions (conviction, distress, preoccupation) respond to treatment at different rates, and that the cognitive bias of 'Jumping to Conclusions' (JTC) may predict treatment outcome. This study investigates changes in delusion dimensions using Experience Sampling Methodology (ESM) and the role of JTC as a predictor of change during the initial 2 weeks of antipsychotic treatment on admission to hospital. Sixteen acute patients with delusions were assessed seven times per day for 14 days using computerised ESM. ESM assessed moment-by-moment experiences of affect, psychotic symptoms, and delusion dimensions. Clinical ratings were completed at baseline, 1 week and 2 weeks later. The 'beads' task was used to measure JTC at baseline. Delusion dimensions improved over the two weeks of antipsychotic treatment and admission to hospital. Different delusional dimensions changed at different rates, with distress and disruption being more responsive than conviction and preoccupation on both PSYRATS and ESM ratings. Eight out of 16 participants showed a JTC bias on the beads task at baseline. Exploratory analyses showed that JTC predicted changes in the ESM ratings of delusion conviction and distress, suggesting that reasoning biases may predict treatment response.

Vigorous physical activity and vagal modulation in young adults.

In: *European journal of cardiovascular prevention and rehabilitation : official journal of the European Society of Cardiology, Working Groups on Epidemiology & Prevention and Cardiac Rehabilitation and Exercise Physiology* 16 (6), S. 705–711. DOI: 10.1097/HJR.0b013e3283316cd1.

Abstract:

BACKGROUND\r\nAerobic exercise leads to reduced sympathetic and increased cardiac vagal modulation, providing an antiarrhythmic effect. The optimal exercise intensity to promote this adaptation remains undefined. The aims of the present investigation were twofold. First, to examine differences in heart rate variability (HRV) measures in participants with different levels of objectively measured physical activity (PA). Second, to identify the characteristic of PA which most influences the cardiac autonomic nervous system (cANS) function in young adults.\r\nMETHODS\r\nCross-sectional evaluation of 84 adults examining relationships between PA amount and intensities, measured by accelerometry, cANS function derived from HRV. Groups were created based on tertiles of PA and analysis of covariance was used to assess between-group differences in HRV. Stepwise regression analysis was used to determine the characteristic of PA, which best predicted vagal HRV indices.\r\nRESULTS\r\nThere were significantly higher levels of vagal HRV indices in the most active group compared with the least active group. Regression analysis revealed that the number of bouts of vigorous PA undertaken was the best predictor of the vagal HRV indices assessed.\r\nCONCLUSION\r\nThis study suggests that vagal modulation is enhanced with high levels of PA and that it is the number of bouts of vigorous PA that is most closely associated with cANS function.

Factors Predicting Compliance to Ecological Momentary Assessment Among Adolescent Smokers.

In: *Nicotine.Tob.Res.* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt154.

Abstract:

INTRODUCTION: Ecological momentary assessments (EMAs) are increasingly used in smoking research to understand contextual and individual differences related to smoking and changes in smoking. To date, there has been little detailed research into the predictors of EMA compliance. However, patterns or predictors of compliance may affect key relationships under investigation and introduce sources of bias in results. The purpose of this study was to investigate predictors of compliance to random prompts among a sample of adolescents who had ever smoked. METHODS: Data for this study were drawn from a sample of 461 adolescents (9th and 10th graders at baseline) participating in a longitudinal study of smoking escalation. We examined 2 outcomes: subject-level EMA compliance (overall rate of compliance over a week-long EMA wave) and in-the-moment prompt-level compliance to the most proximal random prompt. We investigated several covariates including gender, race, smoking rate, alcohol use, psychological symptomatology, home composition, mood, social context, time in study, inter-prompt interval, and location. RESULTS: At the overall subject level, higher mean negative affect, smoking rate, alcohol use, and male gender predicted lower compliance with random EMA prompts. At the prompt level, after controlling for significant subject-level predictors of compliance, increased positive affect, being outside of the home, and longer inter-prompt interval predicted lower momentary compliance. CONCLUSIONS: This study identifies several factors associated with overall and momentary EMA compliance among a sample of adolescents participating in a longitudinal study of smoking. We also propose a conceptual framework for investigating the contextual and momentary predictors of compliance within EMA studies

Clinical assessment of affective instability: comparing EMA indices, questionnaire reports, and retrospective recall.

In: *Psychological Assessment* 21 (3), S. 425–436. DOI: 10.1037/a0016869.

Abstract:

Traditional self-report measures of psychopathology may be influenced by a variety of recall biases. Ecological momentary assessment (EMA) reduces these biases by assessing individuals' experiences as they occur in their natural environments. This study examines the discrepancy between trait questionnaire, retrospective report, and EMA measures of affective instability in psychiatric outpatients either with a borderline personality diagnosis (n = 58) or with a current episode of major depressive disorder or dysthymia (n = 42). The authors examined the agreement of 3 trait measures of affective instability-the Affective Instability subscale of the Personality Assessment Inventory-Borderline Features scale (L. C. Morey, 1991), the Affect Intensity Measure (R. J. Larsen, E. Diener, & R. Emmons, 1986), and the Affect Lability Scales (P. D. Harvey, B. R. Greenberg, & M. R. Serper, 1989)-and 1 retrospective mood recall task with EMA indices of mood and mood instability. Results indicate only modest to moderate agreement between momentary and questionnaire assessments of trait affective instability; agreement between recalled mood changes and EMA indices was poor. Implications for clinical research and practice and possible applications of EMA methodology are discussed.

Translating technology into patient care: Smartphone applications in pediatric health care.

In: *Med J Armed Forces India* 69 (2), S. 156–161. DOI: 10.1016/j.mjafi.2013.03.003.

Abstract:

The latest generations of smartphones are increasingly viewed as handheld computers rather than as phones and the applications on these phones are becoming increasingly popular among the medical professionals. A large number of health care applications are available across various smartphone platforms. At times it may be difficult to identify most appropriate and reliable application for use at the point of care. In this review, we have tried to identify the applications relevant to Pediatrics and Childcare which when used at the point of care might be helpful in improving patient care.

Unraveling the daily stress crossover between unemployed individuals and their employed spouses.

In: *J Appl Psychol* 96 (1), S. 151.

Abstract:

This study examined the dynamic relationship of distress levels between spouses when one is unemployed (and looking for a job) while the other is engaged in full-time employment. Using the diary survey method, we sampled 100 couples in China for 10 days and tested a model comprising three stress crossover mechanisms: the direct crossover, the mediating crossover, and the common stressor mechanisms. Results supported the direct crossover and common stressor mechanisms. Other stressors (e.g., work–family conflict and negative job search experience) were also related to distress of the unemployed individuals and their employed spouses. Additionally, we found a three-way interaction involving gender, marital satisfaction, and distress levels of

employed spouses. We discuss how the study contributes to the unemployment and stress crossover literatures. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Measuring time use in surveys - Concordance of survey and experience sampling measures.

In: *Soc.Sci.Res* 41 (5), S. 1037–1052. DOI: 10.1016/j.ssresearch.2012.03.013.

Abstract:

It is still unclear to what extent time allocation retrospectively reported in questionnaires reflects people's actual behavior. Addressing this research gap, we analyze the congruence of time use information assessed through retrospective questionnaires and through experience sampling methodology. Participants completed standard survey questions on time allocation. In addition, a mobile-phone-based experience sampling technology obtained snapshots of, on average, 54 momentary activities in which respondents participated while pursuing their normal daily routines. Results indicate that the associations between standard survey questions and experience sampling methods are quite substantial for long-lasting and externally structured activities, such as paid work. In contrast, associations between survey and experience sampling methods are somewhat weaker for less externally structured, short-term and infrequent activities, such as errands, housework, and leisure. However, further research is required to elucidate which method (experience sampling method or survey questions) results in more reliable and valid measures for short-term and sporadic activities

Electronic diary evidence on energy erosion in clinical burnout.

In: *Journal of Occupational Health Psychology* 12 (4), S. 402.

Abstract:

Burnout is generally defined as a state of severe exhaustion. So far, research has predominantly focused on relatively mild burnout in employees able to work despite their complaints. This study examines energy depletion in clinical burnout (e.g., the severest cases on extended sick leave) by comparing the diurnal patterns of fatigue and exhaustion with those of healthy individuals. Sixty clinically burned-out and 40 healthy participants kept an electronic diary for 14 days, 7 times a day, yielding a total of 8,116 diary entries. This study shows that burned-out individuals typically suffer continuously from a severe fatigue throughout the day. The resulting flattened diurnal cycles mark a stable exhaustion that is uncommon in healthy persons. The current results provide novel support for the existence of severe energy erosion in clinical burnout. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Sonnenschein, Mieke; Sorbi, Marjolijn J.; van Doornen, Lorenz Jp; Schaufeli, Wilmar B.; Maas, Cora J. M. (2007):

Evidence that impaired sleep recovery may complicate burnout improvement independently of depressive mood in clinical burnout.

In: *Sick with burnout*, S. 63.

Abstract:

Objective

This article examines recovery through sleep in relation to sleep quality, exhaustion, and depression in clinical burnout. We focus on actual recovery per night, given its relevance to burnout improvement.

Methods

Sixty clinically burned-out participants and 40 healthy controls recorded symptoms with an electronic diary for 2 weeks at random times per day. Recovery through sleep was defined as the difference in fatigue between late evening and the next morning.

Results

In clinical burnout, sleep quality and recovery are impaired, and depression is elevated. Poor recovery through sleep is associated with poor same-night sleep quality, clarifying the mechanisms underlying poor recovery. Individual differences in

recovery though sleep were related to differences in refreshed awakening, but not to other sleep problems. Impaired recovery was also related to severity of exhaustion, but not to severity of depressive mood, indicating that, in burnout, nonprofit from sleep is a symptom of energy depletion, not a sign of depression.

Conclusion

Impaired recovery through sleep may hamper recovery from burnout independently of the influence of depression.

Sonnentag, Sabine; Jelden, Stefanie (2009):

Job stressors and the pursuit of sport activities: a day-level perspective.

In: *Journal of Occupational Health Psychology* 14 (2), S. 165–181. DOI: 10.1037/a0014953.

Abstract:

This article addresses the relation between day-specific experiences of job stressors and the pursuit of off-job activities. Following the limited-resources model of self-regulation, the authors proposed that job stressors and long working hours are negatively related to pursuit of sport activities after work because, after stressful days, employees have no resources left for initiating and persisting in effortful behaviors such as sport. Routines for off-job activities were hypothesized to be positively related to the pursuit of sport activities after work. Seventy-eight police employees completed a daily survey over 5 working days and indicated that they perceive sport to be highly useful for recovery. Random coefficient modeling showed that job stressors (particularly situational constraints) encountered on a specific day were negatively related to self-regulatory resources and to the amount of time spent on sport activities after work, whereas the relation with low-effort activities was positive. Thus, after a stressful day when an effective recovery activity such as sport is highly needed, persons tend to engage less in such an activity.

Uncertainty Orientation and Affective Experiences Individual Differences Within and Across Cultures.

In: *Journal of Cross-Cultural Psychology* 39 (2), S. 129–146.

Abstract:

This study examined whether people with the same self-regulatory style of coping with uncertainty differed in their affective experiences as a function of what may be the dominant coping style of their culture. Two hundred twenty men and women from universities in Japan and Canada described the extent to which they experienced various emotions. Consistent with their expectations, the authors found that participants whose uncertainty orientation matched that of their country (i.e., uncertainty-oriented students in Canada, certainty-oriented students in Japan) experienced more active emotions than mismatched participants (i.e., certainty-oriented students in Canada, uncertainty-oriented students in Japan), who experienced more passive emotions. Moreover, those who matched their country's coping style also reported experiencing more positive and fewer negative emotions than mismatched students. These results suggest that the theory of uncertainty orientation has important implications for research on affective experiences within and across cultures.

Sosnoff, Jacob J.; Goldman, Myla D.; Motl, Robert W. (2010):

Real-life walking impairment in multiple sclerosis: preliminary comparison of four methods for processing accelerometry data.

In: *Multiple Sclerosis*.

Abstract:

This study further validates accelerometers as a measure of walking impairment in persons with multiple sclerosis. We examined total movement counts and three novel methods of processing accelerometer data (i.e. standard deviation, approximate entropy and detrended fluctuation analysis) for quantifying real-life walking impairment in this population. A total of 70 individuals with a definite diagnosis of multiple sclerosis completed a battery of patient-rated measures of walking impairment and then wore an ActiGraph accelerometer for 7 days. The data were analyzed using multivariate analysis of variance and bivariate correlation analysis. The results indicated that total daily movement counts and standard deviation of daily movement counts differed between groups of persons with mild, moderate, and severe self-reported disability status and who were independently

ambulatory or ambulatory with assistance. Those two metrics for the accelerometer data further demonstrated strong correlations with patient-rated measures of walking impairment. By comparison, there were smaller and often non-significant differences in approximate entropy and detrended fluctuation analysis metrics for the accelerometer data as a function of disability and ambulatory status, and only moderate correlations with patient-rated measures of walking impairment. The results confirm that the metric of total daily movement counts correlates with level of disability, ambulatory status, and patient reports of walking impairment in persons with multiple sclerosis. We further demonstrate that variability, indexed by the standard deviation of daily movement counts, correlates with multiple sclerosis-related disability, ambulatory status, and self-reported walking impairment. Such results provide preliminary evidence that variability in accelerometer counts is not simply noise and may provide important information about multiple sclerosis-related walking impairment.

Sotgiu, I.; Rusconi, M. L. (2013):

Investigating emotions in Parkinson's disease: what we know and what we still don't know.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 336. DOI: 10.3389/fpsyg.2013.00336.

Abstract:

Over the last decade, there has been an increasing attention to the role played by emotional processes in Parkinson's disease (PD). However, most of what is known in this area is based on research conducted in laboratory or clinical settings. In this article, the authors underline the need to expand our current knowledge of the psychological correlates of PD by investigating patients' everyday emotions in natural contexts. Specifically, the authors illustrate new research avenues based on the implementation of experience sampling methods. It is argued that these methods could permit future researchers to ecologically assess the frequency and intensity with which parkinsonian patients experience specific emotions (either negative or positive) during their everyday life, providing at the same time precious information on what are the most typical situations in which these emotions occur and on how patients behave in these circumstances. Potential practical implications associated with investigating these issues are discussed

Psychometric properties of the 7-day physical activity recall questionnaire in individuals with severe mental illness.

In: *Archives of psychiatric nursing* 21 (6), S. 309–316.

Abstract:

Few self-report measures of physical activity have been validated in individuals with severe mental illness. The purpose of this study was to examine the validity and reliability of a 7-day recall measure (7DR: [Blair, S. N. (1984). How to assess exercise habits and physical fitness. In J. D. Matarazzo, N. E. Miller, & S. M. Weiss, (Eds.), Behavioural health: A handbook of health enhancement and disease prevention (pp. 424-447). New York: Wiley.]) through comparison with RT3 triaxial accelerometry data. Fourteen individuals took part in the study. Validity was considered by Kendall's tau correlation and (Bland, J. M., & Altman, D. G. (1986). Statistical-methods for assessing agreement between 2 methods of clinical measurement. Lancet, 1(8476), 307-310) limits of agreement and test-retest reliability was measured by ICC. The only significant correlation between measures was total energy expenditure (tau = 0.43). The 7-DR over reported moderate physical activity by 16.9 +/- 52.3 min/day, but under reported vigorous physical activity by -10.4 +/- 24.3 min/day. Test retest ICC was significant for all outcome measures. Overall, the 7-DR was reliable but exhibited questionable validity. The use of self-report questionnaires such as the 7-DR may inaccurately estimate the levels of physical activity in this population, and may not be sensitive to monitoring intervention-related changes in physical activity.

South, Susan C.; Miller, Michelle L. (2013):

Measuring momentary stress, affect, and cognition: Relationships with the internalizing and externalizing spectra.

In: *Journal of Psychopathology and Behavioral Assessment*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-25831-001%26site%3dehost-live;ssouth@purdue.edu.

Abstract:

The Internalizing (INT) and Externalizing (EXT) spectra are an emerging way to conceptualize the structure of psychopathology. Demonstrating relationships with emotional reactions to, and cognitive appraisals of, daily stressful events would be strong evidence of ecological validity. In the current study (N = 78), the experience sampling method (ESM, a structured diary technique with Palm Pilots) was used to capture affect and cognition related to current stressor, five times per day, for 1 week. Multilevel random coefficient modeling was used to examine affective and cognitive reactivity to daily stressors as a function of baseline levels of INT and EXT. INT scores were related to higher levels of negative affect (NA), lower levels of positive affect (PA) and more negative cognitive appraisals of the stressful situation. Several cross-level interactions were found between psychopathology scores, cognitive appraisals, and affect. Participants higher in INT psychopathology showed less decrease in NA as level of control increased, compared to participants low in INT. EXT moderated the association between NA and distress, with higher levels of EXT resulting in a stronger association between distress and NA. INT and EXT also moderated the relationships between the cognitive variables (distress and control, coping and control). Findings support both the utility and validity of the INT and EXT dimensions in understanding different forms of stress-related impairment in emotion and cognition. Soylu, Ahmet; Duzenli, Mehmet Akif; Yazici, Mehmet; Ozdemir, Kurtulus; Tokac, Mehmet; Gok, Hasan (2009):

The effect of nondipping blood pressure patterns on cardiac structural changes and left ventricular diastolic functions in normotensives.

In: *Echocardiography (Mount Kisco, N.Y.)* 26 (4), S. 378–387. DOI: 10.1111/j.1540-8175.2008.00821.x.

Abstract:

BACKGROUND\r\nCardiac structural changes have been reported to be more prominent in nondipper normotensives than the dipper ones. But the influence of nondipping status on cardiac diastolic functions of normotensives has not been studied yet. In this study, we investigated the effect of nondipping status on both cardiac structural changes and left ventricular (LV) diastolic functions in normotensives.\r\nMETHODS\r\nWe performed ambulatory blood pressure (BP) monitoring (ABPM) and echocardiography in 62 normotensive subjects with the following criteria: (1) office BP < 140/90 mmHg; (2) average 24-hour ambulatory BP < 130/80 mmHg.\r\nRESULTS\r\nIn the evaluation by tissue Doppler imaging (TDI), the early diastolic myocardial peak velocity (Em) and Em/late diastolic myocardial peak velocity (Am) ratio (Em/Am ratio) were lower in nondippers than those in dippers (P = 0.009 and P < 0.001, respectively). Isovolumic relaxation time (IRT) and myocardial performance index (MPI) were higher in nondippers than those in dippers (P = 0.036 and P = 0.026, respectively). Nondipping status, independent of other factors, was observed to cause both a decrease in the Em and Em/Am ratio and an increase in IRT. However, its effect on IRT was not statistically significant (coefficient =-0.27, P = 0.027; coefficient =-0.37, P = 0.002; coefficient = 0.20, P = 0.082, respectively).\r\nCONCLUSIONS\r\nNondipping of nocturnal BP seems to be a determinant of cardiac remodeling and LV diastolic dysfunction (LVDD) and may result in a cardiovascular (CV) risk independent of the increase in LV mass (LVM) in normotensives.

Spain, Rebecca I.; Mancini, Martina; Horak, Fay B.; Bourdette, Dennis (2014):

Body-worn sensors capture variability, but not decline, of gait and balance measures in multiple sclerosis over 18 months.

In: *Gait Posture* 39 (3), S. 958–964. DOI: 10.1016/j.gaitpost.2013.12.010.

Abstract:

Gait and balance deficits are a frequent complaint in MS but poorly captured by stopwatch-timed tests or rating scales. Body-worn accelerometers and gyroscopes are able to detect gait and balance abnormalities in people with MS who have normal walking speeds. Few longitudinal studies exist using this technology to study the evolution of mobility deficits. The purpose of this study was to determine if body-worn sensors detected any decline in gait and balance measures in people with MS over time. Twenty-seven people with MS (13 mildly disabled, self-rated expanded disability status scale 0-3.5; 14 moderately disabled, SR-EDSS 4.0-5.5) who had normal walking speeds and 18 matched control subjects underwent gait and balance testing using body-worn sensors every 6 months for 18 months. While no parameter worsened over time, the moderately disabled MS cohort performed more poorly than the mildly disabled MS cohort who, in turn, was worse than control subjects for both objective and subjective walking and balance measures. Furthermore, the moderately disabled MS cohort demonstrated greater variation in between-visit performance than did the less disabled MS cohort or controls (Bonferroni-corrected $p<0.05$). Variability may be a key indicator of worsening gait and balance disability in MS.

Sparacino, Giovanni; Zanderigo, Francesca; Corazza, Stefano; Maran, Alberto; Facchinetti, Andrea; Cobelli, Claudio (2007):

Glucose concentration can be predicted ahead in time from continuous glucose monitoring sensor time-series.

In: *Biomedical Engineering, IEEE Transactions on* 54 (5), S. 931–937.

Abstract:

A clinically important task in diabetes management is the prevention of hypo/hyperglycemic events. In this proof-of-concept paper, we assess the feasibility of approaching the problem with continuous glucose monitoring (CGM) devices. In particular, we study the possibility to predict ahead in time glucose levels by exploiting their recent history monitored every 3 min by a minimally invasive CGM system, the Glucoday, in 28 type 1 diabetic volunteers for 48 h. Simple prediction strategies, based on the description of past glucose data by either a first-order polynomial or a first-order autoregressive (AR) model, both with time-varying parameters determined by weighted least squares, are considered. Results demonstrate that, even by using these simple methods, glucose can be predicted ahead in time, e.g., with a prediction horizon of 30 min crossing of the hypoglycemic threshold can be predicted 20-25 min ahead in time, a sufficient margin to mitigate the event by sugar ingestion.

Spicer, J.; Werner, E.; Zhao, Y.; Choi, C. W.; Lopez-Pintado, S.; Feng, T. et al. (2013):

Ambulatory assessments of psychological and peripheral stress-markers predict birth outcomes in teen pregnancy.

In: *J.Psychosom.Res.* 75 (4), S. 305–313. DOI: 10.1016/j.jpsychores.2013.07.001.

Abstract:

OBJECTIVE: Pregnant adolescents have high rates of poor birth outcomes, but the causes are unclear. We present a prospective, longitudinal study of pregnant adolescents assessing associations between maternal psychobiological stress indices and offspring gestational age at birth and birthweight. METHOD: Healthy nulliparous pregnant adolescents were recruited (n=205) and followed during pregnancy. Ambulatory assessments over 24h of perceived psychological stress (collected every 30 min) and salivary cortisol (6 samples) and a summary questionnaire, the Perceived Stress Scale, were collected at three time points (13-16, 24-27, and 34-37 gestational weeks). Corticotropin-releasing hormone, C-reactive protein, and interleukin 6 were assayed from blood taken at the latter 2 sessions. A final sample of 119 participants was selected for analyses. RESULTS: The ambulatory assessment of perceived psychological stress was positively correlated with the Perceived Stress Scale (r=.20, p=.03) but neither was associated with any of the biological assays (all ps>.20). Based on backward selection regression models that included all stress variables and relevant covariates, the ambulatory assessments of perceived psychological stress and cortisol - though not the Perceived Stress Scale - were negatively associated with gestational age at birth (F(4, 107)=3.38, p=.01) while cortisol was negatively related to birthweight (F(5, 107)=14.83, p<.0001). CONCLUSIONS: Targeted interventions to reduce psychological and biological indicators of heightened stress during pregnancy may have positive public health benefits for the offspring given the associations of shortened gestation and lower birthweight with risk for poor mental and physical health outcomes

Spinelli, Alessio; Da Ros, Valerio; Morosetti, Daniele; D'Onofrio, Silvia; Rovella, Valentina; Di Daniele, Nicola; Simonetti, Giovanni (2013):

Technical aspects of renal denervation in end-stage renal disease patients with challenging anatomy.

In: *Diagn Interv Radiol. DOI:* 10.5152/dir.2013.13408.

Abstract:

We describe our preliminary experience with percutaneous renal denervation in end-stage renal disease patients with resistant hypertension and challenging anatomy, in terms of the feasibility, safety, and efficacy of this procedure. Four patients with end-stage renal disease patients with resistant hypertension (mean hemodialysis time, 2.3 years) who had been taking at least four antihypertensive medications underwent percutaneous renal denervation. Renal artery eligibility included the absence of prior renal artery interventions, vessel stenosis <70%, or extended calcifications (more than 30% of the vessel circumference). No cut-off values of vessel diameter were used. All patients were successfully treated with no intra- or postprocedural complications, and all showed 24-hour ambulatory blood pressure reduction at the 12-month follow-up. Percutaneous renal denervation is a feasible approach for end-stage renal disease patients with resistant hypertension with encouraging short-term preliminary results in terms of procedural efficacy and safety.

Spivey, Robin J.; Bishop, Charles M. (2014):

An implantable instrument for studying the long-term flight biology of migratory birds.

In: *Rev Sci Instrum* 85 (1), S. 14301. DOI: 10.1063/1.4854635.

Abstract:

The design of an instrument deployed in a project studying the high altitude Himalayan migrations of bar-headed geese (Anser indicus) is described. The electronics of this archival datalogger measured 22 x 14 x 6.5 mm, weighed 3 g, was powered by a (1/2)AA-sized battery weighing 10 g and housed in a transparent biocompatible tube sealed with titanium electrodes for electrocardiography (ECG). The combined weight of 32 g represented less than 2% of the typical bodyweight of the geese. The primary tasks of the instrument were to continuously record a digitised ECG signal for heart-rate determination and store 12-bit triaxial accelerations sampled at 100 Hz with 15% coverage over each 2 min period. Measurement of atmospheric pressure provided an indication of altitude and rate of ascent or descent during flight. Geomagnetic field readings allowed for latitude estimation. These parameters were logged twice per minute along with body temperature. Data were stored to a memory card of 8 GB capacity. Instruments were implanted in geese captured on Mongolian lakes during the breeding season when the birds are temporarily flightless due to moulting. The goal was to collect data over a ten month period, covering both southward and northward migrations. This imposed extreme constraints on the design's power consumption. Raw ECG can be post-processed to obtain heart-rate, allowing improved rejection of signal interference due to strenuous activity of locomotory muscles during flight. Accelerometry can be used to monitor wing-beat frequency and body kinematics, and since the geese continued to flap their wings continuously even during rather steep descents, act as a proxy for biomechanical power. The instrument enables detailed investigation of the challenges faced by the geese during these arduous migrations which typically involve flying at extreme altitudes through cold, low density air where oxygen availability is significantly reduced compared to sea level.

Spook, J. E.; Paulussen, T.; Kok, G.; Van, Empelen P. (2013):

Monitoring dietary intake and physical activity electronically: feasibility, usability, and ecological validity of a mobile-based ecological momentary assessment tool.

In: *J Med Internet Res* 15 (9), S. e214. DOI: 10.2196/jmir.2617.

Abstract:

BACKGROUND: Despite the growing body of research on complex lifestyle behaviors (eg, Dietary Intake [DI] and Physical Activity [PA]), monitoring of these behaviors has been hampered by a lack of suitable methods. A possible solution to this deficiency is mobile-based Ecological Momentary Assessment (mEMA), which enables researchers to collect data on participants' states in real-time by means of a smartphone application. However, feasibility, usability, and ecological validity need to be anticipated and managed in order to enhance the validity of mEMA. OBJECTIVE: To examine the feasibility, usability, and ecological validity of a mEMA application (app) with regard to DI and PA among Dutch vocational education students. METHODS: The students (n=30) participated in the mEMA study for seven consecutive days. They downloaded the mEMA app on their smartphone. Feasibility and usability of the mEMA app were evaluated by completing an online evaluation after seven days of participation. Ecological validity was measured by assessing the degree to which the content of the mEMA app approximated the real-world setting that was being examined, through several multiple-choice questions. RESULTS: Compliance rates, as registered by the mEMA app, declined 46% over a seven-day period, while self-reported compliance, as measured with an online evaluation questionnaire afterwards, indicated a smaller decrease in compliance (29%). The students evaluated the mEMA app as feasible and usable. Ecological validity analyses showed that all DI and almost all PA multiple-choice options were covered with the compound response categories. CONCLUSIONS: The mEMA app offers the opportunity to assess complex health behaviors (eg, DI and PA) in real-time settings, in which specifically routinized behaviors are involved. However, the mEMA app faced several challenges that needed to be overcome in order to improve its validity. Overall, the present study showed that the mEMA app is a usable and ecologically valid tool to measure DI and PA behaviors among vocational education students, but compliance is still limited

Spruill, Tanya M.; Gerin, William; Ogedegbe, Gbenga; Burg, Matthew; Schwartz, Joseph E.; Pickering, Thomas G. (2009):

Socioeconomic and psychosocial factors mediate race differences in nocturnal blood pressure dipping.

In: *Am J Hypertens* 22 (6), S. 637–642. DOI: 10.1038/ajh.2009.58.

Abstract:

BACKGROUND\r\nReduced nocturnal blood pressure (BP) dipping is more prevalent among blacks living in the United States than whites and is associated with increased target organ damage and cardiovascular risk. The primary aim of this study was to

determine whether socioeconomic and psychosocial factors help to explain racial differences in dipping. In order to address the limited reproducibility of dipping measures, we investigated this question in a sample of participants who underwent multiple ambulatory BP monitoring (ABPM) sessions.\r\nMETHODS\r\nThe study sample included 171 black and white normotensive and mildly hypertensive participants who underwent three ABPM sessions, each 1 month apart, and completed a battery of questionnaires to assess socioeconomic and psychosocial factors.\r\nRESULTS\r\nAs expected, blacks showed less dipping than whites, after adjusting for age, sex, body mass index (BMI), and mean 24-h BP level (mean difference = 3.3%, P = 0.002). Dipping was related to several of the socioeconomic and psychosocial factors examined, with higher education and income, being married, and higher perceived social support, each associated with a larger dipping percentage. Of these, marital status and education were independently associated with dipping and together accounted for 36% of the effect of race on dipping.\r\nCONCLUSIONS\r\nWe identified a number of socioeconomic and psychosocial correlates of BP dipping and found that reduced dipping among blacks vs. whites is partially explained by marital status (being unmarried) and lower education among blacks. We also present results suggesting that repeated ABPM may facilitate the detection of associations between dipping and other variables.

Metabolic syndrome risk score and time expended in moderate to vigorous physical activity in adolescents.

In: *BMC Pediatr* 14, S. 42. DOI: 10.1186/1471-2431-14-42.

Abstract:

BACKGROUND: The clustering of metabolic syndrome risk factors is inversely related to the amount of physical activity. However, the question remains as to how much daily physical activity is enough to prevent the onset of metabolic disorders in adolescents? Therefore, the objectives of this study were to associate the metabolic risk score with the moderate to vigorous physical activity (MVPA) and to identify the amount of daily physical activity to prevent the onset of the metabolic risk factors in Brazilian adolescents. METHODS: The study involved 391 participants aged 10 to 18 years. Physical activity was measured by accelerometry. The counts obtained in the different activities were transformed into metabolic equivalents and classified as light (>/= 1.5 but < 3.0 METs), moderate (>/= 3.0 but < 6.0 METs) and vigorous (>/= 6.0 METs) activities. The continuous risk score for metabolic syndrome was calculated using the following risk factors: waist circumference, blood pressure, blood glucose, HDL-C and triglycerides. RESULTS: Time spent in MVPA was inversely associated with the continuous risk score for metabolic syndrome ($p < 0.05$). Analysis of the ROC curve suggests that these adolescents must perform at least 88 minutes per day of MVPA. CONCLUSIONS: These findings reinforce previous evidence that physical activity relates to metabolic syndrome in adolescents. This population should be encouraged to gradually replace part of their sedentary time with physical activities.

Stamatakis, Emmanuel; Davis, Mark; Stathi, Afroditi; Hamer, Mark (2012):

Associations between multiple indicators of objectively-measured and self-reported sedentary behaviour and cardiometabolic risk in older adults.

In: *Prev Med* 54 (1), S. 82–87. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00602-020&site=ehost-live;e.stamatakis@ucl.ac.uk.

Abstract:

Objective: To examine the associations between sedentary behaviour (SB) measured objectively and by self-report and cardiometabolic risk factors. Method: Cross-sectional analyses of adults ≥60 years who participated in the 2008 Health Survey for England. Main exposures were self-reported leisure-time SB consisting of TV/DVD viewing, non-TV leisure-time sitting, and accelerometry-measured SB. Outcomes included body mass index (BMI), waist circumference, cholesterol ratio (total/HDL), Hb1Ac and prevalent diabetes. Results: 2765 participants (1256 men) had valid self-reported SB and outcomes/confounding variables data, of whom 649 (292 men) had accelerometer data. Total self-reported leisure-time SB showed multivariable-adjusted (including for moderate-to-vigorous physical activity) associations with BMI (beta for mean difference in BMI per 30 min/day extra SB: 0.088 kg/m-&#xfffd;, 95% CI 0.047 to 0.130); waist circumference (0.234, 0.129 to 0.339 cm); cholesterol ratio (0.018, 0.005 to 0.032) and diabetes (odds ratio per 30 min/day extra SB: 1.059, 1.030 to 1.089). Similar associations were observed for TV time while non-TV self-reported SB showed associations only with diabetes (1.057, 1.017 to 1.099). Accelerometry SB was associated with waist circumference only (0.633, 0.173 to 1.093). Conclusion: In older adults SB is associated with cardiometabolic risk factors, but the associations are more consistent when is measured by self-report that includes TV viewing. Stamatakis, E.; Hamer, M.; Tilling, K.; Lawlor, D. A. (2012):

Sedentary time in relation to cardio-metabolic risk factors: differential associations for self-report vs accelerometry in working age adults.

In: *Int.J Epidemiol.* (0300-5771 (Linking)). DOI: 10.1093/ije/dys077.

Abstract:

BACKGROUND: Sedentary behaviour has been proposed to be detrimentally associated with cardio-metabolic risk independently of moderate to vigorous physical activity (MVPA). However, it is unclear how the choice of sedentary time (ST) indicator may influence such associations. The main objectives of this study were to examine the associations between ST and a set of cardio-metabolic risk factors [waist, body mass index (BMI), systolic and diastolic blood pressure, total and high-density lipoprotein cholesterol, glycated haemoglobin] and whether these associations differ depending upon whether ST is assessed by self-report or objectively by accelerometry. METHODS: Multiple linear regression was used to examine the above objectives in a cross-sectional study of 5948 adults (2669 men) aged 16-65 years with self-reported measures of television time, other recreational sitting and occupational sitting or standing. In all, 1150 (521 men) participants had objective (accelerometry) data on ST as well. RESULTS: Total self-reported ST showed multivariable-adjusted (including for MVPA) associations with BMI [(unstandardized beta coefficients corresponding to the mean difference per 10 min/day greater ST: 0.035 kg/m(2); 95% CI: 0.027-0.044), waist circumference (0.083 cm; 0.062-0.105), systolic (0.024 mmHg; 0.000-0.049) and diastolic blood pressure (0.023 mmHg; 0.006-0.040) and total cholesterol (0.004 mmol/l; 0.001-0.006)]. Similar associations were observed for TV time, whereas non-TV self-reported ST showed consistent associations with the two adiposity proxies (BMI/waist circumference) and total cholesterol. Accelerometry-assessed ST was only associated with total cholesterol (0.010 mmol/l; 0.001-0.018). CONCLUSIONS: In this study, ST was associated consistently with cardio-metabolic risk only when it was measured by self-report

Statland, Jeffrey M.; Bundy, Brian N.; Wang, Yunxia; Rayan, Dipa Raja; Trivedi, Jaya R.; Sansone, Valeria A. et al. (2012):

Mexiletine for symptoms and signs of myotonia in nondystrophic myotonia: a randomized controlled trial.

In: *JAMA* 308 (13), S. 1357–1365. DOI: 10.1001/jama.2012.12607.

Abstract:

CONTEXT\r\nNondystrophic myotonias (NDMs) are rare diseases caused by mutations in skeletal muscle ion channels. Patients experience delayed muscle relaxation causing functionally limiting stiffness and pain. Mexiletine-induced sodium channel blockade reduced myotonia in small studies; however, as is common in rare diseases, larger studies of safety and efficacy have not previously been considered feasible.\r\nOBJECTIVE\r\nTo determine the effects of mexiletine for symptoms and signs of myotonia in patients with NDMs.\r\nDESIGN, SETTING, AND PARTICIPANTS\r\nA randomized, double-blind, placebo-controlled 2-period crossover study at 7 neuromuscular referral centers in 4 countries of 59 patients with NDMs conducted between December 23, 2008, and March 30, 2011, as part of the National Institutes of Health-funded Rare Disease Clinical Research Network.\r\nINTERVENTION\r\nOral 200-mg mexiletine or placebo capsules 3 times daily for 4 weeks, followed by the opposite intervention for 4 weeks, with 1-week washout in between.\r\nMAIN OUTCOME MEASURES\r\nPatient-reported severity score of stiffness recorded on an interactive voice response (IVR) diary (scale of 1 = minimal to 9 = worst ever experienced). Secondary end points included IVR-reported changes in pain, weakness, and tiredness; clinical myotonia assessment; quantitative measure of handgrip myotonia; and Individualized Neuromuscular Quality of Life summary quality of life score (INQOL-QOL, percentage of maximal detrimental impact).\r\nRESULTS\r\nMexiletine significantly improved patient-reported severity score stiffness on the IVR diary. Because of a statistically significant interaction between treatment and period for this outcome, primary end point is presented by period (period 1 means were 2.53 for mexiletine and 4.21 for placebo; difference, -1.68; 95% CI, -2.66 to -0.706; P < .001; period 2 means were 1.60 for mexiletine and 5.27 for placebo; difference, -3.68; 95% CI, -3.85 to -0.139; P = .04). Mexiletine improved the INQOL-QOL score (mexiletine, 14.0 vs placebo, 16.7; difference, -2.69; 95% CI, -4.07 to -1.30; P < .001) and decreased handgrip myotonia on clinical examination (mexiletine, 0.164 seconds vs placebo, 0.494 seconds; difference, -0.330; 95% CI, -0.633 to -0.142; P < .001). The most common adverse effect was gastrointestinal (9 mexiletine and 1 placebo). Two participants experienced transient cardiac effects that did not require stopping the study (1 in each group). One serious adverse event was determined to be not study related.\r\nCONCLUSION\r\nIn this preliminary study of patients with NDMs, the use of mexiletine compared with placebo resulted in improved patient-reported stiffness over 4 weeks of treatment, despite some concern about the maintenance of blinding.\r\nTRIAL REGISTRATION\r\nclinicaltrials.gov Identifier: NCT00832000.

Staudenmayer, John; Pober, David; Crouter, Scott; Bassett, David; Freedson, Patty (2009):

An artificial neural network to estimate physical activity energy expenditure and identify physical activity type from an accelerometer.

In: *Journal of Applied Physiology* 107 (4), S. 1300–1307.

Abstract:

The aim of this investigation was to develop and test two artificial neural networks (ANN) to apply to physical activity data collected with a commonly used uniaxial accelerometer. The first ANN model estimated physical activity metabolic equivalents (METs), and the second ANN identified activity type. Subjects (n = 24 men and 24 women, mean age = 35 yr) completed a menu of activities that included sedentary, light, moderate, and vigorous intensities, and each activity was performed for 10 min. There were three different activity menus, and 20 participants completed each menu. Oxygen consumption (in ml x kg(-1) x min(-1)) was measured continuously, and the average of minutes 4-9 was used to represent the oxygen cost of each activity. To calculate METs, activity oxygen consumption was divided by 3.5 ml x kg(-1) x min(-1) (1 MET). Accelerometer data were collected second by second using the Actigraph model 7164. For the analysis, we used the distribution of counts (10th, 25th, 50th, 75th, and 90th percentiles of a minute's second-by-second counts) and temporal dynamics of counts (lag, one autocorrelation) as the accelerometer feature inputs to the ANN. To examine model performance, we used the leave-one-out cross-validation technique. The ANN prediction of METs root-mean-squared error was 1.22 METs (confidence interval: 1.14-1.30). For the prediction of activity type, the ANN correctly classified activity type 88.8% of the time (confidence interval: 86.4-91.2%). Activity types were low-level activities, locomotion, vigorous sports, and household activities/other activities. This novel approach of applying ANNs for processing Actigraph accelerometer data is promising and shows that we can successfully estimate activity METs and identify activity type using ANN analytic procedures.

Long-term intake of North American ginseng has no effect on 24-hour blood pressure and renal function.

In: *Hypertension* 47 (4), S. 791–796. DOI: 10.1161/01.HYP.0000205150.43169.2c.

Abstract:

Ginseng is consumed by 10% to 20% of adults in Asia and by up to 5% in Western countries. Despite observational evidence suggesting a link between its intake and the development of hypertension, there remains no long-term scrutiny for its effect on blood pressure (BP). We therefore undertook a randomized, placebo-controlled, double-blinded, crossover trial in 52 hypertensive individuals to determine the effect of 12-week North American ginseng intake on 24-hour BP; we also measured serum cystatin C as a marker of renal function. After a 4-week placebo run-in, we randomly assigned 52 participants to 3 g/day of ginseng or placebo for 12 weeks. This was followed by an 8-week washout and a subsequent 12-week period in which the opposite treatment was administered. At run-in and at weeks 0 and 12 of each treatment period, participants were fitted with an ambulatory BP monitor to assess 24-hour BP. The primary outcome was the treatment difference at week 12 in mean 24-hour systolic BP. Secondary outcomes were treatment differences at week 12 in other ambulatory BP parameters and serum cystatin C. Forty participants (77%) completed the trial, with 3 removed from main analysis (n=2, antihypertensive drug changes; n=1, incomplete ambulatory monitoring). In the remaining 37, 12-week ginseng treatment was associated with a neutral effect on all ambulatory BP parameters compared with placebo; an intention-to-treat analysis supported this. Ginseng did not affect serum cystatin C level. Overall, long-term ginseng use had no effect on 24-hour BP and renal function in hypertensive individuals.

Parents' self-efficacy beliefs and their children's psychosocial adaptation during adolescence.

In: *Journal of Youth and Adolescence* 40 (3), S. 320–331.

Abstract:

Research has shown that parents' perceived parental self-efficacy (PSE) plays a pivotal role in promoting their children's successful adjustment. In this study, we further explored this issue by comparing psychosocial adaptation in children of parents with high and low PSE during adolescence. One hundred and thirty Italian teenagers (55 males and 75 females) and one of their parents (101 mothers and 29 fathers) participated in the research. Data were collected at T1 (adolescents' mean age = 13.6) and T2 (mean age = 17.5). Parents reported their PSE at T1. At T1 and T2, adolescents reported their perceived academic self-efficacy, aggressive and violent conducts, well-being, and perceived quality of their relationships with parents. At T2, they were

also administered questions by using Experience Sampling Method to assess their quality of experience in daily life. As hypothesized, adolescents with high PSE parents reported higher competence, freedom and well-being in learning activities as well as in family and peer interactions. They also reported fewer problematic aspects and more daily opportunities for optimal experience. Findings pointed to the stability of adolescents' psychosocial adaptation and highlighted possible directions in future research.

Steele, Rebekah M.; Brage, Soren; Corder, Kirsten; Wareham, Nicholas J.; Ekelund, Ulf (2008):

Physical activity, cardiorespiratory fitness, and the metabolic syndrome in youth.

In: *Journal of Applied Physiology* 105 (1), S. 342–351.

Abstract:

The metabolic syndrome is defined as the coexistence of multiple cardiovascular and diabetes risk factors, the prevalence of which has increased dramatically in adult populations in the last decades. More recently, the same cluster of metabolic risk factors has also been recognized in children and adolescents. Epidemiological evidence suggests that high levels of cardiorespiratory fitness (CRF) and physical activity are associated with a favorable metabolic risk profile in adults. However, in youth the role of these factors is less clear. Therefore, the purpose of this mini-review is to examine the recent evidence between objectively measured habitual physical activity and CRF with clustered metabolic risk in youth. In general, it appears that both physical activity and CRF are separately and independently associated with metabolic risk factors in youth, possibly through different causal pathways. Further research is necessary to quantify how much physical activity is needed to prevent the metabolic syndrome and the diseases with which it is associated. Public health approaches that encourage increased physical activity and reduce sedentary behaviors may prove useful in reducing the population burden associated with metabolic risk.

Steele, Rebekah M.; van Sluijs, Esther Mf; Cassidy, Aedín; Griffin, Simon J.; Ekelund, Ulf (2009):

Targeting sedentary time or moderate-and vigorous-intensity activity: independent relations with adiposity in a population-based sample of 10-y-old British children.

In: *Am J Clin Nutr* 90 (5), S. 1185–1192.

Abstract:

BACKGROUND:

It is unclear whether subcomponents of physical activity (PA) are associated with adiposity independent of time spent while sedentary.

OBJECTIVE:

The objective was to examine associations between objectively measured PA and its subcomponents [ie, time spent at light-intensity PA, moderate-intensity PA (MPA), vigorous-intensity PA (VPA), and moderate-plus-vigorous-intensity PA (MVPA)], independent of sedentary time, and self-reported leisure screen time (television and electronic game use) with indexes of adiposity in a population-based sample of British children.

DESIGN:

A cross-sectional study was conducted in 1862 UK children aged 9-10 y. PA and sedentary activity were measured by accelerometry, and indicators of adiposity were waist circumference, body mass index (BMI), and fat mass index calculated from bioimpedance measurements. Screen time was assessed by self-report. We examined the associations between PA subcomponents and adiposity by multilevel linear models adjusted for birth weight, maternal BMI, energy intake, and sleep duration.

RESULTS:

Objectively measured sedentary time was positively associated with waist circumference ($P = 0.04$) and fat mass index ($P = 0.05$), independent of age and sex. However, this association was attenuated after adjustment for MVPA and other covariates. VPA (all $P < 0.0001$), combined MVPA (all $P < 0.01$), and total activity (counts/min) (all $P < 0.001$) were all inversely associated with each of the adiposity indexes, independent of sedentary time and other important covariates. Associations were weaker for MPA: $P = 0.05$, 0.87, and 0.1 for waist circumference, BMI, and fat mass index, respectively.

CONCLUSIONS:

Time spent in VPA appears to be more strongly associated with adiposity than sedentary time. Interventions may therefore need to incorporate higher intensity-based activities to curb the growing obesity epidemic.

Steins, Dax; Dawes, Helen; Esser, Patrick; Collett, Johnny (2014):

Wearable accelerometry-based technology capable of assessing functional activities in neurological populations in community settings: a systematic review.

In: *J Neuroeng Rehabil* 11 (1), S. 36. DOI: 10.1186/1743-0003-11-36.

Abstract:

BACKGROUND: Integrating rehabilitation services through wearable systems has the potential to accurately assess the type, intensity, duration, and quality of movement necessary for procuring key outcome measures. OBJECTIVES: This review aims to explore wearable accelerometry-based technology (ABT) capable of assessing mobility-related functional activities intended for rehabilitation purposes in community settings for neurological populations. In this review, we focus on the accuracy of ABT-based methods, types of outcome measures, and the implementation of ABT in non-clinical settings for rehabilitation purposes. DATA SOURCES: Cochrane, PubMed, Web of Knowledge, EMBASE, and IEEE Xplore. The search strategy covered three main areas, namely wearable technology, rehabilitation, and setting. STUDY SELECTION: Potentially relevant studies were categorized as systems either evaluating methods or outcome parameters. METHODS: Methodological qualities of studies were assessed by two customized checklists, depending on their categorization and rated independently by three blinded reviewers. RESULTS: Twelve studies involving ABT met the eligibility criteria, of which three studies were identified as having implemented ABT for rehabilitation purposes in non-clinical settings. From the twelve studies, seven studies achieved high methodological quality scores. These studies were not only capable of assessing the type, quantity, and quality measures of functional activities, but could also distinguish healthy from non-healthy subjects and/or address disease severity levels. CONCLUSION: While many studies support ABT's potential for telerehabilitation, few actually utilized it to assess mobility-related functional activities outside laboratory settings. To generate more appropriate outcome measures, there is a clear need to translate research findings and novel methods into practice.

Stephens, M. A.; Franks, M. M.; Rook, K. S.; Iida, M.; Hemphill, R. C.; Salem, J. K. (2012):

Spouses' Attempts to Regulate Day-to-Day Dietary Adherence Among Patients With Type 2 Diabetes.

In: *Health Psychol* (0278-6133 (Linking)). DOI: 10.1037/a0030018.

Abstract:

Objective: To investigate daily dietary adherence and diabetes-specific distress among older adults with type 2 diabetes mellitus (T2DM) as a function of spouses' diet-related support and diet-related control (persuasion and pressure) and whether these daily processes differ among couples who do and do not appraise responsibility for managing T2DM as shared. Methods: End-of-day diaries were completed by 126 couples in which one partner had T2DM (patient) and the other did not (spouse). Using electronic diary methods, each partner independently recorded data for 24 consecutive days (patients recorded their day's dietary adherence and diabetes-specific distress; spouses recorded their day's involvement in patients' dietary management). To assess dietary adherence, patients reported the extent to which they followed dietary recommendations that day with items from the Summary of Diabetes Self-Care Activities Measure. To assess diabetes-specific distress, patients reported the extent to which they worried about diabetes that day using items from the Problem Areas in Diabetes (PAID) scale. Results: Multilevel modeling revealed that, relative to the prior day, spouses' diet-related support was associated with increases in patients' adherence whereas diet-related persuasion and pressure were associated with decreases in adherence; spouses' pressure was associated with increases in patients' diabetes-specific distress. When partners appraised responsibility for managing T2DM as shared, support was associated with decreases in diabetes-specific distress; pressure was associated with decreases in adherence. Conclusions: Our findings offer insight into partners' day-to-day disease-related interactions and identify those that are likely to be beneficial versus detrimental for patients' physical and psychological health. Steptoe, A.; Wardle, J. (2011):

Positive affect measured using ecological momentary assessment and survival in older men and women.

In: *Proc.Natl.Acad.Sci U.S A* 108 (45), S. 18244–18248. DOI: 10.1073/pnas.1110892108.

Abstract:

Links between positive affect (PA) and health have predominantly been investigated by using measures of recollected emotional states. Ecological momentary assessment is regarded as a more precise measure of experienced well-being. We analyzed data

from the English Longitudinal Study of Aging, a representative cohort of older men and women living in England. PA was assessed by aggregating momentary assessments over a single day in 3,853 individuals aged 52 to 79 y who were followed up for an average of 5 y. Respondents in the lowest third of PA had a death rate of 7.3%, compared with 4.6% in the medium-PA group and 3.6% in the high-PA group. Cox proportional-hazards regression showed a hazard ratio of 0.498 (95% confidence interval, 0.345-0.721) in the high-PA compared with the low-PA group, adjusted for age and sex. This was attenuated to 0.646 (95% confidence interval, 0.436-0.958) after controlling for demographic factors, negative affect, depressed mood, health indicators, and health behaviors. Negative affect and depressed mood were not related to survival after adjustment for covariates. These findings indicate that experienced PA, even over a single day, has a graded relationship with survival that is not caused by baseline health status or other covariates. Momentary PA may be causally related to survival, or may be a marker of underlying biological, behavioral, or temperamental factors, although reverse causality cannot be conclusively ruled out. The results endorse the value of assessing experienced affect, and the importance of evaluating interventions that promote happiness in older populations

Stergiou, George S.; Argyraki, Katerina K.; Moyssakis, Ioannis; Mastorantonakis, Stylianos E.; Achimastos, Apostolos D.; Karamanos, Vasilios G.; Roussias, Leonidas G. (2007):

Home blood pressure is as reliable as ambulatory blood pressure in predicting target-organ damage in hypertension.

In: *Am J Hypertens* 20 (6), S. 616–621.

Abstract:

BACKGROUND:

Our objective was to assess the value of home blood pressure (BP) monitoring in comparison to office BP measurements and ambulatory monitoring in predicting hypertension-induced target-organ damage.

METHODS:

Sixty-eight untreated patients with hypertension with at least two routine prestudy office visits were included (mean age, 48.6 +/- 9.1 [SD] years; 50 men). Office BP was measured in two study visits, home BP was measured for 6 workdays, and ambulatory BP was monitored for 24 h. All BP measurements were obtained using validated electronic devices. Target-organ damage was assessed by measuring the echocardiographic left-ventricular mass index (LVMI), urinary albumin excretion rate (AER) in two overnight urine collections, and carotid-femoral pulse-wave velocity (PWV) (Complior device; Colson, Garges-les-Gonesse, Paris, France).

RESULTS:

The correlation coefficients of LVMI with office BP were 0.24/0.15 (systolic/diastolic), with home BP 0.35/0.21 (systolic, $P < .01$), and with 24-h ambulatory BP 0.23/0.19, awake 0.21/0.16, and asleep 0.28/0.26 (asleep, both $P < .05$). The correlation coefficients of AER with office BP were 0.24/0.31 (diastolic, $P < .05$), with home BP 0.28/0.26 (both $P < .05$), and with 24-h ambulatory BP 0.25/0.24, awake 0.24/0.25 (diastolic, $P < .05$), and asleep 0.26/0.18 (systolic, $P < .05$). There was a trend for negative correlations between PWV and diastolic BP measurements (not significant). In multiple-regression models assessing independent predictors of each of the three indices of target-organ damage, systolic home BP and age were the only independent predictors of increased LVMI that reached borderline statistical significance.

CONCLUSIONS:

These data suggest that home BP is as reliable as ambulatory monitoring in predicting hypertension-induced target-organ damage, and is superior to carefully taken office measurements.

Stergiou, George S.; Christodoulakis, George R.; Nasothimiou, Efthimia G.; Giovas, Periklis P.; Kalogeropoulos, Petros G. (2008):

Can validated wrist devices with position sensors replace arm devices for self-home blood pressure monitoring? A randomized crossover trial using ambulatory monitoring as reference.

In: *Am J Hypertens* 21 (7), S. 753–758.

Abstract:

BACKGROUND:

Electronic devices that measure blood pressure (BP) at the arm level are regarded as more accurate than wrist devices and are preferred for home BP (HBP) monitoring. Recently, wrist devices with position sensors have been successfully validated using

established protocols. This study assessed whether HBP values measured with validated wrist devices are sufficiently reliable to be used for making patient-related decisions in clinical practice.

METHODS:

This randomized crossover study compared HBP measurements taken using validated wrist devices (wrist-HBP, Omron R7 with position sensor) with those taken using arm devices (arm-HBP, Omron 705IT), and also with measurements of awake ambulatory BP (ABP, SpaceLabs), in 79 subjects (36 men and 43 women) with hypertension. The mean age of the study population was 56.7 +/- 11.8 years, and 33 of the subjects were not under treatment for hypertension.

RESULTS:

The average arm-HBP was higher than the average wrist-HBP (mean difference, systolic 5.2 +/- 9.1 mm Hg, P < 0.001, and diastolic 2.2 +/- 6.7, P < 0.01). Twenty-seven subjects (34%) had a > or =10 mm Hg difference between systolic wrist-HBP and arm-HBP and twelve subjects (15%) showed similar levels of disparity in diastolic HBP readings. Strong correlations were found between arm-HBP and wrist-HBP (r 0.74/0.74, systolic/diastolic, P < 0.0001). However, ABP was more strongly correlated with arm-HBP (r 0.73/0.76) than with wrist-HBP (0.55/0.69). The wrist-arm HBP difference was associated with systolic ABP (r 0.34) and pulse pressure (r 0.29), but not with diastolic ABP, sex, age, arm circumference, and wrist circumference.

CONCLUSIONS:

There might be important differences in HBP measured using validated wrist devices with position sensor vs. arm devices, and these could impact decisions relating to the patient in clinical practice. Measurements taken using arm devices are more closely related to ABP values than those recorded by wrist devices. More research is needed before recommending the widespread use of wrist monitors in clinical practice.

Home blood pressure monitoring in children: how many measurements are needed?

In: *Am J Hypertens* 21 (6), S. 633–638.

Abstract:

OBJECTIVE:

To investigate the minimum schedule of blood pressure (BP) measurements necessary to provide a reliable assessment of home BP (HBP) in children and adolescents.

METHODS:

Subjects aged 6-18 years referred for elevated BP were assessed with HBP monitoring (6 workdays, duplicate morning and evening measurements) and 24-h ambulatory BP monitoring (ABP). Criteria for HBP reliability were its reproducibility (test-retest correlations and SD of differences (SDDs) between repeated measurements), its stability (average home BP of an increasing number of readings and its SD), and its relationship with ABP.

RESULTS:

Data from 100 subjects were analyzed (mean age 13 +/- 2.8 (SD) years, 61 boys). The reproducibility of 3-day HBP (r 0.88/0.79, SDDs 5.1/4.9, systolic/diastolic) was superior to that of a single (r 0.79/0.65, SDDs 7.6/7.1) or 2-day HBP (r 0.85/0.72, SDDs 6.1/5.4). By averaging up to 12 readings (3 days), there was a progressive decline in average HBP, with no further decline thereafter. The SD of average HBP was also progressively reduced, with little change after day 3. The association of HBP with ABP was improved by averaging more readings up to 12, with no further improvement when more readings were averaged. The exclusion of first-day measurements slightly increased the SD of average HBP and weakened the correlation with ABP, probably due to reduced number of readings.

CONCLUSIONS:

In children and adolescents, 3-day monitoring with duplicate morning and evening measurements appears to be the minimum schedule for the reliable assessment of HBP.

Intraindividual reproducibility of blood pressure surge upon rising after nighttime sleep and siesta.

In: *Hypertens Res* 31 (10), S. 1859–1864. DOI: 10.1291/hypres.31.1859.

Abstract:

The surge in blood pressure (BP) upon rising after waking in the morning has been associated with increased risk of target organ damage and cardiovascular events. The reproducibility of this phenomenon within the same 24-h period was tested in subjects with a siesta during ambulatory BP monitoring by assessing the morning surge (MS) vs. the evening surge (ES) after siesta. Ambulatory BP recordings with reported siesta from hypertensive subjects were analyzed. MS and ES were assessed using four different definitions. The intraindividual reproducibility was assessed using the standard deviation of differences between MS and ES, the concordance correlation coefficient, the coefficient of variation and the agreement between MS and ES in detecting \"surgers\" among hypertensive subjects (top quartile of the BP surge distribution). A total of 562 ambulatory recordings were analyzed (476 subjects, mean age 54.9+/-13.2 [SD] years, treated 47%). Average MS (16.3/14.4 mmHg, systolic/diastolic) was higher than ES (13.3/12.1 mmHg, p<0.001) due to higher post-rising BP in the morning (p<0.01). The intraindividual reproducibility was rather poor, with no clear differences among different definitions. However, there was about 70% agreement between MS and ES in the detection of \"surgers\" (systolic and diastolic, kappa statistic 0.18). These data suggest that, although the intraindividual reproducibility of the BP surge within the same 24-h period is rather poor, about 70% of the \"morning surgers\" were also \"evening surgers.\" Thus, the BP surge might be an inherent pathophysiological characteristic of the BP behavior of an individual and deserves further investigation.

Sterling, Michele; Chadwick, Benjamin J. (2010):

Psychologic processes in daily life with chronic whiplash: Relations of posttraumatic stress symptoms and fear-of-pain to hourly pain and uptime.

In: *Clin J Pain* 26 (7), S. 573–582.

Abstract:

OBJECTIVES:

Recent models of the relationship between posttraumatic stress and whiplash pain suggest that psychological stress relating to a motor vehicle crash may influence pain perception. The mechanisms of this relationship may be through more direct, psychological pathways, or through factors proposed by the fear-avoidance models of chronic pain. This study sought to investigate the relative contribution of fear-of-pain and trauma symptomatology to daily pain and time spent in an upright posture (uptime) in chronic whiplash-associated disorder (WAD).

METHODS:

Hourly electronic-diary reports were used to explore the within-day relationship of psychological trauma symptoms and fear-of-pain to same-hour and next-hour pain reports and next-hour uptime (measured by accelerometers) in 32 individuals with a chronic WAD. Within-person effects were analyzed for 329 diary entries using multilevel modeling with fixed slopes and random intercepts.

RESULTS:

Reports of trauma-related hyperarousal were associated with greater same-hour pain, and this relationship was mediated by fear-of-pain. Fear-of-pain and uptime were independently associated with reports of increased next-hour pain (controlling for first-order serial autocorrelation). Fear-of-pain was unrelated to next-hour uptime, but trauma-related avoidance symptoms were associated with reduced uptime. This study supports the relationship between psychological trauma responses and pain, suggesting behavioral (avoidance) pathways and effects on pain perception through fear-of-pain. These findings reinforce the need to evaluate traumatic stress as a factor in recovery from WAD.

Stevens, D. J.; McKenzie, K.; Cui, H. W.; Noble, J. G.; Turney, B. W. (2014):

Smartphone apps for urolithiasis.

In: *Urolithiasis. DOI:* 10.1007/s00240-014-0738-0.

Abstract:

There are an increasing number of healthcare smartphone applications ('apps') available. Urolithiasis presents a major healthcare burden. Patients are increasingly keen to educate themselves regarding the diagnosis and management of their condition. There is no formal regulation of healthcare apps, including a large number of apps relating to urolithiasis. This review aims to examine the range of apps available, and the prevalence of healthcare professional input. Four international smartphone app stores were searched: Apple's App Store, Google Play (Android), BlackBerry App World and the Windows Phone App store. A total of 42 unique apps were downloaded and analysed. Recorded data included the cost (pound/$), publisher information, number of ratings, average rating and any documentation of medical professional involvement. Twenty-one (50 %) apps required payment for download. The mean cost was pound3.58 ($6.04) with range pound0.61- pound34.90 ($1.03-$58.87). Thirty-three (79 %) of

the 42 apps were designed to be used by patients. Fifteen (36 %) of the 42 apps had clear input from health professionals. Twenty-two apps offered patient information, including dietary advice on lowering calcium intake, which is contrary to current evidence-based practice. We conclude that urolithiasis apps have future potential to inform both patients and healthcare professionals on stone management. However, inaccuracies in the recommendations made by some apps can be misleading or even harmful due to a lack of specialist involvement. We recommend improving the usefulness of these apps by seeking a 'quality stamp' from recognised urological organisations and greater clinician involvement in future app development.

Stinson, Jennifer N.; Jibb, Lindsay A.; Nguyen, Cynthia; Nathan, Paul C.; Maloney, Anne Marie; Lee Dupuis, L. et al. (2013):

Development and testing of a multidimensional iPhone pain assessment application for adolescents with cancer.

In: *J Med Internet Res* 15 (3), S. 137–151. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-26867-012%26site%3dehost-live;jennifer.stinson@sickkids.ca.

Abstract:

Background: Pain is one of the most common and distressing symptoms reported by adolescents with cancer. Despite advancements in pain assessment and management research, pain due to cancer and/or its treatments continues to be poorly managed. Our research group has developed a native iPhone application (app) called Pain Squad to tackle the problem of poorly managed pain in the adolescent with cancer group. The app functions as an electronic pain diary and is unique in its ability to collect data on pain intensity, duration, location, and the impact pain has on an adolescent's life (ie, relationships, school work, sleep, mood). It also evaluates medications and other physical and psychological pain management strategies used. Users are prompted twice daily at configurable times to complete 20 questions characterizing their pain and the app transmits results to a database for aggregate reporting through a Web interface. Each diary entry represents a pain case filed by an adolescent with cancer and a reward system (ie, moving up through law-enforcement team ranks, built-in videotaped acknowledgements from fictitious officers) encourages consistent use of the diary. Objective: Our objective was to design, develop, and test the usability, feasibility, compliance, and satisfaction of a game-based smartphone pain assessment tool for adolescents with cancer. Methods: We used both low- and high-fidelity qualitative usability testing with qualitative semi-structured, audio-taped interviews and iterative cycles to design and refine the iPhone based Pain Squad app. Qualitative thematic analysis of interviews using constant comparative methodology captured emergent themes related to app usability. Content validity was assessed using question importance-rating surveys completed by participants. Compliance and satisfaction data were collected following a 2-week feasibility trial where users were alarmed to record their pain twice daily on the app. Results: Thematic analysis of usability interviews showed the app to be appealing overall to adolescents. Analyses of both low- and high-fidelity testing resulted in minor revisions to the app to refine the theme and improve its usability. Adolescents resoundingly endorsed the game-based nature of the app and its virtual reward system. The importance of app pain diary questions was established by content validity analysis. Compliance with the app, assessed during feasibility testing, was high (mean 81%, SD 22%) and adolescents from this phase of the study found the app likeable, easy to use, and not bothersome to complete. Conclusions: A multifaceted usability approach demonstrated how the Pain Squad app could be made more appealing to children and adolescents with cancer. The game-based nature and built-in reward system of the app was appealing to adolescents and may have resulted in the high compliance rates and satisfaction ratings observed during clinical feasibility testing. Comparison of Average Weekly Pain Using Recalled Paper and Momentary Assessment Electronic Diary Reports in Children with Arthritis.

In: *Clin J Pain. DOI:* 10.1097/AJP.0000000000000072.

Abstract:

OBJECTIVE:: The current study investigated the construct validity of a multidimensional pain diary for youth with juvenile idiopathic arthritis and also compared participants' responses on electronic and retrospective diary measures. The purpose of the latter part of this study was to compare absolute agreement, between and within-person consistency and judged change in weekly pain between these two methods of assessing pain. METHODS:: 70 adolescents with Juvenile Idiopathic Arthritis (JIA) completed both weekly recalled and momentary reports of pain over a 2-week period and assessed their change in pain over the 2-week period using 5-point global change in pain scale. Pearson correlations and intra-class correlation coefficients were computed to demonstrate three different ways of comparing the measures on both a between-persons and within-person basis. RESULTS:: Momentary ratings of pain episodes were consistently greater than weekly ratings of recalled pain. Moderate to strong consistency and agreement correlations were computed for between-person momentary and recalled pain intensity. However, these correlations were much weaker when the within-person data were analyzed. The judged change in pain across weeks was significantly associated with computed change in both average momentary and recalled pain. DISCUSSION:: This is one of the few studies to explore the relationship between the measurement methods of pain recall and momentary assessment in adolescents. The poor within-person correlations observed have important implications for research design and practice in pediatric pain.

Stinson, Jennifer N.; Stevens, Bonnie J.; Feldman, Brian M.; Streiner, David; McGrath, Patrick J.; Dupuis, Annie et al. (2008):

Construct validity of a multidimensional electronic pain diary for adolescents with arthritis.

In: *Pain* 136 (3), S. 281–292.

Abstract:

The aim of this study was to evaluate the construct validity and feasibility of a multidimensional electronic pain diary (e-Ouch©) in adolescents with juvenile idiopathic arthritis (JIA). Two descriptive studies with repeated measures were conducted between January and December 2005. Participants were drawn from a large metropolitan rheumatology clinic in a university affiliated pediatric tertiary care centre. In Study 1, 76 adolescents with active arthritis recorded their pain three times a day for 2 weeks using the e-Ouch©. In Study 2, 36 adolescents recorded their pain three times a day for 1 week before and 2 weeks after joint injections. Adolescents in both studies completed multiple measures to determine the construct validity and feasibility of the e-Ouch©. Adolescents reported mild levels of pain intensity, unpleasantness, and interference as well as stiffness, and mild to moderate levels of fatigue. e-Ouch© average weekly pain unpleasantness and interference scores were higher in adolescents with higher pain intensity scores. Correlations between average weekly pain ratings on the e-Ouch© and scores from: (a) recalled least, average and worst weekly pain, (b) health-related quality of life and pain coping, and (c) disease activity were as predicted. Pain ratings were significantly lower following joint injections with effect sizes in the low to moderate and moderate to high ranges at the first and second week post-injection, respectively. These findings provide evidence of the construct validity

and feasibility of the e-Ouch© electronic diary in adolescents with JIA. Use of real-time data capture approaches should be considered in future studies of chronic arthritis.

Stone, Arthur A.; Broderick, Joan E. (2007):

Real-time data collection for pain: appraisal and current status.

In: *Pain Med* 8 Suppl 3, S. S85-93. DOI: 10.1111/j.1526-4637.2007.00372.x.

Abstract:

OBJECTIVE\r\nReal-time data capture (RTDC) techniques have rapidly developed with the advent of computer and information technology. We plan to discuss the use of RTDC in the assessment of pain, including issues pertaining to its rationale, sampling protocols, and our opinion on the current status of the methodology.\r\nDESIGN\r\nThis is \"thought\" piece involving no systematic data collection methods.\r\nRESULTS\r\nWe described the rationale for using RTDC, including issues in recall bias, the desire for detailed information about pain, and the ability to examine within-person associations between pain and other variables. The mechanics of RTDC implementations were discussed with a focus on sampling protocols and data collection methods. The final section concerned the status of RTDC. Current acceptance of RTDC is evaluated and three issues in the science of RTDC were discussed: the interpretation of differences between recall and the average of momentary assessments for the same period; if RTDC is advancing our understanding of pain; and, the issue of what consumers of pain assessments actually desire. RTDC extensions to feedback based on momentary assessments are also discussed.\r\nCONCLUSION\r\nReal-time data collection can be a useful methodology for improving our understanding of pain and especially of its dynamic nature in real-world settings.

Stone, Michelle R.; Faulkner, Guy Ej; Mitra, Raktim; Buliung, Ron N. (2014):

The freedom to explore: examining the influence of independent mobility on weekday, weekend and after-school physical activity behaviour in children living in urban and inner-suburban neighbourhoods of varying socioeconomic status.

In: *Int J Behav Nutr Phys Act* 11, S. 5. DOI: 10.1186/1479-5868-11-5.

Abstract:

BACKGROUND: Children's independent mobility (CIM) is critical to healthy development in childhood. The physical layout and social characteristics of neighbourhoods can impact opportunities for CIM. While global evidence is mounting on CIM, to the authors' knowledge, Canadian data on CIM and related health outcomes (i.e., physical activity (PA) behaviour) are missing. The purpose of this study was to examine if CIM is related to multiple characteristics of accelerometry-measured PA behaviour (total PA, light PA, moderate-to-vigorous PA, time spent sedentary) and whether associations between CIM and PA behaviour systematically vary by place of residence, stratifying by gender and type of day/period (weekdays, after-school, weekend). METHODS: Participants were recruited through Project BEAT (Built Environment and Active Transport; http://www.beat.utoronto.ca). Children (n = 856) were stratified into four neighbourhood classifications based on the period of neighbourhood development (urban built environment (BE) (old BE) versus inner-suburban BE (new BE)) and socioeconomic status (SES; low SES and high SES). Physical activity was measured via accelerometry (ActiGraph GT1M). CIM was assessed via parental report and two categories were created (low CIM, n = 332; high CIM, n = 524). A series of two-factor ANOVAs were used to determine gender-specific differences in PA for weekdays, weekend days and the after-school period, according to level of CIM, across four neighbourhood classifications. RESULTS: Children who were granted at least some independent mobility (high CIM) had more positive PA profiles across the school week, during the after-school period, and over the weekend; they were also less sedentary. The influence of CIM on PA behaviour was particularly salient during the after-school period. Associations of CIM with PA varied by gender, and also by neighbourhood classification. CIM seemed to matter more in urban neighbourhoods for boys and suburban neighbourhoods for girls. CONCLUSION: Our findings highlight the importance of independent mobility to multiple characteristics of children's PA behaviour across the week. Furthermore, they emphasize that independent mobility-activity relationships need to be considered by gender and the type of neighbourhood independent mobility is offered in. Future work will focus on developing a predictive model of CIM that could be used to inform decision-making around alleviating barriers to CIM.

Objectively measured physical activity levels of young children with congenital heart disease.

In: *Cardiol Young*, S. 1–6. DOI: 10.1017/S1047951114000298.

Abstract:

Physical activity tends to be lower in school-age children with congenital heart disease than in healthy controls. To the best of our knowledge, objectively measured physical activity levels of preschool-age children with congenital heart disease have not been studied. Methods: A total of 10 children with either coarctation of the aorta (n=6; age 3.8+/-0.9) or tetralogy of Fallot (n=4, age 4.3+/-0.9) were recruited from the cardiology unit of McMaster Children's Hospital. Height (103.7+/-8.2 cm) and weight (17.3+/-2.7 kg) measurements were recorded, and physical activity was determined using accelerometry over 7 consecutive days. Patients were compared with age-, sex-, and season of data acquisition-matched controls. Parents completed a questionnaire regarding the child's physical activity and sedentary behaviours. Results: Patients spent on average 219.4+/-39.9 minutes engaged in total physical activity per day at the following intensities: light, 147.5+/-22.3; moderate, 44.0+/-11.8; moderate-to-vigorous, 71.9+/-22.6; and vigorous, 27.9+/-11.7. No significant differences were observed between patients and controls for total physical activity (p=0.80) or any of the intensities (p=0.71, 0.46, 0.43, and 0.45, respectively). Only 40% of patients and controls met the new Canadian Physical Activity Guidelines for the Early Years of at least 180 minutes of physical activity at any intensity every day. Of the patients' parents, 90% believed that their child was as active, if not more active, than his/her siblings, and 80% of parents reported their child spending 1-3 hours in screen time activities daily. Conclusion: Children aged 3-5 years old with congenital heart disease have comparable physical activity levels to age-, sex-, and season-matched controls, and many do not meet Canadian Physical Activity Guidelines.

Stone, Michelle R.; Rowlands, Ann V.; Eston, Roger G. (2009):

Characteristics of the activity pattern in normal weight and overweight boys.

In: *Prev Med* 49 (2-3), S. 205–208. DOI: 10.1016/j.ypmed.2009.06.012.

Abstract:

OBJECTIVE\r\nTo assess whether the activity pattern differs between normal weight and overweight boys across weekdays and weekend days.\r\nMETHODS\r\nPhysical activity was recorded every 2 s by accelerometry in 32 normal weight and 15 overweight boys aged 8-10 years for four weekdays and two weekend days (South-West England 2007). Summary activity measures and activity pattern characteristics (frequency, intensity and duration of > or =4 s (short) and > or =5-min (long) bouts of > or =light, > or =moderate, > or =vigorous, and > or =hard activity) were recorded.\r\nRESULTS\r\nNormal weight boys accumulated more > or =hard activity (p<0.05) but other summary measures did not differ by weight status. However, the activity pattern differed in overweight relative to normal weight boys. The most frequent short bouts were shorter and less intense (p<0.05). All long bouts were less intense and > or =moderate long bouts were shorter and less frequent (p<0.05). Overall, less activity was accumulated on weekends (frequency of more intense short bouts, intensity of most frequent long bouts and duration of > or =light, > or =moderate (and for overweight boys > or =vigorous) short bouts dropped-off) (p<0.05).\r\nCONCLUSION\r\nDespite equivalent summary activity measures overweight boys exhibited fewer and shorter bouts, particularly sustained > or =moderate bouts, relative to normal weight boys suggesting that the activity pattern may be important for weight control.

Stopczynski, Arkadiusz; Stahlhut, Carsten; Petersen, Michael Kai; Larsen, Jakob Eg; Jensen, Camilla Falk; Ivanova, Marieta Georgieva et al. (2013):

Smartphones as pocketable labs: Visions for mobile brain imaging and neurofeedback.

In: *International Journal of Psychophysiology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-33925-001%26site%3dehost-live.

Abstract:

Mobile brain imaging solutions, such as the Smartphone Brain Scanner, which combines low cost wireless EEG sensors with open source software for real-time neuroimaging, may transform neuroscience experimental paradigms. Normally subject to the physical constraints in labs, neuroscience experimental paradigms can be transformed into dynamic environments allowing for the capturing of brain signals in everyday contexts. Using smartphones or tablets to access text or images may enable experimental design capable of tracing emotional responses when shopping or consuming media, incorporating sensorimotor responses reflecting our actions into brain machine interfaces, and facilitating neurofeedback training over extended periods.

Even though the quality of consumer neuroheadsets is still lower than laboratory equipment and susceptible to environmental noise, we show that mobile neuroimaging solutions, like the Smartphone Brain Scanner, complemented by 3D reconstruction or source separation techniques may support a range of neuroimaging applications and thus become a valuable addition to high-end neuroimaging solutions. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Stopczynski, Arkadiusz; Stahlhut, Carsten; Larsen, Jakob Eg; Petersen, Michael Kai; Hansen, Lars Kai (2014):

The smartphone brain scanner: a portable real-time neuroimaging system.

In: *PLoS One* 9 (2), S. e86733. DOI: 10.1371/journal.pone.0086733.

Abstract:

Combining low-cost wireless EEG sensors with smartphones offers novel opportunities for mobile brain imaging in an everyday context. Here we present the technical details and validation of a framework for building multi-platform, portable EEG applications with real-time 3D source reconstruction. The system - Smartphone Brain Scanner - combines an off-the-shelf neuroheadset or EEG cap with a smartphone or tablet, and as such represents the first fully portable system for real-time 3D EEG imaging. We discuss the benefits and challenges, including technical limitations as well as details of real-time reconstruction of 3D images of brain activity. We present examples of brain activity captured in a simple experiment involving imagined finger tapping, which shows that the acquired signal in a relevant brain region is similar to that obtained with standard EEG lab equipment. Although the quality of the signal in a mobile solution using an off-the-shelf consumer neuroheadset is lower than the signal obtained using high-density standard EEG equipment, we propose mobile application development may offset the disadvantages and provide completely new opportunities for neuroimaging in natural settings.

Straker, L.; Campbell, A.; Mathiassen, S.; Abbott, R. A.; Parry, S.; Davey, P. (2013):

Capturing the Pattern of Physical Activity and Sedentary Behavior: Exposure Variation Analysis of Accelerometer Data.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23416959.

Abstract:

BACKGROUND: Capturing the complex time pattern of physical activity and sedentary behavior using accelerometry remains a challenge. Research from occupational health suggests Exposure Variation Analysis (EVA) could provide a meaningful tool. This paper 1) explains the application of EVA to accelerometer data, 2) demonstrates how EVA thresholds and derivatives could be chosen and used to examine adherence to physical activity and sedentary behaviour guidelines, and 3) explores the validity of EVA outputs. METHODS: EVA outputs are compared with accelerometer data from 4 individuals (study 1a and1b) and 3 occupational groups (study 2): seated workstation office workers (n=8), standing workstation office workers (n=8) and teachers (n=8). RESULTS: Line graphs and related EVA graphs highlight the use of EVA derivatives for examining compliance with guidelines. EVA derivatives of occupational groups confirm no difference in bouts of activity but clear differences as expected in extended bouts of sedentary behavior and brief bursts of activity, thus providing evidence of construct validity. CONCLUSIONS: EVA offers a unique and comprehensive generic method that is able, for the first time, to capture the time pattern (both frequency and intensity) of physical activity and sedentary behavior, which can be tailored for both occupational and public health research

Stroe-Kunold, Esther; Wesche, Daniela; Friederich, Hans Christoph; Herzog, Wolfgang; Zastrow, Arne; Wild, Beate (2012):

Temporal relationships of emotional avoidance in a patient with anorexia nervosa--A time series analysis.

In: *International Journal of Psychiatry in Medicine* 44 (1), S. 53–62. DOI: 10.1037/t02598-000;

Abstract:

Objective: Anorexia nervosa (AN) is a serious eating disorder marked by self-induced underweight. In patients with AN, the avoidance of emotions appears to be a central feature that is reinforced during the acute state of the disorder. This single case study investigated the role of emotional avoidance of a 25-year-old patient with AN during her inpatient treatment. Method: Throughout the course of 96 days, the patient answered questions daily about her emotional avoidance, pro-anorectic beliefs, perfectionism, and further variables on an electronic diary. The patient's daily self-assessment of emotional avoidance was described in terms of mean value, range, and variability for the various treatment phases. Temporal relationships between

emotional avoidance and further variables were determined using a time series approach (vector autoregressive (VAR) modelling). Results: Diary data reflect that the patient's ability to tolerate unpleasant emotions appeared to undergo a process of change during inpatient treatment. Results of the time series analysis indicate that the more the patient was able to deal with negative emotions on any one day (t–1), the less she would be socially avoidant, cognitively confined to food and eating, as well as feeling less secure with her AN, and less depressive on the following day (t). Conclusions: The findings show that for this patient emotional avoidance plays a central role in the interacting system of various psychosocial variables. Replication of these results in other patients with AN would support the recommendation to focus more on emotional regulation in the treatment of AN. Stucky, Erin R.; Dresselhaus, Timothy R.; Dollarhide, Adrian; Shively, Martha; Maynard, Gregory; Jain, Sonia et al. (2009):

Intern to attending: assessing stress among physicians.

In: *Academic medicine : journal of the Association of American Medical Colleges* 84 (2), S. 251–257. DOI: 10.1097/ACM.0b013e3181938aad.

Abstract:

PURPOSE\r\nOrganizations have raised concerns regarding stress in the medical work environment and effects on health care worker performance. This study's objective was to assess workplace stress among interns, residents, and attending physicians using Ecological Momentary Assessment technology, the gold-standard method for real-time measurement of psychological characteristics.\r\nMETHOD\r\nThe authors deployed handheld computers with customized software to 185 physicians on the medicine and pediatric wards of four major teaching hospitals. The physicians contemporaneously recorded multiple dimensions of physician work (e.g., type of call day), emotional stress (e.g., worry, stress, fatigue), and perceived workload (e.g., patient volume). The authors performed descriptive statistics and t test and linear regression analyses.\r\nRESULTS\r\nParticipants completed 5,673 prompts during an 18-month period from 2004 to 2005. Parameters associated with higher emotional stress in linear regression models included male gender (t = -2.5, P = .01), total patient load (t = 4.2, P < .001), and sleep quality (t = -2.8, P = .006). Stress levels reported by attendings (t = -3.3, P = .001) were lower than levels reported by residents (t = -2.6, P = .009), and emotional stress levels of attendings and residents were both lower compared with interns.\r\nCONCLUSIONS\r\nOn inpatient wards, after recent resident duty hours changes, physician trainees continue to show wide-ranging evidence of workplace stress and poor sleep quality. This is among the first studies of medical workplace stress in real time. These results can help residency programs target education in stress and sleep and readdress workload distribution by training level. Further research is needed to clarify behavioral factors underlying variability in housestaff stress responses.

Design and Usage of the HeartCycle Education and Coaching Program for Patients With Heart Failure.

In: *JMIR Res Protoc* 3 (4), S. e72. DOI: 10.2196/resprot.3411.

Abstract:

BACKGROUND: Heart failure (HF) is common, and it is associated with high rates of hospital readmission and mortality. It is generally assumed that appropriate self-care can improve outcomes in patients with HF, but patient adherence to many self-care behaviors is poor. OBJECTIVE: The objective of our study was to develop and test an intervention to increase self-care in patients with HF using a novel, online, automated education and coaching program. METHODS: The online automated program was developed using a well-established, face-to-face, home-based cardiac rehabilitation approach. Education is tailored to the behaviors and knowledge of the individual patient, and the system supports patients in adopting self-care behaviors. Patients are guided through a goal-setting process that they conduct at their own pace through the support of the system, and they record their progress in an electronic diary such that the system can provide appropriate feedback. Only in challenging situations do HF nurses intervene to offer help. The program was evaluated in the HeartCycle study, a multicenter, observational trial with randomized components in which researchers investigated the ability of a third-generation telehealth system to enhance the management of patients with HF who had a recent (<60 days) admission to the hospital for symptoms or signs of HF (either new onset or recurrent) or were outpatients with persistent New York Heart Association (NYHA) functional class III/IV symptoms despite treatment with diuretic agents. The patients were enrolled from January 2012 through February 2013 at 3 hospital sites within the United Kingdom, Germany, and Spain. RESULTS: Of 123 patients enrolled (mean age 66 years (SD 12), 66% NYHA III, 79% men), 50 patients (41%) reported that they were not physically active, 56 patients (46%) did not follow a low-salt diet, 6 patients (5%) did not restrict their fluid intake, and 6 patients (5%) did not take their medication as prescribed. About 80% of the patients who started the coaching program for physical activity and low-salt diet became adherent by achieving their personal goals for 2 consecutive weeks. After becoming adherent, 61% continued physical activity coaching, but only 36% continued low-salt diet coaching. CONCLUSIONS: The HeartCycle education and coaching program helped most nonadherent patients with HF to adopt recommended self-care behaviors. Automated coaching worked well for most patients who started

the coaching program, and many patients who achieved their goals continued to use the program. For many patients who did not engage in the automated coaching program, their choice was appropriate rather than a failure of the program.

Transient and steady state estimation of human oxygen uptake based on noninvasive portable sensor measurements.

In: *Medical & biological engineering & computing* 47 (10), S. 1111–1117. DOI: 10.1007/s11517-009-0534-0.

Abstract:

The main motivation of this study is to establish an ambulatory cardio-respiratory analysis system for the monitoring and evaluation of exercise and regular daily physical activity. We explored the estimation of oxygen uptake by using noninvasive portable sensors. These sensors are easy to use but may suffer from malfunctions under free living environments. A promising solution is to combine sensors with different measuring mechanisms to improve both reliability and accuracy of the estimation results. For this purpose, we selected a wireless heart rate sensor and a tri-axial accelerometer to form a complementary sensor platform. We analyzed the relationship between oxygen uptake measured by gas analysis and data collected from the simple portable sensors using multivariable nonlinear modeling approaches. It was observed that the resulting nonlinear multivariable model could not only achieve a better estimate compared with single input single output models, but also had greater potential to improve reliability.

Designing web-apps for smartphones can be easy as making slideshow presentations.

In: *BMC Res Notes* 7, S. 94. DOI: 10.1186/1756-0500-7-94.

Abstract:

BACKGROUND: Limited clinician involvement in smartphone application development poses problems considering the extensive use of smartphones among medical professionals and patients. FINDINGS: We present a simple method for the clinician to develop simple web-apps using only an Internet browser and a text editor. CONCLUSIONS: This method may help clinicians develop simple web-apps and increase clinician involvement in smartphone content.

The feasibility of using pedometers and brief advice to increase activity in sedentary older women–a pilot study.

In: *BMC Health Services Research* 8 (1), S. 169.

Abstract:

People over the age of 70 carry the greatest burden of chronic disease, disability and health care use. Participation in physical activity is crucial for health, and walking accounts for much of the physical activity undertaken by sedentary individuals. Pedometers are a useful motivational tool to encourage increased walking and they are cheap and easy to use. The aim of this pilot study was to evaluate the feasibility of the use of pedometers plus a theory-based intervention to assist sedentary older women to accumulate increasing amounts of physical activity, mainly through walking.

METHODS:

Female participants over the age of 70 were recruited from primary care and randomised to receive either pedometer plus a theory-based intervention or a theory-based intervention alone. The theory-based intervention consisted of motivational techniques, goal-setting, barrier identification and self-monitoring with pedometers and daily diaries. The pedometer group were further randomised to one of three target groups: a 10%, 15% or 20% monthly increase in step count to assess the achievability and acceptability of a range of targets. The primary outcome was change in daily activity levels measured by accelerometry. Secondary outcome measures were lower limb function, health related quality of life, anxiety and depression.

RESULTS:

54 participants were recruited into the study, with an average age of 76. There were 9 drop outs, 45 completing the study. All participants in the pedometer group found the pedometers easy to use and there was good compliance with diary keeping (96%

in the pedometer group and 83% in the theory-based intervention alone group). There was a strong correlation (0.78) between accelerometry and pedometer step counts i.e. indicating that walking was the main physical activity amongst participants. There was a greater increase in activity (accelerometry) amongst those in the 20% target pedometer group compared to the other groups, although not reaching statistical significance (p = 0.192).

CONCLUSION:

We have demonstrated that it is feasible to use pedometers and provide theory-based advice to community dwelling sedentary older women to increase physical activity levels and a larger study is planned to investigate this further.

Sugiyama, Takemi; Okely, Anthony D.; Masters, Jane M.; Moore, Gary T. (2012):

Attributes of child care centers and outdoor play areas associated with preschoolers' physical activity and sedentary behavior.

In: *Environment and Behavior* 44 (3), S. 334–349. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-10511-002&site=ehost-live;t.sugiyama@uq.edu.au.

Abstract:

This study examined characteristics of child care centers associated with preschoolers' moderate-to-vigorous physical activity and sedentary behavior while in child care (MVPA-C, SB-C), and attributes of outdoor play areas associated with the same behaviors during outdoor time (MVPA-O, SB-O). Participants were 89 children (3 -5 years) recruited from 10 child care centers in Brisbane, Australia. Children's activity was measured by accelerometer over a 3-day period. Center characteristics and outdoor play area attributes were identified through survey and observation. We found that children were mostly sedentary while in child care. Lower child-staff ratios and using indoor play areas for motor activity were associated with more MVPA-C and less SB-C. Fixed play equipment in outdoor areas was conducive to more MVPA-O and less SB-O. This study suggests the possibility of enhancing preschoolers' activity levels through changing these attributes. Further research with more centers from diverse settings is needed to test these findings. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Applying experience sampling methods to partner violence research: Safety and feasibility in a 90-day study of community women.

In: *Violence against women* 17 (2), S. 251–266.

Abstract:

An experience sampling method (ESM) rarely has been applied in studies of intimate partner violence (IPV) despite the benefits to be gained. Because ESM approaches and women who experience IPV present unique challenges for data collection, an empirical question exists: Is it safe and feasible to apply ESM to community women who currently are experiencing IPV? A 90-day, design-driven feasibility study examined daily telephone data collection, daily paper diaries, and monthly retrospective semistructured interview methods among a community sample of 123 women currently experiencing IPV to study within-person relationships between IPV and substance use. Findings suggest that ESM is a promising method for collecting data among this population and can elucidate daily dynamics of victimization as well as associated behaviors and experiences. Lessons learned from the application of ESM to this population are also discussed.

Summerville, Amy; Roese, Neal J. (2008):

Dare to compare: Fact-based versus simulation-based comparison in daily life.

In: *Journal of Experimental Social Psychology* 44 (3), S. 664–671.

Abstract:

We examined the relative frequency of social, counterfactual, past-temporal, and future-temporal comparison in daily life using an experience-sampling method, in which participants were randomly prompted to record thought samples using palmtop computers carried for two weeks. Comparative thought accounted for 12% of all thoughts, and all four comparison types occurred with equivalent frequency. Comparisons may be either fact-based (i.e., based on actuality, as in social and past-temporal comparison) or simulation-based (i.e., based on imagination, as in counterfactual and future-temporal comparison).

Because the latter are more "unbounded," and because greater perceived opportunity invites greater self-improvement, we predicted and found that counterfactual and future-temporal comparison were more likely to be upward (vs. downward) than social and past-temporal comparison. All comparison types focused on approach more than avoidance motives, except for counterfactuals, which showed equivalent focus on both. These findings reveal the prominence of comparative thought in daily life, and underscore the value an integrative theory that describes social, counterfactual, or temporal comparison using a common theoretical platform.

Sumukadas, Deepa; Laidlaw, Simon; Witham, Miles D. (2008):

Using the RT3 accelerometer to measure everyday activity in functionally impaired older people.

In: *Aging clinical and experimental research* 20 (1), S. 15–18.

Abstract:

BACKGROUND AND AIMS:

Triaxial accelerometry may provide a simple measure of physical activity in older people, but the effect of different walking aids and accelerometer placements on measurement is not known. This study aimed to examine the effect of accelerometer placement, use of walking aids, and different types of physical activity on Stay- Healthy RT3 triaxial accelerometer readings in older people.

METHODS:

Twenty subjects aged over 65 years and five younger volunteers were recruited from Medicine for the Elderly services. Subjects performed six minutes each of standardized standing activity, sitting activity, sitting at rest, walking, and stair climbing. Counts generated from RT3 accelerometers worn anteriorly over both hips were recorded in subjects using different walking aids during these standardized activities.

RESULTS:

There were significant differences between counts generated by the left and right hip positions. The intraclass correlation coefficient of RT3 counts between left and right hip positions was 0.48, 0.39 and 0.99 for sedentary tasks (standing, sitting and rest), stair and walking tasks respectively. Counts ranged between 250-3000 min-1 during the walking task. Counts were proportional to the distance walked. Resting, sitting or standing all generated counts below 250 min-1, but there was no clear demarcation between these activities. The use of different walking aids did not affect the counts generated for any activity.

CONCLUSIONS:

Walking can be distinguished from other activities by upper and lower cutoffs. The RT3 accelerometer should be used on the same side of the body. Different walking aids do not appear to affect RT3 counts in older people.

Sund, Z. M.; Powell, T.; Greenwood, R.; Jarad, N. A. (2009):

Remote daily real-time monitoring in patients with COPD --a feasibility study using a novel device.

In: *Respiratory medicine* 103 (9), S. 1320–1328. DOI: 10.1016/j.rmed.2009.03.017.

Abstract:

New technologies have allowed remote real-time electronic recording of symptoms and spirometry. The feasibility of utilising this technology in COPD patients has not been investigated. This is a feasibility study. The primary objective is to determine whether the use of an electronic diary with a portable spirometer can be performed by COPD patients with a moderate to severe disease. Secondary objectives are to investigate the value of this method in early detection of acute exacerbations of COPD (AECOPD). In this 6-month study, 18 patients recorded daily their symptom score and spirometry. Data was sent on real time. AECOPD which was defined according to pre-set criteria were noted. Spirometry values and scores for health-related quality of life were compared between the start and the end of the study. Hospitalisation rate due to AECOPD was compared with a parallel period in the previous year. On average, patients were able to record 77% of their total study days. The system detected 73% of AECOPD. In further 27% of AECOPD patients sought treatment although the change in symptoms did not meet AECOPD definition. The number of COPD-related hospitalisations significantly reduced compared to the previous year. There was a significant increase in FEV(1) and FVC from the start to the end of the study. The remote monitoring device used in this study can be used in COPD patients. AECOPD was detected early in the majority of cases. Hospitalisation rate due to AECOPD was reduced and FEV(1) and FVC values increased during the study.

Sunner, L. E.; Walls, C.; Blood, E. A.; Mehta, C. M.; Shrier, L. A. (2012):

Feasibility and Utility of Momentary Sampling of Sex Events in Young Couples.

In: *J Sex Res* (0022-4499 (Linking)). DOI: 10.1080/00224499.2012.674574.

Abstract:

Research on couples' sexual behaviors is limited because most studies collect data from only one person, rely on retrospective recall, and lack ecological validity. This study explored the feasibility of using momentary sampling (MS) methods to collect sex event data from both members of heterosexual young adult couples. Over two weeks, 40 participants (20 couples) were asked to use a handheld computer to respond to random auditory signals each day and self-initiate a report as soon as possible after sex. Couples were randomized into two groups: (a) both partners reported after sex events, or (b) one partner reported after sex events during Week 1 and the other during Week 2 (randomized by gender). Descriptive statistics examined protocol compliance, partner agreement on whether an event occurred, condom use, and reason for sex, as well as partner involvement in reporting, comfort with reporting after sex, and study burden. Results indicated that couples were willing and able to adhere to the protocol. Partners agreed on condom use for nearly all sex events, but frequently reported different reasons for sex events. The use of MS methods to collect information about sex events within couples is a promising approach to the study of sexual behavior

Suto, Shin; Hiraoka, Takahiro; Okamoto, Yoshifumi; Okamoto, Fumiki; Oshika, Tetsuro (2014):

Photography of anterior eye segment and fundus with smartphone.

In: *Nihon Ganka Gakkai Zasshi* 118 (1), S. 7–14.

Abstract:

PURPOSE: To evaluate the safety and efficacy of anterior segment and fundus photography with a smartphone (iPhone 4S). METHOD: Safety was evaluated by comparing the luminance of the light emitting diode (LED) of the iPhone 4S and of a binocular indirect ophthalmoscope. Efficacy was assessed by recording the ocular findings in patients. The anterior segment was photographed in 30 patients using a macro lens and a handy slit lamp as a light source, and the retinal image was captured in 60 patients using a fundus lens. RESULT: The luminance of the iPhone LED was approximately 700,000 cd/m2, apparently lower than that of the ophthalmoscope, approximately 1,400,000 cd/m2. Clear images of the anterior segment were captured in all cases, and the fundus was clearly photographed in 58 of 60 cases. It was possible to watch the display and evaluate the real time images with other practitioners. CONCLUSION: We could successfully record and share the images of the anterior segment and fundus recorded with a smartphone. The current method is useful for diagnosis, treatment, and education in ophthalmology.

Suveg, Cynthia; Payne, Mary; Thomassin, Kristel; Jacob, Marni L. (2010):

Electronic diaries: A feasible method of assessing emotional experiences in youth?

In: *Journal of Psychopathology and Behavioral Assessment* 32 (1), S. 57–67.

Abstract:

The primary goal of this study was to examine whether electronic diaries are a feasible method of monitoring transitory emotional states with a school-age, community sample of youth. A second goal was to examine preliminary relations between indices of emotional functioning captured via electronic diaries and other measures of child emotional and psychological functioning. Participants included 38 youth between the ages of 7 and 12 (51% males, M age = 9 [1.52] years and 49% females, M age = 9 [1.94] years) and their mothers (M age = 39 years) and fathers (M age = 42 years). Children were prompted to indicate the intensity of their current emotion four times a day for 1 week using Palm Tungsten E2s. Youth also completed self-report measures of emotion intensity, awareness, and dysregulation. Parents completed measures of child emotion regulation and symptoms of externalizing and internalizing psychopathology. Sixty percent of the prompts were answered as intended. Higher levels of positive emotion intensity based on electronic diary ratings were negatively related to parent reports of adaptive emotion regulation and were positively related to youths' reports of emotion dysregulation and poor emotion awareness. Given that the electronic diary data offered unique information on youth emotional functioning, strategies to increase compliance with the diaries are suggested.

Swartz, Sarah J.; Srivaths, Poyyapakkam R.; Croix, Beth; Feig, Daniel I. (2008):

Cost-effectiveness of ambulatory blood pressure monitoring in the initial evaluation of hypertension in children.

In: *Pediatrics* 122 (6), S. 1177–1181. DOI: 10.1542/peds.2007-3432.

Abstract:

OBJECTIVE\r\nThe goal was to determine the cost-effectiveness of ambulatory blood pressure monitoring in the initial evaluation of stage 1 hypertension.\r\nMETHODS\r\nRetrospective chart review of data for children referred to Texas Children's Hospital hypertension clinic between January 2005 and August 2006 was performed. We compared the costs of standard evaluations versus the initial use of ambulatory blood pressure monitoring for children with clinic blood pressure measurements suggesting stage 1 hypertension. Charges for clinic visits, laboratory tests, and imaging were obtained from the Texas Children's Hospital billing department.\r\nRESULTS\r\nA total of 267 children were referred. One hundred thirty-nine children did not receive ambulatory blood pressure monitoring; 54 met clinical indications for ambulatory blood pressure monitoring but did not receive it because it was not a covered expense (44 children) or the family refused the study (10 children). One hundred twenty-six children received clinically indicated ambulatory blood pressure monitoring, paid for either through insurance or by the family. Fifty-eight children (46%) had confirmed white-coat hypertension, 62 (49%) stage 1 hypertension, and 6 (5%) stage 2 hypertension. With the observed prevalence of white-coat hypertension, initial ambulatory blood pressure monitoring use yielded net savings after evaluation of 3 patients, with projected savings of $2.4 million per 1000 patients.\r\nCONCLUSIONS\r\nAmbulatory blood pressure monitoring in the initial evaluation of suspected childhood hypertension is highly cost-effective. Awareness of cost saving potential may increase the availability of ambulatory blood pressure monitoring for evaluation of new-onset hypertension.

Swendeman, Dallas; Comulada, W. Scott; Ramanathan, Nithya; Lazar, Maya; Estrin, Deborah (2014):

Reliability and validity of daily self-monitoring by smartphone application for health-related quality-of-life, antiretroviral adherence, substance use, and sexual behaviors among people living with hiv.

In: *AIDS and Behavior*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-44594-001%26site%3dehost-live.

Abstract:

This paper examines inter-method reliability and validity of daily self-reports by smartphone application compared to 14-day recall web-surveys repeated over 6 weeks with people living with HIV (PLH). A participatory sensing framework guided participant-centered design prioritizing external validity of methods for potential applications in both research and self-management interventions. Inter-method reliability correlations were consistent with prior research for physical and mental health quality-of-life (r = 0.26–0.61), antiretroviral adherence (r = 0.70–0.73), and substance use (r = 0.65–0.92) but not for detailed sexual encounter surveys (r = 0.15–0.61). Concordant and discordant pairwise comparisons show potential trends in reporting biases, for example, lower recall reports of unprotected sex or alcohol use, and rounding up errors for frequent events. Event-based reporting likely compensated for modest response rates to daily time-based prompts, particularly for sexual and drug use behaviors that may not occur daily. Recommendations are discussed for future continuous assessment designs and analyses. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Swendsen, Joel; Ben-Zeev, Dror; Granholm, Eric (2011):

Real-time electronic ambulatory monitoring of substance use and symptom expression in schizophrenia.

In: *American Journal of Psychiatry* 168 (2), S. 202–209.

Abstract:

Objective:

Despite evidence demonstrating elevated comorbidity between schizophrenia and substance use disorders, the underlying mechanisms of association remain poorly understood. The brief time intervals that characterize interactions between substance use and psychotic symptoms in daily life are inaccessible to standard research protocols. The authors used electronic personal

digital assistants (PDAs) to examine the temporal association of diverse forms of substance use with psychotic symptoms and psychological states in natural contexts.

Method:

Of 199 community-dwelling individuals with schizophrenia or schizoaffective disorder who were contacted to participate in the study, 92% accepted and 73% completed the study. The 145 participants who completed the study provided reports of substance use, psychotic symptoms, mood, and event negativity multiple times per day over 7 consecutive days through PDAs.

Results:

Participants responded to 72% of the electronic interviews (N=2,737) across daily life contexts. Strong within-day prospective associations were observed in both directions between substance use and negative psychological states or psychotic symptoms, but considerable variation was observed by substance type. Consistent with the notion of self-medication, alcohol use was most likely to follow increases in anxious mood or psychotic symptoms. Cannabis and other illicit substances, demonstrating more complex patterns, were more likely to follow certain psychological states but were also associated with the later onset of psychotic symptoms.

Conclusions:

The dynamic interplay of substance use and psychotic symptoms is in many cases consistent with both causal and self-medication mechanisms, and these patterns of association should be considered in the design of treatment and prevention strategies.

Swinnen, Thijs Willem; Scheers, Tineke; Lefevre, Johan; Dankaerts, Wim; Westhovens, Rene; Vlam, Kurt (2014):

Physical activity assessment in patients with axial spondyloarthritis compared to healthy controls: a technology-based approach.

In: *PLoS One* 9 (2), S. e85309. DOI: 10.1371/journal.pone.0085309.

Abstract:

INTRODUCTION: Traditionally, assessment in axial Spondyloarthritis (aSpA) includes the evaluation of the capacity to execute tasks, conceptualized as physical function. The role of physical activity, defined as movement-related energy expenditure, is largely unknown and almost exclusively studied using patient-reported outcome measures. The aims of this observational cross-sectional study are to compare physical activity between patients with aSpA and healthy controls (HC) and to evaluate the contribution of disease activity to physical activity differences between groups. METHODS: Forty patients with aSpA were matched by age, gender, period of data acquisition in terms of days and season to 40 HC. Physical activity was measured during five consecutive days (three weekdays and two weekend days) using ambulatory monitoring (SenseWear Armband). Self-reported disease activity was measured by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Differences in physical activity between patients with aSpA and HC were examined with Wilcoxon signed-rank tests and a mixed linear model. Difference scores between patients and HC were correlated with disease activity. RESULTS: Average weekly physical activity level (Med(IQR); HC:1.54(1.41-1.73); aSpA:1.45(1.31-1.67),MET) and energy expenditure (HC:36.40(33.43-41.01); aSpA:34.55(31.08-39.41),MET.hrs/day) were significantly lower in patients with aSpA. Analyses across intensity levels revealed no significant differences between groups for inactivity and time spent at light or moderate physical activities. In contrast, weekly averages of vigorous (HC:4.02(1.20-12.60); aSpA:0.00(0.00-1.20),min/d), very vigorous physical activities (HC0.00(0.00-1.08); aSpA:0.00(0.00-0.00),mind/d) and moderate/(very)vigorous combined (HC2.41(1.62-3.48); aSpA:1.63(1.20-2.82),hrs/d) were significantly lower in patients with aSpA. Disease activity did not interact with differences in physical activity between patients with aSpA and HC, evidenced by non-significant and very low correlations (range: -0.06-0.17) between BASDAI and HC-aSpA patients' difference scores. CONCLUSIONS: Patients with aSpA exhibit lower physical activity compared to HC and these differences are independent of self-reported disease activity. Further research on PA in patients with aSpA should be prioritized.

Syed, Faiz I.; Oza, Ashish L.; Vanderby, Ray; Heiderscheit, Bryan; Anderson, Paul A. (2007):

A method to measure cervical spine motion over extended periods of time.

In: *Spine* 32 (19), S. 2092–2098.

Abstract:

Objective. To develop and validate a motion sensor system for measuring cervical spine motion over extended time periods.

Summary of Background Data. Many studies using different methodologies have tried to estimate cervical spine motion. These have mostly been carried out in a laboratory setting performing active/passive range of motion or activities of daily living. However, cervical spine performance over extended periods of time in natural environments remains unknown.

Methods. A novel motion sensor system, Wisconsin Analysis of Spine Motion Performance (WASP), was validated using 2 benchmarks: a materials testing machine (MTS) and optical motion tracking laboratory. Parameters tested included drift, frequency response, accuracy, effect of sensor orientation, and coupled motions. Applied motions from the MTS and measured motions in subject volunteers under various conditions were compared with WASP using correlation coefficients. Intersubject and intrasubject variability analyses for WASP were also performed.

Results. The average WASP slopes for accuracy (compared with MTS) in flexion-extension, lateral bending, and axial rotation were 0.89, 0.93, and 0.38, respectively. The correlation coefficient was 0.99 in all cases. Compared with optical motion tracking, the WASP regression slopes were 1.1, 1.02, and 0.4 and the correlation coefficients were 0.98, 0.92, and 0.93 in the 3 axes of motion. Coupled motion was noted during all subject motions. WASP peak detection algorithm had a 0% error discounting boundary conditions.

Conclusion. WASP was accurate in flexion-extension and lateral bending. In axial rotation, WASP was less accurate. However, the system was highly reliable with low intersubject and intrasubject variability. WASP can be used in estimating cervical spine motion with high reliability while keeping in mind the decreased accuracy in measuring axial rotation.

T Prill and J Fahrenberg (2006):

Simultaneous assessment of posture and limb movements (e.g., periodic leg movements) with calibrated multiple accelerometry.

In: *Physiol Meas* 27 (10), S. N47. Online verfügbar unter http://stacks.iop.org/0967-3334/27/i=10/a=N02.

Abstract:

This study describes new applications for the method of calibrated multiple accelerometry , which detects posture and distinct motion patterns, and limb movements continuously. The aim of our study was to evaluate this assessment technique in terms of its suitability for exploring the relationships between pathological limb movement activity (e.g., periodic leg movements) and posture. The new method proved to be appropriate for the simultaneous assessment of pathological leg jerks and posture and provided a means to revealing possible relations. Generally, our study demonstrates the application of this (ambulatory) assessment technique in the field of sleep and neurological disorders.

Telemonitoring of Daily Activity and Symptom Behavior in Patients with COPD.

In: *Int.J Telemed.Appl.* 2012 (1687-6415 (Linking)), S. 438736. DOI: 10.1155/2012/438736.

Abstract:

Objectives. This study investigated the activity behavior of patients with COPD in detail compared to asymptomatic controls, and the relationship between subjective and objective activities (awareness), and readiness to change activity behavior. Methods. Thirty-nine patients with COPD (66.0 years; FEV(1)% predicted: 44.9%) and 21 healthy controls (57.0 years) participated. Objective daily activity was assessed by accelerometry and expressed as amount of activity in counts per minute (cpm). Patients' baseline subjective activity and stage of change were assessed prior to measurements. Results. Mean daily activity in COPD patients was significantly lower compared to the healthy controls (864 +/- 277 cpm versus 1162 +/- 282 cpm, $P < 0.001$). COPD patients showed a temporary decrease in objective activities in the early afternoon. Objective and subjective activities were significantly moderately related and most patients (55.3%) were in the maintenance phase of the stages of change. Conclusions. COPD patients show a distinctive activity decrease in the early afternoon. COPD patients are moderately aware of their daily activity but regard themselves as physically active. Therefore, future telemedicine interventions might consider creating awareness of an active lifestyle and provide feedback that aims to increase and balance activity levels

Tabak, M.; Vollenbroek-Hutten, M. M.; van der Valk, P. D.; van der Palen, J.; Hermens, H. J. (2013):

A telerehabilitation intervention for patients with Chronic Obstructive Pulmonary Disease: a randomized controlled pilot trial.

In: *Clin.Rehabil.* (0269-2155 (Linking)). DOI: 10.1177/0269215513512495.

Abstract:

Objective:First, to investigate the effects of a telerehabilitation intervention on health status and activity level of patients with Chronic Obstructive Pulmonary Disease (COPD), compared to usual care. Second, to investigate how patients comply with the intervention and whether compliance is related to treatment outcomes.Design:a randomized controlled pilot trialSubjects:Thirty-four patients diagnosed with COPD.Intervention:The telerehabilitation application consists of an activity coach (3D-accelerometer with smartphone) for ambulant activity registration and real-time feedback, complemented by a web portal with a symptom diary for self-treatment of exacerbations. The intervention group used the application for 4 weeks. The control group received usual care.Main measures:Activity level measured by a pedometer (in steps/day), health status by the Clinical COPD Questionnaire at baseline and after intervention. Compliance was expressed as the time the activity coach was worn.Results:Fourteen intervention and 16 control patients completed the study. Activity level (steps/day) was not significantly affected by the intervention over time. There was a non-significant difference in improvement in health status between the intervention (-0.34+/-0.55) and control group (0.02+/-0.57, p=0.10). Health status significantly improved within the intervention group (p=0.05). The activity coach was used more than prescribed (108%) and compliance was related to the increase in activity level for the first two feedback weeks (r=0.62, p=0.03).Conclusions:This pilot study shows the potential of the telerehabilitation intervention: compliance with the activity coach was high, which directly related to an improvement in activity levels

The effect of a physical activity intervention on bias in self-reported activity.

In: *Annals of epidemiology* 19 (5), S. 316–322. DOI: 10.1016/j.annepidem.2009.01.001.

Abstract:

PURPOSE\r\nA positive outcome in self-reported behavior could be detected erroneously if an intervention caused over-reporting of the targeted behavior. Data collected from a multi-site randomized trial were examined to determine if adolescent girls who received a physical activity intervention over-reported their activity more than girls who received no intervention.\r\nMETHODS\r\nActivity was measured using accelerometers and self-reports (3-Day Physical Activity Recall, 3DPAR) in cross-sectional samples preintervention (6th grade, n = 1,464) and post-intervention (8th grade, n = 3,114). Log-transformed accelerometer minutes were regressed on 3DPAR blocks, treatment group, and their interaction, while adjusting for race, body mass index, and timing of data collection.\r\nRESULTS\r\nPreintervention, the association between measures did not differ between groups, but post-intervention 3DPAR blocks were associated with fewer log-accelerometer minutes of moderate-vigorous physical activity (MVPA) in intervention girls than in control girls (p = 0.002). The group difference was primarily in the upper 15% of the 3DPAR distribution, where control girls had >1.7 more accelerometer minutes of MVPA than intervention girls who reported identical activity levels. Group differences in this subsample were 8.5%-16.2% of the mean activity levels; the intervention was powered to detect a difference of 10%.\r\nCONCLUSION\r\nSelf-report measures should be interpreted with caution when used to evaluate a physical activity intervention.

Repetitive thought impairs sleep quality: an experience sampling study.

In: *Behav Ther* 45 (1), S. 67–82. DOI: 10.1016/j.beth.2013.09.004.

Abstract:

Although previous research has suggested that presleep negative cognitive activities are associated with poor sleep quality, there is little evidence regarding the association between negative thoughts and sleep in real-life settings. The present study used experience sampling and long-term sleep monitoring with actigraphy to investigate the relationships among negative repetitive thought, mood, and sleep problems. During a 1-week sampling period, 43 undergraduate students recorded their thought content and mood eight times a day at semirandom intervals. In addition to these subjective reports, participants wore actigraphs on their wrists in order to measure sleep parameters. Analyses using multilevel modeling showed that repetitive thought in the evening was significantly associated with longer sleep-onset latency, decreased sleep efficiency, and reduced total sleep time. Furthermore, impaired sleep quality was significantly associated with reduced positive affect the next morning, and decreased positive affect was indirectly associated with increased repetitive thought in the evening. These findings suggest

the existence of a self-reinforcing cycle involving repetitive thought, mood, and impaired sleep quality, highlighting the importance of cognitive and emotional factors in enhancement and maintenance of good-quality sleep.

Concreteness of thinking and self-focus.

In: *Consciousness and cognition* 19 (1), S. 419–425. DOI: 10.1016/j.concog.2009.11.010.

Abstract:

The present study used the experience sampling method to detect fluctuations in thinking, such as self-focus or concreteness in daily life, and to examine their relationship with depressive symptoms and concurrent negative affect. Thirty-one undergraduates recorded their negative affect, ruminative self-focus, and concreteness of thinking eight times a day for 1 week. Multilevel modeling showed that individuals with increasing levels of depression showed lower levels of concreteness in their daily thinking. Further analysis revealed a significant positive association between momentary ruminative self-focus and concurrent negative affect only with low concreteness of thinking. These results suggested that individuals with increasing levels of depression chronically process self-related information on an abstract level, which reflects a malfunction of their self-regulatory cycle and might serve to maintain or even exacerbate dysphoric moods.

Self-focused thinking predicts nighttime physiological de-arousal.

In: *Biol Psychol* 97, S. 9–14. DOI: 10.1016/j.biopsycho.2014.01.001.

Abstract:

Excessive focus on the internal self has maladaptive consequences for mental and physical health. Although the emotional functions of self-focus have been well established, no study has examined physiological arousal during the daily experience of self-focused thinking. The present study investigates the association between self-focus and autonomic activity using the experience sampling method with ambulatory monitoring of heart rate variability (HRV). Forty-five students reported the content of their thoughts during their daily activities while their heart rate (HR) was being recorded. Multilevel modeling analyses showed that HRV was lower (and HR was higher) over the sampling day if participants engaged in more self-focus, while HRV increased (and HR decreased) from midday to nighttime if participants did not engage in self-focused thinking. These results suggest that self-focus at night is associated with increased physiological arousal, and leads to inhibition of de-arousal associated with normal sleep processes. Implications for insomnia are discussed.

Gait posture estimation using wearable acceleration and gyro sensors.

In: *Journal of biomechanics* 42 (15), S. 2486–2494. DOI: 10.1016/j.jbiomech.2009.07.016.

Abstract:

A method for gait analysis using wearable acceleration sensors and gyro sensors is proposed in this work. The volunteers wore sensor units that included a tri-axis acceleration sensor and three single axis gyro sensors. The angular velocity data measured by the gyro sensors were used to estimate the translational acceleration in the gait analysis. The translational acceleration was then subtracted from the acceleration sensor measurements to obtain the gravitational acceleration, giving the orientation of the lower limb segments. Segment orientation along with body measurements were used to obtain the positions of hip, knee, and ankle joints to create stick figure models of the volunteers. This method can measure the three-dimensional positions of joint centers of the hip, knee, and ankle during movement. Experiments were carried out on the normal gait of three healthy volunteers. As a result, the flexion-extension (F-E) and the adduction-abduction (A-A) joint angles of the hips and the flexion-extension (F-E) joint angles of the knees were calculated and compared with a camera motion capture system. The correlation coefficients were above 0.88 for the hip F-E, higher than 0.72 for the hip A-A, better than 0.92 for the knee F-E. A moving stick figure model of each volunteer was created to visually confirm the walking posture. Further, the knee and ankle joint trajectories in the horizontal plane showed that the left and right legs were bilaterally symmetric.

Emotional reactivity and regulation in anxious and nonanxious youth: a cell-phone ecological momentary assessment study.

In: *J Child Psychol Psychiatry* (0021-9630 (Linking)). DOI: 10.1111/j.1469-7610.2011.02469.x.

Abstract:

Background: Reviews have highlighted anxious youths' affective disturbances, specifically, elevated negative emotions and reliance on ineffective emotion regulation strategies. However, no study has examined anxious youth's emotional reactivity and regulation in real-world contexts. Methods: This study utilized an ecological momentary assessment approach to compare real-world emotional experiences of 65 youth with generalized anxiety disorder, social anxiety disorder, or social phobia (ANX) and 65 age-matched healthy controls (CON), ages 9-13 years. Results: Hierarchical linear models revealed that ANX reported higher levels of average past-hour peak intensity of nervous, sad and upset emotions than CON youth but similar levels during momentary reports of current emotion. As expected, ANX youth reported more frequent physiological reactions in response to a negative event; however, there were no group differences in how frequently they used cognitive-behavioral strategies. Avoidance, distraction and problem solving were associated with the down-regulation of all negative emotions except nervousness for both ANX and CON youth; however, group differences emerged for acceptance, rumination and physiological responding. Conclusions: In real-world contexts, ANX youth do not report higher levels of momentary negative emotions but do report heightened negative emotions in response to challenging events. Moreover, ANX youth report no differences in how frequently they use adaptive regulatory strategies but are more likely to have physiological responses to challenging events. They are also less effective at using some strategies to down-regulate negative emotion than CON youth

Daily physical activity in Japanese preschool children evaluated by triaxial accelerometry: the relationship between period of engagement in moderate-to-vigorous physical activity and daily step counts.

In: *Journal of physiological anthropology* 28 (6), S. 283–288.

Abstract:

The purpose of the present study was to evaluate moderate-to-vigorous physical activity using triaxial accelerometry in Japanese preschool children. The relationship between daily step counts as a convenient measure of physical activity and minutes of

engagement in moderate-to-vigorous physical activity was also examined. Physical activity was assessed using a triaxial accelerometer (ActivTracer, GMS) and daily steps using a uniaxial accelerometer for 6 consecutive days, including weekdays and weekend days, in 157 four- to six-year-old Japanese children attending kindergarten or nursery school. Using triaxial and uniaxial accelerometers, nonlocomotive activities and step counts for young children can be evaluated, respectively. Average daily moderate-to-vigorous physical activity (physical activity ratio >or=3) and step counts were 102 (+/-32) min/day and 13,037 (+/-2,846) steps/day, respectively. A strong and significant correlation was observed between minutes of moderate-to-vigorous physical activity and step counts (r=0.832, p<0.001). The daily step counts corresponding to 60 min, 100 min, and 120 min of moderate-to-vigorous physical activity were 9,934, 12,893, and 14,373 steps/day, respectively. The correlation coefficient between minutes of higher intensity activities (physical activity ratio >or=4) and step counts was slightly lower (r=0.604, p<0.001). The daily step count corresponding to 30 min of the higher intensity activities was 14,768 steps/day. These results suggest that approximately 13,000 steps/day are required for preschool children to engage in more than 100 min of moderate-to-vigorous physical activity.

Tanantong, T.; Nantajeewarawat, E.; Thiemjarus, S. (2014):

Toward continuous ambulatory monitoring using a wearable and wireless ECG-recording system: a study on the effects of signal quality on arrhythmia detection.

In: *Biomed.Mater.Eng* 24 (1), S. 391–404. DOI: 10.3233/BME-130823.

Abstract:

Five well-known arrhythmia classification algorithms were compared in this paper based on the recommendations in AAMI standard. They are C4.5, k-Nearest Neighbor, Multilayer Perceptron, PART, and Support Vector Machine, respectively, with inputs related to heartbeat intervals and ECG morphological features. They were evaluated on three independent datasets, including the MIT-BIH arrhythmia database, a collection of ECG signals acquired from healthy subjects by the wireless Body Sensor Network (BSN) nodes, and a third dataset captured also by the BSN nodes. Results showed the overall accuracy on the MIT-BIH arrhythmia database was approximately 99.04%, with high sensitivity, specificity, and selectivity. When tested with ECG signals acquired from the human subjects, which were partially deteriorated due to several factors, e.g., motion artifacts and data transmission problems, the overall accuracy of 94.19% and that of 81.22% were obtained for static activities and dynamic activities, respectively. In addition, the effects of the signal quality from these human subjects on false alarms were investigated. When false alarms occurring in signal segments with low quality were excluded, the number of false detections reduced from 14.17% to 8.65%. When evaluated on signals generated by the patient simulator, which included several types of premature ventricular contraction without artifacts from body movements, a high classification accuracy was also observed

Tang, Jason; Abraham, Charles; Greaves, Colin; Yates, Tom (2014):

Self-directed interventions to promote weight loss: a systematic review of reviews.

In: *J Med Internet Res* 16 (2), S. e58. DOI: 10.2196/jmir.2857.

Abstract:

BACKGROUND: A wide range of self-directed weight-loss interventions are available, providing users with a variety of tools delivered through various formats to regulate weight-related behavior patterns. However, it is unclear how effective self-directed interventions are and how they promote weight loss and weight maintenance. OBJECTIVE: A systematic review of reviews was conducted to examine the effectiveness of such interventions and to identify intervention content associated with effectiveness. METHODS: MEDLINE, Embase, PsycINFO, CINAHL, and the Cochrane Library for systematic reviews were searched from 2000-2012 for reviews of the effectiveness of self-directed interventions on weight loss and weight maintenance in adults. Two reviewers used predefined inclusion criteria to select relevant reviews and assess their quality using the Overview Quality Assessment Questionnaire (OQAQ). We extracted data on effectiveness and on relationships between intervention characteristics and effectiveness. RESULTS: Twenty reviews were included and quality assessed. Findings relevant to self-directed interventions, including interactive websites, smartphone applications, and text messaging (short message service, SMS) were summarized. Findings were mixed but promising. For example, one review of Internet-based interventions found that, when used in conjunction with standard weight loss programs, these interventions resulted in a significant average increase in weight loss of 1.5 kg over evaluation periods. Unfortunately, only 7 of 20 reviews were of high methodological quality according to OQAQ scores, and only 4 employed meta-analyses. Few reviews linked intervention content to effectiveness. CONCLUSIONS: Current evidence suggests that self-directed interventions can independently promote weight loss and can augment interventions involving personal contact. Particular change techniques and delivery modes including individualized feedback, email counseling, and online social support appear to enhance effectiveness. Further reviews of the content of self-directed weight-loss intervention studies are needed to clarify which change techniques delivered through which delivery formats optimize intervention effectiveness.

Tang, Nicole K. Y.; Goodchild, Claire E.; Sanborn, Adam N.; Howard, Jonathan; Salkovskis, Paul M. (2012):

Deciphering the temporal link between pain and sleep in a heterogeneous chronic pain patient sample: A multilevel daily process study.

In: *Sleep: Journal of Sleep and Sleep Disorders Research* 35 (5), S. 657–687. DOI: 10.1037/t14108-000;

Abstract:

Objectives: Because insomnia is a common comorbidity of chronic pain, scientific and clinical interest in the relationship of pain and sleep has surged in recent years. Although experimental studies suggest a sleep-interfering property of pain and a pain-enhancing effect of sleep deprivation/ fragmentation, the temporal association between pain and sleep as experienced by patients is less understood. The current study was conducted to examine the influence of presleep pain on subsequent sleep and sleep on pain reports the next day, taking into consideration other related psychophysiologic variables such as mood and arousal. Design: A daily process study, involving participants to monitor their pain, sleep, mood, and presleep arousal for 1 wk. Multilevel modeling was used to analyze the data. Setting: In the patients' natural living and sleeping environment. Patients: One hundred nineteen patients (73.9% female, mean age = 46 years) with chronic pain and concomitant insomnia. Measurement: An electronic diary was used to record patients' self-reported sleep quality/efficiency and ratings of pain, mood, and arousal at different times of the day; actigraphy was also used to provide estimates of sleep efficiency. Results: Results indicated that presleep pain was not a reliable predictor of subsequent sleep. Instead, sleep was better predicted by presleep cognitive arousal. Although sleep quality was a consistent predictor of pain the next day, the pain-relieving effect of sleep was only evident during the first half of the day. Conclusions: These findings challenge the often-assumed reciprocal relationship between pain and sleep and call for a diversification in thinking of the daily interaction of these 2 processes. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Tang, Nicole K. Y.; Sanborn, Adam N. (2014):

Better quality sleep promotes daytime physical activity in patients with chronic pain? A multilevel analysis of the within-person relationship.

In: *PLoS One* 9 (3), S. e92158. DOI: 10.1371/journal.pone.0092158.

Abstract:

BACKGROUND: Promoting physical activity is key to the management of chronic pain, but little is understood about the factors facilitating an individual's engagement in physical activity on a day-to-day basis. This study examined the within-person effect of sleep on next day physical activity in patients with chronic pain and insomnia. METHODS: 119 chronic pain patients monitored their sleep and physical activity for a week in their usual sleeping and living environment. Physical activity was measured using actigraphy to provide a mean activity score each hour. Sleep was estimated with actigraphy and an electronic diary, providing an objective and subjective index of sleep efficiency (A-SE, SE) and a sleep quality rating (SQ). The individual and relative roles of these sleep parameters, as well as morning ratings of pain and mood, in predicting subsequent physical activity were examined in multilevel models that took into account variations in relationships at the 'Day' and 'Participant' levels. RESULTS: Of the 5 plausible predictors SQ was the only significant within-person predictor of subsequent physical activity, such that nights of higher sleep quality were followed by days of more physical activity, from noon to 11pm. The temporal association was not explained by potential confounders such as morning pain, mood or effects of the circadian rhythm. CONCLUSIONS: In the absence of interventions, chronic pain patients spontaneously engaged in more physical activity following a better night of sleep. Improving nighttime sleep may well be a novel avenue for promoting daytime physical activity in patients with chronic pain.

Taraldsen, Kristin; Chastin, Sebastien F. M.; Riphagen, Ingrid I.; Vereijken, Beatrix; Helbostad, Jorunn L. (2012):

Physical activity monitoring by use of accelerometer-based body-worn sensors in older adults: A systematic literature review of current knowledge and applications.

In: *Maturitas* 71 (1), S. 13–19. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-00510-005&site=ehost-live;Kristin.Taraldsen@ntnu.no.

Abstract:

Objectives: To systematically review the literature on physical activity variables derived from body-worn sensors during long term monitoring in healthy and in-care older adults. Methods: Using pre-designed inclusion and exclusion criteria, a PubMed search strategy was designed to trace relevant reports of studies. Last search date was March 8, 2011. Study selection: Studies

that included persons with mean or median age of >65 years, used accelerometer-based body-worn sensors with a monitoring length of >24 h, and reported values on physical activity in the samples assessed. Results: 1403 abstracts were revealed and 134 full-text papers included in the final review. A variety of variables derived from activity counts or recognition of performed activities were reported in healthy older adults as well as in in-care older adults. Three variables were possible to compare across studies, level of Energy Expenditure in kcal per day and activity recognition in terms of total time in walking and total activity. However, physical activity measured by these variables demonstrated large variation between studies and did not distinguish activity between healthy and in-care samples. Conclusion: There is a rich variety in methods used for data collection and analysis as well as in reported variables. Different aspects of physical activity can be described, but the variety makes it challenging to compare across studies. There is an urgent need for developing consensus on activity monitoring protocols and which variables to report. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Tasca, Giorgio A.; Illing, Vanessa; Balfour, Louise; Krysanski, Valerie; Demidenko, Natasha; Nowakowski, Joanna; Bissada, Hany (2009):

Psychometric properties of self-monitoring of eating disorder urges among treatment seeking women: ecological momentary assessment using a daily diary method.

In: *Eat Behav* 10 (1), S. 59–61. DOI: 10.1016/j.eatbeh.2008.10.004.

Abstract:

OBJECTIVES\r\nThe psychometric properties of an ecological momentary assessment (EMA) method used to evaluate eating disorder (ED) urges were examined.\r\nMETHODS\r\nParticipants, 139 women who sought treatment for an ED, completed a daily diary measuring ED urges after each meal for a three week period at the start of treatment, and a measure of ED attitudes and behaviors pre- and post-treatment.\r\nRESULTS\r\nThe construct validity of this method was indicated by a two factor solution representing binge eating urges and ED compensatory behavior urges, and by significant differences between ED diagnostic groups on ED urge type. Correlations of ED urges early in therapy with outcomes provided evidence for predictive validity. Correlations at pre-treatment between ED urges and ED attitudes and behaviors supported criterion validity. EMA of ED urges showed good retest stability.\r\nCONCLUSIONS\r\nEMA of ED urges is a valid and reliable approach that is associated with ED symptom severity, and predictive of treatment outcome.

Constraint-Induced Therapy Combined with Conventional Neurorehabilitation Techniques in Chronic Stroke Patients with Plegic Hands: A Case Series.

In: *Arch.Phys.Med.Rehabil.* (0003-9993 (Linking)). DOI: 10.1016/j.apmr.2012.07.029.

Abstract:

OBJECTIVE: To determine in this pilot study whether the combination of CI therapy and conventional rehabilitation techniques can produce meaningful motor improvement in chronic stroke patients with initially fisted hands. In the past, limited success has been achieved using CI therapy alone for stroke patients with plegic hands. DESIGN: Case series SETTING: University hospital outpatient laboratory PARTICIPANTS: Consecutive sample of 6 patients > 1 yr post-stroke with plegic hands INTERVENTIONS: Treatment consisted of an initial period of 3 weeks (Phase A) when adaptive equipment in the home, orthotics and splints were employed to improve ability to engage in activities of daily living. This was continued in Phase B, when CI therapy along with selected neurodevelopmental treatment techniques were added. MAIN OUTCOME MEASURES: Motor Activity Log (MAL), accelerometry, Fugl-Meyer Motor Assessment (F-M) RESULTS: Patients exhibited a large improvement in spontaneous real-world use of the more-affected arm (mean lower-functioning MAL change = 1.3+/-0.4 points, P <0.001, d' = 3.0), and a similar pattern of increase in an objective measure of real-world more-affected arm movement (mean change in ratio of more- to less-affected arm accelerometer recordings = 0.12+/-0.1 points, P = 0.016 d' = 1.2). A large improvement in motor status was also recorded (mean F-M change = 5.3+/-3.3 points, P = 0.005, d' = 1.6). CONCLUSIONS: The findings of this pilot study suggest that stroke patients with plegic hands can benefit from CI therapy combined with some conventional rehabilitation techniques, even long after brain injury. More research is warranted

The metrics of societal happiness.

In: *Social Indicators Research* 117 (2), S. 577–600. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-20235-001%26site%3dehost-live.

Abstract:

Growing interest in the measurement of subjective well-being (SWB) has also been accompanied by scientific debate on the optimal method for measuring SWB. The momentary perspective, which is represented by the ecological momentary assessment (EMA) and day reconstruction method (DRM), emphasizes the momentary experiences and aims to measure SWB in an objective manner via the aggregation of happiness levels over time and activities. The global reporting perspective emphasizes the subjective evaluation of life experiences and aims to capture the overall evaluation using retrospection or global evaluations. We discuss the strengths and weaknesses of these different perspectives and methods by examining conceptual, methodological, and practical issues. We propose adopting a multi-method assessment approach to SWB that uses both perspectives and the corresponding methods in a theory-driven and complementary manner. For the purposes of measuring and tracking SWB of societies, we also call for more research on the reliability and validity of EMA and DRM. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Taylor, Lynne M.; Klenk, Jochen; Maney, Alistair J.; Kerse, Ngaire; MacDonald, Bruce M.; Maddison, Ralph (2014):

Validation of a Body-Worn Accelerometer to Measure Activity Patterns in Octogenarians.

In: *Arch Phys Med Rehabil. DOI:* 10.1016/j.apmr.2014.01.013.

Abstract:

OBJECTIVE: To determine the validity of a triaxial body-worn accelerometer for detection of gait and postures in people aged >80 years. DESIGN: Participants performed a range of activities (sitting, lying, walking, standing) in both a controlled and a home setting while wearing the accelerometer. Activities in the controlled setting were performed in a scripted sequence. Activities in the home setting were performed in an unscripted manner. Analyzed accelerometer data were compared against video observation as the reference measure. SETTING: Independent-living and long-term-care retirement village. PARTICIPANTS: Older people (N=22; mean age +/- SD, 88.1+/-5y) residing in long-term-care and independent-living retirement facilities. INTERVENTIONS: Not applicable. MAIN OUTCOME MEASURES: The level of agreement between video observation and the accelerometer for the total duration of each activity, and second-by-second correspondence between video observation and the accelerometer for each activity. RESULTS: The median absolute percentage errors between video observation and the accelerometer were <1% for locomotion and lying. The absolute percentage errors were higher for sitting (median, -22.3%; interquartile range [IQR], -62.8% to 10.7%) and standing (median, 24.7%; IQR, -7.3% to 39.6%). A second-by-second analysis between video observation and the accelerometer found an overall agreement of >/=85% for all activities except standing (median, 56.1%; IQR, 34.8%-81.2%). CONCLUSIONS: This single-device accelerometer provides a valid measure of lying and locomotion in people aged >80 years. There is an error of approximately 25% when discriminating sitting from standing postures, which needs to be taken into account when monitoring longer-term habitual activity in this age group.

Taylor, Rachael W.; Murdoch, Linda; Carter, Philippa; Gerrard, David F.; Williams, Sheila M.; Taylor, Barry J. (2009):

Longitudinal study of physical activity and inactivity in preschoolers: the FLAME study.

In: *Med Sci Sports Exerc* 41 (1), S. 96–102. DOI: 10.1249/MSS.0b013e3181849d81.

Abstract:

PURPOSE\r\nTo investigate patterns of activity and inactivity in a birth cohort of children followed from 3 to 5 yr and to investigate whether changes in activity occurred over time.\r\nMETHODS\r\nTwo hundred and forty-four children (44% female) were seen annually at 3, 4, and 5 yr. Physical activity and inactivity was measured by questionnaire (parent-proxy) and by Actical accelerometers for five consecutive days (24-h monitoring) each year in children and once in each parent for 7 d (69% with data).\r\nRESULTS\r\nRetention of participants was high (92%). Viable accelerometry data were obtained for 76-85% of children at each age. Reliability estimates ranged from 0.80 (3 yr) to 0.84 (5 yr). Day of the week, season, sex, hours of childcare, or birth order did not affect daily average accelerometry counts (AAC) at any age. Parental activity correlated weakly with the child's activity at 3 and 4 yr (r values = 0.17-0.28), but only the father's activity remained a significant predictor of the child's activity after adjustment for confounders. Children spent approximately 90 min.d in screen time (television, videos, DVD, and computers) with an additional 90 min in other sedentary activities (reading, drawing, and music). Physical activity was significantly reduced at 4 and 5 yr compared with 3 yr in both sexes, whether measured as AAC (24-h data, awake time only, weekend days, weekdays),

time in moderate or vigorous activity, or from parental reports of activity.\r\nCONCLUSION\r\nLevels of physical activity declined in boys and girls between the ages 3 and 4-5 yr, whether using objective measures or parental reports of activity.

Te Lindert, Bart H. W.; van Someren, Eus J. W. (2013):

Sleep estimates using microelectromechanical systems (MEMS).

In: *Sleep: Journal of Sleep and Sleep Disorders Research* 36 (5), S. 781–789. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-15433-021%26site%3dehost-live;b.te.lindert@nin.knaw.nl.

Abstract:

Study Objectives: Although currently more affordable than polysomnography, actigraphic sleep estimates have disadvantages. Brand-specific differences in data reduction impede pooling of data in large-scale cohorts and may not fully exploit movement information. Sleep estimate reliability might improve by advanced analyses of three-axial, linear accelerometry data sampled at a high rate, which is now feasible using microelectromechanical systems (MEMS). However, it might take some time before these analyses become available. To provide ongoing studies with backward compatibility while already switching from actigraphy to MEMS accelerometry, we designed and validated a method to transform accelerometry data into the traditional actigraphic movement counts, thus allowing for the use of validated algorithms to estimate sleep parameters. Design: Simultaneous actigraphy and MEMS-accelerometry recording. Setting: Home, unrestrained. Participants: Fifteen healthy adults (23-36 y, 10 males, 5 females). Interventions: None. Measurements: Actigraphic movement counts/15-sec and 50-Hz digitized MEMS-accelerometry. Analyses: Passing-Bablok regression optimized transformation of MEMS-accelerometry signals to movement counts. Kappa statistics calculated agreement between individual epochs scored as wake or sleep. Bland-Altman plots evaluated reliability of common sleep variables both between and within actigraphs and MEMS-accelerometers. Results: Agreement between epochs was almost perfect at the low, medium, and high threshold (kappa = 0.87 -&#65533; 0.05, 0.85 -&#65533; 0.06, and 0.83 -&#65533; 0.07). Sleep parameter agreement was better between two MEMS-accelerometers or a MEMS-accelerometer and an actigraph than between two actigraphs. Conclusions: The algorithm allows for continuity of outcome parameters in ongoing actigraphy studies that consider switching to MEMS-accelerometers. Its implementation makes backward compatibility feasible, while collecting raw data that, in time, could provide better sleep estimates and promote cross-study data pooling. Smartphones in ecology and evolution: a guide for the app-rehensive.

In: *Ecol Evol* 3 (16), S. 5268–5278. DOI: 10.1002/ece3.888.

Abstract:

Smartphones and their apps (application software) are now used by millions of people worldwide and represent a powerful combination of sensors, information transfer, and computing power that deserves better exploitation by ecological and evolutionary researchers. We outline the development process for research apps, provide contrasting case studies for two new research apps, and scan the research horizon to suggest how apps can contribute to the rapid collection, interpretation, and dissemination of data in ecology and evolutionary biology. We emphasize that the usefulness of an app relies heavily on the development process, recommend that app developers are engaged with the process at the earliest possible stage, and commend efforts to create open-source software scaffolds on which customized apps can be built by nonexperts. We conclude that smartphones and their apps could replace many traditional handheld sensors, calculators, and data storage devices in ecological and evolutionary research. We identify their potential use in the high-throughput collection, analysis, and storage of complex ecological information.

Telford, C.; McCarthy-Jones, S.; Corcoran, R.; Rowse, G. (2012):

Experience sampling methodology studies of depression: The state of the art.

In: *Psychological Medicine* 42 (6), S. 1119–1129. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-11782-001&site=ehost-live;s.mccarthyjones@gmail.com.

Abstract:

Background: Experience Sampling Methodology (ESM) is ideally suited to test the predictions, and inform the development of contemporary cognitive models of depression. Yet there has been no systematic examination of ESM in depression research. Method: A search of databases (PsychARTICLES, PsycINFO, AMED, Ovid Medline and CINAHL) was conducted to identify studies published within the last 25 years investigating major depressive disorder (MDD) using ESM. Results: Altogether, 19 studies using ESM, or comparable methodologies, with clinically depressed individuals were identified and critically reviewed. The identified studies examined six aspects of MDD: methodological issues ; positive and negative affect ; cortisol secretion ; antidepressant treatment ; work performance; genetic risk factors. Conclusions: Despite some methodological limitations of existing studies, ESM has made a significant contribution to our current understanding of depression by consolidating existing theories, uncovering new and clinically relevant findings and identifying questions for future research. This review concludes by introducing the possibility of using ESM as an intervention tool in clinical practice and proposing that ESM could be useful for furthering knowledge of the causes of MDD. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

Temple, Viviene A.; Stanish, Heidi I. (2009):

Pedometer-measured physical activity of adults with intellectual disability: predicting weekly step counts.

In: *Am J Intellect Dev Disabil* 114 (1), S. 15–22. DOI: 10.1352/2009.114:15-22.

Abstract:

Pedometers are objective, inexpensive, valid, and reliable measures of physical activity. The minimum number of days of pedometer monitoring needed to estimate average weekly step counts was investigated. Seven days of pedometer data were collected from 154 ambulatory men and women (ns = 88 and 66, respectively) with intellectual disability. Correlations between average weekly steps and 3-day combinations ranged from .80 to .94, and adjusted R(2) for 3 days of monitoring was .886. Results suggest that 3 days of pedometer wear is sufficient to predict average weekly steps among ambulatory adults with intellectual disability. This finding will allow researchers to reduce participant burden and study costs, may guide measurement procedures, and inform missing data protocols.

Tenderenda-Banasiuk, Edyta; Wasilewska, Anna; Filonowicz, Renata; Jakubowska, Urszula; Waszkiewicz-Stojda, Marlena (2014):

Serum copeptin levels in adolescents with primary hypertension.

In: *Pediatr Nephrol* 29 (3), S. 423–429. DOI: 10.1007/s00467-013-2683-5.

Abstract:

BACKGROUND: The prevalence of hypertension continues to rise in the pediatric population. In recent years, there has been an increasing amount of reports on serum arginine vasopressin and its derivative, copeptin, in blood pressure control, but its role is still unclear. The objective of this study was to assess serum copeptin in adolescents with essential hypertension. METHODS: The study cohort consisted of 84 subjects (30 girls and 54 boys) aged 11-18 years, divided into two groups: hypertension (HT) - 53 subjects with confirmed primary hypertension and R - reference group - 31 subjects in whom hypertension was excluded on the basis of ambulatory blood pressure monitoring (ABPM) (white-coat hypertension). Serum copeptin concentration was measured using a commercially available enzyme-linked immunosorbent assay kit (USCN). RESULTS: Hypertensive patients had higher serum copeptin levels (median, 267 [Q1-Q3: 151.1-499.7 pg/ml]) than controls (median, 107.3 [Q1-Q3: 36.7-203.4 pg/ml]), ($p < 0.01$). Statistically significant difference was found both in males and females. In both groups, positive correlations between serum copeptin and uric acid levels ($r = 0.31$, $p < 0.01$), albuminuria ($r = 0.45$, $p < 0.01$), serum triglycerides ($r = 0.3$, $p < 0.05$), body mass index (BMI) standard deviation score (SDS) ($r = 0.24$, $p < 0.05$) and 24-h systolic blood pressure (SBP) ($r = 0.37$, $p < 0.01$) and diastolic blood pressure (DBP) ($r = 0.23$, $p < 0.05$) were found. CONCLUSIONS: In summary, higher serum copeptin levels, a surrogate for arginine vasopressin (AVP) release, are associated not only with systolic and diastolic blood pressure but also with several components of metabolic syndrome including obesity, elevated concentration of triglycerides, albuminuria, and serum uric acid level. However, for the time being, more research is needed in order to confirm the role of serum copeptin as a novel marker of elevated blood pressure and predictor of metabolic syndrome.

Tennen, Howard; Affleck, Glenn; Zautra, Alex (2006):

Depression history and coping with chronic pain: a daily process analysis.

In: *Health Psychol* 25 (3), S. 370–379. DOI: 10.1037/0278-6133.25.3.370.

Abstract:

This study examined how a previous episode of depression is related to daily pain and reactions to pain among individuals with fibromyalgia, a chronic pain syndrome. Seventy-one women with fibromyalgia (including 30 who were previously depressed) rated their pain and mood 3 times daily for 30 days. Each night, participants rated the extent to which they responded to pain by catastrophizing, how much control they had over that day's pain, their ways of coping with pain that day, and the effectiveness of their coping efforts. Multivariate multilevel regression models revealed that after controlling for neuroticism and current depressive symptoms, formerly depressed and never-depressed individuals differed in how they coped with increased pain and in how they appraised the efficacy of their coping efforts. Formerly depressed participants who also reported more current depressive symptoms showed a greater decline in pleasant mood on more painful days than did formerly depressed participants who were experiencing fewer current depressive symptoms. These findings illustrate how a history of depression can be captured in the dynamics of daily life.

Personality Traits and Circadian Blood Pressure Patterns: A 7-Year Prospective Study.

In: *Psychosom Med. DOI:* 10.1097/PSY.0000000000000035.

Abstract:

ObjectiveA nighttime dip in blood pressure is associated with decreased risk of cardiovascular morbidity and mortality. We examined whether personality traits predict nighttime dipping blood pressure.MethodsA community-based sample of 2848 adults from Sardinia (Italy) completed the Revised NEO Personality Inventory and 7 years later were examined with 24-hour ambulatory blood pressure monitoring. The primary analyses examined the associations of personality traits with continuous and categorical measures of mean arterial, systolic, and diastolic blood pressure nighttime dipping.ResultsAgreeableness and conscientiousness were associated with more nocturnal blood pressure dipping (beta = .05 [p = .025] and beta = .07 [p < .001], respectively) and lower systolic blood pressure at night (beta = -.05 [p = .018] and beta = -.03 [p = .072], respectively). Nondippers were particularly more impulsive (p = .009), less trusting (p = .004), and less self-disciplined (p = .001), but there was no significant association between nocturnal dipping blood pressure and trait anxiety (p = .78) or depression (p = .59). The associations were stronger when comparing extreme dippers (nighttime drop >/=20%) to reverse dippers (nighttime increase in blood pressure). Indeed, scoring 1 standard deviation higher on conscientiousness was associated with approximately 40% reduced risk of reverse dipping (odds ratio = 1.43, confidence interval = 1.08-1.91).ConclusionsWe found evidence that reduced nighttime blood pressure dipping is associated with antagonism and impulsivity-related traits but not with measures of emotional vulnerability. The strongest associations were found with conscientiousness, a trait that may have a broad impact on cardiovascular health.

Teste de respiração lenta aumenta a suspeita da hipertensão do avental branco no consultório.

In: *Arq. Bras. Cardiol.* 91 (4), S. 267–273. DOI: 10.1590/S0066-782X2008001600010.

Abstract:

FUNDAMENTO: Seria útil dispor de um teste clínico que aumentasse a suspeita da hipertensão do avental branco (HAB) durante a consulta.

OBJETIVO: Avaliar o teste de respiração lenta (TRL) na diferenciação entre hipertensão e HAB.

MÉTODOS: Cento e um pacientes hipertensos selecionados em triagem tiveram a medicação suspensa por duas a três semanas. A pressão arterial (PA) foi medida antes e depois do TRL em duas visitas. O teste consistiu em respirar por 1 minuto na freqüência de um ciclo respiratório a cada 10 segundos. Dois critérios diagnósticos foram comparados: 1- queda da PA diastólica >10% em pelo menos uma consulta, ou 2- queda da PA para níveis normais (<140/90 mmHg) em pelo menos uma consulta. A MAPA foi realizada de forma cega às medidas clínicas.

RESULTADOS: Setenta e uma mulheres e 30 homens, idade média 51+10 anos, média pré e pós-teste de 152+17/ 99+11 e 140+18/ 91+11 mmHg. Nove pacientes tiveram medidas clínicas e ambulatoriais normais. De 92 pacientes, 28 (30%) foram classificados como HAB; 15 tiveram teste positivo para o critério 1, e 21 para o critério 2. Entre 64 (70%) hipertensos, 14 testaram positivo para o critério 1, e 12 para o critério 2. Sensibilidade e especificidade (95% IC): 0,54 (0,36-0,71) e 0,78 (0,67-0,87) critério 1; 0,75 (0,57-0,87) e 0,81 (0,70-0,89) critério 2.

CONCLUSÃO: O TRL mostrou aumento da suspeita clínica de HAB em duas consultas ao utilizar o critério de normalização da PA. Isso sugere que esse teste pode auxiliar na otimização dos pedidos de MAPA para casos suspeitos.

Palavras-chave: Hipertensão / diagnóstico, testes de função respiratória, monitorização ambulatorial da pressão arterial.

Use of viber app: a fast, easy and cost effective method of communication in neurosurgery.

In: *Neurol India* 61 (6), S. 610–613. DOI: 10.4103/0028-3886.125260.

Abstract:

OBJECTIVE: Neurosurgeons often have to rely on judgments of junior staffs to decide on patients whom they cannot attend immediately. Viber is a free to use application for image transfer on Internet. We evaluated the use of viber in neurosurgical scenario, to show it is cheap, fast, accessible, reliable and feasible. MATERIALS AND METHODS: We conducted a prospective study from March 2013 to July 2013. Residents were taught to take sharp pictures and upload them immediately using viber on Internet. Primary endpoints were discordance between opinion of residents and consultants on viber images and subsequent actual image evaluation and time delay in decision-making. Discordance was considered significant if it changed management decision. RESULTS: During the study period, 120 (mean age: 42 years, 58% males) patients were enrolled. Wi-Fi is freely available in the institute and thus no costs were involved. Decision could be made on images received on viber at an average of 20 min. There was discordance in 56.7% cases between residents' reports and images on viber, which was significant in 88.2% cases. However in 5% cases decision changed after actual images were reviewed. Of all imaging modalities, computed tomography angiographic images were associated with statistically significant discordance (P <0.05). CONCLUSION: This study suggests that the use of viber app in neurosurgery can be an easy fast reliable and almost free mode of communicating images enabling a quick decision. However this cost-effective method should be used with caution particularly with imaging modalities, which require processing and review on console.

Theuns, Dominic A M J; Rivero-Ayerza, Maximo; Knops, Paul; Res, Jan C. J.; Jordaens, Luc (2009):

Analysis of 57,148 transmissions by remote monitoring of implantable cardioverter defibrillators.

In: *Pacing and clinical electrophysiology : PACE* 32 Suppl 1, S. S63-5. DOI: 10.1111/j.1540-8159.2008.02230.x.

Abstract:

INTRODUCTION\r\nRemote monitoring of implantable cardioverter defibrillators (ICD) is designed to decrease the number of ambulatory visits and facilitate the early detection of adverse events. We examined the impact of remote monitoring on clinical workload by a comprehensive analysis of transmitted events.\r\nMETHODS\r\nThe study population consisted of 146 recipients of ICD capable of remote monitoring. Data were transmitted daily or in case of pre-specified events (e.g., arrhythmia, out-of-range lead and/or shock impedance). Transmitted events were classified as clinical (disease-related) or system-related. Event rates/patient/month were calculated and compared according to events classification and clinical groups.\r\nRESULTS\r\nDuring a mean follow-up of 22 +/- 16 months, a total of 57,148 remote transmissions were recorded. Of these transmissions, 1009 (1.8%) were triggered by a pre-specified event, including induced ventricular fibrillation (VF) episodes during defibrillation threshold testing. The median number of events/patient/month was 0.14. Event rates were similar in patients with primary and secondary prevention indications for ICD (0.15 vs. 0.11). After exclusion of the induced VF episodes, 5.6% of transmitted events were classified as system-related and 94.4% as clinical. The median number of clinical events/patient/month was 0.023. The clinical event-free rates were 62% and 45%, at 1 and 4 years, respectively.\r\nCONCLUSION\r\nRemote monitoring of ICD patients is feasible. Despite the large number of data transmissions, remote monitoring imposed a minimal additional burden on the clinical workload. The rate of triggered data transmissions by critical events was, relatively, very low.

Thewissen, Viviane; Bentall, Richard P.; Oorschot, Margreet; A Campo, Joost; van Lierop, Thom; van Os, Jim; Myin-Germeys, Inez (2011):

Emotions, self-esteem, and paranoid episodes: an experience sampling study.

In: *British Journal of Clinical Psychology* 50 (2), S. 178–195. DOI: 10.1348/014466510X508677.

Abstract:

OBJECTIVES. The evidence to date for a causal role of emotions in the generation of paranoid symptoms is scarce, mainly because of a lack of studies investigating the longitudinal association between emotional processes and paranoia. The primary aim of this study was to investigate whether momentary emotional experiences (anxiety, depression, anger/irritability) and self-esteem predicted the onset and duration of a paranoid episode. We also studied whether levels of emotional experiences and self-esteem were respectively higher and lower during a paranoid episode. DESIGN. A 1-week, prospective momentary assessment study. METHODS. Data were collected using the experience sampling method, a structured self-assessment diary technique. The sample consisted of 158 individuals who ranged across the paranoia continuum. Participants with a psychotic disorder were recruited from in-patient and out-patient mental health services. Participants without psychotic disorder were sampled from the general population. RESULTS. Specific aspects of emotional experience were implicated in the onset and persistence of paranoid episodes. Both an increase in anxiety and a decrease in self-esteem predicted the onset of paranoid episodes. Cross-sectionally, paranoid episodes were associated with high levels of all negative emotions and low level of self-esteem. Initial intensity of paranoia and depression was associated with longer, and anger/irritability with shorter duration of paranoid episodes. CONCLUSIONS. Paranoid delusionality is driven by negative emotions and reductions in self-esteem, rather than serving an immediate defensive function against these emotions and low self-esteem. Clinicians need to be aware of the central role of emotion-related processes and especially self-esteem in paranoid thinking.

Thieden, Elisabeth (2008):

Sun exposure behaviour among subgroups of the Danish population.

In: *Danish medical bulletin* 55 (1), S. 47–68.

Abstract:

Solar ultraviolet radiation (UVR) is known to be an important etiological factor in the development of melanoma as well as non-melanoma cancer of the skin. Malignant melanoma of the skin, CMM, is supposed to be provoked by high intermittent UVR doses, while quamous cell cancer, SCC, is more connected with the cumulative UVR dose and basal cell cancer, BCC, is believed to be provoked by both exposure patterns (Elwood and Jopson 1997; Armstrong and Kricker, 2001). Different UVR exposure patterns seem therefore to provoke different skin cancer forms and call for different sun protection strategies. In spite of this, many people want to be able to enjoy the benefits of the sun, mentally, socially and with respect to D-vitamin synthesis. A better understanding of UVR exposure patterns and corresponding UVR doses can point at the most suitable approach a person can take to lower the UVR dose, and thereby reduce the risk of skin cancer. However, no one has previously conducted studies where individual UVR exposure doses have been established through actual measurements. Apart from the ambient UVR dose available, several parameters have been debated as to their influence on the UVR dose received by a person, such as age, sex, outdoor work, sunbathing, and long lasting outdoor leisure activities (Holman et al, 1983; Herlihy et al, 1994; Diffey et al, 1996). In addition, to actually cause skin damages and add to the cumulative UVR dose of a person, the UVR dose exposed to should be transmitted into the skin. Factors as dark complexion, acquired skin pigmentation, clothing, and sunscreen use can reduce the part of the UVR dose transmitted into the skin. Yet, no one has actually measured with which power these factors influence on the UVR dose received and transmitted into the skin of an individual. My primary task was therefore to conduct a prospective study among groups of healthy Danes to assess objectively, by personal, UVR dosimetry supported by sun exposure diaries, the annual UVR dose received by an individual an to estimate the lifetime UVR dose. In addition, to establish basic knowledge about how different UVR exposure behaviour patterns influence on the UVR exposure dose received. A model to assess individual skin cancer risk including the UVR exposure pattern could help doctors and health advisers in choosing the UVR precautions needed to avoid the development of skin cancer. However, although skin cancer risk assessment was the reason for performing these studies, it is not a subject of discussion in this thesis.

Thom, Nicole K.; Lewis, Gregory G.; Yeung, Kimy; Phillips, Scott T. (2014):

Quantitative Fluorescence Assays Using a Self-Powered Paper-Based Microfluidic Device and a Camera-Equipped Cellular Phone.

In: *RSC Adv* 4 (3), S. 1334–1340. DOI: 10.1039/C3RA44717K.

Abstract:

Fluorescence assays often require specialized equipment and, therefore, are not easily implemented in resource-limited environments. Herein we describe a point-of-care assay strategy in which fluorescence in the visible region is used as a readout, while a camera-equipped cellular phone is used to capture the fluorescent response and quantify the assay. The fluorescence assay is made possible using a paper-based microfluidic device that contains an internal fluidic battery, a surface-mount LED, a 2-mm section of a clear straw as a cuvette, and an appropriately-designed small molecule reagent that transforms from weakly fluorescent to highly fluorescent when exposed to a specific enzyme biomarker. The resulting visible fluorescence is digitized by

photographing the assay region using a camera-equipped cellular phone. The digital images are then quantified using image processing software to provide sensitive as well as quantitative results. In a model 30 min assay, the enzyme beta-D-galactosidase was measured quantitatively down to 700 pM levels. This Communication describes the design of these types of assays in paper-based microfluidic devices and characterizes the key parameters that affect the sensitivity and reproducibility of the technique.

Thomas, J. Graham; Bond, Dale S. (2014):

Review of innovations in digital health technology to promote weight control.

In: *Curr Diab Rep* 14 (5), S. 485. DOI: 10.1007/s11892-014-0485-1.

Abstract:

Advances in technology have contributed to the obesity epidemic and worsened health by reducing opportunities for physical activity and by the proliferation of inexpensive calorie-dense foods. However, much of the same technology can be used to counter these troublesome trends by fostering the development and maintenance of healthy eating and physical activity habits. In contrast to intensive face-to-face treatments, technology-based interventions also have the potential to reach large numbers of individuals at low cost. The purpose of this review is to discuss studies in which digital technology has been used for behavioral weight control, report on advances in consumer technology that are widely adopted but insufficiently tested, and explore potential future directions for both. Web-based, mobile (eg, smartphone), virtual reality, and gaming technologies are the focus of discussion. The best evidence exists to support the use of digital technology for self-monitoring of weight-related behaviors and outcomes. However, studies are underway that will provide additional, important information regarding how best to apply digital technology for behavioral weight control.

Thomas, J. Graham; Bond, Dale S.; Ryder, Beth A.; Leahey, Tricia M.; Vithiananthan, Siva; Roye, G. Dean; Wing, Rena R. (2011):

Ecological momentary assessment of recommended postoperative eating and activity behaviors.

In: *Surg Obes Relat Dis* 7 (2), S. 206–212.

Abstract:

Background

Successful weight loss after bariatric surgery depends on the patient's adherence to prescribed eating and physical activity behaviors. However, few studies have assessed patients' adherence to the behavioral recommendations and most have used retrospective self-report measures. The present study is the first to use ecological momentary assessment (EMA) via a palmtop computer to assess bariatric surgery patients' eating and activity behaviors in real-time in the natural environment. The study was conducted at Miriam Hospital (Providence, RI).

Methods

A total of 21 patients (14 laparoscopic adjustable gastric banding and 7 Roux-en-Y; 81% women; mean age 48.5 yr) were studied 6.1 ± 2.1 months postoperatively. The participants used a palmtop computer for 6 days to report on all eating and physical activity episodes as they occurred in the natural environment.

Results

All participants demonstrated good compliance with the EMA, using the device on ≥5 full days. Most participants (94.8%) adhered to the recommendation to not drink while eating, and most took their vitamin supplements and medication as prescribed (85.7% and 90.5%, respectively). Few (4.8%) participants ate the recommended ≥5 meals daily, most participants exceeded the recommended portion sizes during meals and snacks (100% and 72.0% of the participants, respectively), and 47.6% of the participants consumed ≥5 servings of fruit and vegetables daily. Only 15.8% regularly consumed adequate liquids. Only 23.8% of participants engaged in moderate to vigorous physical activity for ≥30 minutes daily, as recommended.

Conclusion

The EMA results suggested that adherence to the recommended behaviors varied considerably, depending on the behavior, with greater adherence to simple versus complex behaviors. EMA might eventually be a useful tool to help optimize the outcomes of bariatric surgery by identifying behavioral targets for additional monitoring and intervention.

Thomas, J. Graham; Doshi, Sapna; Crosby, Ross D.; Lowe, Michael R. (2011):

Ecological Momentary Assessment of obesogenic eating behavior: Combining person-specific and environmental predictors.

In: *Obesity* 19 (8), S. 1574–1579. DOI: 10.1037/t02178-000;

Abstract:

Obesity has been promoted by a food environment that encourages excessive caloric intake. An understanding of how the food environment contributes to obesogenic eating behavior in different types of individuals may facilitate healthy weight control efforts. In this study, Ecological Momentary Assessment (EMA) via palmtop computers was used to collect real-time information about participants' environment and eating patterns to predict overeating (i.e., greater than usual intake during routine meals/snacks, and eating outside of a participant's normal routine) that could lead to weight gain. Thirty-nine women (BMI = 21.6 ± 1.8; age = 20.1 ± 2.0 years; 61% white) of normal weight (BMI 18.5-25) completed the Three Factor Eating Questionnaire and the Power of Food Scale (PFS), and carried a palmtop computer for 7-10 days, which prompted them to answer questions about eating events, including a count of the types of good tasting high-calorie foods that were available. None of the self-report measures predicted overeating, but BMI interacted with the number of palatable foods available to predict overeating (P = 0.035). Compared to leaner individuals who reported a relatively low frequency of overeating regardless of the availability of palatable food, the probability of overeating among heavier individuals was very low in the absence of palatable food, but quickly increased in proportion to the number of palatable foods available. Our findings suggest that the eating behavior of those with higher relative weights is susceptible to the presence of palatable foods in the environment. Individuals practicing weight control may benefit from limiting their exposure to good tasting high-calorie food in their immediate environment.

Physical activity may facilitate diabetes prevention in adolescents.

In: *Diabetes Care* 32 (1), S. 9–13. DOI: 10.2337/dc08-0780.

Abstract:

OBJECTIVE\r\nThe aim of this study was to examine the association of physical activity with glucose tolerance and resting energy expenditure (REE) among adolescents.\r\nRESEARCH DESIGN AND METHODS\r\nSubjects were 32 male and female adolescents aged 12-18 years. Intravenous glucose tolerance (K(g)) and REE were assessed under inpatient conditions after an overnight fast. K(g) was determined as the inverse slope of time versus (ln) glucose over minutes 8-19 of an intravenous glucose tolerance test. Physical activity was assessed over 8 days using accelerometry (counts per minute).\r\nRESULTS\r\nIn multiple linear regression analysis, K(g) was positively associated with total physical activity (TPA), moderate physical activity (MPA), and 5-min bouts of MPA. Similarly, REE was positively associated with TPA, MPA, and 5-min bouts of MPA.\r\nCONCLUSIONS\r\nIn this population, physical activity was positively related to both glucose tolerance and REE. These results suggest that moderate activity may be beneficial in the prevention of diabetes in adolescent populations both through promoting efficient glucose disposal and through increasing energy expenditure.

Personal exposure to mobile phone frequencies and well-being in adults: A cross-sectional study based on dosimetry.

In: *Bioelectromagnetics* 29 (6), S. 463–470.

Abstract:

The use of mobile phone telecommunication has increased in recent years. In parallel, there is growing concern about possible adverse health effects of cellular phone networks. We used personal dosimetry to investigate the association between exposure to mobile phone frequencies and well-being in adults. A random population-based sample of 329 adults living in four different Bavarian towns was assembled for the study. Using a dosimeter (ESM-140 Maschek Electronics), we obtained an exposure profile over 24 h for three mobile phone frequency ranges (measurement interval 1 s, limit of determination 0.05 V/m). Exposure levels over waking hours were totalled and expressed as mean percentage of the International Commission on Non-Ionizing Radiation Protection (ICNIRP) reference level. Each participant reported acute symptoms in a day-long diary. Data on five groups of chronic symptoms and potential confounders were assessed during an interview. The overall exposure to high-frequency electromagnetic fields was markedly below the ICNIRP reference level. We did not find any statistically significant association between the exposure and chronic symptoms or between the exposure and acute symptoms. Larger studies using mobile phone dosimetry are warranted to confirm these findings.

Emotion reporting using electronic diaries reduces anxiety symptoms in girls with emotion dysregulation.

In: *Journal of Contemporary Psychotherapy* 42 (4), S. 207–213. DOI: 10.1037/t05050-000;

Abstract:

Theory and empirical research suggest that electronic diaries, which require children to report on their emotional experiences, might encourage emotional processing and facilitate a reduction in symptoms of anxiety, particularly for children exhibiting emotion-related deficits. Electronic diaries were given to 52 children (aged 7–12) to track their emotions and associated intensity for 7 days; anxiety was assessed prior to and after the use of the electronic diary by both parent- and child-report. It was hypothesized that the use of an electronic diary to track emotional experiences would lead to a reduction in anxiety symptoms for those children high in poor awareness, high in expressive reluctance, and low in emotion coping. The use of electronic diaries was effective at reducing child self-reported anxiety symptoms in girls who reported low emotion coping and reducing parent-reported anxiety for girls who reported a high reluctance to express emotions. Current findings suggest that having children identify their emotions using electronic diaries may be particularly beneficial for girls who are reluctant to express emotions and who report poor coping abilities. Assessment of low-to-moderate intensity physical activity thermogenesis in young adults using synchronized heart rate and accelerometry with branched-equation modeling.

In: *The Journal of nutrition* 136 (4), S. 1037–1042.

Abstract:

Low-to-moderate intensity physical activity thermogenesis is a highly variable and quantitatively important component of total energy expenditure that is difficult to assess outside the laboratory. Greater precision and accuracy in the measurement of this key contributor to energy balance is a research priority. We developed a laboratory-based protocol that simulated a range of low-to-moderate intensity physical activities. We characterized the bias and random (individual) error in estimating energy expenditure using combined accelerometry and heart rate (AHR) with branched-equation modeling and a simple motion sensor (pedometer) against an indirect calorimetry criterion. Twenty young adult subjects performed a 2-h laboratory-based protocol, simulating 6 low-to-moderate intensity physical activities interspersed with periods of rest. The physical activity level during the laboratory-based protocol reflected an energy expenditure toward the lower end of the active category. We found that AHR-derived energy expenditure showed no evidence of substantial fixed or proportional bias (mean bias 6%), whereas pedometer-derived energy expenditure showed both fixed and proportional bias (bias at minimum, mean, and maximum energy expenditure +11, -20, and -36%, respectively). It appears that AHR provides an accurate estimate of criterion energy expenditure whereas a simple motion sensor (pedometer) does not. It is noteworthy that AHR provides quantitative information about the nature and patterns of physical activity, such as the amount of time and/or energy spent engaged in physical activity above critical health-related thresholds.

Thompson, Dylan; Batterham, Alan M.; Markovitch, Daniella; Dixon, Natalie C.; Lund, Adam J. S.; Walhin, Jean-Philippe (2009):

Confusion and conflict in assessing the physical activity status of middle-aged men.

In: *PLoS One* 4 (2), S. e4337. DOI: 10.1371/journal.pone.0004337.

Abstract:

BACKGROUND\r\nPhysical activity (including exercise) is prescribed for health and there are various recommendations that can be used to gauge physical activity status. The objective of the current study was to determine whether twelve commonly-used physical activity recommendations similarly classified middle-aged men as sufficiently active for general health.\r\nMETHODS AND FINDINGS\r\nWe examined the commonality in the classification of physical activity status between twelve variations of physical activity recommendations for general health in ninety men aged 45-64 years. Physical activity was assessed using synchronised accelerometry and heart rate. Using different guidelines but the same raw data, the proportion of men defined as active ranged from to 11% to 98% for individual recommendations (median 73%, IQR 30% to 87%). There was very poor absolute agreement between the recommendations, with an intraclass correlation coefficient (A,1) of 0.24 (95% CI, 0.15 to 0.34). Only 8% of men met all 12 recommendations and would therefore be unanimously classified as active and only one man failed to meet every recommendation and would therefore be unanimously classified as not sufficiently active. The wide variability in physical activity classification was explained by ostensibly subtle differences between the 12 recommendations for thresholds related to activity volume (time or energy), distribution (e.g., number of days of the week), moderate intensity cut-point (e.g., 3

vs. 4 metabolic equivalents or METs), and duration (including bout length).\r\nCONCLUSIONS\r\nPhysical activity status varies enormously depending on the physical activity recommendation that is applied and even ostensibly small differences have a major impact. Approximately nine out of every ten men in the present study could be variably described as either active or not sufficiently active. Either the effective dose or prescription that underlies each physical activity recommendation is different or each recommendation is seeking the same prescriptive outcome but with variable success.

Thompson, Patricia; Beath, Tricia; Bell, Jacqueline; Jacobson, Gabrielle; Phair, Tegan; Salbach, Nancy M.; Wright, Fvirginia (2008):

Test–retest reliability of the 10-metre fast walk test and 6-minute walk test in ambulatory school-aged children with cerebral palsy.

In: *Developmental Medicine & Child Neurology* 50 (5), S. 370–376.

Abstract:

Short-term test-retest reliability of the 10-metre fast walk test (10mFWT) and 6-minute walk test (6MWT) was evaluated in 31 ambulatory children with cerebral palsy (CP), with subgroup analyses in Gross Motor Function Classification System (GMFCS) Levels I (n=9), II (n=8), and III (n=14). Sixteen females and 15 males participated, mean age 9 years 5 months (SD 3y 7mo, range 4y 3mo-18y 2mo). Twenty had spastic diplegia, while the others had another form of CP. Retest interval varied from 1 to 4 weeks (mean 10.6d [SD 6.4]). Intraclass correlation coefficients (ICCs) estimated reliability. The 10mFWT ICC was 0.81 (95% confidence interval [CI] 0.65-0.90) across participants, and >0.59 in GMFCS subgroups (95% CI lower bound >0.01). The 6MWT ICC was 0.98, and >0.90 in GMFCS subgroups (95% CI lower bound >0.64). Bland-Altman plots indicated bias towards higher 6MWT retest distances in GMFCS Level I. Minimum detectable change (95% CI) was 61.9, 64.0, and 47.4m for the 6MWT within GMFCS Levels I, II, and III respectively. The conclusion is that while the 10mFWT showed inadequate test-retest reliability given its wide 95% CI, the 6MWT demonstrated good to excellent reliability. Investigation of the need for a practice walk when administering the 6MWT with children in GMFCS Level I is recommended to establish their fastest pace.

Texting to Increase Physical Activity Among Teenagers (TXT Me!): Rationale, Design, and Methods Proposal.

In: *JMIR Res Protoc* 3 (1), S. e14. DOI: 10.2196/resprot.3074.

Abstract:

BACKGROUND: Physical activity decreases from childhood through adulthood. Among youth, teenagers (teens) achieve the lowest levels of physical activity, and high school age youth are particularly at risk of inactivity. Effective methods are needed to increase youth physical activity in a way that can be maintained through adulthood. Because teens text a great deal, text messages promoting walking, a low cost physical activity, may be an effective method for promoting sustainable physical activity. OBJECTIVE: The objective of our study was to determine the effect of pedometers, self selected step goals, and texts grounded in the self-determination theory (SDT) on physical activity among the teens. METHODS: "TXT Me!" was a 12 week intervention that texted 14-17 year olds to increase their daily physical activity by increasing the number of steps they take each day. The intervention was grounded in the SDT. Formative research with the teens helped construct the intervention and develop the texts. A total of 84 texts were developed (12 to set a step goal, and 72 promoting autonomy, competence, and relatedness). The pilot evaluation used a four group, randomized design (n=160). After baseline data collection, the participants were randomized to one of four conditions (no treatment control, pedometer only, pedometer + weekly prompts, pedometer + weekly prompts + SDT grounded texts). Data were collected at baseline and immediately upon completion of the study. The primary outcome was physical activity, measured by 7 days of accelerometry. Basic psychological needs, physical activity motivation, process evaluation, and program satisfaction data were also collected. RESULTS: To our knowledge, this is one of the first studies to explore the use of stand alone, SDT grounded texts, supported by pedometers and prompts to set a self selected step goal, as a method for increasing physical activity among teens. CONCLUSIONS: This pilot study will contribute valuable information regarding whether theoretically grounded text messages show promise as an effective method to increase physical activity among teens. Thompson, Wesley K.; Gershon, Anda; O'Hara, Ruth; Bernert, Rebecca A.; Depp, Colin A. (2014):

The prediction of study-emergent suicidal ideation in bipolar disorder: A pilot study using ecological momentary assessment data.

In: *Bipolar Disorders*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-23653-001%26site%3dehost-live.

Abstract:

Objectives Bipolar disorder is associated with idiosyncratic precursors of clinically important states such as suicidal ideation. Ecological momentary assessment (EMA) – high frequency data collection in a subject's usual environment – provides the potential for development of temporal, individualized prediction of risk states. The present study tested the ability of EMA data to predict individual symptom change in clinician-rated suicidal ideation. Methods Thirty-five adults diagnosed with inter-episode bipolar disorder completed daily measures of affect in their home environments using diaries administered over an eight-week assessment timeline. Suicidal ideation was assessed monthly at in-person visits using the Inventory of Depressive Symptomatology–Clinician Rated. We used a novel application of functional linear models (FLMs) to generate prospective predictions of suicidal ideation at in-person clinician assessments based on intensively sampled trajectories of daily affect. Results Eight instances of suicidal ideation scores > 0 were recorded during the study period on six participants. Utilizing trajectories of negative and positive affect, cross-validated predictions attained 88% sensitivity with 95% specificity for elevated suicidal ideation one week prior to in-person clinician assessment. This model strongly outperformed prediction models using cross-sectional data obtained at study visits alone. Conclusions Utilizing EMA data with FLM prediction models substantially increases the accuracy of prediction of study-emergent suicidal ideation. Prediction algorithms employing intensively sampled longitudinal EMA data could sensitively detect the warning signs of suicidal ideation to facilitate improved suicide risk assessment and the timely delivery of preventative interventions. Thompson, R. J.; Mata, J.; Jaeggi, S. M.; Buschkuehl, M.; Jonides, J.; Gotlib, I. H. (2013):

The role of attention to emotion in recovery from major depressive disorder.

In: *Depress.Res Treat.* 2013 (2090-1321 (Linking)), S. 540726. DOI: 10.1155/2013/540726.

Abstract:

Major Depressive Disorder (MDD) is characterized by several emotional disturbances. One possible but not well-examined disturbance is in attention to emotion, an important facet of emotional awareness. We examined whether attention to emotion predicted recovery from MDD. Fifty-three adults with current MDD completed a week of experience sampling (Time 1). At each prompt, participants reported attention to emotion, negative affect (NA), and positive affect (PA). Approximately one year later (Time 2), the depressive status of 27 participants was reassessed. Participants who had recovered from MDD (n = 8) indicated paying less attention to their emotions at Time 1 than did participants who had not fully recovered (n = 19). Attention to emotion was better predictor of recovery than was severity of MDD, NA, or PA at Time 1. Levels of attention to emotion at Time 1 in participants who recovered from MDD did not differ significantly from the levels reported by 53 never-depressed individuals who had participated in the experience sampling. Findings indicate that high levels of an otherwise adaptive emotional facet can adversely affect the course of MDD

Increases in Plasma Lutein through Supplementation Are Correlated with Increases in Physical Activity and Reductions in Sedentary Time in Older Adults.

In: *Nutrients* 6 (3), S. 974–984. DOI: 10.3390/nu6030974.

Abstract:

Cross-sectional studies have reported positive relationships between serum lutein concentrations and higher physical activity levels. The purpose of the study was to determine whether increasing plasma lutein levels increases physical activity. Forty-four older adults (BMI, 25.3 +/- 2.6 kg/m2; age, 68.8 +/- 6.4 year) not meeting Australian physical activity guidelines (150 min/week of moderate to vigorous activity) were randomized to consume capsules containing 21 mg of lutein or placebo with 250 mL of full-cream milk per day for 4 weeks and encouraged to increase physical activity. Physical activity was assessed by self-report, pedometry and accelerometry (daily activity counts and sedentary time). Exercise self-efficacy was assessed by questionnaire. Thirty-nine participants competed the study (Lutein = 19, Placebo = 20). Lutein increased plasma lutein concentrations compared with placebo ($p < 0.001$). Absolute and percentage changes in plasma lutein were inversely associated with absolute (r

= -0.36, p = 0.03) and percentage changes (r = -0.39, p = 0.02) in sedentary time. Percentage change in plasma lutein was positively associated with the percentage change in average daily activity counts (r = 0.36, p = 0.03). Exercise self-efficacy did not change (p = 0.16). Lutein increased plasma lutein, which was associated with increased physical activity and reduced sedentary time in older adults. Larger trials should evaluate whether Lutein can provide health benefits over the longer term.

Thrul, Johannes; Buhler, Anneke; Ferguson, Stuart G. (2014):

Situational and mood factors associated with smoking in young adult light and heavy smokers.

In: *Drug Alcohol Rev. DOI:* 10.1111/dar.12164.

Abstract:

INTRODUCTION AND AIMS: Antecedents of smoking have been widely researched in studies with older adults. However, less is known about the smoking patterns and antecedents of smoking in young adult smokers. DESIGN AND METHODS: In this study, we used ecological momentary assessment collected with an Internet-based survey instrument and used the participants' own mobile phones to contrast the smoking patterns of young adult light and intermittent smokers (n = 23) with heavy smokers (n = 18). Overall, 1543 smoking and non-smoking situations were analysed. By means of generalised estimating equations, we used a range of situational characteristics to predict smoking in both groups. RESULTS: Craving and smoking of others increased the odds of smoking, and smoking bans were associated with a decreased probability of smoking among both light and intermittent smokers and heavy smokers. Situational antecedents differed between both groups. Cue-associated smoking played a bigger role for light and intermittent smokers than for heavy smokers. Situational antecedents, such as craving, being at the home of others, drinking alcohol and smoking by others, were more strongly associated with the smoking of light and intermittent smokers compared with heavy smokers. DISCUSSION AND CONCLUSIONS: Smoking among young adults is associated with both internal and external situational characteristics. Compared with heavy smokers, light and intermittent smoking seems to be under more stimulus control and more characterised by social smoking. These results are consistent with several findings from previous studies and provide further information on different subgroups of smokers in early adulthood. [Thrul J, Buhler A, Ferguson SG. Situational and mood factors associated with smoking in young adult light and heavy smokers. Drug Alcohol Rev 2014].

An internet-based ecological momentary assessment study relying on participants' own mobile phones: insights from a study with young adult smokers.

In: *Eur Addict Res* 21 (1), S. 1–5. DOI: 10.1159/000363231.

Abstract:

BACKGROUND: In this paper we describe a novel Internet-based cell phone-optimized assessment technique (ICAT) to conduct an ecological momentary assessment (EMA) study. Participants could access the assessment instrument via the web browsers of their mobile phones. METHODS: We report results from 92 young adult smokers (18-25 years old) who completed the baseline assessment and the first of 4 waves (3 days/wave) of EMA. Random prompts were issued via text messages sent to the participants. The participants were also instructed to self-initiate reports of smoking situations. RESULTS: Compliance with the study protocols was low. In total, the participants completed 885 assessments during the 3 days of monitoring. Only 50.2% of random prompts were responded to, and 52.4% of those were completed within the first 10 min after issuing. Furthermore, reports of smoking situations were rarely self-initiated. In a multivariate regression analysis, age (positively) and female gender (negatively) predicted the number of completed assessments. CONCLUSIONS: This study adds to the limited experiences made with ICAT in substance use research. Similar to the few prior ICAT studies, compliance was low compared to traditional EMA studies. While using ICAT is technically feasible, specific improvements should be implemented to tap ICAT's full potential in future studies. (c) 2014 S. Karger AG, Basel.

Thurman, S. Kenneth; McGrath, Marie C. (2008):

Environmentally based assessment practices: Viable alternatives to standardized assessment for assessing emergent literacy skills in young children.

In: *Reading & Writing Quarterly* 24 (1), S. 7–24.

Abstract:

Ecological validity is an important construct in the assessment of young children. The argument is made that using environmentally based assessment practices as well as understanding the child's ecology will help assure that assessments are carried out in an ecologically valid manner. The discussion focuses on play-based assessment, curriculum-based assessment, and dynamic assessment. Each of these approaches is based on authentic procedures and is typically carried out in the child's natural environment. In addition, there is a discussion of how specific environments can be delineated as well as stressing the importance of developing operational definitions of specific skills in the natural environment.

Tidey, Jennifer W.; Monti, Peter M.; Rohsenow, Damaris J.; Gwaltney, Chad J.; Miranda, Robert; McGeary, John E. et al. (2008):

Moderators of naltrexone's effects on drinking, urge, and alcohol effects in non-treatment-seeking heavy drinkers in the natural environment.

In: *Alcohol Clin Exp Res* 32 (1), S. 58–66. DOI: 10.1111/j.1530-0277.2007.00545.x.

Abstract:

BACKGROUND\r\nNaltrexone (NTX) has proven to be effective with alcoholics in treatment, with most controlled clinical trials showing beneficial effects on heavy drinking rates. However, little is known about the behavioral mechanisms underlying the effects of NTX on drinking, or about patient characteristics that may moderate NTX's effects on drinking. In this study, ecological momentary assessment (EMA) techniques were used to investigate some of the putative mechanisms of naltrexone's effects on drinking in heavy drinkers who were not seeking treatment for alcohol problems. Polymorphisms in the D4 dopamine receptor (DRD4) gene and the mu-opiate receptor (OPRM1) gene, family history of alcohol problems, age of onset of alcoholism and gender were explored as potential moderators of NTX's effects.\r\nMETHODS\r\nAfter a 1-week placebo lead-in period, heavy drinkers (n = 180), 63% of whom were alcohol-dependent, were randomized to 3 weeks of daily naltrexone (50 mg) or placebo. Throughout the study, participants used EMA on palm-pilot computers to enter, in real time, drink data, urge levels, and subjective effects of alcohol consumption.\r\nRESULTS\r\nNaltrexone reduced percentage drinking days in all participants and reduced percent heavy drinking days in DRD4-L individuals; NTX decreased urge levels in participants with younger age of alcoholism onset; NTX increased time between drinks in participants who had more relatives with alcohol problems; and NTX reduced the stimulating effects of alcohol in women. OPRM1 status did not moderate any of NTX's effects.\r\nCONCLUSIONS\r\nThese results confirm earlier findings of NTX's effects on drinking and related subjective effects, and extend them by describing individual difference variables that moderate these effects in the natural environment, using data collected in real time.

Tikkanen, Olli; Karkkainen, Salme; Haakana, Piia; Kallinen, Mauri; Pullinen, Teemu; Finni, Taija (2014):

EMG, Heart Rate, and Accelerometer as Estimators of Energy Expenditure in Locomotion.

In: *Med Sci Sports Exerc. DOI:* 10.1249/MSS.0000000000000298.

Abstract:

PURPOSE: Precise measures of energy expenditure (EE) during everyday activities are needed. This study assessed the validity of novel shorts measuring electromyography (EMG) and compared this method to heart rate (HR) and accelerometry (ACC) when estimating EE. METHODS: 54 volunteers (39.4 +/- 13.9 yrs) performed a maximal treadmill test (3 min loads) including walking with different speeds uphill, downhill and on level ground and one running load. The data were categorized into all, low and level loads. EE was measured by indirect calorimetry, while HR, ACC and EMG were measured continuously. EMG from quadriceps (Q) and hamstrings (H) was measured using shorts with textile electrodes. Validity of the methods used to estimate EE was compared using Pearson correlations, regression coefficients, linear mixed models providing Akaike information criteria (AIC) and applying cross-validation at the individual and population level. RESULTS: At all loads, correlations with EE were as follows: EMG(QH) 0.94+/-0.03, EMG(Q) 0.91+/-0.03, EMG(H) 0.94+/-0.03, HR 0.96+/-0.04 and ACC 0.77+/-0.10. The corresponding correlations at low loads were 0.89+/-0.08, 0.79+/-0.10, 0.93+/-0.07, 0.89+/-0.23, 0.80+/-0.07 and at level loads they were 0.97+/-0.03, 0.97+/-0.05, 0.96+/-0.04, 0.95+/-0.08, 0.99+/-0.02, respectively. AIC ranked the methods in accordance with the individual correlations. CONCLUSIONS: It is shown for the first time that EMG shorts can be used for EE estimations across a wide range of physical activity intensities in a heterogeneous group. Across all loads HR is a superior method of predicting EE, while ACC is most accurate for level loads at the population level. At low levels of physical activity in changing terrains, thigh muscle EMG provides more accurate EE estimations than ACC and HR if individual calibrations are performed.

A clinical case study of the use of ecological momentary assessment in obsessive compulsive disorder.

In: *Front Psychol* 5, S. 339. DOI: 10.3389/fpsyg.2014.00339.

Abstract:

Accurate assessment of obsessions and compulsions is a crucial step in treatment planning for Obsessive-Compulsive Disorder (OCD). In this clinical case study, we sought to determine if the use of Ecological Momentary Assessment (EMA) could provide additional symptom information beyond that captured during standard assessment of OCD. We studied three adults diagnosed with OCD and compared the number and types of obsessions and compulsions captured using the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) compared to EMA. Following completion of the Y-BOCS interview, participants then recorded their OCD symptoms into a digital voice recorder across a 12-h period in reply to randomly sent mobile phone SMS prompts. The EMA approach yielded a lower number of symptoms of obsessions and compulsions than the Y-BOCS but produced additional types of obsessions and compulsions not previously identified by the Y-BOCS. We conclude that the EMA-OCD procedure may represent a worthy addition to the suite of assessment tools used when working with clients who have OCD. Further research with larger samples is required to strengthen this conclusion.

Ambulant cognitive assessment using a smartphone.

In: *Appl Neuropsychol Adult* 21 (2), S. 136–142. DOI: 10.1080/09084282.2013.778261.

Abstract:

The focus of neuropsychology is to understand the relationship between assessment results and everyday cognitive abilities and disabilities. However, the generalizability of traditional neuropsychological tests to real-life behaviors, the ecological validity, is compromised by the test environment, among other things. Neuropsychological tests are often completed in a laboratory setting that is typically quiet with few distractions. This is very unlike most everyday environments. The aim of the present study was to investigate the possibility of using a smartphone in standardized cognitive assessment. A short-term memory task was obtained from young adults in either an everyday-life environment or a controlled test setting at four time points during a day. Results show no significant differences between the task performances in both conditions. There was no indication that fatigue, tension, or environmental noise had an effect on task performance. High correlations between subsequent time points were found in the everyday-life environment, suggesting a high test-retest reliability and commitment of the participants. The present study demonstrates that smartphones can be used to assess cognitive functions outside a laboratory setting.

A Dynamical Systems Approach to Understand Self-Regulation in Smoking Cessation Behavior Change.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt149.

Abstract:

INTRODUCTION: Self-regulation, a key component of the addiction process, has been challenging to model precisely in smoking cessation settings, largely due to the limitations of traditional methodological approaches in measuring behavior over time. However, increased availability of intensive longitudinal data (ILD) measured through ecological momentary assessment facilitates the novel use of an engineering modeling approach to better understand self-regulation. METHODS: Dynamical systems modeling is a mature engineering methodology that can represent smoking cessation as a self-regulation process. This article shows how a dynamical systems approach effectively captures the reciprocal relationship between day-to-day changes in craving and smoking. Models are estimated using ILD from a smoking cessation randomized clinical trial. RESULTS: A system of low-order differential equations is presented that models cessation as a self-regulatory process. It explains 87.32% and 89.16% of the variance observed in craving and smoking levels, respectively, for an active treatment group and 62.25% and 84.12% of the variance in a control group. The models quantify the initial increase and subsequent gradual decrease in craving occurring postquit as well as the dramatic quit-induced smoking reduction and postquit smoking resumption observed in both groups. Comparing the estimated parameters for the group models suggests that active treatment facilitates craving reduction and slows postquit smoking resumption. CONCLUSIONS: This article illustrates that dynamical systems modeling can effectively leverage ILD in order to understand self-regulation within smoking cessation. Such models quantify group-level dynamic responses in smoking cessation and can inform the development of more effective interventions in the future

Tims, Maria; Bakker, Arnold B.; Xanthopoulou, Despoina (2011):

Do transformational leaders enhance their followers' daily work engagement?

In: *The Leadership Quarterly* 22 (1), S. 121–131.

Abstract:

This diary study investigated whether and how supervisors' leadership style influences followers' daily work engagement. On the basis of leadership theories and the job demands–resources model, we predicted that a transformational leadership style enhances employees' work engagement through the mediation of self-efficacy and optimism, on a day-to-day basis. Forty-two employees first filled in a general questionnaire, and then a diary survey over five consecutive workdays. The results of multilevel analyses offered partial support for our hypotheses. Daily transformational leadership related positively to employees' daily engagement, and day-levels of optimism fully mediated this relationship. However, daily self-efficacy did not act as a mediator. These findings expand theory and previous research by illuminating the role of transformational leaders in fostering employee work engagement.

Within-person relationships between mood and creativity.

In: *J Appl Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-25018-001&site=ehost-live.

Abstract:

State mood has been proposed as a facilitator of creative behavior. Whereas positive mood compared to neutral mood generally facilitates creative performance, mood effects are weaker and less consistent when positive mood is compared to negative mood. These inconsistent results may be due to focusing only on mood valence, while neglecting or confounding mood activation. The current study is based on the dual-pathway model, which describes separate roles for mood valence and mood activation in facilitating creativity. We used experience sampling methodology to investigate the concurrent and lagged effects of mood valence and activation on creative process engagement (CPE) within-person over time among individuals working on a long-term project requiring creativity. We also investigated the moderating effects of individual differences in goal orientation and supervisory support on within-person mood–creativity relationships. As expected, we found that activating positive and activating negative moods were positively associated with concurrent CPE, whereas deactivating moods of both valences were negatively related to CPE. Activating negative mood had a significant lagged effect on CPE, whereas activating positive mood did not. We also found that activating positive mood was more strongly related to concurrent CPE among individuals with high rather than low learning goal orientation. Further, activating positive mood interacted with prove goal orientation and supervisory support for creativity, such that activating positive mood had the strongest association with CPE when both prove goal orientation and supervisory support were high. Tobin, Erin T.; Kane, Heidi S.; Saleh, Daniel J.; Naar-King, Sylvie; Poowuttikul, Pavadee; Secord, Elizabeth et al. (2014):

Naturalistically Observed Conflict and Youth Asthma Symptoms.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-37737-001%26site%3dehost-live.

Abstract:

Objective: To investigate the links between naturalistically observed conflict, self-reported caregiver−youth conflict, and youth asthma symptoms. Method: Fifty-four youth with asthma (age range: 10–17 years) wore the Electronically Activated Recorder (EAR) for a 4-day period to assess interpersonal conflict and caregiver−youth conflict as they occur in daily life. Conflict also was assessed with baseline self-report questionnaires and daily diaries completed by youth participants and their caregivers. Asthma symptoms were assessed using daily diaries, baseline self-reports, and wheezing, as coded from the EAR. Results: EAR-observed measures of conflict were strongly associated with self-reported asthma symptoms (both baseline and daily diaries) and wheezing coded from the EAR. Further, when entered together in regression analyses, youth daily reports of negative caregiver−youth interactions and EAR-observed conflict uniquely predicted asthma symptoms; only EAR-observed conflict was associated with EAR-observed wheezing. Conclusion: These findings demonstrate the potential impact of daily conflict on youth asthma symptoms and the importance of assessing conflict as it occurs in everyday life. More broadly, they point to the importance of formulating a clear picture of family interactions outside of the lab, which is essential for understanding how family relationships “get under the skin” to affect youth health. Toet, Alexander; van Schaik, Martin G. (2012):

Effects of signals of disorder on fear of crime in real and virtual environments.

In: *Journal of Environmental Psychology* 32 (3), S. 260–276. DOI: 10.1037/t02469-000;

Abstract:

Despite the fact that virtual environments are increasingly deployed to study the relation between urban planning, physical and social disorder, and fear of crime, their ecological validity for this type of research has not been established. This study compares the effects of similar signs of public disorder (litter, warning signs, cameras, signs of vandalism and car burglary) in an urban neighborhood and in its virtual counterpart on the subjective perception of safety and livability of the neighborhood. Participants made a walking tour through either the real or the virtual neighborhood, which was either in an orderly (baseline) state or adorned with numerous signs of public disorder. During their tour they reported the signs of disorder they noticed and the degree to which each of these affected their emotional state and feelings of personal safety. After finishing their tour they appraised the perceived safety and livability of the environment. Both in the real and in the simulated urban neighborhood, signs of disorder evoked associations with social disorder. In all conditions, neglected greenery was spontaneously reported as a sign of disorder. Disorder did not inspire concern for personal safety in reality and in the virtual environment with a realistic soundscape. However, in the absence of sound disorder compromised perceived personal safety in the virtual environment. Signs of disorder were associated with negative emotions more frequently in the virtual environment than in its real-world counterpart, particularly in the absence of sound. Also, signs of disorder degraded the perceived livability of the virtual, but not of the real neighborhood. Hence, it appears that people focus more on details in a virtual environment than in reality. We conclude that both a correction for this focusing effect and realistic soundscapes are required to make virtual environments an appropriate medium for both etiological (e.g. the effects of signs of disorder on fear of crime) and intervention (e.g. CPTED) research. A review of activity monitors as a new technology for objectifying function in lumbar spinal stenosis.

In: *J Back.Musculoskelet.Rehabil.* 25 (3), S. 177–185. DOI: 10.3233/BMR-2012-0325.

Abstract:

The purpose of this review article is to introduce the concept of activity monitoring, and to discuss the application of accelerometry in rehabilitation research and clinical practice using lumbar spinal stenosis as a model. Function is a complex concept, and changes in function have historically been challenging to measure. The International Classification of Functioning (ICF) defines two distinct components of function: capacity and performance. Capacity, the ability to perform a given task in a controlled environment can be measured through any number of existing functional measures. Performance, defined as activities performed on a day to day basis in the context of real life is challenging to measure, yet important in identifying the impact of pathology on real life. Recent advances in technology have allowed us to begin to measure performance, using activity monitors (accelerometers). Activity monitoring has the potential to change our concepts of outcomes, and as a result, expand our ideas about appropriateness of interventions in rehabilitation. Researchers and clinicians might benefit from using the new technology of activity monitors to measure the impact of intervention and to assess function. Therefore, this review will discuss the concept of activity monitoring and highlight potential uses for activity monitors in spine research and clinical care

Tomko, R. L.; Brown, W. C.; Tragesser, S. L.; Wood, P. K.; Mehl, M. R.; Trull, T. J. (2012):

Social Context of Anger in Borderline Personality Disorder and Depressive Disorders: Findings from a Naturalistic Observation Study.

In: *J Pers.Disord.* (0885-579X (Linking)). DOI: 10.1521/pedi_2012_26_064.

Abstract:

Anger and affective instability are key features of borderline personality disorder (BPD). Given the dynamic nature of affect, it is ideally studied using ambulatory assessment (AA). Recently, several major studies have examined affective instability via momentary self-report, using electronic diaries, which participants can use throughout their daily routine. The present study sought to complement this research by using an unobtrusive naturalistic observation method, the Electronically Activated Recorder (EAR). The EAR, which captures interpersonal behavior by periodically recording 50-second snippets of ambient sounds, was worn by 25 participants with BPD who also met the specific affective instability (AI) criterion as well as 13 participants with a depressive disorder (who did not meet criteria for AI or BPD) for three days. Trained coders listened to the captured recordings and rated participants' affect during each 50-second clip (i.e., in naturally varying social contexts). Results

suggested that there were differences between diagnostic groups regarding the social context of anger, such that anger at a previous time interval predicted spending time alone in the subsequent time interval for the depressed group, but not for the BPD group. As an ambulatory observational method, the EAR offers an alternative to self-report and can provide insight into the naturalistic expression of emotions in BPD

Measuring Impulsivity in Daily Life: The Momentary Impulsivity Scale.

In: *Psychological Assessment*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-41144-001%26site%3dehost-live.

Abstract:

Impulsivity is a core feature of many psychiatric disorders. Traditionally, impulsivity has been assessed using retrospective questionnaires or laboratory tasks. Both approaches neglect intraindividual variability in impulsivity and do not capture impulsivity as it occurs in real-world settings. The goal of the current study was to provide a method for assessing impulsivity in daily life that provides both between-individual and within-individual information. Participants with borderline personality disorder (BPD; n = 67) or a depressive disorder (DD; n = 38) carried an electronic diary for 28 days and responded to 9 impulsivity items up to 6 times per day. Item distributions and iterative exploratory factor analysis (EFA) results were examined to select the items that best captured momentary impulsivity. A brief 4-item scale was created that can be used for the assessment of momentary impulsivity. Model fit was good for both within- and between-individual EFA. As expected, the BPD group showed significantly higher scores on our Momentary Impulsivity Scale than the DD group, and the resulting scale was moderately correlated with common trait impulsivity scales. Tončić, Marko; Anić, Petra (2014):

Everyday activities: Beneficial effects of eudaimonic and hedonic motivation on subjective well-being.

In: *Current Psychology: A Journal for Diverse Perspectives on Diverse Psychological Issues*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-41860-001%26site%3dehost-live.

Abstract:

The study focuses on the impact of time and motives for everyday activities on mood and daily satisfaction. One hundred twenty-one undergraduate students participated in study using experience sampling method. The short PANAS scale, one item momentary satisfaction measure and state orientation to happiness scale were used. The measures were administered five times a day for 7 days via hand-held devices. The data were modeled using a linear mixed-effects approach. The models fitted the data reasonably well, especially for satisfaction and positive affect (PA) sharing similar parameter estimates. Both showed a nonlinear increase through the week while PA showed a similarly shaped circa-diurnal rhythm too. Negative affect (NA) showed almost no rhythm at all. Both hedonic and eudaimonic motives increased satisfaction and PA. Hedonic motives had a negative impact on NA. Generally, on momentary level, hedonic motives have a greater impact while longer intervals seem to emphasize the importance of eudaimonic motives. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Tong, Eddie M. W. (2010):

Personality influences in appraisal-emotion relationships: the role of neuroticism.

In: *J Personality* 78 (2), S. 393–417. DOI: 10.1111/j.1467-6494.2010.00620.x.

Abstract:

Although appraisal theorists have pointed out that appraisal-emotion relationships should vary as a function of personality traits, evidence demonstrating this is limited and inconsistent. To examine this issue, Ecological Momentary Assessment was employed in which undergraduates indicated their negative emotions and appraisals at regular intervals for 2 days in natural contexts. The results revealed that individuals higher in Neuroticism showed more negative appraisal styles than those lower in Neuroticism. More important, higher Neuroticism was associated with stronger appraisal-emotion relationships of 4 negative emotions

(anger, sadness, fear, and guilt). These findings imply that Neuroticism affects not only how people appraise their environments but also the reactivity of their negative emotions to appraisals.

Török, Katalin; Pálfi, Anita; Szelényi, Zoltán; Molnár, Dénes (2008):

Circadian variability of blood pressure in obese children.

In: *Nutr Metab Cardiovasc Dis* 18 (6), S. 429–435.

Abstract:

BACKGROUND AND AIMS:

The aim of the present study was to evaluate the circadian rhythm of blood pressure pattern in obese children, and to investigate if the lack of normal diurnal rhythm of blood pressure is associated with cardiovascular risk factors.

METHODS AND RESULTS:

73 obese children (body weight [mean+/-SD]: 89.0+/-17.8 kg; age [mean+/-SD]: 14.2+/-2.3 years), 42 dippers and 31 non-dippers were investigated. Following ambulatory blood pressure monitoring (ABPM), physical fitness testing was performed on a treadmill. Physical working capacity at 130, -150, -170 beat/min (PWC-130, -150, -170), resting and peak oxygen consumption (VO(2)rest, VO(2)peak) were determined. Forty-two percent of obese children were non-dipper. PWC-130 (74.8+/-48.8 watts; 48.0+/-38.5 watts), PWC-150 (132.9+/-52.1 watts; 104.2+/-49.3 watts), PWC-170 (185.9+/-49.5 watts; 154.9+/-53.4 watts) and VO(2)rest, ([mean+/-SD]: 0.29+/-0.08 L/min; 0.26+/-0.07 L/min), and VO(2) peak (2.77+/-0.61 L/min; 2.44+/-0.62 L/min) were significantly lower in the non-dipper group, as compared to dippers ($p<0.05$). The prevalence of hypertension, on the basis of ABPM, was significantly higher in the non-dipper group (45.2% vs 83.9%, $p<0.001$). This is due to increased prevalence of masked hypertension in the non-dipper group (19.0% vs 32.3%, $p<0.001$).

CONCLUSION:

The normal circadian variation of the blood pressure is frequently absent in obese children. Most of the non-dipper obese children are hypertensive, and their physical fitness is decreased.

Tortella-Feliu, M.; Aguayo, B.; Sese, A.; Morillas-Romero, A.; Balle, M.; Gelabert, J. M. et al. (2012):

Effects of temperament and emotion regulation styles in determining negative emotional states.

In: *Actas Esp.Psiquiatr.* 40 (6), S. 315–322. Online verfügbar unter PM:23165414.

Abstract:

INTRODUCTION: The interplay of reactive and regulatory temperamental processes appears to be essential for a better understanding of emotional states and disorders. In this study we explored the prospective relationship between reactive temperament (negative affect), regulatory temperament (effortful control), negative emotion regulation styles (rumination and suppression) and self-recorded anxiety, worry, and avoidance in naturalistic conditions. METHOD: Thirty-two young adults were first assessed through questionnaires on negative affectivity, effortful control, and two forms of negative emotion regulation (rumination and suppression). After this they recorded anxiety, worry, and avoidance three times a day over 50 consecutive days through an on-line access electronic diary. RESULTS: High levels of negative affect and low levels of effortful control were associated with higher levels of anxiety, worry, and avoidance ($p<.01$). The prospective association between negative affectivity and avoidance was moderated by effortful control (Total $R(2)=.49$). Moreover, the brooding facet of rumination totally mediated the association between negative affect and anxiety with a significant indirect effect (Effect=.30, Boot CI95%=.09 to .69). CONCLUSIONS: Avoidance patterns are significantly determined by negative affect--effortful control interaction and rumination, especially brooding, totally mediates the relationship between negative affect and anxiety

Toschke, Julia Anna; Kries, Rüdiger; Rosenfeld, Eva; Toschke, André Michael (2007):

Reliability of physical activity measures from accelerometry among preschoolers in free-living conditions.

In: *Clinical nutrition* 26 (4), S. 416–420.

Abstract:

Background & aims

Physical activity (PA) is a major determinant of obesity. Accelerometers have been reported to provide valid measures among adults. However, studies among preschoolers rarely report positive findings. To assess the day-to-day variability of accelerometers in preschoolers.

Methods

Uni-axial accelerometer (Actigraph monitor AM 7164-2.2) counts including one weekend from the time of getting up in the morning until bedtime.

Results

On average, boys showed 899 counts per minute (cpm) compared to 764 for girls ($p<0.01$; overall mean 828 cpm). Intra-individual correlation for accelerometry data between single days of examination was low with Pearson correlation coefficients between r=0.31 and 0.51. Furthermore, child's body mass index (BMI) and accelerometer measures were not related to each other (Pearson's correlation coefficient r=−0.06). Subsequent analyses showed higher measures (+50% cpm; $p<0.01$) for instruments placed in front of the umbilicus compared to instruments placed at the right hip.

Conclusions

Measurements of uni-axial accelerometers showed a low reliability among preschoolers. Uni-axial accelerometers placed on elastic belts might measure PA with low precision among preschoolers under free-living conditions possibly due to slipping instruments. This might explain lacking findings of an association between PA and obesity in studies among preschoolers.

Tossell, Chad C.; Kortum, Philip; Shepard, Clayton W.; Rahmati, Ahmad; Zhong, Lin (2012):

Getting real: A naturalistic methodology for using smartphones to collect mediated communication.

In: *Advances in Human-Computer Interaction* 2012. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-15760-001%26site%3dehost-live;chad.tossell@rice.edu.

Abstract:

This paper contributes an intentionally naturalistic methodology using smartphone logging technology to study communications in the wild. Smartphone logging can provide tremendous access to communications data from real environments. However, researchers must consider how it is employed to preserve naturalistic behaviors. Nine considerations are presented to this end. We also provide a description of a naturalistic logging approach that has been applied successfully to collecting mediated communications from iPhones. The methodology was designed to intentionally decrease reactivity and resulted in data that were more accurate than self-reports. Example analyses are also provided to show how data collected can be analyzed to establish empirical patterns and identify user differences. Smartphone logging technologies offer flexible capabilities to enhance access to real communications data, but methodologies employing these techniques must be designed appropriately to avoid provoking naturally occurring behaviors. Functionally, this methodology can be applied to establish empirical patterns and test specific hypotheses within the field of HCI research. Topically, this methodology can be applied to domains interested in understanding mediated communications such as mobile content and systems design, teamwork, and social networks. Toth, Kalman (2014):

Antihypertensive Efficacy of Triple Combination Perindopril/Indapamide Plus Amlodipine in High-Risk Hypertensives: Results of the PIANIST Study (Perindopril-Indapamide plus AmlodipiNe in high rISk hyperTensive patients).

In: *Am J Cardiovasc Drugs* 14 (2), S. 137–145. DOI: 10.1007/s40256-014-0067-2.

Abstract:

OBJECTIVE: Our objective was to evaluate a triple-drug antihypertensive strategy for blood pressure control in patients with difficult-to-treat hypertension. DESIGN: The Perindopril-Indapamide plus AmlodipiNe in high rISk hyperTensive patients (PIANIST) trial was an observational, 4-month, open-label study. PATIENTS AND INTERVENTIONS: A total of 4,731 patients at high or very high cardiovascular risk with hypertension that was not properly controlled despite antihypertensive therapy, and for whom study treatment (fixed-dose perindopril 10 mg/indapamide 2.5 mg + amlodipine 5 or 10 mg) was consistent with their

existing therapeutic plan, were included. OUTCOMES: One-sample t tests and Chi-squared tests were performed to evaluate changes in blood pressure. RESULTS: Mean baseline office blood pressure (OBP) was 160.5 +/- 13.3/93.8 +/- 8.7 mmHg. After 4 months of therapy, OBP decreased by 28.3 +/- 13.5/13.8 +/- 9.4 to 132.2 +/- 8.6/80.0 +/- 6.6 mmHg ($p < 0.0001$). Blood pressure targets were reached by 72.0 % of patients and by 81 and 91 % of patients previously treated with an angiotensin-converting enzyme inhibitor/hydrochlorothiazide or an angiotensin receptor blocker/hydrochlorothiazide, respectively. Changes in OBP were 18.7 +/- 8.3/9.7 +/- 7.2 mmHg for grade 1 (n = 1,679), 30.4 +/- 10.1/14.7 +/- 8.6 mmHg for grade 2 (n = 2,397), and 45.4 +/- 15.1/20.7 +/- 12.1 mmHg for grade 3 patients (n = 655; all $p < 0.0001$). In patients who underwent ambulatory blood pressure monitoring (n = 104), 24-h mean blood pressure decreased from 147.4 +/- 13.8/82.1 +/- 11.9 to 122.6 +/- 9.1/72.8 +/- 7.4 mmHg ($p < 0.0001$). Ankle edema was infrequent (0.2 % of patients). CONCLUSION: Triple combination perindopril/indapamide/amlodipine was effectively and safely administered to a large population of high- and very high-risk hypertensive patients who had not reached target OBP values with previous treatment.

Treuth, Margarita S.; Baggett, Chris D.; Pratt, Charlotte A.; Going, Scott B.; Elder, John P.; Charneco, Eileen Y.; Webber, Larry S. (2009):

A longitudinal study of sedentary behavior and overweight in adolescent girls.

In: *Obesity* 17 (5), S. 1003–1008.

Abstract:

The aim of this study is to examine sedentary and light activity in relation to overweight in adolescent girls. Adolescent girls were randomly recruited from 36 schools participating in the Trial of Activity for Adolescent Girls (TAAG). Assessments included age, ethnicity, socioeconomic status, and body composition estimated from weight, height, and triceps skinfold. Sedentary and light activity was measured for 6 days using accelerometry in 6th and in 8th grade among two randomly sampled cross-sections of girls. Sedentary activity increased from the 6th to 8th grade by 51.5 min/day. In the 8th grade, a significantly higher number of hours in sedentary activity for each of the 6-days of measurement were evident with higher tertiles of percent body fat (30–35%, >35% fat) ($P < 0.05$), but not across all increasing tertiles of BMI (5th to 85th, 85th to 95th, and >95th percentiles). The increase in sedentary activity was observed on weekdays, but not on weekends for percent body fat tertiles. In the cohort of girls measured in both 6th and 8th grades, the mean cross-sectional coefficient estimates were significant for percent body fat, but not BMI for sedentary and light activities. Adolescent girls from the 6th to 8th grade are shifting their time from light to more sedentary activity as measured by accelerometers. In addition, the increase in sedentary activity is not associated with an adverse effect on BMI or percent body fat. The eventual impact of this shift to a more sedentary lifestyle on body composition and other outcomes needs to be evaluated further.

Treuth, Margarita S.; Catellier, Diane J.; Schmitz, Kathryn H.; Pate, Russell R.; Elder, John P.; McMurray, Robert G. et al. (2007):

Weekend and Weekday Patterns of Physical Activity in Overweight and Normal-weight Adolescent Girls.

In: *Obesity* 15 (7), S. 1782–1788.

Abstract:

Objective

To describe the patterns (specifically comparing weekdays and weekends classified by intensities) of physical activity (PA) measured by accelerometry in adolescent girls.

Research Methods and Procedures

Healthy sixth grade girls (n = 1603), 11 to 12 years old, were randomly recruited from 36 schools participating in the Trial of Activity in Adolescent Girls. Age, ethnicity, socioeconomic status, weight, and height were taken. PA patterns were measured for 6 days using accelerometry.

Results

Adolescent girls spend most of their time in sedentary (52% to 57% of the day) and light activity (40% to 45% of the day) on weekdays and weekends. In all girls, total PA comprised 44.5% of the day (41.7% light, 2.2% moderate, and 0.7% vigorous) with sedentary activity comprising 55.4%. Moderate-to-vigorous PA (MVPA) was higher ($p < 0.001$) on weekdays than weekends in all girls, but MVPA was lower in at-risk of overweight + overweight girls ($p < 0.001$) on both weekdays and weekends compared with normal-weight girls.

Discussion

Adolescent girls are more active at moderate and vigorous intensities on weekdays than on weekends, and at-risk of overweight and those overweight spend less time engaging in MVPA than normal-weight girls.

Keywords: activity monitors, physical activity assessment, sedentary activity, accelerometry

Trivedi, Ranak; Sherwood, Andrew; Strauman, Timothy J.; Blumenthal, James A. (2008):

Laboratory-based blood pressure recovery is a predictor of ambulatory blood pressure.

In: *Biol Psychol* 77 (3), S. 317–323.

Abstract:

The recovery phase of the stress response is an individual difference characteristic that may predict cardiovascular risk. The purpose of this study was to examine whether laboratory-based blood pressure (BP) recovery predicts ambulatory BP (ABP). One hundred and eighty-two participants underwent a standard laboratory stress protocol, involving a 20-min baseline rest period, and four stressors presented in a counterbalanced order, each followed by a 10-min recovery period. Participants also wore an ABP monitor for 24 h during a typical workday. Hierarchical regression analyses showed that BP recovery accounted for significant additional variance for daytime SBP ($p < 0.001$), nighttime SBP ($p < 0.001$), daytime DBP ($p < 0.001$), and nighttime DBP ($p < 0.001$), after controlling for baseline and reactivity BP. Results suggest that persistence of the BP response following stress may be a more salient characteristic of the stress response in understanding its potential impact on longer term cardiovascular regulation.

Tropeano, Anne-Isabelle; Boutouyrie, Pierre; Pannier, Bruno; Joannides, Robinson; Balkestein, Elisabeth; Katsahian, Sandrine et al. (2006):

Brachial pressure-independent reduction in carotid stiffness after long-term angiotensin-converting enzyme inhibition in diabetic hypertensives.

In: *Hypertension* 48 (1), S. 80–86. DOI: 10.1161/01.HYP.0000224283.76347.8c.

Abstract:

Hypertension and diabetes are associated with an increased arterial stiffness. A direct blood pressure-independent effect of angiotensin-converting enzyme inhibitors on arterial stiffness has never been unequivocally demonstrated. In this mechanistic study, we used an experimental design in which patients responding to 1 month treatment with 4 mg perindopril were randomized double-blind to either 4 mg perindopril or 8 mg perindopril for 6 months. We determined carotid distensibility with echotracking and applanation tonometry at baseline and after the 7-month treatment period in 57 essential hypertensive patients with type 2 diabetes (age 63+/-7 years). We monitored ambulatory blood pressure at baseline and after treatment. After 7 months treatment, 24-hour ambulatory blood pressure significantly decreased, with no significant difference between 4 mg and 8 mg perindopril. Carotid distensibility increased more after 8 mg perindopril compared with 4 mg perindopril (8 mg: from 13.1+/-5.9 to 16.0+/-6.7 kPa(-1)x10(-3); 4 mg: from 13.2+/-5.2 to 12.7+/-5.9 kPa(-1)x10(-3); ANOVA, dose-period interaction, $P<0.05$). Carotid internal diameter and elastic modulus were significantly lower after 8 mg perindopril compared with 4 mg perindopril, independent of blood pressure reduction. These results indicate a dose-dependent and blood pressure-independent reduction in carotid stiffness under chronic treatment with an angiotensin-converting enzyme inhibitor. They suggest that arterial distensibility was increased through an inward remodeling, leading to a reduction in wall stress, thus reducing elastic modulus. They also suggest that long-term administration of high doses (8 mg) of perindopril is required to improve carotid structure and function in hypertensive patients with type 2 diabetes.

Trudeau, Jeremiah; van Inwegen, Richard; Eaton, Thomas; Bhat, Gajanan; Paillard, Florence; Ng, Dik et al. (2014):

Assessment of Pain and Activity Using an Electronic Pain Diary and Actigraphy Device in a Randomized, Placebo-Controlled Crossover Trial of Celecoxib in Osteoarthritis of the Knee.

In: *Pain Pract. DOI:* 10.1111/papr.12167.

Abstract:

OBJECTIVE: The primary goal was to determine whether a composite measure of pain and activity is a more responsive assessment of analgesic effect than pain alone or activity alone in patients with osteoarthritis (OA) of the knee. DESIGN: We

conducted a randomized, double-blind, placebo-controlled, 2-period, crossover study of celecoxib vs. placebo in subjects with chronic pain due to knee OA. Patients with knee OA and baseline pain intensity score >/=4 on a 0-10 numerical rating scale (NRS) before each period were randomized. Pain endpoints included in-clinic pain score (24-hour and 1-week recall), daily paper diary pain score, current pain on an electronic pain diary (each on NRS), and WOMAC pain subscale. Activity measures included WOMAC function subscale and actigraphy using a device. Three composite pain-activity measures were prespecified. RESULTS: Sixty-three patients were randomized and 47 completed the study. The WOMAC pain subscale was the most responsive of all five pain measures. Pain-activity composites resulted in a statistically significant difference between celecoxib and placebo but were not more responsive than pain measures alone. However, a composite responder defined as having 20% improvement in pain or 10% improvement in activity yielded much larger differences between celecoxib and placebo than with pain scores alone. Actigraphy was more responsive than the WOMAC function scale, possibly due to lower placebo responsiveness. CONCLUSION: We have identified composite pain-activity measures that are similarly or more responsive than pain-alone measures in patients with OA. Further research is warranted to determine the optimal method for computing these composites.

Trudel, Xavier; Brisson, Chantal; Larocque, Brigitte; Milot, Alain (2009):

Masked hypertension: different blood pressure measurement methodology and risk factors in a working population.

In: *J Hypertens* 27 (8), S. 1560–1567. DOI: 10.1097/HJH.0b013e32832cb036.

Abstract:

OBJECTIVES\r\nTo estimate the prevalence of masked hypertension when the same ambulatory device is used for both manual and ambulatory blood pressure measurements and to measure associations with lifestyle risk factors in a working population.\r\nMETHODS\r\nWhite-collar workers were recruited from three public organizations. Blood pressure was measured at the workplace using Spacelabs 90207 for manual measurements (mean of the first three readings taken by a trained assistant) followed by ambulatory measurements (mean of every other reading obtained during the working day). Masked hypertension was defined as manual blood pressure measurement of less than 140/90 mmHg and ambulatory blood pressure measurement of at least 135/85 mmHg. Smoking, alcohol intake, BMI and leisure physical activity were also assessed.\r\nRESULTS\r\nBlood pressure measurements were obtained from 2370 workers (80% participation, 61% women; mean age = 44 years). Masked hypertension was diagnosed in 15.02% of the participants. The prevalence was higher in men [adjusted odds ratio (OR) = 2.38, 95% confidence interval (CI) = 1.86-3.05]. The prevalence in men increased with age (adjusted OR = 2.08 for 40-49 years, 95% CI = 1.33-3.26 and adjusted OR = 1.91 for > or =50 years, 95% CI = 1.20-3.04) and BMI (adjusted OR = 1.78 for BMI > or = 27, 95% CI = 1.21-2.64). The prevalence in women increased with BMI (adjusted OR = 1.65 for BMI > or =27, 95% CI = 1.14-2.39) and alcohol intake (adjusted OR = 2.12 for at least six drinks per week, 95% CI = 1.34-3.35).\r\nCONCLUSION\r\nMasked hypertension is frequent and still present when blood pressure is measured out of the office, using the same device for manual and ambulatory measurements. Sex, age, BMI and alcohol intake are associated with masked hypertension.

“I Thought You Were Japanese”: Ethnic Miscategorization and Identity Assertion.

In: *Cultural Diversity and Ethnic Minority Psychology*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-45472-001%26site%3dehost-live.

Abstract:

Across 2 studies we examined how ethnic minorities respond to ethnic miscategorization. Using a 21-day experience sampling procedure (Study 1), we found that ethnic minorities exhibited greater ethnic identity assertion when they had reported being ethnically miscategorized the previous day. Similarly, we found that ethnic minorities who were ethnically miscategorized (vs. not) by a White partner in the laboratory exhibited greater ethnic identity assertion and expressed greater dislike of their partner (Study 2). In both studies, these effects were stronger for individuals whose ethnic identity was central to their self-concept. The implications of these findings for ethnic identity development and intergroup relations are discussed. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Using experience sampling methods/ecological momentary assessment (ESM/EMA) in clinical assessment and clinical research: introduction to the special section.

In: *Psychological Assessment* 21 (4), S. 457–462. DOI: 10.1037/a0017653.

Abstract:

This article introduces the special section on experience sampling methods and ecological momentary assessment in clinical assessment. We review the conceptual basis for experience sampling methods (ESM; Csikszentmihalyi & Larson, 1987) and ecological momentary assessment (EMA; Stone & Shiffman, 1994). Next, we highlight several advantageous features of ESM/EMA as applied to psychological assessment and clinical research. We provide a brief overview of the articles in this special section, each of which focuses on 1 of the following major classes of psychological disorders: mood disorders and mood dysregulation (Ebner-Priemer & Trull, 2009), anxiety disorders (Alpers, 2009), substance use disorders (Shiffman, 2009), and psychosis (Oorschot, Kwapil, Delespaul, & Myin-Germeys, 2009). Finally, we discuss prospects, future challenges, and limitations of ESM/EMA.

Trull, T. J.; Ebner-Priemer, U. (2012):

Ambulatory Assessment.

In: *Annu.Rev.Clin.Psychol.* (1548-5943 (Linking)). DOI: 10.1146/annurev-clinpsy-050212-185510.

Abstract:

Ambulatory assessment (AA) covers a wide range of assessment methods to study people in their natural environment, including self-report, observational, and biological/physiological/behavioral. AA methods minimize retrospective biases while gathering ecologically valid data from patients' everyday life in real time or near real time. Here, we report on the major characteristics of AA, and we provide examples of applications of AA in clinical psychology (a) to investigate mechanisms and dynamics of symptoms, (b) to predict the future recurrence or onset of symptoms, (c) to monitor treatment effects, (d) to predict treatment success, (e) to prevent relapse, and (f) as interventions. In addition, we present and discuss the most pressing and compelling future AA applications: technological developments (the smartphone), improved ecological validity of laboratory results by combined lab-field studies, and investigating gene-environment interactions. We conclude with a discussion of acceptability, compliance, privacy, and ethical issues. Expected final online publication date for the Annual Review of Clinical Psychology Volume 9 is March 26, 2013. Please see http://www.annualreviews.org/catalog/pubdates.aspx for revised estimates

Trull, Timothy J.; Ebner-Priemer, Ulrich (2014):

The Role of Ambulatory Assessment in Psychological Science.

In: *Curr Dir Psychol Sci* 23 (6), S. 466–470. DOI: 10.1177/0963721414550706.

Abstract:

We describe the current use and future promise of an innovative methodology, ambulatory assessment (AA), that can be used to investigate psychological, emotional, behavioral, and biological processes of individuals in their daily life. The term AA encompasses a wide range of methods used to study people in their natural environment, including momentary self-report, observational, and physiological. We emphasize applications of AA that integrate two or more of these methods, discuss the smart phone as a hub or access point for AA, and discuss future applications of AA methodology to the science of psychology. We pay particular attention to the development and application of Wireless Body Area Networks (WBANs) that can be implemented with smart phones and wireless physiological monitoring devices, and we close by discussing future applications of this approach to matters relevant to psychological science.

Clinical psychology. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 620–635. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-035%26site%3dehost-live.

Abstract:

(from the chapter) Contemporary clinical psychology emphasizes empirically supported approaches to the assessment, prevention, and treatment of conditions that lead to human suffering (Trull, 2007). This wide-ranging definition reflects the broad array of activities that characterize clinical psychologists; they may serve as assessment specialists, consultants, researchers, or clinicians, to name just a few of the possibilities. In this chapter, we highlight the application of experience sampling methods (ESM; Csikszentmihalyi & Larson, 1987) and ecological momentary assessment methods (EMA; Stone & Shiffman, 1994) to the field of clinical psychology. Specifically, we discuss how these methods can shed light on the nature of mental illness and its symptoms, monitor treatment progress and outcome, and assist in the delivery of treatment in daily life. Finally, we conclude with a discussion of future applications and challenges in using these methods. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Reducing Hyperactivity with a Feedback Actigraph: Initial Findings.

In: *Clinical Child Psychology and Psychiatry* 11 (4), S. 607–617. DOI: 10.1177/1359104506067881.

Abstract:

Schulman and colleagues demonstrated that classroom activity level can be reduced in hyperactive boys using activity-level feedback and positive reinforcement. This article reports preliminary results using a device that combines modern beeper and actigraphy technology for the purpose of measuring, monitoring, and modifying motor excess in children with confirmed diagnoses of Attention Deficit Hyperactivity Disorder (ADHD). Nine boys ranging in age from 8 to 9 years with the ADHD Combined Type wore prototype BuzzBee® feedback actigraphs during school periods and were reinforced for activity-level reductions in the context of a simple pre/post research design. The findings indicated that 7 of the 9 boys reduced their activity level from 20 to 47% of baseline levels while the activity levels of the two remaining boys increased from 2 to 7% of baseline levels. These changes were statistically significant and constitute a large effect.

Tseng, Wen Chih (2010):

The quality of subjective experience in daily lives of college students: The effect of perceived challenges and skills.

In: *Chinese Journal of Psychology* 52 (2), S. 133–153. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-09517-002&site=ehost-live;wenchih@mail.nhcue.edu.tw.

Abstract:

This study conducted two major examinations. First, the present study examined whether varying ratios of perceived challenge and skill can explain the range of negative to positive variations in daily experience. Second, the article investigated the effects that perceived challenges and skills in activities have on the quality of everyday life experience. The design of the study involved an experience sampling methodology; 101 college students completed experience surveys at eight times during the day for a period of one week, resulting in a total 5,640 observations. The experience surveys measure daily variations in five dimensions of experience (concentration, control, interest, enjoyment, and involvement) in four contexts. Findings showed that the quality of experience in high-challenge/high-skill conditions was characterized by high concentration, control, interest, and involvement of the situation. Results from hierarchical linear modeling analyses showed that prediction of flow theory that the interaction of challenges and skills has a positive effect on the quality of experience. Yet some differences of parameter estimates were found between dimensions of experience and between social contexts of activity. The perceived challenges, skills, and their interaction explained 11%-39% of the with-individual variance in dimensions of experience. These findings suggest implications for improving the quality of Taiwanese college students' life and call for a further improvement of the flow model. Tsukasaki, Keiko; Makimoto, Kiyoko; Kido, Teruhiko (2008):

The impact of sleep on ambulatory blood pressure of female caregivers providing home care in Japan: an observational study.

In: *International journal of nursing studies* 45 (12), S. 1721–1730. DOI: 10.1016/j.ijnurstu.2008.04.006.

Abstract:

BACKGROUND\r\nElderly family caregivers are presumed to be susceptible to having various health problems. However, biomedical indicators of health in these caregivers are rarely examined.\r\nOBJECTIVE\r\nTo examine the effect of sleep quality, measured by hours of sleep and the number of times leaving bed, on various blood pressure parameters in elderly caregivers.\r\nDESIGN\r\nObservational study.\r\nSETTING\r\nNorthern Japan.\r\nPARTICIPANTS\r\nSeventy-eight female family caregivers.\r\nMETHODS\r\nAmbulatory blood pressure was monitored at 30-60-min intervals for a 24-h period. An actigraph was used to determine sleep/wake status. Face-to-face interviews were conducted to obtain home care and demographic information, and self-administered questionnaires were used to collect information on activities in a 24-h period.\r\nRESULTS\r\nThe mean age of the caregivers was 62.5+/-9.6 years, and the mean hours of sleep were 7.3. Out of 78 caregivers, 19 were on antihypertensive medication. Of the remaining 59, this study found 45.8% to be hypertensive, with the mean maximum systolic pressure exceeding 180mmHg. The hours of sleep at night and for the 24-h period were inversely associated with the mean systolic blood pressure. The majority of caregivers on antihypertensive medication also had high blood pressure.\r\nCONCLUSIONS\r\nThis study suggests the importance of 24-h ambulatory blood pressure monitoring for elderly caregivers, so as to screen for hypertension as well as to monitor the effectiveness of antihypertensive medication.

Assessment of Physical Activity and Energy Expenditure by GPS Combined with Accelerometry in Real-Life Conditions.

In: *J Phys.Act.Health* (1543-3080 (Linking)). Online verfügbar unter PM:23072762.

Abstract:

BACKGROUND. Physical activity (PA) and related energy expenditure (EE) is often assessed by means of a single technique. Because of inherent limitations, single techniques may not allow for an accurate assessment both PA and related EE. The aim of this study was to develop a model to accurately assess common PA types and durations and thus EE in free-living conditions, combining data from global positioning system (GPS) and two accelerometers. METHODS. Forty-one volunteers participated in the study. First, a model was developed and adjusted to measured EE with a first group of subjects (Protocol I, n=12) who performed six structured and supervised PA. Then, the model was validated over 2 experimental phases with two groups (n=12 and n=17) performing scheduled (Protocol I) and spontaneous common activities in real-life condition (Protocol II). Predicted EE was compared to actual EE as measured by portable indirect calorimetry. RESULTS. In protocol I, performed PA types could be recognized with little error. The duration of each PA type could be predicted with an accuracy below 1 minute. Measured and predicted EE were strongly associated (r=0.97, P<0.001). CONCLUSION. Combining GPS and two accelerometers allows for an accurate assessment of PA and EE in free-living situations

Tudor-Locke, Catrine; Barreira, Tiago V.; Schuna, John M.; Mire, Emily F.; Katzmarzyk, Peter T. (2014):

Fully automated waist-worn accelerometer algorithm for detecting children's sleep-period time separate from 24-h physical activity or sedentary behaviors.

In: *Appl Physiol Nutr Metab* 39 (1), S. 53–57. DOI: 10.1139/apnm-2013-0173.

Abstract:

Analysis of 24-h waist-worn accelerometer data for physical activity and sedentary behavior requires that sleep-period time (from sleep onset to the end of sleep, including all sleep epochs and wakefulness after onset) is first identified. To identify sleep-period time in children in this study, we evaluated the validity of a published automated algorithm that requires nonaccelerometer bed- and wake-time inputs, relative to a criterion expert visual analysis of minute-by-minute waist-worn accelerometer data, and validated a refined fully automated algorithm. Thirty grade 4 schoolchildren (50% girls) provided 24-h waist-worn accelerometry data. Expert visual inspection (criterion), a published algorithm (Algorithm 1), and 2 additional automated refinements (Algorithm 2, which draws on the instrument's inclinometer function, and Algorithm 3, which focuses on bedtime and wake time points) were applied to a standardized 24-h time block. Paired t tests were used to evaluate differences in mean sleep time (expert criterion minus algorithm estimate). Compared with the criterion, Algorithm 1 and Algorithm 2 significantly overestimated sleep time by 43 min and 90 min, respectively. Algorithm 3 produced the smallest mean difference (2 min), and was not significantly different from the criterion. Relative to expert visual inspection, our automated Algorithm 3 produced an estimate that was precise and within expected values for similarly aged children. This fully automated algorithm for 24-h waist-worn accelerometer data will facilitate the separation of sleep time from sedentary behavior and physical activity of all intensities during the remainder of the day.

Tudor-Locke, Catrine; Brashear, Meghan M.; Johnson, William D.; Katzmarzyk, Peter T. (2010):

Accelerometer profiles of physical activity and inactivity in normal weight, overweight, and obese U.S. men and women.

In: *Int J Behav Nutr Phys Act* 7. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32472-001%26site%3dehost-live;Tudor-Locke@pbrc.edu.

Abstract:

BACKGROUND:

The 2005-2006 National Health and Nutrition Examination Survey (NHANES) is used to describe an accelerometer-derived physical activity/inactivity profile in normal weight (BMI < 25 kg/m2), overweight (25 </= BMI < 30 kg/m2), and obese (BMI >/= 30 kg/m2) U.S. adults.

METHODS:

We computed physical activity volume indicators (activity counts/day, uncensored and censored steps/day), rate indicators (e.g., steps/minute), time indicators (employing NHANES activity counts/minute cut points to infer time in non-wear, sedentary, low, light, moderate, and vigorous intensities), the number of breaks in sedentary time (occasions when activity counts rose from < 100 activity/counts in one minute to >/= 100 activity counts in the subsequent minute), achievement of public health guidelines, and classification by step-defined physical activity levels. Data were examined for evidence of consistent and significant gradients across BMI-defined categories.

RESULTS:

In 2005-2006, U.S adults averaged 6,564 +/- SE 107 censored steps/day, and after considering non-wear time, they spent approximately 56.8% of the rest of the waking day in sedentary time, 23.7% in low intensity, 16.7% in light intensity, 2.6% in moderate intensity, and 0.2% in vigorous intensity. Overall, approximately 3.2% of U.S. adults achieved public health guidelines. The normal weight category took 7,190 +/- SE 157 steps/day, and spent 25.7 +/- 0.9 minutes/day in moderate intensity and 7.3 +/- 0.4 minutes/day in vigorous intensity physical activity. The corresponding numbers for the overweight category were 6,879 +/- 140 steps/day, 25.3 +/- 0.9 minutes/day, and 5.3 +/- 0.5 minutes/day and for the obese category 5,784 +/- 124 steps/day, 17.3 +/- 0.7 minutes/day and 3.2 +/- 0.4 minutes/day. Across BMI categories, increasing gradients and significant trends were apparent in males for sedentary time and decreasing gradients and significant trends were evident in time spent in light intensity, moderate intensity, and vigorous intensity. For females, there were only consistent gradients and significant trends apparent for decreasing amounts of time spent in moderate and vigorous intensity.

CONCLUSIONS:

Simple indicators of physical activity volume (i.e., steps/day) and time in light, moderate or vigorous intensity physical activity differ across BMI categories for both sexes, suggesting that these should continue to be targets for surveillance.

Tudor-Locke, C.; Camhi, S. M.; Troiano, R. P. (2012):

A catalog of rules, variables, and definitions applied to accelerometer data in the national health and nutrition examination survey, 2003-2006.

In: *Prev.Chronic.Dis.* 9 (1545-1151 (Electronic)), S. E113. Online verfügbar unter PM:22698174.

Abstract:

INTRODUCTION: The National Health and Nutrition Examination Survey (NHANES) included accelerometry in the 2003-2006 data collection cycles. Researchers have used these data since their release in 2007, but the data have not been consistently treated, examined, or reported. The objective of this study was to aggregate data from studies using NHANES accelerometry data and to catalogue study decision rules, derived variables, and cut point definitions to facilitate a more uniform approach to these data. METHODS: We conducted a PubMed search of English-language articles published (or indicated as forthcoming) from January 2007 through December 2011. Our initial search yielded 74 articles, plus 1 article that was not indexed in PubMed. After excluding 21 articles, we extracted and tabulated details on 54 studies to permit comparison among studies. RESULTS: The 54 articles represented various descriptive, methodological, and inferential analyses. Although some decision rules for treating data (eg, criteria for minimal wear-time) were consistently applied, cut point definitions used for accelerometer-derived variables (eg, time spent in various intensities of physical activity) were especially diverse. CONCLUSION: Unique research questions may require equally unique analytical approaches; some inconsistency in approaches must be tolerated if scientific discovery is to be encouraged. This catalog provides a starting point for researchers to consider relevant and/or comparable accelerometer decision rules, derived variables, and cut point definitions for their own research questions

Tudor-Locke, Catrine; Johnson, William D.; Katzmarzyk, Peter T. (2011):

Relationship between accelerometer-determined steps/day and other accelerometer outputs in US adults.

In: *J Phys Act Health* 8 (3), S. 410–419.

Abstract:

BACKGROUND:

The purpose of this study was to examine the relationship between 2005-2006 National Health and Nutrition Examination Survey (NHANES) accelerometer-determined steps/day and activity counts/day, and between steps/day and estimates of nonwear time (as an indicator of the unmonitored day) and time spent in sedentary behaviors as well as a range of physical activity intensities.

METHODS:

Linear regression models were used to characterize the relationship between steps/day, activity counts/day, estimates of wear time, and intensity categories.

RESULTS:

1781 males (mean age = 46.5 years) and 1963 females (mean age = 47.7 years) wore accelerometers 14.0 ± SEM0.06 hours/day. The relationship between steps/day and activity counts/day was positive and strong (R2 = .87). The relationship between steps/day and time spent in sedentary behaviors was inverse and moderate (R2 = .25). Stronger and positive relationships were apparent between steps/day and time in light (R2 = .69) and moderate (R2 = .63) intensity activities. There was no discernable relationship between steps/day and time spent in low or vigorous intensity activities or with wear time.

CONCLUSIONS:

Assessed by accelerometer, steps/day explains 87% of the variation in activity counts/day, 25% of the variation in time in sedentary behaviors, 69% of time in light intensity, and 63% of time in moderate intensity.

Tully, Laura M.; Lincoln, Sarah Hope; Hooker, Christine I. (2014):

Lateral prefrontal cortex activity during cognitive control of emotion predicts response to social stress in schizophrenia.

In: *Neuroimage Clin* 6, S. 43–53. DOI: 10.1016/j.nicl.2014.08.012.

Abstract:

LPFC dysfunction is a well-established neural impairment in schizophrenia and is associated with worse symptoms. However, how LPFC activation influences symptoms is unclear. Previous findings in healthy individuals demonstrate that lateral prefrontal cortex (LPFC) activation during cognitive control of emotional information predicts mood and behavior in response to interpersonal conflict, thus impairments in these processes may contribute to symptom exacerbation in schizophrenia. We investigated whether schizophrenia participants show LPFC deficits during cognitive control of emotional information, and whether these LPFC deficits prospectively predict changes in mood and symptoms following real-world interpersonal conflict. During fMRI, 23 individuals with schizophrenia or schizoaffective disorder and 24 healthy controls completed the Multi-Source Interference Task superimposed on neutral and negative pictures. Afterwards, schizophrenia participants completed a 21-day online daily-diary in which they rated the extent to which they experienced mood and schizophrenia-spectrum symptoms, as well as the occurrence and response to interpersonal conflict. Schizophrenia participants had lower dorsal LPFC activity (BA9) during cognitive control of task-irrelevant negative emotional information. Within schizophrenia participants, DLPFC activity during cognitive control of emotional information predicted changes in positive and negative mood on days following highly distressing interpersonal conflicts. Results have implications for understanding the specific role of LPFC in response to social stress in schizophrenia, and suggest that treatments targeting LPFC-mediated cognitive control of emotion could promote adaptive response to social stress in schizophrenia.

Tuomisto, M. T.; Terho, T.; Korhonen, I.; Lappalainen, R.; Tuomisto, T.; Laippala, P.; Turjanmaa, V. (2006):

Diurnal and weekly rhythms of health-related variables in home recordings for two months.

In: *Physiol Behav* 87 (4), S. 650–658. DOI: 10.1016/j.physbeh.2005.12.012.

Abstract:

Several telecare systems for long-term monitoring of the well-being of patients at home have been developed as an aid in healthcare and to reduce hospitalization costs. Most of the systems have been designed to measure only one or two variables. Because well-being is a combination of both psychological and physiological wellness, there is a need to monitor several psychophysiological variables simultaneously in out-of-hospital conditions for a long period. To understand better the variability of patients' wellness-related variables in long-term recordings, the knowledge of the normal variation in health-related variables in healthy people is necessary. In our study, 14 healthy working middle-aged men were studied daily for 24 h and periods of 50 to 79 days. The variables measured were beat-to-beat heart rate, motor activity, blood pressure, body weight, and temperature. At night respiratory frequency, time of movements, amount of quiet sleep, and ballistocardiographic respiratory variation were also measured. Heart rate variability in the waking period was calculated later (standard deviation of the 5 min average of the successive normal to normal beat to beat intervals). Daily self-reported well-being, activities, and consumption of alcohol were monitored by keeping a behavioral diary. After normalizing the physiological data, the diurnal and weekly variability was calculated for each variable. In several variables the most notable diurnal and weekly variability was found between working time and free time. In conclusion, diurnal and weekly rhythms in several wellness-related physiological and psychological variables were identified, depending on working and free-time in healthy middle-aged men.

Turner, James E.; Markovitch, Daniella; Betts, James A.; Thompson, Dylan (2010):

Nonprescribed physical activity energy expenditure is maintained with structured exercise and implicates a compensatory increase in energy intake.

In: *Am J Clin Nutr* 92 (5), S. 1009–1016.

Abstract:

BACKGROUND:

Exercise interventions elicit only modest weight loss, which might reflect a compensatory reduction in nonprescribed physical activity energy expenditure (PAEE).

OBJECTIVE:

The objective was to investigate whether there is a reduction in nonprescribed PAEE as a result of participation in a 6-mo structured exercise intervention in middle-aged men.

DESIGN:

Sedentary male participants [age: 54 ± 5 y; body mass index (in kg/m^2): 28 ± 3] were randomly assigned to a 6-mo progressive exercise (EX) or control (CON) group. Energy expenditure during structured exercise (prescribed PAEE) and nonprescribed PAEE were determined with the use of synchronized accelerometry and heart rate before the intervention, during the intervention (2, 9, and 18 wk), and within a 2-wk period of detraining after the intervention.

RESULTS:

Structured prescribed exercise increased total PAEE and had no detrimental effect on nonprescribed PAEE. Indeed, there was a trend for greater nonprescribed PAEE in the EX group ($P = 0.09$). Weight loss in the EX group (-1.8 ± 2.2 kg compared with +0.2 ± 2.2 kg in the CON group, $P < 0.02$) reflected only ≈40% of the 300-373 kcal/kg body mass potential energy deficit from prescribed exercise. Serum leptin concentration decreased by 24% in the EX group (compared with 3% in the CON group, $P < 0.03$), and we estimate that this was accompanied by a compensatory increase in energy intake of ≈100 kcal/d.

CONCLUSIONS:

The adoption of regular structured exercise in previously sedentary, middle-aged, and overweight men does not result in a negative compensatory reduction in nonprescribed physical activity. The less-than-predicted weight loss is likely to reflect a compensatory increase in energy intake in response to a perceived state of relative energy insufficiency.

Uchino, Bert N.; Berg, Cynthia A.; Smith, Timothy W.; Pearce, Gale; Skinner, Michelle (2006):

Age-related differences in ambulatory blood pressure during daily stress: evidence for greater blood pressure reactivity with age.

In: *Psychology and Aging* 21 (2), S. 231–239. DOI: 10.1037/0882-7974.21.2.231.

Abstract:

Prior research on age and emotions has found that older adults may show better physiological regulation to stressful stimuli than do younger adults. However, the stress reactivity literature has shown that age is associated with higher cardiovascular reactivity to laboratory stress (J. R. Jennings et al., 1997). The authors investigated these conflicting findings further by examining daily ambulatory blood pressure in 428 middle-aged to older adults. Consistent with the age and reactivity literature, relatively old individuals showed significantly greater increases in ambulatory diastolic blood pressure compared with younger individuals when dealing with daily stressors. However, results also revealed that relatively old individuals reported less of an increase in negative affect during daily stress compared with their younger counterparts. The results of this study are consistent with the age-related increase in cardiovascular risk but highlight the complex links between stress and different facets of the aging process.

Uchino, Bert N.; Sanbonmatsu, David M.; Birmingham, Wendy (2013):

Knowing your partner is not enough: Spousal importance moderates the link between attitude familiarity and ambulatory blood pressure.

In: *Journal of Behavioral Medicine* 36 (6), S. 549–555. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-40215-001%26site%3dehost-live;Wendy.Birmingham@hci.utah.edu;david.sanbonmatsu@psych.utah.edu;bert.uchino@psych.utah.edu.

Abstract:

Close relationships have been linked to cardiovascular morbidity and mortality. More research is needed, however, on the social and biological processes responsible for such links. In this study, we examined the role of relationship-based attitudinal processes (i.e., attitude familiarity and partner importance) on ambulatory blood pressure during daily life. Forty-seven married couples completed a questionnaire regarding their own attitudes, perceptions of their partner's attitudes, and perceptions of partner importance. They also underwent a 1-day ambulatory assessments of daily spousal interactions and blood pressure. Partner importance was related to better interpersonal functioning (e.g., partner responsiveness) and lower ambulatory systolic blood pressure. More interestingly, partner importance moderated the links between attitude familiarity and both ambulatory systolic and diastolic blood pressure. This statistical interaction revealed that simply knowing a partner's attitudes was not enough as partner knowledge was primarily related to lower ambulatory blood pressure when they were also viewed as more important. These data are discussed in light of how attitude familiarity and spousal importance may jointly influence health outcomes and the social-cognitive mechanisms potentially responsible for such links. Udachina, Alisa; Thewissen, Viviane; Myin-Germeys, Inez; Fitzpatrick, Sam; O'Kane, Aisling; Bentall, Richard P. (2009):

Understanding the relationships between self-esteem, experiential avoidance, and paranoia: structural equation modelling and experience sampling studies.

In: *The Journal of nervous and mental disease* 197 (9), S. 661–668. DOI: 10.1097/NMD.0b013e3181b3b2ef.

Abstract:

Hypothesized relationships between experiential avoidance (EA), self-esteem, and paranoia were tested using structural equation modeling in a sample of student participants (N = 427). EA in everyday life was also investigated using the Experience Sampling Method in a subsample of students scoring high (N = 17) and low (N = 15) on paranoia. Results showed that paranoid students had lower self-esteem and reported higher levels of EA than nonparanoid participants. The interactive influence of EA and stress predicted negative self-esteem: EA was particularly damaging at high levels of stress. Greater EA and higher social stress independently predicted lower positive self-esteem. Low positive self-esteem predicted engagement in EA. A direct association between EA and paranoia was also found. These results suggest that similar mechanisms may underlie EA and thought suppression. Although people may employ EA to regulate self-esteem, this strategy is maladaptive as it damages self-esteem, incurs cognitive costs, and fosters paranoid thinking.

Udachina, A.; Varese, F.; Oorschot, M.; Myin-Germeys, I.; Bentall, R. P. (2012):

Dynamics of self-esteem in "poor-me" and "bad-me" paranoia.

In: *J Nerv.Ment.Dis.* 200 (9), S. 777–783. DOI: 10.1097/NMD.0b013e318266ba57.

Abstract:

ABSTRACT: The dynamics of self-esteem and paranoia were examined in 41 patients with past or current paranoia and 23 controls using questionnaires and the Experience Sampling Method (a structured diary technique). For some analyses, patients were further divided into three groups: a) individuals who believed that persecution is underserved ("poor me"; PM), b) individuals who believed that persecution is justified ("bad me"; BM), and c) remitted patients. The results revealed that PM and especially BM patients had highly unstable psychological profiles. Beliefs about deservedness of persecution fluctuated over 6 days. BM beliefs were associated with low self-esteem and depression. Measured concurrently, paranoia predicted lower self-esteem in the BM patients. Prospectively, paranoia predicted lower subsequent self-esteem in BM patients but higher subsequent self-esteem in PM patients. Our results suggest that paranoia can serve a defensive function in some circumstances. The reasons for inconsistencies in self-esteem research in relation to paranoia are discussed

Udachina, Alisa; Varese, Filippo; Myin-Germeys, Inez; Bentall, Richard P. (2014):

The role of experiential avoidance in paranoid delusions: An experience sampling study.

In: *British Journal of Clinical Psychology* 53 (4), S. 422–432. DOI: 10.1037/t20074-000;

Abstract:

Objectives. The study examined (1) the role of experiential avoidance (EA), conceptualized as intolerance towards aversive mental states, in paranoid delusions and (2) the mechanisms underlying EA. Design. A 6-day prospective momentary assessment study. Methods. Paranoid patients (N = 41) were studied using the experience sampling method (ESM), a structured diary technique, assessing psychopathology and current context in daily life. Results. The results showed that both low self-esteem and EA contributed to paranoid thinking. The relationship between low self-esteem and paranoia was partially mediated by EA and the relationship between EA and paranoia was partially mediated by low self-esteem. The detrimental effect of EA on self-esteem was more pronounced under high activity-related stress. Both EA and social stress were independently associated with low self-esteem. EA was associated with self-esteem instability. Conclusions. Our results implicate mental control strategies in the development of paranoia and are compatible with the attributional model of paranoia, which suggests that persecutory delusions arise as a result of dysfunctional attempts to avoid unpleasant thoughts about the self. Practitioner points. Interventions for paranoid individuals should target low tolerance towards negative mental states, for example using mindfulness and ACT therapeutic approaches. Interventions designed for individuals suffering from persecutory delusions should also address unfavourable views about the self. Limitations. Avoidance of unpleasant mental states may operate outside the individual's awareness and self-report measures of EA may be unable to adequately tap this process. Self-reflection abilities of psychotic patients may be impaired. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Uebel, Henrik; Albrecht, Bjorn; Kirov, Roumen; Heise, Alexander; Dopfner, Manfred; Joseph Freisleder, Franz et al. (2010):

What can actigraphy add to the concept of labschool design in clinical trials?

In: *Current pharmaceutical design* 16 (22), S. 2434–2442.

Abstract:

Pharmacological intervention with methylphenidate (MPH) is very common and helpful in the treatment of attention-deficit/hyperactivity disorder (ADHD). It ameliorates inattention, impulsivity and hyperactivity and improves psychosocial functioning. The core symptoms of ADHD are problematic mainly in demanding structured situations such as in the classroom. It was argued that MPH does not only lead to a decrease of hyperactivity in these situations but may also result in a general dampening of motor activity during non-structured leisure time. Unfortunately, only few clinical trials have investigated this practically important issue and thus it is still a matter of debate. It follows that many parents hesitate to accept psychotropic drugs for their children. To elucidate this problem in the current study, not only overall behavioral ratings (half-day blocks) but also day-long actigraphy was applied during an analogue classroom setting, where structured and non-structured situations alternated over time. Fourty-nine children with ADHD were assessed for treatment effects of once-daily extended-release and twice daily immediate-release methylphenidate (MPH) as well as placebo. Both MPH regimes yielded improved behavioral ratings during morning and afternoon, while actigraphy showed reduced motor activity in structured situations, but not during leisure time. Furthermore, the movement information obtained with actigraphy during structured situations could be differentiated from the one gained with overall behavioral ratings. Thus, while behavioral ratings provide a valid estimate of the overall symptomatology, additional information gathered with actigraphy may help to differentiate the impact of medication on hyperactive movement in different situations during the day. This may reflect a more valid picture of a child's real life and improve the quality of clinical trials. Thus, both methods may be regarded as complementary for the assessment of drug effects in children with ADHD and should be a standard of further laboratory school protocols in clinical trials.

Uen, Sakir; Fimmers, Rolf; Brieger, Miriam; Nickenig, Georg; Mengden, Thomas (2009):

Reproducibility of wrist home blood pressure measurement with position sensor and automatic data storage.

In: *BMC cardiovascular disorders* 9, S. 20. DOI: 10.1186/1471-2261-9-20.

Abstract:

BACKGROUND\r\nWrist blood pressure (BP) devices have physiological limits with regards to accuracy, therefore they were not preferred for home BP monitoring. However some wrist devices have been successfully validated using established validation protocols. Therefore this study assessed the reproducibility of wrist home BP measurement with position sensor and automatic data storage.\r\nMETHODS\r\nTo compare the reproducibility of three different(BP) measurement methods: 1) office BP, 2) home BP (Omron wrist device HEM- 637 IT with position sensor), 3) 24-hour ambulatory BP(24-h ABPM) (ABPM-04, Meditech, Hun)conventional sphygmomanometric office BP was measured on study days 1 and 7, 24-h ABPM on study days 7 and 14 and home BP between study days 1 and 7 and between study days 8 and 14 in 69 hypertensive and 28 normotensive subjects. The correlation coefficient of each BP measurement method with echocardiographic left ventricular mass index was analyzed. The schedule of home readings was performed according to recently published European Society of Hypertension (ESH)-guidelines.\r\nRESULTS\r\nThe reproducibility of home BP measurement analyzed by the standard deviation as well as the squared differences of mean individual differences between the respective BP measurements was significantly higher than the reproducibility of office BP ($p < 0.001$ for systolic and diastolic BP) and the reproducibility of 24-h ABPM ($p < 0.001$ systolic BP, $p = 0.127$ diastolic BP). The reproducibility of systolic and diastolic office versus 24-h ABPM was not significantly different ($p = 0.80$ systolic BP, $p = 0.1$ diastolic BP). The correlation coefficient of 24-h ABMP ($r = 0.52$) with left ventricular mass index was significantly higher than with office BP ($r = 0.31$). The difference between 24-h ABPM and home BP ($r = 0.46$) was not significant.\r\nCONCLUSION\r\nThe short-term reproducibility of home BP measurement with the Omron HEM-637 IT wrist device was superior to the reproducibility of office BP and 24- h ABPM measurement. Furthermore, home BP with the wrist device showed similar correlations to targeted organ damage as recently reported for upper arm devices. Although wrist devices have to be used cautious and with defined limitations, the use of validated devices with position sensor according to recently recommended measurement schedules might have the potential to be used for therapy monitoring.

Unsworth, Nash; McMillan, Brittany D.; Brewer, Gene A.; Spillers, Gregory J. (2013):

Individual differences in everyday retrospective memory failures.

In: *Journal of Applied Research in Memory and Cognition* 2 (1), S. 7–13. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-09216-002%26site%3dehost-live;nashu@uoregon.edu.

Abstract:

The present study examined individual differences in everyday retrospective memory failures. Undergraduate students completed various cognitive ability measures in the laboratory and recorded everyday retrospective memory failures in a diary over the course of a week. The majority of memory failures were forgetting information pertaining to exams and homework, forgetting names, and forgetting login and ID information. Using latent variable techniques the results also suggested that individual differences in working memory capacity and retrospective memory were related to some but not all everyday memory failures. Furthermore, everyday memory failures predicted SAT scores and partially accounted for the relation between cognitive abilities and SAT scores. These results provide important evidence for individual differences in everyday retrospective memory failures as well as important evidence for the ecological validity of laboratory measures of working memory capacity and retrospective memory. Urbin, M. A.; Hong, Xin; Lang, Catherine E.; Carter, Alex R. (2014):

Resting-State Functional Connectivity and Its Association With Multiple Domains of Upper-Extremity Function in Chronic Stroke.

In: *Neurorehabil Neural Repair. DOI:* 10.1177/1545968314522349.

Abstract:

BACKGROUND: Recent work has shown that resting-state functional connectivity (rsFC) between homotopic, motor-related brain regions is associated with upper-extremity control early after stroke. OBJECTIVES: This study examined various patterns of rsFC in chronic stroke, a time at which extensive neural reorganization has occurred. Associations between homotopic somatomotor connectivity and clinical measures, representing separate domains of upper-extremity function, were determined. METHODS: A total of 19 persons >/=6 months poststroke participated. Four connectivity patterns within a somatomotor network were

quantified using functional magnetic resonance imaging. Upper-extremity gross muscle activation, control, and real-world use were evaluated with the Motricity Index, Action Research Arm Test, and accelerometry, respectively. RESULTS: Connectivity between homotopic regions was stronger than that in the contralesional and ipsilesional hemispheres. No differences in connectivity strength were noted between homotopic pairs, indicating that a specific brain structure was not driving somatomotor network connectivity. Homotopic connectivity was significantly associated with both upper-extremity control (r = 0.53; P= .02) and real-world use (r = 0.54; P= .02); however, there was no association with gross muscle activation (r = 0.23; P=.34). The combination of clinical measures accounted for 40% of the variance in rsFC (= .05). CONCLUSIONS: The results reported here expand on previous findings, indicating that homotopic rsFC persists in chronic stroke and discriminates between varying levels of upper-extremity control and real-world use. Further work is needed to evaluate its adequacy as a biomarker of motor recovery following stroke.

Uswatte, Gitendra; Giuliani, Carol; Winstein, Carolee; Zeringue, Angelique; Hobbs, Laura; Wolf, Steven L. (2006):

Validity of accelerometry for monitoring real-world arm activity in patients with subacute stroke: evidence from the extremity constraint-induced therapy evaluation trial.

In: *Arch Phys Med Rehabil* 87 (10), S. 1340–1345.

Abstract:

OBJECTIVE:

To examine the psychometric properties of an objective method for assessing real-world arm activity in a large sample with subacute stroke.

DESIGN:

Validation study.

SETTING:

Community.

PARTICIPANTS:

Persons 3 to 9 months poststroke (N=169) with mild to moderate motor impairment of their hemiparetic arm enrolled in a multisite, randomized clinical trial of constraint-induced movement therapy.

INTERVENTIONS:

Not applicable.

MAIN OUTCOME MEASURES:

Participants wore an accelerometer on each arm outside the laboratory for 3 days before and after treatment or an equivalent no-treatment period. They also completed the Actual Amount of Use Test (AAUT), which is an observational measure of spontaneous more-impaired arm use, and the Motor Activity Log (MAL), which is an interview assessing more-impaired arm use in daily life.

RESULTS:

Low-pass-filtered accelerometer recordings were reliable (r range, >.8) and stable (P range, >.48). Their validity was also supported. Correlations calculated across all participants at baseline between the ratio of more-impaired to less-impaired arm accelerometer recordings and AAUT and MAL scores were .60 and .52, respectively.

CONCLUSIONS:

Accelerometry provides an objective, real-world index of more-impaired arm activity with good psychometric properties.

Uswatte, Gitendra; Hobbs Qadri, Laura (2009):

A behavioral observation system for quantifying arm activity in daily life after stroke.

In: *Rehabilitation Psychology* 54 (4), S. 398–403. DOI: 10.1037/a0017501.

Abstract:

OBJECTIVE\r\nEvaluate psychometric properties of the Functional Arm Activity Behavioral Observation System (FAABOS) for measuring hemiparetic arm use.\r\nPARTICIPANTS AND MEASURES\r\nAll participants acquired their brain injury > 1 year prior to study entry; most had mild-to-moderate upper-extremity hemiparesis. In Study 1, 9 stroke survivors wore accelerometers and

were videotaped for 15 min in the hospital or at home after they were asked to behave as usual. In Study 2, 1 traumatic brain injury and 8 stroke survivors wore accelerometers and were videotaped at home for 3 days with a motion-triggered camera. Observers independently rated 15-min segments of the Study 1 and 2 videotapes in 2-s blocks with a 4-step arm-activity coding scheme.\r\nRESULTS\r\nInterrater reliability was excellent; the mean Cohen's kappa in each study was > or = .84. For data from both studies combined, validity was supported by a strong correlation between amount of hemiparetic arm functional activity, as determined by the observers, and the ratio of hemiparetic to other arm movement, as determined by accelerometry.\r\nCONCLUSION\r\nFAABOS reliably and validly quantifies amount of spontaneous hemiparetic arm activity outside the laboratory.

Uswatte, Gitendra; Taub, Edward; Morris, Dppt; Light, Kppt; Thompson, P. A. (2006):

The Motor Activity Log-28 assessing daily use of the hemiparetic arm after stroke.

In: *Neurology* 67 (7), S. 1189–1194.

Abstract:

Data from monkeys with deafferented forelimbs and humans after stroke indicate that tests of the motor capacity of impaired extremities can overestimate their spontaneous use. Before the Motor Activity Log (MAL) was developed, no instruments assessed spontaneous use of a hemiparetic arm outside the treatment setting.

OBJECTIVE:

To study the MAL's reliability and validity for assessing real-world quality of movement (QOM scale) and amount of use (AOU scale) of the hemiparetic arm in stroke survivors.

METHODS:

Participants in a multisite clinical trial completed a 30-item MAL before and after treatment (n = 106) or an equivalent no-treatment period (n = 116). Participants also completed the Stroke Impact Scale (SIS) and wore accelerometers that monitored arm movement for three consecutive days outside the laboratory. All were 3 to 12 months post-stroke and had mild to moderate paresis of an upper extremity.

RESULTS:

After an item analysis, two MAL tasks were eliminated. Revised participant MAL QOM scores were reliable (r =0.82). Validity was also supported. During the first observation period, the correlation between QOM and SIS Hand Function scale scores was 0.72. The corresponding correlation for QOM and accelerometry values was 0.52. Participant QOM and AOU scores were highly correlated (r = 0.92).

CONCLUSIONS:

The participant Motor Activity Log is reliable and valid in individuals with subacute stroke. It might be employed to assess the real-world effects of upper extremity neurorehabilitation and detect deficits in spontaneous use of the hemiparetic arm in daily life.

Uy, Marilyn A.; Foo, Maw-Der; Aguinis, Herman (2010):

Using experience sampling methodology to advance entrepreneurship theory and research.

In: *Organizational Research Methods* 13 (1), S. 31–54.

Abstract:

The authors propose the use of experience sampling methodology (ESM) as an innovative methodological approach to address critical questions in entrepreneurship research. ESM requires participants to provide reports of their thoughts, feelings, and behaviors at multiple times across situations as they happen in the natural environment. Thus, ESM allows researchers to capture dynamic person-by-situation interactions as well as between- and within-person processes, improve the ecological validity of results, and minimize retrospective biases. The authors provide a step-by-step description of how to design and implement ESM studies beginning with research design and ending with data analysis, and including issues of implementation such as time and resources needed, participant recruitment and orientation, signaling procedures, and the use of computerized devices and wireless technologies. The authors also describe a cell phone ESM protocol that enables researchers to monitor and interact with participants in real time, reduces costs, expedites data entry, and increases convenience. Finally, the authors discuss implications of ESMbased research for entrepreneurs, business incubators, and entrepreneurship educators.

Uys, A. S.; Malan, L.; van Rooyen, J. M.; Steyn, H. S.; Reimann, M.; Ziemssen, T. (2014):

Attenuated NOx responses and myocardial ischemia, a possible risk for structural vascular disease in African men: the SABPA study.

In: *J Hum Hypertens. DOI:* 10.1038/jhh.2013.128.

Abstract:

Chronically elevated blood pressure has been associated with impaired NO-mediated vasodilation and structural vascular disease risk. This study aimed to determine whether significant associations exist regarding NO metabolite (NOx) responses, cardiovascular function and structural vascular disease in a cohort of African and Caucasian men. The study included 81 African and 94 Caucasian male teachers stratified via median splits into low and high NOx ethnic groups. Ambulatory blood pressure, electrocardiogram monitoring and ultrasound carotid intima-media thickness (CIMT) images were obtained. Cardiovascular measurements and fasting blood for NOx responses were measured during rest and on challenging the cardiovascular system with the Stroop colour-word conflict test. African men displayed significantly higher resting NOx as well as higher number of 24 h silent ischemic events than their Caucasian counterparts. Low NOx African men displayed enhanced alpha-adrenergic and ECG ST segment depression acute mental stress responses as well as 24 h silent ischemic events associated with CIMT (adjusted R2=0.47; beta=0.25; confidence interval (CI)=0.13, 0.41). African men demonstrated a vulnerable cardiovascular profile. Novel findings revealed alpha-adrenergic-driven blood pressure responses and less NO bioavailability during acute stress. The association between myocardial ischemia and CIMT in this group emphasized their risk for future coronary artery disease and cerebrovascular events.Journal of Human Hypertension advance online publication, 9 January 2014; doi:10.1038/jhh.2013.128.

Vahabzadeh, Massoud; Lin, Jia-Ling; Mezghanni, Mustapha; Epstein, David H.; Preston, Kenzie L. (2009):

Automation in an addiction treatment research clinic: computerised contingency management, ecological momentary assessment and a protocol workflow system.

In: *Drug and Alcohol Review* 28 (1), S. 3–11. DOI: 10.1111/j.1465-3362.2008.00007.x.

Abstract:

INTRODUCTION AND AIMS\r\nA challenge in treatment research is the necessity of adhering to protocol and regulatory strictures while maintaining flexibility to meet patients' treatment needs and to accommodate variations among protocols. Another challenge is the acquisition of large amounts of data in an occasionally hectic environment, along with the provision of seamless methods for exporting, mining and querying the data.\r\nDESIGN AND METHODS\r\nWe have automated several major functions of our outpatient treatment research clinic for studies in drug abuse and dependence. Here we describe three such specialised applications: the Automated Contingency Management (ACM) system for the delivery of behavioural interventions, the transactional electronic diary (TED) system for the management of behavioural assessments and the Protocol Workflow System (PWS) for computerised workflow automation and guidance of each participant's daily clinic activities. These modules are integrated into our larger information system to enable data sharing in real time among authorised staff.\r\nRESULTS\r\nACM and the TED have each permitted us to conduct research that was not previously possible. In addition, the time to data analysis at the end of each study is substantially shorter. With the implementation of the PWS, we have been able to manage a research clinic with an 80 patient capacity, having an annual average of 18,000 patient visits and 7300 urine collections with a research staff of five. Finally, automated data management has considerably enhanced our ability to monitor and summarise participant safety data for research oversight.\r\nDISCUSSION AND CONCLUSIONS\r\nWhen developed in consultation with end users, automation in treatment research clinics can enable more efficient operations, better communication among staff and expansions in research methods.

Vahlkvist, S.; Pedersen, S. (2009):

Fitness, daily activity and body composition in children with newly diagnosed, untreated asthma.

In: *Allergy* 64 (11), S. 1649–1655. DOI: 10.1111/j.1398-9995.2009.02081.x.

Abstract:

BACKGROUND\r\nInformation about how the asthma disease affects the life style and health in children is sparse.\r\nAIM\r\nTo measure fitness, daily physical activity and body composition in children with newly diagnosed, untreated asthma and healthy controls, and to assess the association between the level of asthma control and these parameters.\r\nMETHODS\r\nDaily physical activity measured using accelerometry, cardiovascular fitness and body composition (per cent fat, per cent lean tissue and bone mineral density) were measured in 57 children with newly diagnosed, untreated asthma and in 157 healthy age- and

sex-matched controls. The level of asthma control was assessed by measurements of a variety of asthma outcomes.\r\nRESULTS\r\nChildren with asthma were less fit (35.1 vs 39.3 ml O(2)/min/kg) (P < 0.001), had a higher body per cent fat (22.8 vs 19.5%) (P < 0.01) and a higher frequency of overweight (24.6 vs 14.2%) (P < 0.05) than healthy controls. Per cent body fat correlated negativly to overall daily activity (P < 0.001) and to time spent in high or vigorous activity (P < 0.001). Fitness corrrelated positively to time spent in high and vigorous activity (P < 0.001). Within the asthma group, the level of asthma control, fitness and the time spent in vigorous activity correlated positively (P < 0.02).\r\nCONCLUSION\r\nChildren with untreated asthma are less fit and have a higher body per cent fat and frequency of obesity than their healthy peers. Uncontrolled asthma is associated with a reduced fitness and daytime spent in intensive activity. Overweight children are physically less active than normal weight children.

Vakil, N.; Bjorck, K.; Denison, H.; Halling, K.; Karlsson, M.; Paty, J. et al. (2012):

Validation of the reflux symptom questionnaire electronic diary in partial responders to proton pump inhibitor therapy.

In: *Clin.Transl.Gastroenterol.* 3 (2155-384X (Electronic)), S. e7. DOI: 10.1038/ctg.2012.1.

Abstract:

OBJECTIVES: We aimed to develop and validate the Reflux Symptom Questionnaire electronic Diary (RESQ-eD) for use in clinical trials in patients with a partial response to proton pump inhibitor (PPI) therapy, using methods that meet US Food & Drug Administration (FDA) regulatory standards. METHODS: Patient interviews were performed to elicit new items and evaluate existing items from the Reflux Disease Questionnaire. The instrument's measurement properties were evaluated, based on data from two clinical trials of patients with gastroesophageal reflux disease (GERD) with a partial response to PPIs who received lesogaberan or placebo as an add-on to PPI therapy. RESULTS: The content validity phase resulted in 13 RESQ-eD items. Principal component analysis supported a four-domain structure. All domains had a high inter-item correlation (Cronbach's alpha lower 95% confidence limit: 0.87-0.95). Test-retest reliability was good to excellent (intraclass correlation coefficient: 0.65-0.85). Convergent and discriminant validity was confirmed by correlation assessments referencing the Gastrointestinal Symptom Rating Scale. The RESQ-eD demonstrated a good ability to capture change in mean intensity and proportion of symptom-free days. Confirmatory psychometric evaluation verified internal consistency reliability, test-retest reliability, and ability to capture change. CONCLUSIONS: The RESQ-eD demonstrated good content validity and psychometric properties in the clinical trial setting in patients with GERD who have a partial response to PPI therapy. To our knowledge, the RESQ-eD is the first electronic symptom diary for use in partial responders to PPI that has been developed in line with the FDA guidance on patient-reported outcomes

Valdivieso-Lopez, E.; Flores-Mateo, G.; Molina-Gomez, J. D.; Rey-Renones, C.; Barrera Uriarte, M. L.; Duch, J.; Valverde, A. (2013):

Efficacy of a mobile application for smoking cessation in young people: study protocol for a clustered, randomized trial.

In: *BMC Public Health* 13 (1471-2458 (Linking)), S. 704. DOI: 10.1186/1471-2458-13-704.

Abstract:

BACKGROUND: Tobacco consumption is the most preventable cause of morbidity-mortality in the world. One aspect of smoking cessation that merits in-depth study is the use of an application designed for smartphones (app), as a supportive element that could assist younger smokers in their efforts to quit. To assess the efficacy of an intervention that includes the assistance of a smoking cessation smartphone application targeted to young people aged 18 to 30 years who are motivated to stop smoking. METHODS/DESIGN: Cluster randomised clinical trial. Setting: Primary Health Care centres (PHCCs) in Catalonia. Analyses based on intention to treat. Participants: motivated smokers of 10 or more cigarettes per day, aged 18 to 30 years, consulting PHCCs for any reason and who provide written informed consent to participate in the trial. Intervention group will receive a 6-month smoking cessation programme that implements recommendations of a Clinical Practice Guideline, complemented with a smartphone app designed specifically for this programme. Control group will receive the usual care. The outcome measure will be abstinence at 12 months confirmed by exhaled-air carbon monoxide concentration of at least 10 parts per million at each control test. DISCUSSION: To our knowledge this is the first randomised controlled trial of a programme comparing the efficacy of usual care with a smoking cessation intervention involving a mobile app. If effective, the modality could offer a universal public health management approach to this common health concern. TRIAL REGISTRATION: NCT01734421

Vallée-Smejda, Sophie; Hahn, Marion; Aubin, Nathalie; Rosmus, Christina (2009):

Recording practices and satisfaction of hemophiliac patients using two different data entry systems.

In: *Comput Inform Nurs* 27 (6), S. 372–378. DOI: 10.1097/NCN.0b013e3181bcad12.

Abstract:

Record keeping is integral to home treatment for hemophilia. Identified problems with paper diaries include suboptimal compliance and questionable data validity and quality. The effects of an electronic data recording system, Advoy, on data quality, patient adherence, and satisfaction were examined. An exploratory approach was used to examine the sequential use of paper diaries and e-diaries by 38 patients. Data were obtained from paper records for the 6 months preceding the introduction of the electronic record and from the first 6 months of use of Advoy. Completion of mandatory and additional treatment details was also compared. More mandatory information (27.57%) was recorded with the e-diary. As well, the amount of completed additional fields nearly doubled (19.9%-36.5%). Patients tended to complete a greater variety of additional fields with the e-diary than with paper records. Finally, a higher percentage of survey respondents (29.4%) indicated that they were \"very satisfied\" with Advoy compared with paper records (6.7%). Most survey respondents (94.4%) had a previous experience with electronic programs. The use of the e-diary significantly improved patient adherence in recording mandatory treatment information; the increase in additional data provided by the patients was also found to be an added benefit of this technology.

van Cauwenberghe, Eveline; Gubbels, Jessica; Bourdeaudhuij, Ilse; Cardon, Greet (2011):

Feasibility and validity of accelerometer measurements to assess physical activity in toddlers.

In: *Int J Behav Nutr Phys Act* 8. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-31387-001%26site%3dehost-live;eveline.vancauwenberghe@ugent.be.

Abstract:

Background

Accelerometers are considered to be the most promising tool for measuring physical activity (PA) in free-living young children. So far, no studies have examined the feasibility and validity of accelerometer measurements in children under 3 years of age. Therefore, the purpose of the present study was to examine the feasibility and validity of accelerometer measurements in toddlers (1- to 3-year olds).

Methods

Forty-seven toddlers (25 boys; 20 ± 4 months) wore a GT1M ActiGraph accelerometer for 6 consecutive days and parental perceptions of the acceptability of wearing the monitor were assessed to examine feasibility. To investigate the validity of the ActiGraph and the predictive validity of three ActiGraph cut points, accelerometer measurements of 31 toddlers (17 boys; 20 ± 4 months) during free play at child care were compared to directly observed PA, using the Observational System for Recording Physical Activity in Children-Preschool (OSRAC-P). Validity was assessed using Pearson and Spearman correlations and predictive validity using area under the Receiver Operating Characteristic curve (ROC-AUC).

Results

The feasibility examination indicated that accelerometer measurements of 30 toddlers (63.8%) could be included with a mean registration time of 564 ± 62 min during weekdays and 595 ± 83 min during weekend days. According to the parental reports, 83% perceived wearing the accelerometer as 'not unpleasant and not pleasant' and none as 'unpleasant'. The validity evaluation showed that mean ActiGraph activity counts were significantly and positively associated with mean OSRAC-P activity intensity ($r = 0.66$; $p < 0.001$; $n = 31$). Further, the correlation among the ActiGraph activity counts and the OSRAC-P activity intensity level during each observation interval was significantly positive ($\rho = 0.52$; $p < 0.001$; $n = 4218$). Finally, the three sedentary cut points exhibited poor to fair classification accuracy (ROC-AUC: 0.56 to 0.71) while the three light PA (ROC-AUC: 0.51 to 0.62) and the three moderate-to-vigorous PA cut points (ROC-AUC: 0.53 to 0.57) demonstrated poor classification accuracy with respect to detecting sedentary behavior, light PA and moderate-to-vigorous PA, respectively.

Conclusions

The present findings suggest that ActiGraph accelerometer measurements are feasible and valid for quantifying PA in toddlers. However, further research is needed to accurately identify PA intensities in toddlers using accelerometry.

van de Leemput, I. A.; Wichers, M.; Cramer, A. O.; Borsboom, D.; Tuerlinckx, F.; Kuppens, P. et al. (2014):

Critical slowing down as early warning for the onset and termination of depression.

In: *Proc.Natl.Acad.Sci.U.S.A* 111 (1), S. 87–92. DOI: 10.1073/pnas.1312114110.

Abstract:

About 17% of humanity goes through an episode of major depression at some point in their lifetime. Despite the enormous societal costs of this incapacitating disorder, it is largely unknown how the likelihood of falling into a depressive episode can be assessed. Here, we show for a large group of healthy individuals and patients that the probability of an upcoming shift between a depressed and a normal state is related to elevated temporal autocorrelation, variance, and correlation between emotions in fluctuations of autorecorded emotions. These are indicators of the general phenomenon of critical slowing down, which is expected to occur when a system approaches a tipping point. Our results support the hypothesis that mood may have alternative stable states separated by tipping points, and suggest an approach for assessing the likelihood of transitions into and out of depression

van den Berg-Emons, Rita J; Bussmann, Johannes B.; Haisma, Janneke A.; Sluis, Tebbe A.; van der Woude, Lucas H; Bergen, Michael P.; Stam, Henk J. (2008):

A prospective study on physical activity levels after spinal cord injury during inpatient rehabilitation and the year after discharge.

In: *Arch Phys Med Rehabil* 89 (11), S. 2094–2101. DOI: 10.1016/j.apmr.2008.04.024.

Abstract:

OBJECTIVES\r\nTo assess the change over time in the physical activity level after a spinal cord injury (SCI), to explore its determinants, and to compare the physical activity level 1 year after discharge from the rehabilitation center with the level in able-bodied persons.\r\nDESIGN\r\nProspective cohort study. Measurements were obtained at the start of active rehabilitation, 3 months later, at discharge, 2 months after discharge, and 1 year after discharge.\r\nSETTING\r\nRehabilitation center in The Netherlands and the participant's home.\r\nPARTICIPANTS\r\nPersons (n=40) with SCI.\r\nINTERVENTIONS\r\nNot applicable.\r\nMAIN OUTCOME MEASURES\r\nThe physical activity level, as indicated by the duration of dynamic activities (ie, wheelchair driving, walking, cycling, noncyclic movement) per day, and the intensity of everyday activity; both were measured with an accelerometry-based activity monitor during 2 consecutive weekdays.\r\nRESULTS\r\nRandom coefficient analyses showed that the duration of dynamic activities and the intensity of everyday activity increased during inpatient rehabilitation at rates of 41% and 19%, respectively (P<.01). Shortly after discharge, there was a strong decline (33%; P<.001) in the duration of dynamic activities. One year after discharge, this decline was restored to the discharge level but was low in comparison with levels in able-bodied persons. The level of lesion and completeness of lesion were determinants of the change in the physical activity level after discharge.\r\nCONCLUSIONS\r\nThe physical activity level increased during inpatient rehabilitation, but this increase did not continue after discharge, and the level 1 year after discharge was distinctly lower than the level in able-bodied persons. Subpopulations had a different change over time in the physical activity level after discharge.

van den Berg-Emons, Rita J; Schasfoort, Fabiënne C.; Vos, Leonard A.; Bussmann, Johannes B.; Stam, Henk J. (2007):

Impact of chronic pain on everyday physical activity.

In: *Eur J Pain* 11 (5), S. 587–593.

Abstract:

Although patients with chronic pain are often considered to have reduced levels of everyday physical activity, data on their activity levels are scarce and inconclusive. Therefore, this study explored whether patients with chronic pain have reduced activity levels, as objectively measured with an activity monitor. The activity monitor is based on long-term ambulatory monitoring of signals from body-fixed accelerometers during everyday life, aimed at assessment of mobility-related activities. Measurements with the monitor were performed during a weekday (24 h) in 18 patients with chronic pain and compared with measurements obtained from 18 gender and age matched healthy comparison subjects.

The mean (SD) age of the patients was 44 (11) years, and the mean (SD) duration of their complaints was 8 (7) years. Compared with the healthy subjects, the duration of dynamic activities was not significantly reduced (p = 0.10) in the patient group. Mean (SD) intensity of everyday physical activity was lower (p = 0.03) in the patients than in the healthy comparison subjects (0.021 [0.006] g versus 0.026 [0.004] g), and patients spent more time lying down (47.0 [10.2]% versus 34.3 [5.6] %; p = 0.000) and less time sitting (29.2 [8.9]% versus 36.4 [9.3]%; p = 0.03) than the healthy comparison subjects.

In spite of significant differences between patients and healthy comparison subjects for some aspects of the activity pattern (which may reflect pain behaviour), the impact of chronic pain on everyday physical activity was relatively small.

van der Kuip, Martijn; Meer, Kees; Westerterp, Klaas R.; Gemke, Reinoud J. (2007):

Physical activity as a determinant of total energy expenditure in critically ill children.

In: *Clinical nutrition* 26 (6), S. 744–751.

Abstract:

For adequate nutritional support of critically ill children, knowledge of the patient's energy expenditure is required. Steady state measurement by a metabolic monitor are defined as resting energy expenditure and may underestimate total energy expenditure in clinical practise. The aim of this study was to investigate total energy expenditure, resting energy expenditure and the relation with physical activity during critical illness and initial recovery.

METHODS:

We enrolled 20 patients (0-16 yr) with sepsis or following surgery. During the first week following admission, total energy expenditure was measured with doubly labelled water, and compared with daily resting energy expenditure measurements (metabolic monitor). Activity levels were independently determined by tri-axial accelerometry.

RESULTS:

Resting energy expenditure was not different from Schofield's predicted basal metabolic rate, but was 20% lower than total energy expenditure (P=0.006). Overall physical activity level (=total energy expenditure divided by resting energy expenditure) was 1.22 (95%CI: 1.08-1.36) and activity related energy expenditure (=total energy expenditure minus resting energy expenditure) was associated with accelerometry recordings (R(2)=0.72, P=0.02).

CONCLUSIONS:

During the week following pediatric intensive care admission, in the individual critically ill patient, activity related energy expenditure should be taken into account to prevent a negative energy balance.

van der Weegen, Sanne; Verwey, Renee; Tange, Huibert J.; Spreeuwenberg, Marieke D.; Witte, Luc P. (2014):

Usability testing of a monitoring and feedback tool to stimulate physical activity.

In: *Patient Prefer Adherence* 8, S. 311–322. DOI: 10.2147/PPA.S57961.

Abstract:

INTRODUCTION: A MONITORING AND FEEDBACK TOOL TO STIMULATE PHYSICAL ACTIVITY, CONSISTING OF AN ACTIVITY SENSOR, SMARTPHONE APPLICATION (APP), AND WEBSITE FOR PATIENTS AND THEIR PRACTICE NURSES, HAS BEEN DEVELOPED: the 'It's LiFe!' tool. In this study the usability of the tool was evaluated by technology experts and end users (people with chronic obstructive pulmonary disease or type 2 diabetes, with ages from 40-70 years), to improve the user interfaces and content of the tool. PATIENTS AND METHODS: THE STUDY HAD FOUR PHASES: 1) a heuristic evaluation with six technology experts; 2) a usability test in a laboratory by five patients; 3) a pilot in real life wherein 20 patients used the tool for 3 months; and 4) a final lab test by five patients. In both lab tests (phases 2 and 4) qualitative data were collected through a thinking-aloud procedure and video recordings, and quantitative data through questions about task complexity, text comprehensiveness, and readability. In addition, the post-study system usability questionnaire (PSSUQ) was completed for the app and the website. In the pilot test (phase 3), all patients were interviewed three times and the Software Usability Measurement Inventory (SUMI) was completed. RESULTS: After each phase, improvements were made, mainly to the layout and text. The main improvement was a refresh button for active data synchronization between activity sensor, app, and server, implemented after connectivity problems in the pilot test. The mean score on the PSSUQ for the website improved from 5.6 (standard deviation [SD] 1.3) to 6.5 (SD 0.5), and for the app from 5.4 (SD 1.5) to 6.2 (SD 1.1). Satisfaction in the pilot was not very high according to the SUMI. DISCUSSION: The use of laboratory versus real-life tests and expert-based versus user-based tests revealed a wide range of usability issues. The usability of the It's LiFe! tool improved considerably during the study.

van Deutekom, A. W.; Chinapaw, M. J.; Vrijkotte, T. G.; Gemke, R. J. (2013):

Study protocol: the relation of birth weight and infant growth trajectories with physical fitness, physical activity and sedentary behavior at 8-9 years of age - the ABCD study.

In: *BMC Pediatr* 13 (1471-2431 (Linking)), S. 102. DOI: 10.1186/1471-2431-13-102.

Abstract:

BACKGROUND: Low birth weight and accelerated infant growth have been identified as independent risk factors for childhood and adult obesity and cardiovascular disease. This led to the 'Developmental Origins of Health and Disease' (DOHaD) hypothesis, stating that environmental factors during pregnancy and early postnatal life affect disease risk in later life. There is growing evidence that perinatal factors may influence adult health through the programming of energy balance regulation, including sedentary behavior and physical activity. The present study focuses on the influence of birth weight and infant growth on physical fitness, physical activity and sedentary behavior in 8-9 year old children, as this might partly explain the higher obesity and cardiovascular risk associated with low birth weight and accelerated infant growth. In addition, this study provides the opportunity for a validation study of a linguistic and cross-cultural translated physical activity questionnaire compared to accelerometer data. This article describes the study protocol for this study. METHODS/DESIGN: This is a study embedded in the Amsterdam Born Children and their Development (ABCD) birth cohort. In 200 children of Dutch ethnicity, physical fitness, physical activity and sedentary behavior were assessed at age 8-9. We measured aerobic fitness using the 20 meter multistage shuttle run test, and neuromuscular fitness using the standing broad jump and handgrip strength test. Sedentary behavior and physical activity levels were measured using accelerometry. All children also completed a translated physical activity questionnaire, the scores of which will be compared to accelerometry data to assess the construct validity of the questionnaire in Dutch school-aged children. DISCUSSION: This study will be the first population-based prospective cohort study to address the association of both prenatal and postnatal growth with physical fitness and objectively-assessed physical activity and sedentary behavior. This will contribute to a better understanding of the way perinatal growth relate to lifestyle and obesity in later life. The results may guide both future studies in the field of DOHaD, and public health strategies in the prevention of childhood obesity

van Dijk, A. E.; Van, Lien R.; Van, Eijsden M.; Gemke, R. J.; Vrijkotte, T. G.; Geus, E. J. (2013):

Measuring cardiac autonomic nervous system (ANS) activity in children.

In: *J Vis.Exp.* (74), S. e50073. DOI: 10.3791/50073.

Abstract:

The autonomic nervous system (ANS) controls mainly automatic bodily functions that are engaged in homeostasis, like heart rate, digestion, respiratory rate, salivation, perspiration and renal function. The ANS has two main branches: the sympathetic nervous system, preparing the human body for action in times of danger and stress, and the parasympathetic nervous system, which regulates the resting state of the body. ANS activity can be measured invasively, for instance by radiotracer techniques or microelectrode recording from superficial nerves, or it can be measured non-invasively by using changes in an organ's response as a proxy for changes in ANS activity, for instance of the sweat glands or the heart. Invasive measurements have the highest validity but are very poorly feasible in large scale samples where non-invasive measures are the preferred approach. Autonomic effects on the heart can be reliably quantified by the recording of the electrocardiogram (ECG) in combination with the impedance cardiogram (ICG), which reflects the changes in thorax impedance in response to respiration and the ejection of blood from the ventricle into the aorta. From the respiration and ECG signals, respiratory sinus arrhythmia can be extracted as a measure of cardiac parasympathetic control. From the ECG and the left ventricular ejection signals, the preejection period can be extracted as a measure of cardiac sympathetic control. ECG and ICG recording is mostly done in laboratory settings. However, having the subjects report to a laboratory greatly reduces ecological validity, is not always doable in large scale epidemiological studies, and can be intimidating for young children. An ambulatory device for ECG and ICG simultaneously resolves these three problems. Here, we present a study design for a minimally invasive and rapid assessment of cardiac autonomic control in children, using a validated ambulatory device (1-5), the VU University Ambulatory Monitoring System (VU-AMS, Amsterdam, the Netherlands, www.vu-ams.nl)

van Dooren, Miesje; Staals, Julie; Leeuw, Peter W.; Kroon, Abraham A.; Henskens, Leon H.; van Oostenbrugge, Robert J. (2014):

Progression of Brain Microbleeds in Essential Hypertensive Patients: A 2-Year Follow-up Study.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu032.

Abstract:

BACKGROUND: Brain microbleeds (BMBs) are common in hypertensive patients and are associated with higher blood pressure (BP) levels. Little is known about risk factors for progression of BMBs, in particular the contribution of ambulatory BP levels. We aimed to determine BMB progression and the association with BP levels in a cohort of essential hypertensive patients. METHODS: At baseline and after 2 years of follow-up, 193 participants underwent brain magnetic resonance imaging (MRI) and 24-hour ambulatory BP measurement in addition to office BP measurement. The relation between BMB progression and baseline untreated BP characteristics was tested in logistic regression analyses. RESULTS: Progression of BMBs on follow-up MRI was seen in 12 (6%) participants. Patients with progression were significantly older, and the prevalence as well as total number of BMBs at baseline was greater. With correction for age and sex, baseline 24-hour systolic and diastolic BP and 24-hour pulse pressure significantly predicted progression. Similar results were seen for baseline awake and asleep BP. On additional adjustments for baseline presence of BMBs, the associations remained significant for 24-hour, awake, and asleep systolic BP, awake diastolic BP, and awake and asleep pulse pressure. Office systolic BP was also associated with progression of BMBs, whereas office diastolic BP was not. CONCLUSIONS: High ambulatory BP levels are important and possibly modifiable predictors for progression of BMBs. This warrants further study, with an adequately long follow-up period and early adequate treatment of hypertension.

van Hedel, Hubertus J A; Dietz, Volker (2009):

Walking during daily life can be validly and responsively assessed in subjects with a spinal cord injury.

In: *Neurorehabilitation and Neural Repair* 23 (2), S. 117–124. DOI: 10.1177/1545968308320640.

Abstract:

OBJECTIVE\r\nThis study assessed the validity and responsiveness of the Spinal Cord Independence Measure (SCIM II) items indoor mobility, mobility for moderate distances, and outdoor mobility.\r\nMETHODS\r\nThe data of 886 spinal cord injury subjects were derived from the European Multicenter Study for Human Spinal Cord Injury (EM-SCI) and analyzed at 2 weeks and 1, 3, 6, and 12 months after injury. The SCIM II items were compared using the preferred walking speed and the Walking Index for Spinal Cord Injury (WISCI II). The responsiveness to assess differences over time was determined. The analyses were performed for subjects with varying impairment scales according to the American Spinal Injury Association (ASIA).\r\nRESULTS\r\nAn initially moderate correlation between walking capacity and the SCIM II mobility items improved to excellent at 6 and 12 months after injury. The correlations were higher for indoor mobility compared with outdoor mobility. These correlations increased in ASIA C, but decreased over time in ASIA D subjects. The SCIM II mobility items showed initially positive responsiveness in ASIA A and B subjects. In ASIA C and D subjects, SCIM II responsiveness was significant within the first 6 months.\r\nCONCLUSIONS\r\nThe SCIM II items assess mobility (wheelchair and walking) during daily life. They show good validity and responsiveness, including postdischarge. They can be considered appropriate for evaluating the efficacy of new interventions on ambulatory function. Depending on the severity of the initial lesion and time of assessment, clinically applied walking tests can accurately predict walking performance during daily life.

van Mulder, Timothi; Verwulgen, Stijn; Beyers, Koen; Scheelen, Linda; Elseviers, Monique; van Damme, Pierre; Vankerckhoven, Vanessa (2014):

Assessment of acceptability and usability of new delivery prototype device for intradermal vaccination in healthy subjects.

In: *Hum Vaccin Immunother*, S. 0. DOI: 10.4161/21645515.2014.979655.

Abstract:

Abstract Background The objectives of this study was to assess the acceptability and usability of a newly developed intradermal prototype device, VAX-ID, in healthy subjects. Materials & Methods In April 2012 an investigational study was conducted in healthy subjects aged 18 to 65 years. To compare injection site and route of administration, subjects were allocated to four subgroups, either receiving subsequently two intradermal (ID) injections (one in the forearm & one in the deltoid) or an ID (forearm) and an intramuscular (IM) (deltoid) injection. All injections contained saline solution. Acceptability was assessed with a subjects' questionnaire and a daily electronic diary for 5 days. Usability was assessed with a vaccinators' questionnaire and an expert panel. A 10-point Visual Analogue Scale was used to score several statements on usability and acceptability. Results A total of 102 healthy subjects were enrolled in the study (age: 19-63). No statistically significant differences were seen in demographic characteristics between the ID and IM groups. Anxiety before injection, pain during injection and duration of injection were rated significantly lower for ID compared to IM. One day after the injections, redness was reported more often after ID injection in the forearm versus ID in the deltoid; pain at injection site was reported significantly more often after IM versus ID injection. The new VAX-ID prototype device was found easy to handle, easy to use and safe. Conclusion The new VAX-ID prototype device was shown to have a high degree of acceptability as well as usability. Further studies with VAX-ID will be

conducted using vaccine antigen allowing assessment of immunogenicity and safety. Additionally, these studies will help to further improve VAX-ID in terms of accuracy of delivered dose and feedback to the vaccinator. (NCT01963338).

van Os, Jim; Delespaul, Philippe; Barge, Daniela; Bakker, Roberto P. (2014):

Testing an mHealth Momentary Assessment Routine Outcome Monitoring Application: A Focus on Restoration of Daily Life Positive Mood States.

In: *PLoS One* 9 (12), S. e115254. DOI: 10.1371/journal.pone.0115254.

Abstract:

BACKGROUND: Routine Outcome Monitoring (ROM) is used as a means to enrich the process of treatment with feedback on patient outcomes, facilitating patient involvement and shared decision making. While traditional ROM measures focus on retrospective accounts of symptoms, novel mHealth technology makes it possible to collect real life, in-the-moment ambulatory data that allow for an ecologically valid assessment of personalized and contextualized emotional and behavioural adjustment in the flow daily life (mROM). METHOD: In a sample of 34 patients with major depressive disorder, treated with antidepressants, the combined effect of treatment and natural course was examined over a period of 18 weeks with Ecological Momentary Assessment (EMA). EMA consisted of repeated, within-subject, mini-measurements of experience (eg positive affect, negative affect, medication side effects) and context (eg stressors, situations, activities) at 10 unselected semi-random moments per day, for a period of six days, repeated three times over the 18-week period (baseline, week 6 and week 18). RESULTS: EMA measures of emotional and behavioural adjustment were sensitive to the effects of treatment and natural course over the 18-week period, particularly EMA measures focussing on positive mood states and the ability to use natural rewards (impact of positive events on positive mood states), with standardized effect sizes of 0.4-0.5. EMA measures of activities, social interaction, stress-sensitivity and negative mood states were also sensitive to change over time. CONCLUSION: This study supports the use of mROM as a means to involve the patient in the process of needs assessment and treatment. EMA data are meaningful to the patient, as they reflect daily life circumstances. Assessment of treatment response with mROM data allows for an interpretation of the effect of treatment at the level of daily life emotional and social adjustment - as an index of health, obviating the need for an exclusive focus on traditional measures of 'sickness'.

van Reijen, Miriam; Vriend, Ingrid I.; Zuidema, Victor; van Mechelen, Willem; Verhagen, Evert A. (2014):

The implementation effectiveness of the 'Strengthen your ankle' smartphone application for the prevention of ankle sprains: design of a randomized controlled trial.

In: *BMC Musculoskelet Disord* 15, S. 2. DOI: 10.1186/1471-2474-15-2.

Abstract:

BACKGROUND: Ankle sprains continue to pose a significant burden to the individual athlete, as well as to society as a whole. However, despite ankle sprains being the single most common sports injury and despite an active approach by various Dutch organisations in implementing preventive measures, large-scale community uptake of these preventive measures, and thus actual prevention of ankle sprains, is lagging well behind. In an attempt to bridge this implementation gap, the Dutch Consumer Safety Institute VeiligheidNL developed a freely available interactive App ('Strenghten your ankle' translated in Dutch as: 'Versterk je enkel; available for iOS and Android) that contains - next to general advice on bracing and taping - a proven cost-effective neuromuscular program. The 'Strengthen your ankle' App has not been evaluated against the 'regular' prevention approach in which the neuromuscular program is advocated through written material. The aim of the current project is to evaluate the implementation value of the 'Strengthen your ankle' App as compared to the usual practice of providing injured athletes with written materials. In addition, as a secondary outcome measure, the cost-effectiveness will be assessed against usual practice. METHODS/DESIGN: The proposed study will be a randomised controlled trial. After stratification for medical caregiver, athletes will be randomised to two study groups. One group will receive a standardized eight-week proprioceptive training program that has proven to be cost-effective to prevent recurrent ankle injuries, consisting of a balance board (machU/MSG Europe BVBA), and a traditional instructional booklet. The other group will receive the same exercise program and balance board. However, for this group the instructional booklet is exchanged by the interactive 'Strengthen your ankle' App. DISCUSSION: This trial is the first randomized controlled trial to study the implementation effectiveness of an App for proprioceptive balance board training program in comparison to a traditional printed instruction booklet, with the recurrence of ankle sprains among athletes as study outcome. Results of this study could possibly lead to changes in practical guidelines on the treatment of ankle sprains and in the use of mobile applications for injury prevention. Results will become available in 2014. TRIAL REGISTRATION: The Netherlands National Trial Register NTR4027. The NTR is part of the WHO Primary Registries.

van Remoortel, Hans; Camillo, Carlos Augusto; Langer, Daniel; Hornikx, Miek; Demeyer, Heleen; Burtin, Chris et al. (2013):

Moderate intense physical activity depends on selected Metabolic Equivalent of Task (MET) cut-off and type of data analysis.

In: *PLoS One* 8 (12), S. e84365. DOI: 10.1371/journal.pone.0084365.

Abstract:

BACKGROUND: Accelerometry data are frequently analyzed without considering whether moderate-to-vigorous physical activities (MVPA) were performed in bouts of >10 minutes as defined in most physical activity guidelines. We aimed i) to quantify MVPA by using different commonly-applied physical activity guidelines, ii) to investigate the effect of bouts versus non-bouts analysis, and iii) to propose and validate a MVPA non-bouts cut-point to classify (in-) active subjects. METHODS: Healthy subjects (n=110;62+/-6yrs) and patients with Chronic Obstructive Pulmonary Disease (COPD) (n=113;62+/-5yrs) wore an activity monitor for 7 days. Three Metabolic Equivalent of Task (MET) cut-offs and one individual target (50% VO(2) reserve) were used to define MVPA. First, all minutes of MVPA were summed up (NON-BOUTS). Secondly, only minutes performed in bouts of >10 minutes continuous activity were counted (BOUTS). Receiver operating characteristic (ROC) curve analyses were used to propose and (cross-) validate new MVPA non-bout cut-points based on the criterion of 30 minutes MVPA per day (BOUTS). Likelihood ratios (sensitivity/[1-specificity]) were used to express the association between the proposed MVPA non-bout target and the MVPA bout target of 30 min*day(-)(1). RESULTS: MVPA was variable across physical activity guidelines with lowest values for age-specific cut-offs. Selecting a METs cut-point corresponding to 50% VO(2) reserve revealed no differences in MVPA between groups. MVPA's analyzed in BOUTS in healthy subjects were 2 to 4 fold lower than NON-BOUTS analyses and this was even 3 to 12 fold lower in COPD. The MVPA non-bouts cut-point of 80 min*day(-)(1) using a 3 METs MVPA threshold delivered positive likelihood ratios of 5.1[1.5-19.6] (healthy subjects) and 2.3[1.6-3.3] (COPD). CONCLUSION: MVPA varies upon the selected physical activity guideline/targets and bouts versus non-bouts analysis. Accelerometry measured MVPA non-bouts target of 80 min*day(-)(1), using a 3 METs MVPA threshold, is associated to the commonly-used MVPA bout target of 30 min*day(-)(1).

van Rijsbergen, Gerard D.; Burger, Huibert; Hollon, Steven D.; Elgersma, Hermien J.; Kok, Gemma D.; Dekker, Jack et al. (2014):

How do you feel? Detection of recurrent Major Depressive Disorder using a single-item screening tool.

In: *Psychiatry Res* 220 (1-2), S. 287–293. DOI: 10.1037/t04757-000.

Abstract:

Mood is a key element of Major Depressive Disorder (MDD), and is perceived as a highly dynamic construct. The aim of the current study was to examine whether a single-item mood scale can be used for mood monitoring. One hundred thirty remitted out-patients were assessed using the Structured Clinical Interview for DSM-IV Axis-I Disorders (SCID-I), Visual Analogue Mood Scale (VAMS), 17-item Hamilton Depression Rating Scale (HAM-D_{17}), and Inventory of Depressive Symptomatology-Self Report (IDS-SR). Of all patients, 13.8% relapsed during follow-up assessments. Area under the curves (AUCs) for the VAMS, HAM-D_{17} and IDS-SR were 0.94, 0.91, and, 0.86, respectively. The VAMS had the highest positive predictive value (PPV) without any false negatives at score 55 (PPV = 0.53; NPV = 1.0) and was the best predictor of current relapse status (variance explained for VAMS: 60%; for HAM-D_{17}: 49%; for IDS-SR: 34%). Only the HAM-D_{17} added significant variance to the model (7%). Assessing sad mood with a single-item mood scale seems to be a straightforward and patient-friendly avenue for life-long mood monitoring. Using a diagnostic interview (e.g., the SCID) in case of a positive screen is warranted. Repeated assessment of the VAMS using Ecological Momentary Assessment (EMA) might reduce false positives. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

van Schooten, Kimberley S.; Rispens, Sietse M.; Elders, Petra J. M.; van Dieen, Jaap H.; Pijnappels, Mirjam (2014):

Toward ambulatory balance assessment: estimating variability and stability from short bouts of gait.

In: *Gait Posture* 39 (2), S. 695–699.

Abstract:

Stride-to-stride variability and local dynamic stability of gait kinematics are promising measures to identify individuals at increased risk of falling. This study aimed to explore the feasibility of using these metrics in clinical practice and ambulatory assessment, where only a small number of consecutive strides are available. The concurrent validity and reliability were assessed compared to more continuous walking. Twenty young adults walked continuously for 500 m, as well as 36 bouts of 20 m while wearing an accelerometer (DynaPort MiniMod) on the trunk. Within-day reliability was high for stride time variability,

mediolateral trunk variability and local dynamic stability, while between-day reliability was low for both variability estimates and moderate for local dynamic stability. Stride time variability and mediolateral trunk variability were increased when walking short bouts and did not correlate well with the longer walking trials. Local dynamic stability did correlate highly between the long and short bouts trials, and 15 bouts of eight strides appeared to be sufficient for valid estimation. These results imply task-specific differences and low reliability of variability estimates rendering them unsuitable for application to short bouts of gait, while local dynamic stability can be readily employed.

van Sluijs, E M F; Page, A.; Ommundsen, Y.; Griffin, S. J. (2010):

Behavioural and social correlates of sedentary time in young people.

In: *British Journal of Sports Medicine* 44 (10), S. 747–755. DOI: 10.1136/bjsm.2008.049783.

Abstract:

OBJECTIVE\r\nIn this study, behavioural and social correlates of objectively measured sedentary time in young people were identified.\r\nDESIGN\r\nCross-sectional analysis of data from the European Youth Heart Study (EYHS).\r\nSETTING\r\nSchools in Denmark, Estonia, Portugal and Norway.\r\nPARTICIPANTS\r\nRespondents were invited using a twostage cluster sampling procedure. Analyses include 2107 children (9-10 years old) and adolescents (14-15 years old). ASSESSMENT OF INDEPENDENT VARIABLES: Seven behavioural and 15 social variables assessed by parental and computerised child questionnaires.\r\nMAIN OUTCOME MEASURE\r\nSedentary activity as assessed by accelerometry (10 min blocks at <200 counts/min). Analyses were stratified by country, and interactions with grade and sex were investigated.\r\nRESULTS\r\nAdolescents were more sedentary than children (335.4 (90.4 min/day) vs 217.2 (75.6 min/day), p<0.001). Patterns of associations differed across countries. High computer use and no television viewing before school in Norway, and being sedentary during school breaks in Estonia were positively associated with sedentary time. No behavioural variables were associated with sedentary time in the Danish and Portuguese models. Socioeconomic position was positively associated with sedentary time in Portugal and Estonia, father's body mass index negatively in the Estonian model. Norwegian participants with a game console at home and Portuguese participants with a television in their bedroom were more sedentary.\r\nCONCLUSIONS\r\nA single strategy aimed at reducing sedentary behaviour is unlikely to be effective across Europe as the target populations and behaviours of focus differ between countries. Targeting high socioeconomic groups in Portugal and Estonia or focusing on reducing computer use in Norway might be effective intervention strategies to reduce overall sedentary time.

van Sluijs, Esther M F; van Poppel, Mireille N M; Twisk, Jos W. R.; van Mechelen, Willem (2006):

Physical activity measurements affected participants' behavior in a randomized controlled trial.

In: *Journal of clinical epidemiology* 59 (4), S. 404–411. DOI: 10.1016/j.jclinepi.2005.08.016.

Abstract:

BACKGROUND AND OBJECTIVE\r\nAssessing levels and determinants of physical activity as outcome measurements might have an independent effect on participant's physical activity behavior. The objective is to study this effect in a randomized controlled trial (RCT) promoting regular physical activity in Dutch general practice.\r\nMETHODS\r\nUsing a Solomon four-group design, participants were randomized twice. After randomization to a control or intervention-condition at general practice level (N = 29), participants were randomized to a group participating in measurements at baseline, 2 and 6 months (3M-group, N = 361), or a group only participating in measurements at 6 months (1M-group, N = 356). Outcome measures assessed at 6 months included: level of physical activity (self-reported and objectively measured with accelerometry), meeting ACSM/CDC guideline for regular physical activity, stage of change, and determinants of physical activity.\r\nRESULTS\r\nFollow-up data on 635 participants (89%) was collected. Statistically significant measurement effects were found for meeting the ACSM/CDC guideline (self-reported), self-efficacy for resisting relapse, knowledge, and on awareness. Other outcome measures showed positive trends, except stages of change.\r\nCONCLUSION\r\nMeasurements of physical activity affect participant's physical activity behavior, possibly triggered by a raised awareness about their own physical activity level. Implications for future research are discussed, as well as methodologic limitations of the study design.

van Voorhees, E. E.; Dennis, M. F.; McClernon, F. J.; Calhoun, P. S.; Buse, N. A.; Beckham, J. C. (2013):

The Association of Dehydroepiandrosterone and Dehydroepiandrosterone Sulfate With Anxiety Sensitivity and Electronic Diary Negative Affect Among Smokers With and Without Posttraumatic Stress Disorder.

In: *J Clin.Psychopharmacol.* (0271-0749 (Linking)). DOI: 10.1097/JCP.0b013e3182968962.

Abstract:

Posttraumatic stress disorder (PTSD) is associated with increased smoking initiation, maintenance, and relapse. Dehydroepiandrosterone (DHEA) and DHEA sulfate (DHEAS) are neurosteroids that have been associated with mood measures as well as smoking status, and nicotine is associated with increased DHEA and DHEAS levels. Given the difficulties with mood experienced by smokers with PTSD, the purpose of the current study was to evaluate the association between negative affect and anxiety sensitivity with DHEA and DHEAS levels. Ninety-six smokers with and without PTSD provided blood samples for neurosteroid analyses and completed self-report measures of anxiety sensitivity and electronic diary ratings of negative affect. As expected, PTSD smokers reported higher levels of anxiety sensitivity (F1,94 = 20.67, partial eta = 0.18, P < 0.0001) and negative affect (F1,91 = 7.98, partial eta = 0.08, P = 0.006). After accounting for age and sex, DHEAS was significantly inversely associated with both anxiety sensitivity (F3,92 = 6.97, partial eta = 0.07, P = 0.01) and negative affect (F3,87 = 10.52, partial eta = 0.11, P = 0.002) across groups. Effect sizes indicated that these effects are moderate to high. No significant interactions of diagnosis and DHEA(S) levels with mood measures were detected. Given that nicotine is known to elevate DHEA(S) levels, these results suggest that DHEAS may serve as a biomarker of the association between mood and nicotine among smokers. Implications for the results include (1) the use of DHEAS measurement across time and across quit attempts and (2) the potential for careful use of DHEA supplementation to facilitate abstinence during smoking cessation

Daily physical activities in chronic lower back pain patients assessed with accelerometry.

In: *Eur J Pain* 13 (6), S. 649–654. DOI: 10.1016/j.ejpain.2008.07.005.

Abstract:

BACKGROUND\r\nNormalization of activities in daily living is an important goal in rehabilitation treatment of chronic lower back pain (CLBP) patients. Clinicians indicate that CLBP patients often show deconditioning but also CLBP patients who seem to be too active are seen. The objective of the present cross-sectional study was to gain more insight into the daily activity pattern of CLBP patients compared to controls, using accelerometry.\r\nMETHODS\r\nDaily activities were assessed by measuring body movement with a tri-axial accelerometer that was worn for seven consecutive days during waking hours. Measurements were performed in the daily environment (in-doors and out-doors) of the participant. Differences between activity level, time of day and work status were tested.\r\nRESULTS\r\nData were obtained from 29 CLBP patients and 20 controls. Results show that the overall activity levels of patients (mean 0.75; SD 0.43) are not significantly different from those of controls (mean 0.71; SD 0.44). However, patients show significantly higher activity levels in the morning (p<0.001) and significantly lower activity levels in the evening (p<0.01) compared to controls. No significant differences in activity levels were found between leisure time and working days within either group; furthermore no significant differences in activity levels were found between patients with different work status.\r\nCONCLUSION\r\nOverall activity levels do not differ significantly between CLBP patients and controls, but the distribution of activities over the day differs significantly.

van Weering, M. G. H.; Vollenbroek-Hutten, M. M. R.; Hermens, H. J. (2011):

The relationship between objectively and subjectively measured activity levels in people with chronic low back pain.

In: *Clinical Rehabilitation* 25 (3), S. 256–263. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-06634-006&site=ehost-live;m.vanweering@rrd.nl.

Abstract:

Objective: To compare self-report measures of daily activities with objective activity data to determine whether patients with chronic lower back pain report their activity levels as accurately as controls do. Design: A cross-sectional study was performed in patients and controls. Setting: The study was carried out in the daily environment of the subjects. Subjects: Thirty-two chronic lower back pain patients with symptoms more than three months and 20 healthy controls from the Netherlands, aged 18–65 years. Main measures: A tri-axial accelerometer was worn for five weekdays and the Baecke Physical Activity Questionnaire was

filled in. Pearson's correlation was calculated to get insight in the awareness of patients and controls. Comparisons of the relationship between the objective and subjective scores of each individual patient with those of the group of controls were used to allocate each patient into subgroups: overestimators, underestimators and aware patients. Physical and psychological characteristics of these groups were explored. Results: Patients showed weak correlations between the objective and subjective scores of physical activity and appear to have problems in estimating their activity levels (r = −0.27), in contrast to controls who showed strong correlations between the objective and subjective scores (r = 0.66). Comparison of the individual relationships of patients with those of controls showed that 44% of the patients were not aware of their activity level. There were relatively more underestimators (30%) than overestimators (14%). Physical characteristics between the three groups tended to be different. Conclusions: Patient self-reports about their activity level are relatively inaccurate when compared to objective measurements. van Winkel, Ruud; Henquet, Cécile; Rosa, Araceli; Papiol, Sergi; Fananás, Lourdes; Hert, Marc et al. (2008):

Evidence that the COMT(Val158Met) polymorphism moderates sensitivity to stress in psychosis: an experience-sampling study.

In: *American journal of medical genetics. Part B, Neuropsychiatric genetics : the official publication of the International Society of Psychiatric Genetics* 147B (1), S. 10–17. DOI: 10.1002/ajmg.b.30559.

Abstract:

Gene-environment interactions involving the catechol-O-methyltransferase Val(158)Met polymorphism (COMT(Val158Met)) have been implicated in the causation of psychosis. Evidence from general population studies suggests that Met/Met subjects are sensitive to stress, a trait associated with psychosis. We hypothesized that the Met allele would moderate the effects of stress on negative affect (NA) in controls, and on NA and psychosis in patients with a psychotic disorder. Thirty-one patients with a psychotic disorder and comorbid cannabis misuse and 25 healthy cannabis users were studied with the experience sampling method (ESM), a structured diary technique assessing current context and emotional and psychotic experiences in daily life. A significant interaction between COMT(Val158Met) genotype and ESM stress in the model of NA was found for patients (interaction chi(2) = 7.4, P = 0.02), but not for controls (interaction chi(2) = 3.8, P = 0.15). In the model of ESM psychosis, a significant interaction between COMT(Val158Met) genotype and ESM stress was also apparent (interaction chi(2) = 11.6, P < 0.01), with Met/Met patients showing the largest increase in psychotic experiences as well as NA in reaction to ESM stress. The findings suggest that the COMT(Val158Met) polymorphism moderates affective and psychotic responses to stress in patients with psychosis, providing evidence for gene-environment interaction mechanisms in the formation of psychotic symptoms.

van Winkel, Mark; Peeters, Frenk; van Winkel, Ruud; Kenis, Gunter; Collip, Dina; Geschwind, Nicole et al. (2014):

Impact of variation in the BDNF gene on social stress sensitivity and the buffering impact of positive emotions: Replication and extension of a gene-environment interaction.

In: *Eur Neuropsychopharmacol. DOI:* 10.1016/j.euroneuro.2014.02.005.

Abstract:

A previous study reported that social stress sensitivity is moderated by the brain-derived-neurotrophic-factorVal66Met (BDNF rs6265) genotype. Additionally, positive emotions partially neutralize this moderating effect. The current study aimed to: (i) replicate in a new independent sample of subjects with residual depressive symptoms the moderating effect of BDNFVal66Met genotype on social stress sensitivity, (ii) replicate the neutralizing impact of positive emotions, (iii) extend these analyses to other variations in the BDNF gene in the new independent sample and the original sample of non-depressed individuals. Previous findings were replicated in an experience sampling method (ESM) study. Negative Affect (NA) responses to social stress were stronger in "Val/Met" carriers of BDNFVal66Met compared to "Val/Val" carriers. Positive emotions neutralized the moderating effect of BDNFVal66Met genotype on social stress sensitivity in a dose-response fashion. Finally, two of four additional BDNF SNPs (rs11030101, rs2049046) showed similar moderating effects on social stress-sensitivity across both samples. The neutralizing effect of positive emotions on the moderating effects of these two additional SNPs was found in one sample. In conclusion, ESM has important advantages in gene-environment (GxE) research and may attribute to more consistent findings in future GxE research. This study shows how the impact of BDNF genetic variation on depressive symptoms may be explained by its impact on subtle daily life responses to social stress. Further, it shows that the generation of positive affect (PA) can buffer social stress sensitivity and partially undo the genetic susceptibility.

van Zundert, R. M.; Kuntsche, E.; Engels, R. C. (2012):

In the heat of the moment: Alcohol consumption and smoking lapse and relapse among adolescents who have quit smoking.

In: *Drug Alcohol Depend* (0376-8716 (Linking)). DOI: 10.1016/j.drugalcdep.2012.05.016.

Abstract:

BACKGROUND: The present study tested the co-occurrence of alcohol use and the first lapse and relapse into smoking among daily smoking adolescents who quit smoking. METHODS: In this ecological momentary assessment study, participants completed web-based questionnaires three times a day during one week prior to and three weeks after a quit attempt in their own natural environments. Participants were 134 daily smoking adolescents in the aged 15-19. Hierarchical linear modeling was applied to test whether alcohol use was related to the first lapse and relapse. Lapse was defined as the first incidence of smoking after achieving 24-h abstinence, relapse was defined as smoking at least five cigarettes on three consecutive days. RESULTS: The first lapse was strongly associated with alcohol use. Individual characteristics (age, sex, and baseline smoking status) did not predict the first lapse nor did they moderate the association between alcohol use and the first lapse. Progression from lapse to relapse did not seem to be associated with alcohol consumption, although this association appeared to be moderated by baseline smoking status. More specifically, alcohol use only posed a significant risk factor for relapse among those who smoked less frequently before the start of the study than others who relapsed. Intermittent smoking between the first lapse and relapse (or end of data) was strongly associated with alcohol use. CONCLUSIONS: Adolescent drinking during smoking cessation seems to be associated with the first lapse into smoking after quitting and subsequent intermittent smoking and should be targeted in adolescent smoking cessation interventions

Van Zundert, Rinka M P; Boogerd, Emiel A.; Vermulst, Ad A.; Engels, Rutger C M E (2009):

Nicotine withdrawal symptoms following a quit attempt: an ecological momentary assessment study among adolescents.

In: *Nicotine Tob Res* 11 (6), S. 722–729. DOI: 10.1093/ntr/ntp055.

Abstract:

INTRODUCTION\r\nThe present study describes growth curves of withdrawal symptoms among 138 daily smoking adolescents before, during, and after a quit attempt.\r\nMETHODS\r\nParticipants reported their levels of withdrawal symptoms (craving, negative affect, and hunger) three times a day over a period of 28 days: 1 week prior to and 3 weeks following a quit attempt.\r\nRESULTS\r\nAll withdrawal symptoms were quite stable at a relatively low level during the 5 days prior to the quit day. At Day 8, withdrawal symptoms (especially craving) increased substantially. A significant decrease in symptoms was visible during the week following the quit day, and within 2 weeks postquit, both abstinent and relapsed adolescents had reverted to levels comparable to those during the prequit period. The course over time for craving and hunger were best described by a quadratic term, and a linear model best suited negative affect. Individual intercepts and slopes of the growth curves were used to predict abstinence during the last week of the study and at the 2-month follow-up. Analyses revealed that higher levels of craving at the beginning of the prequit week and on the target quit day (intercepts) decreased the odds of being abstinent during the last week of the study. In addition, the quadratic term for hunger predicted abstinence during the last week. Finally, among all three symptoms, none of the growth model characteristics predicted abstinence at follow-up.\r\nDISCUSSION\r\nThe findings generally suggest that smoking cessation among daily smoking adolescents does not largely depend on how their withdrawal symptoms evolve over time after achieving abstinence.

Van Zundert, Rinka M P; Engels, Rutger C M E (2009):

Parental factors in association with adolescent smoking relapse.

In: *Eur Addict Res* 15 (4), S. 209–215. DOI: 10.1159/000231884.

Abstract:

The present study examined the role of parents in smoking relapse among adolescents who embarked on a serious attempt to quit. Participants were 135 adolescents aged 15-20 years who smoked daily and participated in an ecological momentary assessment study. Daily questions about their quitting experiences were administered during 4 weeks. Longitudinal logistic regression analyses were applied to test whether parental smoking, expected parental support, parental norms about cessation, and smoking cessation-specific parenting at baseline predicted the first lapse into smoking as well as mild and heavy relapse during the 4-week period, and abstinence at follow-up 2 months later. Neither parental smoking nor hardly any of the parenting variables explained successful smoking cessation among adolescents, except for expected parental support. Although parents

have been found to be influential in the development of adolescent smoking, our findings suggest that parents' influence is limited when it concerns actual smoking cessation and relapse.

Van Zundert, Rinka M P; Ferguson, Stuart G.; Shiffman, Saul; Engels, Rutger C M E (2010):

Dynamic effects of self-efficacy on smoking lapses and relapse among adolescents.

In: *Health Psychol* 29 (3), S. 246–254. DOI: 10.1037/a0018812.

Abstract:

OBJECTIVE\r\nThe present study examined whether dynamic day-to-day variations in self-efficacy predicted success in quit attempts among daily smoking adolescents.\r\nDESIGN\r\nA sample of 149 adolescents recorded their smoking and self-efficacy three times per day during 1 week prior to and 3 weeks after a quit attempt.\r\nMAIN OUTCOME MEASURES\r\nThe first lapse, second lapse, and relapse after at least 24 hours of abstinence from smoking were the main outcome measures.\r\nRESULTS\r\nSelf-efficacy was relatively high and moderately variable prior to the first lapse, but decreased and became more variable thereafter. Lower self-efficacy as measured at the lapse assessment significantly increased the risk that a second lapse and relapse would occur. Individual differences in baseline self-efficacy did not predict any of the treatment outcomes. The time-varying analyses, however, showed that lower self-efficacy on a given day predicted the first lapse, the second lapse, and relapse on the succeeding day. Daily concomitant smoking (any smoking on the preceding day) was not significantly related to relapse.\r\nCONCLUSION\r\nThe present results emphasize the importance of self-efficacy among adolescents in cessation and highlight the need for dynamic formulations and assessments of adolescents' self-efficacy and relapse.

Van Zundert, Rinka M P; Nijhof, Linda M.; Engels, Rutger C M E (2009):

Testing Social Cognitive Theory as a theoretical framework to predict smoking relapse among daily smoking adolescents.

In: *Addict Behav* 34 (3), S. 281–286. DOI: 10.1016/j.addbeh.2008.11.004.

Abstract:

Predictors of adolescent smoking relapse are largely unknown, since studies either focus on relapse among adults, or address (long-term) smoking cessation but not relapse. In the present study, Social Cognitive Theory (SCT) was used as a theoretical framework to examine the first and second lapses, as well as mild and heavy relapse into smoking among 135 daily smoking adolescents who embarked on a serious quit attempt. Baseline predictors were pros of smoking, pros of quitting, self-efficacy, and intensity of smoking. Using an ecological momentary assessment (EMA) study design, participants were monitored three times a day during 4 weeks. A follow-up was administered 2 months after the monitoring period. Perceiving many pros of smoking, reporting a low self-efficacy to quit, and high levels of baseline smoking significantly predicted relapse within 3 weeks after quitting. The effects of pros of smoking and self-efficacy on relapse, however, appeared to be accounted for by differences in intensity of smoking. Besides that pros of quitting showed a marginal effect on abstinence at the 2-month follow-up, no long-term effects were detected.

Van, Cauwenberghe E.; De,Bourdeaudhuij,I; Maes, L.; Cardon, G. (2012):

Efficacy and feasibility of lowering playground density to promote physical activity and to discourage sedentary time during recess at preschool: A pilot study.

In: *Prev.Med.* (0091-7435 (Linking)). DOI: 10.1016/j.ypmed.2012.07.014.

Abstract:

OBJECTIVE: This pilot study examined if lowering playground density is feasible and effective in improving preschoolers' activity and sedentary levels during recess. METHOD: Between November and December 2011, a within-subject design was used to study preschoolers' activity via accelerometry during recesses in the usual conditions (baseline) and with lower playground density (intervention). During the intervention, preschools scheduled extra recesses so that the number of classes usually sharing the playground was halved. Effects were investigated, using two-level linear regression models, in 1

Van, Cauwenberghe E.; Jones, R. A.; Hinkley, T.; Crawford, D.; Okely, A. D. (2012):

Patterns of physical activity and sedentary behavior in preschool children.

In: *Int.J Behav.Nutr.Phys.Act.* 9 (1), S. 138. DOI: 10.1186/1479-5868-9-138.

Abstract:

ABSTRACT: BACKGROUND: Little is known about patterns of sedentary behavior (SB) and physical activity among preschoolers. Therefore, in this observational study patterns of SB and moderate-to-vigorous physical activity (MVPA) were examined in detail throughout the week in preschool-aged boys and girls. METHODS: A sample of 703 Melbourne preschool children (387 boys; 4.6 +/- 0.7 y) were included in data analysis. SB and MVPA data were collected using accelerometry over an eight-day period. Percentage of time per hour in SB and in MVPA between 08:00h and 20:00h was calculated. Multi-level logistic regression models were created to examine the hour-by-hour variability in SB and MVPA for boys and girls across weekdays and weekend days. Odds ratios (OR) were calculated to interpret differences in hour-by-hour SB and MVPA levels between boys and girls, and between weekdays and weekend days. RESULTS: The highest SB levels co-occurred with the lowest MVPA levels from the morning till the early afternoon on weekdays, and during the morning and around midday on weekends. Besides, participation in SB was the lowest and participation in MVPA was the highest from the mid afternoon till the evening on weekdays and weekend days. The variability across the hours in SB and, especially, in MVPA was rather small throughout weekdays and weekends. These patterns were found in both boys and girls. During some hours, girls were found to be more likely than boys to demonstrate higher SB levels (OR from 1.08 to 1.16; all $p<0.05$) and lower MVPA levels (OR from 0.75 to 0.88; all $p<0.05$), but differences were small. During weekends, hour-by-hour SB levels were more likely to be lower (OR from 0.74 to 0.98; all $p<0.05$) and hour-by-hour MVPA levels were more likely to be higher (OR from 1.15 to 1.50; all $p<0.05$), than during weekdays, in boys and girls. CONCLUSION: Entire weekdays, especially from the morning till the early afternoon, and entire weekend days are opportunities to reduce SB and to promote MVPA in preschool-aged boys and girls. Particularly weekdays hold the greatest promise for improving SB and MVPA. No particular time of the week was found where one sex should be targeted

Van, Roekel E.; Verhagen, M.; Scholte, R. H.; Kleinjan, M.; Goossens, L.; Engels, R. C. (2013):

The Oxytocin Receptor Gene (OXTR) in Relation to State Levels of Loneliness in Adolescence: Evidence for Micro-Level Gene-Environment Interactions.

In: *PLoS.One.* 8 (11), S. e77689. DOI: 10.1371/journal.pone.0077689.

Abstract:

Previous research has shown that the rs53576 variant of the oxytocin receptor gene (OXTR) is associated with trait levels of loneliness, but results are inconsistent. The aim of the present study is to examine micro-level effects of the OXTR rs53576 variant on state levels of loneliness in early adolescents. In addition, gene-environment interactions are examined between this OXTR variant and positive and negative perceptions of company. Data were collected in 278 adolescents (58% girls), by means of the Experience Sampling Method (ESM). Sampling periods consisted of six days with nine assessments per day. A relation was found between the OXTR rs53576 variant and state loneliness, in girls only. Girls carrying an A allele had higher levels of state loneliness than girls carrying the GG genotype. In addition, adolescents with an A allele were more affected by negative perceptions of company than GG carriers, on weekend days only. No significant gene-environment interactions were found with positive company. Adolescents carrying an A allele were more susceptible to negative environments during weekend days than GG carriers. Our findings emphasize the importance of operationalizing the phenotype and the environment accurately

Vandercammen, Leen; Hofmans, Joeri; Theuns, Peter (2014):

Relating specific emotions to intrinsic motivation: on the moderating role of positive and negative emotion differentiation.

In: *PLoS One* 9 (12), S. e115396. DOI: 10.1371/journal.pone.0115396.

Abstract:

Despite the fact that studies on self-determination theory have traditionally disregarded the explicit role of emotions in the motivation eliciting process, research attention for the affective antecedents of motivation is growing. We add to this emerging research field by testing the moderating role of emotion differentiation -individual differences in the extent to which people can differentiate between specific emotions- on the relationship between twelve specific emotions and intrinsic motivation. To this end, we conducted a daily diary study (N = 72) and an experience sampling study (N = 34). Results showed that the relationship between enthusiasm, cheerfulness, optimism, contentedness, gloominess, miserableness, uneasiness (in both studies 1 and 2), calmness, relaxation, tenseness, depression, worry (only in Study 1) on one hand and intrinsic motivation on the other hand was moderated by positive emotion differentiation for the positive emotions and by negative emotion differentiation for the

negative emotions. Altogether, these findings suggest that for people who are unable to distinguish between different specific positive emotions the relationship between those specific positive emotions and intrinsic motivation is stronger, whereas the relationship between specific negative emotions and intrinsic motivation is weaker for people who are able to distinguish between the different specific negative emotions. Theoretical and practical implications are discussed.

Vanhaebost, Jessica; Faouzi, Mohamed; Mangin, Patrice; Michaud, Katarzyna (2014):

New reference tables and user-friendly Internet application for predicted heart weights.

In: *Int J Legal Med. DOI:* 10.1007/s00414-013-0958-9.

Abstract:

BACKGROUND: Knowledge of normal heart weight ranges is important information for pathologists. Comparing the measured heart weight to reference values is one of the key elements used to determine if the heart is pathological, as heart weight increases in many cardiac pathologies. The current reference tables are old and in need of an update. AIMS: The purposes of this study are to establish new reference tables for normal heart weights in the local population and to determine the best predictive factor for normal heart weight. We also aim to provide technical support to calculate the predictive normal heart weight. METHODS: The reference values are based on retrospective analysis of adult Caucasian autopsy cases without any obvious pathology that were collected at the University Centre of Legal Medicine in Lausanne from 2007 to 2011. We selected 288 cases. The mean age was 39.2 years. There were 118 men and 170 women. Regression analyses were performed to assess the relationship of heart weight to body weight, body height, body mass index (BMI) and body surface area (BSA). RESULTS: The heart weight increased along with an increase in all the parameters studied. The mean heart weight was greater in men than in women at a similar body weight. BSA was determined to be the best predictor for normal heart weight. New reference tables for predicted heart weights are presented as a web application that enable the comparison of heart weights observed at autopsy with the reference values. CONCLUSIONS: The reference tables for heart weight and other organs should be systematically updated and adapted for the local population. Web access and smartphone applications for the predicted heart weight represent important investigational tools.

Vanhelst, J.; Baquet, G.; Gottrand, F.; Beghin, L. (2012):

Comparative interinstrument reliability of uniaxial and triaxial accelerometers in free-living conditions.

In: *Percept.Mot.Skills* 114 (2), S. 584–594. Online verfügbar unter PM:22755462.

Abstract:

The aim of this study was to measure the inter-instrument reliability of the ActiGraph and RT3 accelerometers in free-living conditions. 15 healthy adults wore eight ActiGraph accelerometers and five RT3 accelerometers fastened to their back with an elastic belt and adjustable buckle in free-living conditions. For both accelerometers, the inter-instrument coefficient of variation (CV) decreased with increasing physical activity intensity. The inter-instrument CV of the ActiGraph (3% to 10.5%) was significantly lower than that of the RT3 (12.6% to 35.5%; $p < 0.05$). This finding demonstrates that the ActiGraph has higher inter-instrument reliability than the RT3. For both accelerometers, the inter-instrument reliability was higher for moderate and vigorous physical activity, the two intensities recommended for public health purposes. Studies using these devices can be compared with a low risk of misclassification of participants who meet the recommendation to perform moderate to vigorous physical activity

Vanhelst, J.; Beghin, L.; Duhamel, A.; Bergman, P.; Sjotrom, M.; Gottrand, F. (2012):

Comparison of uniaxial and triaxial accelerometry in the assessment of physical activity among adolescents under free-living conditions: the HELENA study.

In: *BMC.Med.Res.Methodol.* 12 (1), S. 26. DOI: 10.1186/1471-2288-12-26.

Abstract:

ABSTRACT: BACKGROUND: Different types of devices are available and the choice about which to use depends on various factors: cost, physical characteristics, performance, and the validity and intra- and interinstrument reliability. Given the large number of studies that have used uniaxial or triaxial devices, it is of interest to know whether the different devices give similar information about PA levels and patterns. The aim of this study was to compare physical activity (PA) levels and patterns

obtained simultaneously by triaxial accelerometry and uniaxial accelerometry in adolescents in free-living conditions. METHODS: Sixty-two participants, aged 13-16 years, were recruited in this ancillary study, which is a part of the Healthy Lifestyle in Europe by Nutrition in Adolescence (HELENA). All participants wore a uniaxial accelerometer (ActiGraph GT1M(R), Pensacola, FL) and a triaxial accelerometer (RT3(R), Stayhealthy, Monrovia, CA) simultaneously for 7 days. The patterns were calculated by converting accelerometer data output as a percentage of time spent at sedentary, light, moderate, and vigorous PA per day. Analysis of output data from the two accelerometers were assessed by two different tests: Equivalence Test and Bland & Altman method. RESULTS: The concordance correlation coefficient between the data from the triaxial accelerometer and uniaxial accelerometer at each intensity level was superior to 0.95. The ANOVA test showed a significant difference for the first three lower intensities while no significant difference was found for vigorous intensity. The difference between data obtained with the triaxial accelerometer and the uniaxial monitor never exceeded 2.1% and decreased as PA level increased. The Bland & Altman method showed good agreement between data obtained between the both accelerometers ($p < 0.05$). CONCLUSIONS: Uniaxial and triaxial accelerometers do not differ in their measurement of PA in population studies, and either could be used in such studies

Vanhelst, J.; Fardy, P. S.; Duhamel, A.; Beghin, L. (2013):

How many days of accelerometer monitoring predict weekly physical activity behaviour in obese youth?

In: *Clin.Physiol Funct.Imaging* (1475-0961 (Linking)). DOI: 10.1111/cpf.12109.

Abstract:

The aim of this study was to determine the type and the number of accelerometer monitoring days needed to predict weekly sedentary behaviour and physical activity in obese youth. Fifty-three obese youth wore a triaxial accelerometer for 7 days to measure physical activity in free-living conditions. Analyses of variance for repeated measures, Intraclass coefficient (ICC) and regression linear analyses were used. Obese youth spent significantly less time in physical activity on weekends or free days compared with school days. ICC analyses indicated a minimum of 2 days is needed to estimate physical activity behaviour. ICC were 0.80 between weekly physical activity and weekdays and 0.92 between physical activity and weekend days. The model has to include a weekday and a weekend day. Using any combination of one weekday and one weekend day, the percentage of variance explained is >90%. Results indicate that 2 days of monitoring are needed to estimate the weekly physical activity behaviour in obese youth with an accelerometer. Our results also showed the importance of taking into consideration school day versus free day and weekday versus weekend day in assessing physical activity in obese youth

Vanhelst, Jeremy; Fardy, Paul S.; Beghin, Laurent (2014):

Technical variability of the Vivago wrist-worn accelerometer.

In: *J Sports Sci*, S. 1–7. DOI: 10.1080/02640414.2014.918643.

Abstract:

Abstract The aim was to assess the technical variability of a new wrist-worn accelerometer under controlled conditions with a shaker device and during normal daily physical activities (PAs). In the first experiment, 10 wrist-worn accelerometers (Vivago(R) Wellness, Paris, France) were attached to the shaker device. Variability was tested at five shaking frequencies (1.1, 2.1, 3.1, 4.1, and 10 Hz) for 10 min at each frequency. In the second experiment, 21 participants wore wrist-worn accelerometers and performed six consecutive 10-min periods of activity at increasing levels of intensity from sedentary to vigorous. Results from the first experiment show a modest inter- and intra-instrument reliability at low frequencies and that reliability improved as frequency increased. The inter-instrument coefficient of variation (CV) was 2.6-18.3%. The intra-instrument CV was 4.1-23.2%. Variability was similar in the second experiment with a CV inversely related to PA intensity. The inter- and intra-instrument CV varied from 24.2% and 19.9% for sedentary activities to 3.7% and 4.3% for vigorous PA, respectively. Results suggest that reliability was higher at high intensities, corresponding to moderate and vigorous PA, intensities generally recommended for public health purposes.

Validation of the Vivago Wrist-Worn accelerometer in the assessment of physical activity.

In: *BMC.Public Health* 12 (1), S. 690. DOI: 10.1186/1471-2458-12-690.

Abstract:

ABSTRACT: BACKGROUND: Most accelerometers are worn around the waist (hip or lower back) to assess habitual physical activity. Wrist-worn accelerometers may be an alternative to the waist-worn monitors and may improve compliance in studies with prolonged wear. The aim of this study was to validate the Vivago[REGISTERED SIGN] Wrist-Worn Accelerometer at various intensities of physical activity (PA) in adults. METHODS: Twenty-one healthy adults aged 20--34 years were recruited for the study. Accelerometer data and oxygen uptake (VO2) were measured at sedentary, light, moderate and vigorous levels of PA. RESULTS: Activity categories and accelerometer counts were: sedentary, 0--15 counts[DOT OPERATOR]min[MINUS SIGN]1; light, 16--40 counts[DOT OPERATOR]min[MINUS SIGN]1; moderate, 41--85 counts[DOT OPERATOR]min[MINUS SIGN]1; and vigorous activity, > 85 counts[DOT OPERATOR]min[MINUS SIGN]1. ANOVA repeated measures was used to determine the relationship between accelerometry data output and oxygen consumption (r = .89; p < .001). The Bland and Altman method showed good agreement in the assessment of energy expenditure between the indirect calorimetry and the data obtained by the accelerometer. CONCLUSIONS: Results of the study suggest that the Vivago[REGISTERED SIGN] wrist-worn accelerometer is a valid measure of PA at varying levels of intensity. The study has also defined threshold values at four intensities and hence the Vivago[REGISTERED SIGN] accelerometer may be used to quantify PA in free living conditions among adults. This device has possible application in treating a variety of important health concerns

ReadySteady: app for accelerometer-based activity monitoring and wellness-motivation feedback system for older adults.

In: *AMIA.Annu.Symp.Proc.* 2012 (1559-4076 (Linking)), S. 931–939. Online verfügbar unter PM:23304368.

Abstract:

Increased physical activity and exercise have been found to reduce falls and decrease mortality and age-related morbidity in older adults. However, a large percentage of this population fail to achieve the necessary levels of activity needed to support health living. In this work, we present a mobile app developed on the iOS platform that monitors activity levels using accelerometry. The data captured by the sensor is utilized to provide real-time motivational feedback to enable reinforcement of positive behaviors in older adults. Pilot experiments (conducted with younger adults) performed to assess validity of activity measurement showed that system accurately measures sedentary, light, moderate and vigorous activities in a controlled lab setting. Pilot tests (conducted with older adults) in the user setting showed that while the app is adept at capturing gross body activity (such as sitting, walking and jogging), additional sensors may be required to capture activities involving the extremities

Variability in Affective Activation Predicts Non-suicidal Self-injury in Eating Disorders.

In: *Eur.Eat.Disord.Rev.* (1072-4133 (Linking)). DOI: 10.1002/erv.2220.

Abstract:

We examined whether affective variability can predict non-suicidal self-injury (NSSI) in eating disorders. Affect was represented by valence (positive versus negative) and activation (high versus low). Twenty-one patients with anorexia nervosa-restricting type, 18 patients with anorexia nervosa-binge-purging type and 20 patients with bulimia nervosa reported their momentary affect at nine random times a day during a one week period using a hand-held computer. Affective variability was calculated as the within-person standard deviation of valence and activation over time. Results indicate that patients displaying greater variability in activation and using selective serotonin reuptake inhibitors have a higher probability to engage in lifetime NSSI after adjustment for depression and borderline personality disorder. Neither variability of valence nor mean level of valence and activation had any predictive association with engaging in NSSI. It is suggested that the treatment of NSSI should focus on affect stabilization rather than reducing negative affect. Copyright (c) 2012 John Wiley & Sons, Ltd and Eating Disorders Association

Holter monitoring of central and peripheral temperature: possible uses and feasibility study in outpatient settings.

In: *Journal of clinical monitoring and computing* 23 (4), S. 209–216. DOI: 10.1007/s10877-009-9184-x.

Abstract:

BACKGROUND\r\nConventional clinical thermometry has important limitations. A continuous monitoring of temperature may offer significant advantages, including the use of chronobiological and complexity analysis of temperature profile and eventually the identification of a \"pre-febrile\" pattern.\r\nOBJECTIVE\r\nWe present a clinical model designed to measure, store and/or transmit in real time a central and a peripheral temperature reading. The results of its use in a healthy, free-living population is reported.\r\nMETHODS\r\nThirty subjects (15 women, 15 men, 20-70 years old), were monitored for 24 h while following their normal life. Temperatures were recorded every minute at the external auditory channel (EAC) and on the skin, at the intersection of the 5th intercostal space and the anterior axillary line. A Cosinor analysis and Approximate Entropy (ApEn) (m = 2, r = 0.15*SD, N = 180) were calculated for both temperatures.\r\nRESULTS\r\nMedian temperature was 35.55 degrees C [interquartile range (IR) 0.77 degrees C] in the external auditory channel (EAC) and 34.62 degrees C (IR 1.61) in the specified skin location. Median gradient between AEC and skin was 0.93 (IR 1.57). A circadian rhythm was present both in EAC and skin temperature, with a mean amplitude of 0.44 degrees C and an acrophase at 21:02 for the EAC and 0.70 degrees C and 00:42 for the skin. During the night there was a sizable increase in peripheral temperature, with a decrease in gradient and a loss of complexity in the temperature profile, most significantly in the peripheral temperature.\r\nCONCLUSIONS\r\nContinuous monitoring of central and peripheral temperature may be a helpful tool in both ambulatory and admitted patients and may offer new approaches in clinical thermometry.

Time-varying processes involved in smoking lapse in a randomized trial of smoking cessation therapies.

In: *Nicotine Tob Res* 16 Suppl 2, S. S135-43. DOI: 10.1093/ntr/ntt185.

Abstract:

INTRODUCTION: Researchers have increasingly begun to gather ecological momentary assessment (EMA) data on smoking, but new statistical methods are necessary to fully unlock information from such data. In this paper, we use a new technique, the logistic time-varying effect model (logistic TVEM), to examine the odds of smoking in the 2 weeks after a quit attempt. METHODS: Data are from a subsample of participants from a randomized, placebo-controlled trial of smoking cessation pharmacotherapies who achieved initial abstinence (N = 1,106, 58% female). Participants completed up to 4 EMA assessments per day during the 2 weeks after their quit day. Predictors include baseline nicotine dependence, EMA measures of craving and negative affect, and whether an individual was assigned to a placebo, monotherapy, or combination therapy condition. Time-varying effects of these predictors were estimated using logistic TVEM. RESULTS: Cravings were a significant predictor of smoking throughout the entire 2 weeks postquit, whereas the effect of baseline dependence became nonsignificant by the second week, and the effect of negative affect increased over time. Individuals in the monotherapy and combination therapy conditions had decreased odds of smoking compared with placebo in the first week postquit, but these differences were nonsignificant in the second week. CONCLUSIONS: Findings suggest that pharmacotherapies are more effective compared with placebo earlier in a quit attempt, when the effect of baseline nicotine dependence on smoking is stronger, whereas the effect of craving and negative affect increased over time. Future cessation therapies may be more successful by providing additional support in the second week after quit attempt.

Respiratory Impairment and Dyspnea and Their Associations with Physical Inactivity and Mobility in Sedentary Community-Dwelling Older Persons.

In: *J Am Geriatr Soc. DOI:* 10.1111/jgs.12738.

Abstract:

OBJECTIVES: To evaluate the prevalence of respiratory impairment and dyspnea and their associations with objectively measured physical inactivity and performance-based mobility in sedentary older persons. DESIGN: Cross-sectional. SETTING: Lifestyle Interventions and Independence for Elders Study. PARTICIPANTS: Community-dwelling older persons (n = 1,635, mean age 78.9) who reported being sedentary (<20 min/wk of regular physical activity and <125 min/wk of moderate physical activity in past month). MEASUREMENTS: Respiratory impairment was defined as low ventilatory capacity (forced expiratory volume in 1 second less than lower limit of normal (LLN)) and respiratory muscle weakness (maximal inspiratory pressure <LLN). Dyspnea was defined as moderate to severe ratings on the modified Borg index, immediately after a 400-m walk test (400-MWT). Physical inactivity was defined according to high sedentary time as the highest quartile of participants with accelerometry-measured activity of <100 counts/min. Performance-based mobility was evaluated using the Short Physical Performance Battery (</=7 defined as moderate to severe mobility impairment) and 400-MWT gait speed (<0.8 m/s defined as slow). RESULTS: Prevalence rates were 17.7% for low ventilatory capacity, 14.7% for respiratory muscle weakness, 31.6% for dyspnea, 44.7% for moderate to

severe mobility impairment and 43.6% for slow gait speed. Significant associations were found between low ventilatory capacity and slow gait speed (adjusted odds ratio (aOR) = 1.41, 95% confidence interval (CI) = 1.03-1.92), between respiratory muscle weakness and moderate to severe mobility impairment (aOR = 1.42, 95% CI = 1.03-1.95), and between dyspnea and high sedentary time (aOR = 1.98, 95% CI = 1.28-3.06) and slow gait speed (aOR = 1.70, 95% CI = 1.22-2.38). CONCLUSION: Respiratory impairment and dyspnea are prevalent in sedentary older persons and are associated with objectively measured physical inactivity and poor performance-based mobility. Because they are modifiable, respiratory impairment and dyspnea should be considered in the evaluation of sedentary older persons.

Knowing me, knowing you: the accuracy and unique predictive validity of self-ratings and other-ratings of daily behavior.

In: *Journal of Personality and Social Psychology* 95 (5), S. 1202–1216. DOI: 10.1037/a0013314.

Abstract:

Many people assume that they know themselves better than anyone else knows them. Recent research on inaccuracies in self-perception, however, suggests that self-knowledge may be more limited than people typically assume. In this article, the authors examine the possibility that people may know a person as well as (or better than) that person knows himself or herself. In Study 1, the authors document the strength of laypeople's beliefs that the self is the best expert. In Study 2, the authors provide a direct test of self- and other-accuracy using an objective and representative behavioral criterion. To do this, the authors compared self- and other-ratings of daily behavior to real-life measures of act frequencies assessed unobtrusively over 4 days. Our results show that close others are as accurate as the self in predicting daily behavior. Furthermore, accuracy varies across behaviors for both the self and for others, and the two perspectives often independently predict behavior. These findings suggest that there is no single perspective from which a person is known best and that both the self and others possess unique insight into how a person typically behaves.

Vella, Elizabeth J.; Kamarck, Thomas W.; Shiffman, Saul (2008):

Hostility moderates the effects of social support and intimacy on blood pressure in daily social interactions.

In: *Health Psychol* 27 (2S), S. S155.

Abstract:

This study sought to determine the role of hostility in moderating the effects of positive social interactions on ambulatory blood pressure (ABP).

DESIGN:

Participants (341 adults) completed the Cook-Medley Hostility Scale and underwent ABP monitoring, assessed every 45 min during waking hours across 6 days. An electronic diary measuring mood and social interactions was completed at each ABP assessment.

MAIN OUTCOME MEASURES:

The dependent variables from the ABP monitor included systolic blood pressure, diastolic blood pressure, and heart rate.

RESULTS:

Different patterns of ambulatory diastolic blood pressure (ADBP) responding to social interactions perceived as intimate or supportive among high- versus low-hostile individuals were observed. Higher intimacy ratings were linked to reductions in ADBP among low-hostile but not high-hostile individuals. Conversely, high-hostile, but not low-hostile, individuals showed increases in ADBP to situations rated high in social support. Although findings for ambulatory systolic blood pressure were nonsignificant, the pattern of results was similar to ADBP.

CONCLUSION:

Hostile individuals may find offers of support stressful and may fail to benefit from intimacy during daily life. The pathogenic effects of hostility may be mediated in part by responses to social interactions, both positive and negative.

Hostile mood and social strain during daily life: A test of the transactional model.

In: *Annals of Behavioral Medicine* 44 (3), S. 341–352. DOI: 10.1037/t02043-000;

Abstract:

Background: Hostility is a multidimensional construct related to cardiovascular (CV) disease risk. Daily hostile mood and social interactions may precipitate stress-related CV responses in hostile individuals. Purpose: Determine whether trait cognitive hostility best predicts daily hostile mood and social interactions relative to other trait hostility factors and explore the temporal links between these daily measures. Methods: One hundred seventy-one participants completed assessments of four trait hostility scales. Participants completed an electronic diary across 3 days, assessing current hostile mood and social interaction quality. Results: Multiple regression analyses revealed both affective and cognitive hostility to be significant predictors of daily hostile mood, and cognitive hostility alone to predict daily social strain. Additional analyses revealed previous social strain to predict elevated subsequent hostile mood. Conclusions: Episodes of social strain may give rise to elevated hostile mood. Trait cognitive hostility may be an important factor in predicting daily social strain. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

Acculturation and metabolic syndrome risk factors in young Mexican and Mexican–American women.

In: *Journal of immigrant and minority health* 13 (1), S. 119–126.

Abstract:

Little is known about effects of acculturation on disease risk in young Mexican and Mexican–American women living in a border community. The purpose of this study was to examine relationships between acculturation and features of metabolic syndrome (MetS) in Mexican and Mexican–American women (n = 60) living in the largest US-Mexico border community. Acculturation was measured by the short acculturation scale for Hispanics and birthplace. Body composition was measured by Bod Pod and daily physical activity was measured by questionnaire and accelerometer. Increased acculturation was related to individual features of MetS and increased risk of MetS. These relationships were mediated by fat mass rather than inactivity. Fat mass mediates the relationships between acculturation and individual features of MetS in young Mexican and Mexican–American women. These findings suggest that fat mass, rather than inactivity, is an important contributor to disease risk in young Mexican and Mexican–American women living in a large US/Mexico border community.

Environmental and psychosocial correlates of accelerometer-assessed and self-reported physical activity in Belgian adults.

In: *International Journal of Behavioral Medicine* 18 (3), S. 235–245. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-16658-009&site=ehost-live;Delfien.VanDyck@UGent.be.

Abstract:

Background: Despite the well-known benefits of physical activity (PA) on overall health, the majority of the adult population does not engage in sufficient PA. To develop effective interventions to increase PA, it is necessary to understand the most important PA correlates and to investigate whether correlates are similar in different population subgroups. Purpose: This study examined associations between physical environmental perceptions and self-reported and objectively assessed PA in Belgian adults. Moreover, associations between psychosocial factors and PA, and the moderating effects of sociodemographic factors were investigated. Method: A sample of 1,200 Belgian adults (20–65 years; 47.9% males) completed a survey measuring sociodemographic variables and psychosocial correlates, the Neighborhood Environmental Walkability Scale and the long-version International Physical Activity Questionnaire. They wore an accelerometer for 7 days. Results: Perceiving neighborhoods to be high walkable (high residential density, high land use mix access, and high land use mix diversity) and recreation facilities to be convenient, and the availability of home PA equipment were the most consistent physical environmental correlates of PA. The strongest psychosocial correlates were social support from friends and family and self-efficacy. The psychosocial associations were most consistent for self-reported leisure-time PA and less clear for self-reported active transportation and accelerometer-assessed PA. Few significant sociodemographic moderators were found. Conclusion: Both physical environmental and psychosocial factors were associated with PA in adults, with psychosocial factors being important especially for leisure-time PA. Correlates of PA were similar regardless of gender, age, or socio-economic status, so interventions to change these factors could have population-wide effects. [Experiences with a self developed accelerometer].

In: *Ideggyogy.Sz* 66 (1-2), S. 29–34. Online verfügbar unter PM:23607227.

Abstract:

OBJECTIVE: In neurology the objective evaluation of improvement of paresis on every-day practice. The aim of this study was to develop and test a small 3-d acceleration measuring device and validate its usefulness. PATIENTS AND METHODS: We collected data from 17 mild and medium severity hemiparetic, bedridden acute ischaemic and hemorrhagic stroke patients and compared with data of 22 control subjects. The devices were attached to the paretic and non-paretic extremities and any movements (m/s2) and movement-durations were registered (24h). The data of movement-monitors were compared also with the changes of National Institute of Health Stroke Scale and European Stroke Scale. The electromyograph-sensor of polysomnograph was used for validation. RESULTS: Mild differences could be found in the use of dominant and non-dominant upper extremities of control persons. The control persons used their upper extremities more frequently than the stroke patients. Our data showed significant correlation with National Institute of Health Stroke Scale. Higher values on the scores were accompanied with less intensive use of extremities. We found a correlation between the consiousness level of patients and their activity of upper extremities. If the patients had severe consiousness disturbances they used significantly less their upper extremities. CONCLUSION: Our device sensitively detected the movement-differences between paretic and non-paretic extremities and can be used for quantitative evaluation of patient's neurological and consciousness status

Self-Measurement of Blood Pressure at Home Reduces the Need for Antihypertensive Drugs A Randomized, Controlled Trial.

In: *Hypertension* 50 (6), S. 1019–1025.

Abstract:

It is still uncertain whether one can safely base treatment decisions on self-measurement of blood pressure. In the present study, we investigated whether antihypertensive treatment based on self-measurement of blood pressure leads to the use of less medication without the loss of blood pressure control. We randomly assigned 430 hypertensive patients to receive treatment

either on the basis of self-measured pressures (n=216) or office pressures (OPs; n=214). During 1-year follow-up, blood pressure was measured by office measurement (10 visits), ambulatory monitoring (start and end), and self-measurement (8 times, self-pressure group only). In addition, drug use, associated costs, and degree of target organ damage (echocardiography and microalbuminuria) were assessed. The self-pressure group used less medication than the OP group (1.47 versus 2.48 drug steps; P<0.001) with lower costs ($3222 versus $4420 per 100 patients per month; P<0.001) but without significant differences in systolic and diastolic OP values (1.6/1.0 mm Hg; P=0.25/0.20), in changes in left ventricular mass index (−6.5 g/m2 versus −5.6 g/m2; P=0.72), or in median urinary microalbumin concentration (−1.7 versus −1.5 mg per 24 hours; P=0.87). Nevertheless, 24-hour ambulatory blood pressure values at the end of the trial were higher in the self-pressure than in the OP group: 125.9 versus 123.8 mm Hg (P<0.05) for systolic and 77.2 versus 76.1 mm Hg (P<0.05) for diastolic blood pressure. These data show that self-measurement leads to less medication use than office blood pressure measurement without leading to significant differences in OP values or target organ damage. Ambulatory values, however, remain slightly elevated for the self-pressure group.

The voltage of R wave in lead aVL improves risk stratification in hypertensive patients without ECG left ventricular hypertrophy.

In: *J Hypertens* 27 (8), S. 1697–1704. DOI: 10.1097/HJH.0b013e32832c0031.

Abstract:

OBJECTIVES\r\nWe tested the hypothesis that the voltages of QRS on ECG improve risk stratification in hypertensive patients without left ventricular hypertrophy on ECG.\r\nMETHODS AND RESULTS\r\nWe studied 2042 initially untreated patients with hypertension (mean age 49 years, 46% women) without left ventricular hypertrophy on ECG and no history of cardiovascular disease. At entry, all patients underwent diagnostic tests, including 24-h ambulatory blood pressure monitoring and echocardiography. Among the different ECG voltages, the R wave in lead aVL showed the closest association with left ventricle (LV) mass (r = 0.31; P < 0.001), followed by the R wave in D1 (r = 0.25) and the S wave in V3 (r = 0.22). Patients were followed up for a mean of 7.7 years (range 1-22 years), and treatment was tailored individually. During follow-up, there were 188 major cardiovascular events. The relationship between LV voltage and outcome was assessed using a Cox model with adjustment for age, sex, diabetes, smoking, total cholesterol, serum creatinine, LV mass on echocardiography and average 24-h ambulatory blood pressure. A 0.1 mV higher R wave voltage in lead aVL was associated with a 9% higher risk of cardiovascular disease (95% confidence interval = 0.04-0.15%; P < 0.001). Other ECG voltages and minor repolarization changes were not related to clinical outcome.\r\nCONCLUSION\r\nOur results show for the first time that the voltage of the R wave in lead aVL improves cardiovascular risk stratification in hypertensive patients without left ventricular hypertrophy on ECG. Its prognostic value is independent of LV mass on echocardiography and 24-h ambulatory blood pressure.

Predicting the duration of emotional experience: two experience sampling studies.

In: *Emotion* 9 (1), S. 83–91. DOI: 10.1037/a0014610.

Abstract:

The authors present 2 studies to explain the variability in the duration of emotional experience. Participants were asked to report the duration of their fear, anger, joy, gratitude, and sadness episodes on a daily basis. Information was further collected with regard to potential predictor variables at 3 levels: trait predictors, episode predictors, and moment predictors. Discrete-time survival analyses revealed that, for all 5 emotions under study, the higher the importance of the emotion-eliciting situation and the higher the intensity of the emotion at onset, the longer the emotional experience lasts. Moreover, a reappearance, either physically or merely mentally, of the eliciting stimulus during the emotional episode extended the duration of the emotional experience as well. These findings display interesting links with predictions within N. H. Frijda's theory of emotion, with the phenomenon of reinstatement (as studied within the domain of learning psychology), and with the literature on rumination.

A pilot study of a tool to stimulate physical activity in patients with COPD or type 2 diabetes in primary care.

In: *J Telemed Telecare* 20 (1), S. 29–34. DOI: 10.1177/1357633X13519057.

Abstract:

We tested the performance, acceptance and user satisfaction of a tool to stimulate physical activity. The tool consisted of an accelerometer, a smartphone app and a server/web application. Patients received feedback concerning their physical activity relative to a goal, which was set in dialogue with their practice nurse. Nurses could monitor their patients' physical activity via a website. Twenty patients with COPD or type 2 diabetes used the tool for three months, combined with behaviour change counselling. Physical activity data were collected at the server and a log file was used to record technical problems. We interviewed patients and nurses after every consultation. At baseline, and after the intervention, patients completed questionnaires. Participants were positive about the tool, although motivation dropped when technical problems occurred caused by log-in and connectivity errors. On average, physical activity increased from 29 (SD 21) min per day in the first two weeks to 39 (SD 24) min per day in the last two weeks (P = 0.02), and quality of life scores increased from 0.76 (SD 0.21) to 0.84 (SD 0.17) (P = 0.04). Provided that no connectivity problems occur, the tool is a feasible intervention when embedded in primary care, and has a positive effect on physical activity levels.

Verwey, Renee; van der Weegen, Sanne; Spreeuwenberg, Marieke; Tange, Huibert; van der Weijden, Trudy; Witte, Luc (2014):

Upgrading physical activity counselling in primary care in the Netherlands.

In: *Health Promot Int. DOI:* 10.1093/heapro/dau107.

Abstract:

The systematic development of a counselling protocol in primary care combined with a monitoring and feedback tool to support chronically ill patients to achieve a more active lifestyle. An iterative user-centred design method was used to develop a counselling protocol: the Self-management Support Programme (SSP). The needs and preferences of future users of this protocol were identified by analysing the literature, through qualitative research, and by consulting an expert panel. The counselling protocol is based on the Five A's model. Practice nurses apply motivational interviewing, risk communication and goal setting to support self-management of patients in planning how to achieve a more active lifestyle. The protocol consists of a limited number of behaviour change consultations intertwined with interaction with and responses from the It's LiFe! monitoring and feedback tool. This tool provides feedback on patients' physical activity levels via an app on their smartphone. A summary of these levels is automatically sent to the general practice so that practice nurses can respond to this information. A SSP to stimulate physical activity was defined based on user requirements of care providers and patients, followed by a review by a panel of experts. By following this user-centred approach, the organization of care was carefully taken into account, which has led to a practical and affordable protocol for physical activity counselling combined with mobile technology.

Vilardaga, Roger (2013):

An experience sampling study of psychological processes and their relation to functional outcome among individuals with severe psychopathology.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 74 (2-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-99160-333%26site%3dehost-live.

Abstract:

Background. The functional relations between daily contextual factors, psychological coping and functional outcome among individuals with severe psychopathology are still largely unexamined as compared to other aspects in this population, such as the genetic makeup of these individuals, their performance on cognitive tests, or their retrospective self-reports. Aims and method. To compare the role of cognitive and emotional regulation strategies versus contextual and behavioral regulation strategies in predicting different types of functional outcome after controlling for the occurrence of positive psychotic events and other negative stressors. A group of 31 individuals diagnosed with severe psychopathology from a Program for Assertive Community Treatment (PACT) of the Northern Nevada Adult Mental Health Services (NNAMHS) were recruited for this study. The study design was observational, with the added feature of an experience sampling method; 685 experience sampling moments were gathered during the course of six days. Additional psychological processes were examined in this study such as empathy, perspective taking ability and values. Results The study suggests that the occurrence of positive psychotic symptoms and stressful events had a negative impact on functional outcome, but not after accounting for the role of some contextual and behavioral regulation strategies. More specifically, behavioral regulation strategies such as experiential acceptance and overt avoidance had a superior association with functional outcome than emotional regulation strategies such as cognitive reappraisal. Moreover, data suggests that cognitive reappraisal tended to increase individual's distress, although not after accounting for cognitive suppression and overt avoidance. Finally, due to small sample size and design considerations it was not possible to reliably explore the association between perspective taking, values and functional outcome, however, additional exploratory analysis were conducted in order to test the direction and strength of these associations. Conclusions. Behavioral and contextual

regulation strategies seem to have a superior effect on functional outcome as compared to cognitive and emotional regulation strategies among individuals with severe psychopathology that regularly experience psychotic and/or negative experiences. Vilardaga, Roger; Hayes, Steven C.; Atkins, David C.; Bresee, Christie; Kambiz, Alaei (2013):

Comparing experiential acceptance and cognitive reappraisal as predictors of functional outcome in individuals with serious mental illness.

In: *Behav Res Ther* 51 (8), S. 425–433. DOI: 10.1037/t16491-000;

Abstract:

Background: Two psychological regulation strategies to cope with psychotic symptoms proposed by the cognitive behavioral tradition were examined in this study: cognitive reappraisal and experiential acceptance. Although cognitive behavior therapy for psychosis has increasing empirical support, little is known about the role of these two strategies using methods of known ecological validity. Methods: Intensive longitudinal data was gathered from 25 individuals diagnosed with a psychiatric disorder with psychotic features. During the course of six days we measured contextual factors, psychotic and stressful events, psychological regulation strategies and functional outcome. Results: Positive psychotic symptoms and stressful events had negative associations with quality of life and affect, whereas experiential acceptance had positive associations with them. Cognitive reappraisal had inconsistent associations with quality of life and no association with affect. Social interactions and engagement in activities had a positive association with quality of life. Results were supported by additional and exploratory analyses. Conclusions: Across measures of functional outcome, experiential acceptance appears to be an effective coping strategy for individuals facing psychotic and stressful experiences, whereas cognitive reappraisal does not. In order to inform treatment development efforts, results suggest the need to further investigate the role of these psychological regulation strategies using ecologically valid methods. Villars, C.; Bergouignan, A.; Dugas, J.; Antoun, E.; Schoeller, D. A.; Roth, H. et al. (2012):

Validity of combining heart rate and uniaxial acceleration to measure free-living physical activity energy expenditure in young men.

In: *J Appl.Physiol* (0161-7567 (Linking)). DOI: 10.1152/japplphysiol.01413.2011.

Abstract:

Background: Combining accelerometry (ACC) with heart rate (HR) monitoring is thought to improve activity energy expenditure (AEE) estimations compared to ACC alone. Objective: To evaluate the validity of ACC and HR used alone or combined to estimate AEE in free living conditions, compared to doubly-labeled water (DLW). Methods: Ten-day free-living AEE was measured by a DLW protocol in thirty-five 18-55 y men (11 lean active, 12 lean sedentary, 12 overweight sedentary) wearing an Actiheart (combining ACC and HR) and a RT3 accelerometer. AEE was estimated using group- or individual-calibration of the HR/AEE relationship, based on an exercise tolerance test. In a subset (n=21), AEE changes were measured after one month of detraining (active subjects) or an 8-week training (sedentary subjects). Results: Actiheart combined ACC/HR estimates were more accurate than estimates from HR or ACC alone. Accuracy of the Actiheart group-calibrated ACC/HR estimates was modest (intra-class correlation coefficient [ICC]=0.62), with no bias but high root mean square error (RMSE) and limits of agreement (LOA). The mean bias of the estimates was reduced by one third, like RMSE and LOA, by individual calibration (ICC=0.80). Contrasting with group-calibrated estimates, the Actiheart individual-calibrated ACC/HR estimates explained 38% of the variance of the DLW-AEE change (ICC=0.63). Conclusion: This study supports a good level of agreement between the Actiheart ACC/HR estimates and DLW-measured AEE in lean and overweight men with varying fitness levels. Individual calibration of the HR/AEE relationship is necessary for AEE-estimations at individual level rather than at group scale and for AEE change evaluation

Night-time heart rate cut-off point definition by resting office tachycardia in untreated hypertensive patients: data of the Spanish ABPM registry.

In: *J Hypertens* 32 (5), S. 1016–1024. DOI: 10.1097/HJH.0000000000000124.

Abstract:

OBJECTIVE: Epidemiological studies have shown that an elevated resting heart rate (HR) is a risk factor for both total and cardiovascular mortality. Our aim was to estimate the night-time HR cut-off point that best predicts cardiovascular risk office tachycardia in hypertensive patients. DESIGN AND METHOD: Untreated hypertensive patients without concomitant cardiovascular diseases were included. Office and ambulatory HRs were measured. Cardiovascular risk office tachycardia was defined by office HR at least 85 beats per minute (bpm). Different night-time HR cut-offs were estimated by receiver operating characteristic curve analyses to predict cardiovascular risk office tachycardia. The best cut-off was selected on the basis of its combined sensitivity and specificity. RESULTS: A total of 32 569 hypertensive patients were included: 46.5% women, mean age (SD) 52 (14) years, office blood pressure 146 (16)/89 (11) mmHg, diabetes 10.3%, smoking 19.2%, BMI 29 (6.8) kg/m, office HR 77 (11.2) bpm, and night-time HR 64.9 (9.3) bpm. A total of 7070 (21.7%) patients were found to have cardiovascular risk office tachycardia. The night-time HR value that better predicted cardiovascular risk office tachycardia was more than 66 bpm. In comparison with patients with night HR below this value, those with night-time tachycardia were predominantly women, younger, with higher ambulatory blood pressure, greater BMI, and higher prevalence of diabetes and smoking. All comparisons were statistically significant (P less than 0.001). CONCLUSION: A mean night-time HR more than 66 bpm is a good predictor of cardiovascular risk office tachycardia in untreated hypertensive patients and could be considered a variable associated with an increased cardiovascular risk.

Predicting arterial stiffness with ambulatory blood pressure: an 11-year follow-up.

In: *Clinical physiology and functional imaging* 28 (6), S. 378–383.

Abstract:

No prospective data have been published on whether ambulatory blood pressure (BP) works better than casual measurements in predicting arterial stiffness. This study with 11-year follow-up was launched to evaluate the usefulness of ambulatory intra-arterial BP in predicting pulse wave velocity (PWV). Ninety-seven previously healthy men were recruited from a routine physical check-up at baseline. BP was measured with standard cuff and intra-arterial ambulatory methods. Sixty-seven subjects with no antihypertensive medication were enrolled for a visit after a follow-up of 11 years. Arterial stiffness was estimated with PWV derived with impedance cardiography. Ambulatory 24-h systolic blood pressure (SBP) (r = 0·30, P = 0·01), 24-h mean arterial pressure (r = 0·27, P = 0·03), 24-h pulse pressure (r = 0·27, P = 0·03) and daytime SBP (r = 0·26, P = 0·03) were the best BP variables in predicting future PWV. Casual BP values did not bear significant correlations with future PWV. In hierarchical regression analysis, the best predictive value for future PWV was achieved with the model including ambulatory 24-h SBP, smoking (number of cigarettes) and age (adjusted R2 = 0·26). In conclusion, to our knowledge, this is the only prospective follow-up study to show that ambulatory BP is superior to casual BP measurement in predicting future PWV.

Volmer, J.; Binnewies, C.; Sonnentag, S.; Niessen, C. (2012):

Do social conflicts with customers at work encroach upon our private lives? A diary study.

In: *J Occup.Health Psychol.* 17 (3), S. 304–315. DOI: 10.1037/a0028454.

Abstract:

Social interactions at work can strongly influence people's well-being. Extending past research, we examined how social conflicts with customers at work (SCCs) are related to employees' well-being (i.e., state negative affect, NA) and nonwork experiences (i.e., psychological detachment from work and negative work reflection at home) on a daily level. Using experience-sampling methodology, we collected data from 98 civil service agents over 5 working days. Hierarchical linear modeling revealed that on the daily level, SCCs were related to employees' NA as well as with their nonwork experiences. Specifically, SCCs were negatively related to psychological detachment from work and positively related to negative work reflection after work. Furthermore, results provide support for the mediating role of NA in the SCC-nonwork experiences relationship. The findings of the present study broaden the scope of workplace conflict research by showing that conflicts are not only associated with employees' impaired well-being but even encroach on their nonwork experiences

Volz, Sebastian; Andersson, Bert; Manhem, Karin; Haraldsson, Inger; Rundqvist, Bengt (2014):

Effect of catheter-based renal sympathetic denervation on 24-h ambulatory blood pressure in patients with resistant hypertension.

In: *Blood Press. DOI:* 10.3109/08037051.2013.867663.

Abstract:

We investigated the effect of renal denervation on office blood pressure (OBP) and 24-h ambulatory blood pressure (BP) measurement (ABPM) at baseline and 6 months after intervention in 25 consecutive patients with resistant hypertension. Mean baseline 24-h ABPM and OBP were 158/88 mmHg and 169/96 mmHg, respectively. Patients were treated with an average of 4 +/- 1 antihypertensive drugs. Among the 22 patients included in data analysis, mean ambulatory systolic and diastolic BP were reduced by 6 mmHg from 158 +/- 17 to 152 +/- 20 mmHg ($p < 0.05$) and by 3 mmHg from 88 +/- 12 to 85 +/- 14 mmHg (p = ns) after 6 months follow-up, respectively. Blood pressure reduction was most pronounced during daytime with a decrease of 9 mmHg from 164 +/- 17 to 155 +/- 19 ($p < 0.05$) in systolic (SBP) and 6 mmHg from 94 +/- 14 to 88 +/- 14 mmHg in diastolic BP (DBP) ($p < 0.05$). Night-time SBP mmHg and DBP were similar at baseline compared with follow-up. Systolic and diastolic OBP during follow-up were significantly reduced by 17 mmHg from 169 +/- 20 to 152 +/- 21 ($p < 0.05$) and by 9 mmHg from 96 +/- 16 to 87 +/- 13 mmHg ($p < 0.05$), respectively. These results provide new insight into the effect of renal denervation on ABPM day- and night-time blood pressure profile in comparison with OBP. The decrease in ABPM was identified during daytime registration and was less pronounced compared with reduction of OBP.

Volz, Angela R.; Dennis, Paul A.; Dennis, Michelle F.; Calhoun, Patrick S.; Wilson, Sarah M.; Beckham, Jean C. (2014):

The Role of Daily Hassles and Distress Tolerance in Predicting Cigarette Craving During a Quit Attempt.

In: *Nicotine Tob Res. DOI:* 10.1093/ntr/ntt286.

Abstract:

INTRODUCTION: Ecological momentary assessment (EMA) has shown that smoking behavior is linked to transient variables in the smoker's immediate context. Such research suggests that daily hassles (e.g., losing one's keys) may be more likely to lead to cigarette craving and eventual lapse than infrequent, large-scale stressors (e.g., death of a loved one) in individuals attempting to quit smoking. However, individual differences in distress tolerance (DT) may moderate the relationship between daily hassles and daily cigarette craving during a quit attempt. METHODS: A sample of 56 veterans and community members drawn from a larger smoking-cessation study completed structured interviews and paper-and-pencil questionnaires during an initial laboratory visit and, directly following a quit attempt, were monitored via EMA. Multilevel modeling was used to examine the relationship between daily hassles and daily cigarette craving, and to determine whether DT moderated this relationship. RESULTS: Daily hassles were positively associated with daily cigarette craving, and this association was moderated by individual differences in DT, such that the lower one's DT, the stronger the relationship between daily hassles and daily cigarette craving. This model explained 13% of the intraindividual variability and 8% of the interindividual variability in daily cigarette craving. CONCLUSIONS: Smoking-cessation interventions may be strengthened by targeting smokers' individual responses to contextual factors, such as by helping smokers develop skills to cope more effectively with distress prior to and during the quit phase.

Voogt, C. V.; Kuntsche, E.; Kleinjan, M.; Poelen, E. A.; Lemmers, L. A.; Engels, R. C. (2013):

Using ecological momentary assessment in testing the effectiveness of an alcohol intervention: a two-arm parallel group randomized controlled trial.

In: *PLoS.One.* 8 (11), S. e78436. DOI: 10.1371/journal.pone.0078436.

Abstract:

BACKGROUND: Alcohol consumption of college students has a fluctuating nature, which might impact the measurement of intervention effects. By using 25 follow-up time-points, this study tested whether intervention effects are robust or might vary over time. METHODS: Data were used from a two-arm parallel group randomized controlled trial applying ecological momentary assessment (EMA) with 30 data time-points in total. Students between 18 and 24 years old who reported heavy drinking in the past six months and who were ready to change their alcohol consumption were randomly assigned to the experimental (n = 456: web-based brief alcohol intervention) and control condition (n = 451: no intervention). Outcome measures were weekly alcohol consumption, frequency of binge drinking, and heavy drinking status. RESULTS: According to the intention-to-treat principle, regression analyses revealed that intervention effects on alcohol consumption varied when exploring multiple follow-up time-points. Intervention effects were found for a) weekly alcohol consumption at 1, 2, 3, 4, and 7 weeks follow-up, b) frequency of

binge drinking at 1, 2, 7, and 12 weeks follow-up, and c) heavy drinking status at 1, 2, 7, and 16 weeks follow-up. CONCLUSIONS: This research showed that the commonly used one and six month follow-up time-points are relatively arbitrary and not using EMA might bring forth erroneous conclusions on the effectiveness of interventions. Therefore, future trials in alcohol prevention research and beyond are encouraged to apply EMA when assessing outcome measures and intervention effectiveness. TRIAL REGISTRATION: Netherlands Trial Register NTR2665

Voogt, Carmen V.; Kuntsche, Emmanuel; Kleinjan, Marloes; Engels, Rutger C M E (2014):

The effect of the 'What Do You Drink' web-based brief alcohol intervention on self-efficacy to better understand changes in alcohol use over time: Randomized controlled trial using ecological momentary assessment.

In: *Drug Alcohol Depend. DOI:* 10.1016/j.drugalcdep.2014.02.009.

Abstract:

BACKGROUND: To examine whether (1) the 'What Do You Drink' (WDYD) intervention resulted in drinking refusal self-efficacy (DRSE) changes directly after the intervention, and if so, whether these changes sustained at six-months follow-up and (2) DRSE was related to alcohol use over time, and if so, whether the strength of these relationships differed across conditions. Insight herein can help explain the sustained preventive effects of the WDYD intervention on alcohol use, as reported previously. METHODS: Alcohol use and DRSE data were collected from 907 participants (60.3% male; M=20.8 (SD=1.7) in a two-arm parallel group randomized controlled trial applying ecological momentary assessment with 30 time-points. Participants were randomized to the experimental (n=456: WDYD intervention) or control condition (n=451: no intervention). RESULTS: Latent Growth Curve (LGC) analyses that modeled individual change in DRSE over time by condition revealed that participants in the experimental condition experienced a higher social pressure DRSE compared to participants in the control condition at six-months follow-up. Moreover, LGC analyses with time-varying covariates revealed that DRSE was negatively related to weekly alcohol consumption and social pressure DRSE to frequency of binge drinking. The WDYD intervention did not affect the strength of these relationships. CONCLUSIONS: The WDYD intervention increased the level of social pressure DRSE directly after the intervention that sustained at six-months follow-up. This change is likely to be responsible for the sustained preventive effects of the WDYD intervention on alcohol use, as reported previously.

Voogt, Carmen; Kuntsche, Emmanuel; Kleinjan, Marloes; Poelen, Evelien; Engels, Rutger (2014):

Using ecological momentary assessment to test the effectiveness of a web-based brief alcohol intervention over time among heavy-drinking students: randomized controlled trial.

In: *J Med Internet Res* 16 (1), S. e5. DOI: 10.2196/jmir.2817.

Abstract:

BACKGROUND: Web-based brief alcohol interventions are effective in reducing alcohol use among students when measured at limited follow-up time points. To date, no studies have tested Web-based brief alcohol intervention effectiveness over time by using a large number of measurements. OBJECTIVE: Testing whether the What Do You Drink (WDYD) Web-based brief alcohol intervention can sustain a reduction in alcohol use among heavy-drinking students aged 18-24 years at 1-, 3-, and 6-month follow-up intervals. METHODS: A purely Web-based, 2-arm, parallel-group randomized controlled trial applying an ecological momentary assessment approach with 30 weekly measurements was conducted in the Netherlands (2010-2011). Participants were recruited offline and online. A total of 907 participants were randomized into the experimental condition (n=456) including the single-session and fully automated WDYD intervention, or into the control condition (n=451) including assessment only. Weekly alcohol consumption and frequency of binge drinking were the self-assessed outcome measures. RESULTS: Attrition rates of the 907 participants were 110 (12.1%), 130 (14.3%), and 162 (17.9%) at 1-, 3-, and 6-month follow-up intervals, respectively. Latent growth curve analyses according to the intention-to-treat principle revealed that participants in the experimental condition had significantly lower weekly alcohol consumption compared to participants in the control condition that was sustained at 3-month follow-up (intercept=-2.60, P<.001; slope=0.16, P=.08). Additional linear regression analyses indicated that this intercept difference resulted from significantly higher levels of alcohol units per week for participants in the control condition compared to those in the experimental condition at 1-month (beta=-2.56, SE 0.74, Cohen's d=0.20, P=.001), 3-month (beta=-1.76, SE 0.60, Cohen's d=0.13, P=.003), and 6-month (beta=-1.21, SE 0.58, Cohen's d=0.09, P=.04) follow-up intervals. Latent growth curve analyses further indicated that participants in the experimental condition had a significantly lower frequency of binge drinking compared to participants in the control condition that was sustained at 6-month follow-up (intercept=-0.14, P=.01; slope=0.004, P=.19). This intercept difference resulted from higher levels in this outcome for participants in the control condition relative to participants in the experimental condition at 1-month (beta=-1.15, SE 0.06, Cohen's d=0.16,

P=.01), 3-month (beta=-0.12, SE 0.05, Cohen's d=0.09, P=.01), and 6-month (beta=-0.09, SE 0.05, Cohen's d=0.03, P=.045) follow-up intervals. CONCLUSIONS: The WDYD intervention was shown to be effective in preventing an increase in weekly alcohol consumption and frequency of binge drinking directly after the intervention. This effect was sustained 3 and 6 months after the intervention. TRIAL REGISTRATION: Netherlands Trial Register NTR2665; http://www.trialregister.nl/trialreg/admin/rctview.asp?TC=2665 (Archived by WebCite at http://webcitation.org/6LuQVn12M).

Vorwerg, Y.; Petroff, D.; Kiess, W.; Bluher, S. (2013):

Physical activity in 3-6 year old children measured by SenseWear Pro(R): direct accelerometry in the course of the week and relation to weight status, media consumption, and socioeconomic factors.

In: *PLoS.One.* 8 (4), S. e60619. DOI: 10.1371/journal.pone.0060619.

Abstract:

BACKGROUND: Data on objectively measured physical activity (PA) in preschoolers are controversial. Direct accelerometry was performed in children aged 3-6 years, and differences in PA patterns over the course of the week were evaluated. Data were analyzed with gender, BMI, lifestyle, and socioeconomic parameters as covariates. METHODS: PA was measured in 119 children by the SensewearPro(R) accelerometer and analyzed in the 92 (40 girls) that wore it for at least 4 days including one day of the weekend. Median measuring time in this group was 7 consecutive days (median/mean daily measuring time: 23.5 h/d and 21.8 h/d, respectively), corresponding to 834,000 analyzed minutes. PA questionnaires were completed by 103 parents and 87 preschool teachers to collect anthropometric, lifestyle, and socioeconomic data. RESULTS: Median daily PA (MET>3) was 4.3 hours (mean: 4.4 hours). Boys spent an estimated 52 min/week more being very active (MET>6) than girls (95% CI [6, 96] min/week, p = 0.02). PA was lower during the weekend (3.7 h/d) compared to weekdays (4.5 h/d), p = 3 x 10(-6)), where a 95% CI for the difference is [0.5, 1.0] h/d. PA levels did not differ between overweight/obese children (median 4.7 h/d) and normal-weight peers (median 4.2 h/d). Daily media consumption increased with decreasing social class on weekdays (p = 0.05) and during the weekend (p = 0.01), but was not related to the amount of daily PA. A multivariate regression with BMI-SDS as independent variable and gender, age, amount of PA>6 MET, parental BMI, media time and socioeconomic status as explanatory variables revealed that only SES had a significant contribution. CONCLUSION: The negative impact of obesity-promoting factors in older children is rather low for preschoolers, but there is evidently a gradient in PA between weekdays and weekends already in this age group. Weight status of preschoolers is already considerably influenced by SES, but not physical activity levels

Pervasive e-health services using the dvb-rcs communication technology.

In: *J Med Syst* 31 (4), S. 237–246.

Abstract:

Two-way satellite broadband communication technologies, such as the Digital Video Broadcasting with Return Channel via Satellite (DVB-RCS) technology, endeavour to offer attractive wide-area broadband connectivity for telemedicine applications, taking into consideration the available data rates, Quality of Service (QoS) provision, survivability, flexibility and operational costs, even in remote areas and isolated regions where the terrestrial technologies suffer. This paper describes a wide-area tele-medicine platform, specially suited for homecare services, based on the DVB-RCS and Wi-Fi communication technologies. The presented platform combines medical data acquisition and transfer, patient remote monitoring and teleconference services. Possible operational scenarios concerning this platform and experimental results regarding tele-monitoring, videoconference and medical data transfer are also provided and discussed in the paper.

Depressive symptoms and momentary affect: the role of social interaction variables.

In: *Depression and anxiety* 26 (5), S. 464–470. DOI: 10.1002/da.20384.

Abstract:

BACKGROUND\r\nInterpersonal functioning may be one important factor in the development and course of depression symptomatology. This study used ecological momentary assessment to test the associations among depressive symptoms, social experiences and momentary affect in women.\r\nMETHODS\r\nMiddle-aged women (N=108, M age: 41.6 years, 81% White)

completed diary questions on handheld computers for 2 days. Diary items assessed social (conflictive versus supportive) and affective (negative versus positive) experiences at random times during the day. Women also completed a self-report measure of recent depressive symptoms.\r\nRESULTS\r\nMultilevel modeling analyses showed that higher levels of symptoms of depression were related to higher negative affect and lower positive affect both directly and indirectly, through experiences of social conflict. Depressive symptoms were not significantly related to socially supportive interactions. In an alternative model testing the reverse association, neither positive nor negative affect significantly predicted social experiences. Generalizability is limited by the homogenous small sample and strict inclusionary criteria (working full-time or part-time, cohabitating or married, healthy). Due to the cross sectional nature of the data as well as the manner in which social and affective experiences were assessed, definitive conclusions regarding the temporal associations among depression symptoms, social functioning, and affect are not possible. Results are consistent with prior reports suggesting the salience of socially conflictive experiences, and the role of affect, in the etiology and maintenance of depression symptoms.\r\nCONCLUSIONS\r\nInterventions that attempt to decrease socially conflictive experiences via cognitive-behavioral skills training, whereas concomitantly targeting positive and negative affect, could help prevent the development of full-blown depressive episodes in vulnerable individuals.

Vrijheid, Martine (2014):

The exposome: a new paradigm to study the impact of environment on health.

In: *Thorax. DOI:* 10.1136/thoraxjnl-2013-204949.

Abstract:

Environmental factors, here taken to include pollutants, lifestyle factors and behaviours, can play an important role in serious, chronic pathologies with large societal and economic costs, including respiratory disease. However, measurement of the environmental component in epidemiological studies has traditionally relied on much more uncertain and incomplete assessments than measurement of the genome. The 'exposome' has therefore been proposed as a new paradigm to encompass the totality of human environmental (meaning all non-genetic) exposures from conception onwards, complementing the genome. Evidently, there are large challenges in developing the exposome concept into a workable approach for epidemiological research. These include: (1) the accurate and reliable measurement of many exposures in the external environment, (2) the measurement of a wide range of biological responses in the internal environment, and (3) addressing the dynamic, life course nature of the exposome. New tools and technologies that can be applied to address these challenges include exposure biomarker technologies, geographical mapping and remote sensing technologies, smartphone applications and personal exposure sensors, and high-throughput molecular 'omics' techniques. Prospective, population-based cohort studies have recently started to implement these methods using the exposome framework. The exposome thus offers a new and exciting paradigm for improvement and integration of currently scattered and uncertain data on the environmental component in disease aetiology. This should lead to a better understanding of the role of environmental risk factors in respiratory disease and other chronic pathologies, and ultimately to better primary prevention strategies.

Vyssoulis, Gregory; Karpanou, Eva; Adamopoulos, Dionysios; Kyvelou, Stella-Maria; Gymnopoulou, Elpida; Cokkinos, Dennis; Stefanadis, Christodoulos (2008):

Nocturnal blood pressure fall and metabolic syndrome score in patients with white coat hypertension.

In: *Blood Press Monit* 13 (5), S. 251–256.

Abstract:

Background: Accumulating data report that white coat hypertension (WCH) is associated with target organ damage. Metabolic syndrome (MS), and nondipping pattern is also associated with increased cardiovascular risk. The purpose of this study was to explore the nocturnal blood pressure fall in WCH patients according to their MS score.

Methods: The study comprised 2300 patients with WCH who attended our outpatient clinics. All underwent repeated office blood pressure measurements, 24-h ambulatory blood pressure monitoring, full clinical and laboratory evaluation. The diagnosis of MS was made according to the Adult Treatment Panel III criteria and patients were classified into five groups: group I (hypertension), group II (hypertension and any one component), group III (hypertension and any two components), group IV (hypertension and any three components), and group V (all five components). Dipping pattern was defined as ‘dippers’ with nocturnal systolic blood pressure (NSBP) fall greater than or equal to 10% but less than 20%, ‘nondippers’ with NSBP fall greater than or equal to 0% but less than 10%, ‘extreme dippers’ with NSBP fall greater than or equal to 20%, and ‘reverse dippers’ with NSBP increase.

Results: Patients were divided into two groups according to the presence (n=522) and absence (n=1778) of MS. The overall prevalence of MS in the study population was 22.7%. Comparing the non-MS group with the MS we observed significant

differences for nondippers (24.5% vs. 38.9%, P<0.001), dippers (54.4% vs. 43.5%, P<0.001), extreme dippers (17.8% vs. 11.3%, P<0.001), and reverse dippers (3.3% vs. 6.3%, P=0.007).

Conclusion: Patients with WCH and increased number of MS components present with elevated nighttime SBP levels. This observation is of a great significance in the assessment of the cardiovascular risk in these patients.

Wackel, Philip; Beerman, Lee; West, Laura; Arora, Gaurav (2014):

Tachycardia Detection Using Smartphone Applications in Pediatric Patients.

In: *J Pediatr. DOI:* 10.1016/j.jpeds.2014.01.047.

Abstract:

OBJECTIVES: To use smartphone applications (apps) to measure heart rates during supraventricular tachycardia (SVT) in pediatric patients and compare them with heart rates measured by standard electrocardiogram (ECG). STUDY DESIGN: Patients <18 years of age (n = 26) undergoing an electrophysiology study were enrolled. During the study, heart rates were measured at baseline and during SVT by the use of 2 smartphone apps. The obtained heart rates were compared with a simultaneous standard ECG. Pearson correlation coefficient (r) was used to compare the accuracy of the apps with ECG. RESULTS: At baseline, 33 heart rates were obtained with apps and all were within +/-4 beats per minute (bpm) of the ECG heart rate. During SVT, 38 heart rate measurements were attempted during 21 SVT events in 18 patients. App 1 failed to provide a measured heart rate in 11 of 21 attempts. The 10 heart rates obtained had an r of 0.56. When tachycardia rates were <210 bpm, accuracy increased (r = 0.86) and when tachycardia rates were <200 bpm, the accuracy increased further (r = 0.99). App 2 failed to provide a measured heart rate in 12 of 17 attempts. The 5 heart rates obtained had an r of -0.43. CONCLUSIONS: During tachycardia, neither of the 2 apps consistently determined an accurate heart rate at rates >200 bpm. The apps tested should not be considered an accurate tool for assessment of heart rates during SVT in pediatric patients. Select apps may have utility detecting slower SVT or confirming normal heart rates with further validation.

Ambulatory blood pressure monitoring: essential for diagnosing and treating hypertension?

In: *Rev Med Suisse* 10 (412-413), S. 57-8, 60.

Abstract:

According to recent international guidelines, 24-h ambulatory blood pressure monitoring plays an important role in the diagnostic and therapeutic approach of arterial hypertension. Indications of this technique are multiple, concerning both day- and night-time blood pressures. Blood pressures provided by ambulatory monitoring may be used to stratify cardiovascular risk.

Driving it home: How workplace emotional labor harms employee home life.

In: *Personnel Psychology* 67 (2), S. 487–516. DOI: 10.1037/t16260-000.

Abstract:

To date, the majority of research on emotional labor has focused on outcomes that occur in the workplace. However, research has yet to consider the possibility that the daily effects of emotional labor spill over to life outside of work, even though a large body of literature examining the spillover from work life to home life indicates that work experiences influence employees after they leave the workplace. Accordingly, we examined the influence of day-to-day surface acting on 3 types of theoretically derived stress outcomes experienced at home: emotional exhaustion, work-to-family conflict, and insomnia. In an experience sampling field study of 78 bus drivers, we found that daily surface acting was connected to increases in each of the outcomes noted above. Moreover, surface acting had an indirect effect on emotional exhaustion and insomnia via state anxiety. (PsycINFO Database Record (c) 2014 APA, all rights reserved). (journal abstract)

Walerius, Danielle M.; Reyes, Rachel A.; Rosen, Paul J.; Factor, Perry I. (2014):

Functional Impairment Variability in Children With ADHD Due to Emotional Impulsivity.

In: *J Atten Disord. DOI:* 10.1177/1087054714561859.

Abstract:

OBJECTIVE: The present study utilized ecological momentary assessment (EMA) to examine the effects of emotional impulsivity on overall functional impairment and functional impairment variability (FIV) of children with and without ADHD. METHOD: Parents of 74 children, 8- to 12-year-olds (42 with ADHD, 32 without ADHD), completed EMA assessment protocol ratings of their child's mood (3 times daily) and functional impairment (1 time daily) over the course of 28 days. RESULTS: Hierarchical regression analyses supported the interaction of ADHD diagnostic status and greater EMA-derived emotional impulsivity in the estimation of total functional impairment (Total FI) and FIV. Thus, greater emotional impulsivity was found to be related to greater Total FI and FIV among children with ADHD but not among children without ADHD. CONCLUSION: This study suggests that children with ADHD and greater emotional impulsivity demonstrate greater overall levels of functional impairment, with the severity of their impairment varying significantly over time.

Walker, Paul P.; Burnett, Angela; Flavahan, Paul W.; Calverley, Peter M. A. (2008):

Lower limb activity and its determinants in chronic obstructive pulmonary disease.

In: *Thorax*.

Abstract:

Background: Patients with chronic obstructive pulmonary disease (COPD) walk less than healthy older people and their self-reported activity predicts exacerbation risk. The relationship between lower limb activity and total daily activity is not known, nor are there any data which relate objectively assessed daily activity to laboratory assessments made before and after rehabilitation.

Methods: Lower limb activity was measured by leg actigraphy over 3 days in 45 patients with moderate to severe COPD and 18 controls of similar age. Thirty-three patients with COPD entered an 8-week rehabilitation programme in which the change in leg activity was measured and related to other outcomes.

Results: In patients with COPD the mean level of activity measured by whole body and leg activity monitors was closely related ($r = 0.92$; $p < 0.001$), but leg activity was consistently reduced compared with controls of similar age ($p = 0.001$). Mean leg activity, mean intensity of leg activity and the time that patients spent mobile at home were all related to forced expiratory volume in 1 s (FEV1) ($r = 0.57$, $p = 0.001$; $r = 0.5$, $p = 0.003$; and $r = 0.51$, $p = 0.002$, respectively), but intensity of activity and time spent mobile were not related. Subjects completing pulmonary rehabilitation showed significant improvements in mean activity ($p = 0.001$) and spent more time moving ($p = 0.014$). These changes were unrelated to improvement in muscle strength or walking distance but correlated with baseline FEV1 ($r = 0.8$, $p < 0.001$).

Conclusions: Total daily activity in patients with COPD is closely related to leg activity which is reduced compared with controls of similar age. Individuals differ in the time spent mobile during the day, but subjective and objectively assessed activity improves after rehabilitation and is predicted by FEV1. The change in activity is unrelated to improvements in corridor walking and health status.

Wallace, Lorraine S.; Dhingra, Lara K. (2014):

A systematic review of smartphone applications for chronic pain available for download in the United States.

In: *J Opioid Manag* 10 (1), S. 63–68. DOI: 10.5055/jom.2014.0193.

Abstract:

OBJECTIVE: A Smartphone app could be useful in aiding patients in self-monitoring and self-managing their chronic pain-related symptoms. The purpose of this study was to systematically review English-language pain-related Smartphone apps available for download in the United States. DESIGN: During July 2012, official Android, BlackBerry, and iPhone Smartphone app platform stores were searched. "Pain" was entered into the search-bar of each Smartphone app store. Of the pain apps meeting inclusion criteria, the following were retrieved: release date, download cost (US dollars [US $], file size, documentation of a healthcare professional's (HCP) involvement in app development, primary purpose of the app (pain education, pain self-management, or a combination of pain education and self-management), targeted pain-related condition(s), and inclusion of features that addressed four common self-monitoring and/or management strategies. RESULTS: Of the 220 apps meeting inclusion criteria, the majority were available through the iPhone (80.0 percent). The cost for downloading each app ranged from US $0.00 to 89.99; however, the majority of apps were </=US $4.99. There was no evidence of HCP involvement in the development of the

majority of apps (65.0 percent). Chronic, nonspecific pain was the focus of half (50.5 percent) of the apps, followed by back and/or neck pain (25.9 percent). The primary purpose of the apps was categorized as follows: pain education (n = 53, 24.1 percent), pain self-management (n = 137, 62.3 percent), and both pain education and self management (n = 30, 13.6 percent). CONCLUSION: Overall, most of the pain-related apps included within our review not only lacked evidence of HCP input regarding development but also contained few evidence-based pain management features.

Waller, Jennifer M.; Silk, Jennifer S.; Stone, Lindsey B.; Dahl, Ronald E. (2014):

Co-rumination and co-problem solving in the daily lives of adolescents with major depressive disorder.

In: *J Am Acad Child Adolesc Psychiatry* 53 (8), S. 869–878. DOI: 10.1016/j.jaac.2014.05.004.

Abstract:

OBJECTIVE: This study examines differences in the prevalence and nature of co-rumination during real-world social interactions with peers and parents among adolescents with major depressive disorder (MDD) compared to healthy controls. METHOD: A total of 60 youth (29 with current MDD and 31 controls without psychopathology) completed a self-report measure of co-rumination and a 3-week ecological momentary assessment (EMA) protocol that measured the nature of face-to-face social interactions with peers and parents after a negative event in the adolescents' daily lives. Specifically, EMA was used to assess rates of problem talk, including both co-rumination and co-problem solving. Group differences in self-report and EMA measures were examined. RESULTS: Adolescents with MDD reported co-ruminating more often than adolescents with no Axis 1 disorders during daily interactions with both parents (Cohen's d = 0.78) and peers (d = 1.14), and also reported more co-rumination via questionnaire (d = 0.58). Adolescents with MDD engaged in co-problem solving with peers less often than did healthy controls (d = 0.78), but no group differences were found for rates of co-problem solving with parents. CONCLUSIONS: Results are consistent with previous research linking co-rumination and depression in adolescence and extend these self-report-based findings to assessment in an ecologically valid context. Importantly, the results support that MDD youth tend to co-ruminate more and to problem-solve less with peers in their daily lives compared to healthy youth, and that co-rumination also extends to parental relationships. Interventions focused on decreasing co-rumination with peers and parents and improving problem-solving skills with peers may be helpful for preventing and treating adolescent depression.

Walter, K.; Von, Haaren B.; Loffler, S.; Hartel, S.; Jansen, C. P.; Werner, C. et al. (2013):

Acute and medium term effects of a 10-week running intervention on mood state in apprentices.

In: *Front Psychol* 4 (1664-1078 (Electronic)), S. 411. DOI: 10.3389/fpsyg.2013.00411.

Abstract:

Exercise and physical activity have proven benefits for physical and psychological well-being. However, it is not clear if healthy young adults can enhance mood in everyday life through regular exercise. Earlier studies mainly showed positive effects of acute exercise and exercise programs on psychological well-being in children, older people and in clinical populations. Few studies controlled participants' physical activity in daily life, performed besides the exercise program, which can impact results. In addition the transition from mood enhancement induced by acute exercise to medium or long-term effects due to regular exercise is not yet determined. The purpose of this pilot study was to examine the acute effects of an aerobic running training on mood and trends in medium term changes of mood in everyday life of young adults. We conducted a 10-week aerobic endurance training with frequent mood assessments and continuous activity monitoring. 23 apprentices, separated into experimental and control group, were monitored over 12 weeks. To control the effectiveness of the aerobic exercise program, participants completed a progressive treadmill test pre and post the intervention period. The three basic mood dimensions energetic arousal, valence and calmness were assessed via electronic diaries. Participants had to rate their mood state frequently on 3 days a week at five times of measurement within 12 weeks. Participants' physical activity was assessed with accelerometers. All mood dimensions increased immediately after acute endurance exercise but results were not significant. The highest acute mood change could be observed in valence (p = 0.07; eta(2) = 0.27). However, no medium term effects in mood states could be observed after a few weeks of endurance training. Future studies should focus on the interaction between acute and medium term effects of exercise training on mood. The decreasing compliance over the course of the study requires the development of strategies to maintain compliance over longer periods

Walther, Sebastian; Horn, Helge; Razavi, Nadja; Koschorke, Philipp; Müller, Thomas J.; Strik, Werner (2009):

Quantitative motor activity differentiates schizophrenia subtypes.

In: *Neuropsychobiology* 60 (2), S. 80–86. DOI: 10.1159/000236448.

Abstract:

BACKGROUND\r\nMotor symptoms are frequent in schizophrenia and relevant to the diagnosis of subtypes. However, the assessment has been limited to observations recorded in scales and experimental designs. The aim of this study was to use wrist actigraphy to obtain motor activity data in 3 schizophrenia subtypes.\r\nMETHODS\r\nIn total, 60 patients with schizophrenia (35 paranoid, 12 catatonic, 13 disorganized) were investigated using continuous wrist actigraphy over 24 h in an inpatient setting on average 38 days after admission. Data of the wakeful hours of the day were analyzed.\r\nRESULTS\r\nThe activity level was predicted by schizophrenia subtype and by the type of antipsychotic medication. The movement index and mean duration of uninterrupted immobility were found to be predicted only by the schizophrenia subtype. Age, gender, duration of illness and chlorpromazine equivalents did not contribute to the variance of the activity data. A MANOVA demonstrated the significant differences in the 3 parameters between schizophrenia subtypes (p = 0.001). Patients with catatonic schizophrenia had lower activity levels, a lower movement index and a longer duration of immobility than those with paranoid schizophrenia.\r\nCONCLUSIONS\r\nSchizophrenia subtypes can be differentiated using objective measures of quantitative motor activity. The increased duration of immobility appears to be the special feature of catatonic schizophrenia.

Walther, S.; Hugli, S.; Hofle, O.; Federspiel, A.; Horn, H.; Bracht, T. et al. (2012):

Frontal white matter integrity is related to psychomotor retardation in major depression.

In: *Neurobiol.Dis.* (0969-9961 (Linking)). DOI: 10.1016/j.nbd.2012.03.019.

Abstract:

Altered frontal white matter integrity has been reported in major depression. Still, the behavioral correlates of these alterations are not established. In healthy subjects, motor activity correlated with white matter integrity in the motor system. To explore the relation of white matter integrity and motor activity in major depressive disorder, we investigated 21 medicated patients with major depressive disorder and 21 matched controls using diffusion tensor imaging and wrist actigraphy at the same day. Patients had lower activity levels (AL) compared with controls. Fractional anisotropy (FA) differed between groups in frontal white matter regions and the posterior cingulum. AL was linearly associated with white matter integrity in two clusters within the motor system. Controls had an exclusive positive association of FA and AL in white matter underneath the right dorsal premotor cortex. Only patients had a positive association within the posterior cingulum. Furthermore, patients had negative associations of FA and AL underneath the left primary motor cortex and within the left parahippocampal gyrus white matter. These differences in the associations between structure and behavior may contribute to well-known impaired motor planning or gait disturbances in major depressive disorder. Therefore, signs of psychomotor slowing in major depressive disorder may be linked to changes of the white matter integrity of the motor system

Walther, Sebastian; Koschorke, Philipp; Horn, Helge; Strik, Werner (2009):

Objectively measured motor activity in schizophrenia challenges the validity of expert ratings.

In: *Psychiatry Res* 169 (3), S. 187–190. DOI: 10.1016/j.psychres.2008.06.020.

Abstract:

Motor symptoms are frequent in schizophrenia and relevant to diagnosis. They are usually assessed by clinical observation and ratings based on psychometric scales. However, investigations with quantitative measurements are rare. To understand the relationship between the objective parameters of a quantitative motor activity measurement and the items related to motor symptoms of the Positive and Negative Syndrome Scale (PANSS), 55 schizophrenia patients were studied with 24-h continuous wrist actigraphy. Activity level, movement index, and mean duration of uninterrupted immobility periods were analyzed for wakeful periods. Actigraphic parameters were strongly inter-correlated. High PANSS negative syndrome subscale scores predicted low activity levels. Single PANSS items, such as suspiciousness, hallucinatory behavior, and emotional withdrawal, contributed largely to the variance in activity level and movement index. Age, gender, medication, and duration of illness had no significant impact on the actigraphic parameters. Interestingly, correlations between the specific motor symptoms of the PANSS and the actigraphic parameters were only found as a non-significant trend. We conclude that the objectively measured quantity of movement is related to the clinically assessed negative syndrome in schizophrenia. In contrast, PANSS items related to psychomotor behavior imprecisely reflect real quantitative motor activity.

Walther, S.; Ramseyer, F.; Horn, H.; Strik, W.; Tschacher, W. (2013):

Less Structured Movement Patterns Predict Severity of Positive Syndrome, Excitement, and Disorganization.

In: *Schizophr.Bull* (0586-7614 (Linking)). DOI: 10.1093/schbul/sbt038.

Abstract:

Disorganized behavior is a key symptom of schizophrenia. The objective assessment of disorganized behavior is particularly challenging. Actigraphy has enabled the objective assessment of motor behavior in various settings. Reduced motor activity was associated with negative syndrome scores, but simple motor activity analyses were not informative on other symptom dimensions. The analysis of movement patterns, however, could be more informative for assessing schizophrenia symptom dimensions. Here, we use time series analyses on actigraphic data of 100 schizophrenia spectrum disorder patients. Actigraphy recording intervals were set at 2 s. Data from 2 defined 60-min periods were analyzed, and partial autocorrelations of the actigraphy time series indicated predictability of movements in each individual. Increased positive syndrome scores were associated with reduced predictability of movements but not with the overall amount of movement. Negative syndrome scores were associated with low activity levels but unrelated with predictability of movement. The factors disorganization and excitement were related to movement predictability but emotional distress was not. Thus, the predictability of objectively assessed motor behavior may be a marker of positive symptoms and disorganized behavior. This behavior could become relevant for translational research

Walz, Laura C.; Nauta, Maaike H.; Aan Het Rot, Marije (2014):

Experience sampling and ecological momentary assessment for studying the daily lives of patients with anxiety disorders: A systematic review.

In: *J Anxiety Disord* 28 (8), S. 925–937. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-52177-025%26site%3dehost-live.

Abstract:

Anxiety disorders are highly prevalent. Symptoms may occur unpredictably (e.g., panic attacks) or predictably in specific situations (e.g., social phobia). Consequently, it may be difficult to assess anxiety and related constructs realistically in the laboratory or by traditional retrospective questionnaires. Experience sampling methods (ESM) and ecological momentary assessment (EMA) can deepen the understanding of the course of anxiety disorders by frequently assessing symptoms and other variables in the natural environment. We review 34 ESM/EMA studies on adult panic disorder, generalized anxiety disorder, social phobia, post-traumatic stress disorder, and obsessive–compulsive disorder, as well as anxiety disorders in youth. Benefits of ESM/EMA for the study of anxiety disorders include generating insight into the temporal variability of symptoms and into the associations among daily affect, behaviors, and situational cues. Further, ESM/EMA has been successfully combined with ambulatory assessment of physiological variables and with treatment evaluations. We provide suggestions for future research, as well as for clinical applications. (PsycINFO Database Record (c) 2015 APA, all rights reserved). (journal abstract)

Wang, Chao; Chen, Peijie; Zhuang, Jie (2013):

A national survey of physical activity and sedentary behavior of Chinese city children and youth using accelerometers.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S12-28.

Abstract:

PURPOSE: The purpose of this study was to objectively assess levels of physical activity (PA) and sedentary behavior (SB) of Chinese city children and youth aged 9 to 17 years old using accelerometers and to examine their differences by gender, age, grade, and weight status. METHOD: The PA and SB of 2,163 students in 4th grade through 11th grade (M(age) = 160.87 +/- 27.00 months [13.41 +/- 2.25 years], 50.21% boys) from 11 cities in China were measured by accelerometers. The amount of time spent in SB, light PA, moderate PA, vigorous PA, and moderate-to-vigorous PA (MVPA) was computed based on cutoff points developed specifically for the Chinese children and youth. The participants were classified into normal-weight, overweight, and obese groups based on their body mass index (BMI). Paired-sample t tests were conducted to examine the differences in PA and SB between weekdays and weekend days. Multivariate analysis of variance was used to test the differences in PA and SB variables by gender, age, grade, and weight status, respectively. RESULTS: Chinese city children and youth spent an average of 28.26 +/- 17.66 min/day in MVPA and 521.50 +/- 110.02 min/day in SB. Only 9.4% of boys and 1.9% of girls met the

recommendation of 60 min/day of MVPA. Chinese city children and youth were more active during weekdays than during weekend days, and boys were more active than girls; older children and youth spent more daily time in MVPA, but also spent more time being sedentary. No differences in PA and SB were found across different BMI categories. CONCLUSION: The findings warn of the insufficiency of PA and the excess of SB in Chinese city children and youth.

Wang, Chao; Chen, Peijie; Zhuang, Jie (2013):

Validity and reliability of International Physical Activity Questionnaire-Short Form in Chinese youth.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S80-6.

Abstract:

PURPOSE: The psychometric profiles of the widely used International Physical Activity Questionnaire-Short Form (IPAQ-SF) in Chinese youth have not been reported. The purpose of this study was to examine the validity and reliability of the IPAQ-SF using a sample of Chinese youth. METHOD: One thousand and twenty-one youth (M(age) = 14.26 +/- 1.63 years, 52.8% boys) from 11 cities in China wore accelerometers for 7 consecutive days and completed the IPAQ-SF on the 8th day to recall their physical activity (PA) during accelerometer-wearing days. A subsample of 92 youth (M(age) = 15.90 +/- 1.35 years, 46.7% boys) completed the IPAQ-SF again a week later to recall their PA during accelerometer-wearing days. Differences in PA estimated by the IPAQ-SF and accelerometer were examined by paired-sample t test. Spearman correlation coefficients were used to examine the correlation between the IPAQ-SF and accelerometer. Test-retest reliability of the IPAQ-SF was determined by the intraclass correlation coefficient (ICC). RESULTS: Compared with accelerometer, the IPAQ-SF overestimated sedentary time, moderate PA (MPA), vigorous PA (VPA), and moderate-to-vigorous PA (MVPA). Correlations between PA (total PA, MPA, VPA, and MVPA) and sedentary time measured by 2 instruments ranged from "none" to "low" (p = .08-.31). Test-retest ICC of the IPAQ-SF ranged from "moderate" to "high" (ICC = .43-.83), except for sitting in boys (ICC = .06), sitting for the whole sample (ICC = .32), and VPA in girls (ICC = .35). CONCLUSION: The IPAQ-SF was not a valid instrument for measuring PA and sedentary behavior in Chinese youth.

Wang, Jijun; Fan, Xiaoduo; Liu, Dengtang; Yi, Zhenghui; Freudenreich, Oliver; Goff, Donald; Henderson, David C. (2012):

Both physical activity and food intake are associated with metabolic risks in patients with schizophrenia.

In: *Schizophrenia Research* 140 (1-3), S. 260–261. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-26705-016%26site%3dehost-live;xfan@partners.org.

Abstract:

This study assessed the relationship between physical activity, food intake and metabolic risks in a sample of schizophrenia patients. The study was approved by the institutional review board of the Massachusetts General Hospital (MGH). Subjects were recruited from the Freedom Trial Clinic at the Erich Lindemann Mental Health Center and were studied at the Clinical Research Center (CRC) at MGH. They were instructed to record 4-day physical activity and dietary food intake. Data of day-to-day physical activity were collected using a uniaxial accelerometer, which measures and records the amount and intensity of activity over a given period of time. Accelerometer data were recorded in 1-min epochs. Specific food intake variables, including total energy, percent of calories from saturated fat acids, percent of calories from monounsaturated fat acids and percent of calories from polyunsaturated fat acids were derived. Relationships between physical activity, food intake and metabolic parameters were examined using Pearson correlation analysis controlling for age, gender, race and antipsychotic agent. Our data suggested that both physical activity and dietary food intake were associated with metabolic abnormalities in schizophrenia patients. A lack of physical activity and low monounsaturated fat intake may place patients at a high risk for metabolic abnormalities. Anti-inflammatory effects of both physical activity and monounsaturated fatty acid intake have been associated with decreased levels of CRP in the general population. Similar effects presumably could be extended to patients with schizophrenia. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

Wang, Ning; Redmond, Stephen J.; Ambikairajah, Eliathamby; Celler, Branko G.; Lovell, Nigel H. (2010):

Can triaxial accelerometry accurately recognize inclined walking terrains?

In: *IEEE transactions on bio-medical engineering* 57 (10), S. 2506–2516. DOI: 10.1109/TBME.2010.2049357.

Abstract:

The standard method for the analysis of body accelerations cannot accurately estimate the energy expenditure (EE) of uphill or downhill walking. The ability to recognize the grade of the walking surface will most likely improve upon the accuracy of the EE estimates for daily physical activities. This paper investigates the benefits of automatic gait analysis approaches including step-by-step gait segmentation and heel-strike recognition of the accelerometry signal in classifying various gradients. Triaxial accelerometry signals were collected from 12 subjects, performing walking on seven different gradient surfaces: 1) 92 m of 0(°) flat ground; 2) 85 m of ±2.70(°) inclined ramp; 3) 24 m of ±9.86(°) inclined ramp; and 4) 6-m pitch line of ±28.03(°) rake of stairway. Validity studies performed on a group of randomly selected healthy subjects showed high agreement scores between the automated heel-strike recognition markers, manual gait annotation markers, and video-based gait-segmentation markers. Thirteen subset features were found using a subset-selection search procedure from 57 extracted features which maximize the classification accuracy, performed with a Gaussian mixture model classifier, as estimated using sixfold cross-validation. An overall walking pattern-recognition accuracy of 82.46% was achieved on seven different inclined terrains using the 13 selected features. This system should, therefore, improve the accuracy of daily EE estimates with accurate measures on terrain inclinations.

Wani, Shabeer Ahmad; Rabah, Sari M.; Alfadil, Sara; Dewanjee, Nancy; Najmi, Yahya (2013):

Efficacy of communication amongst staff members at plastic and reconstructive surgery section using smartphone and mobile WhatsApp.

In: *Indian J Plast Surg* 46 (3), S. 502–505. DOI: 10.4103/0970-0358.121990.

Abstract:

OBJECTIVE: The objective of this study is to assess the efficacy of smartphone and its WhatsApp application as a communication method amongst the staff of plastic and reconstructive surgery section at tertiary care health facility. MATERIALS AND METHODS: From January 2012 onwards, the authors used smartphones and its WhatsApp application as a communication method amongst their team for various aspects of patient management and as a tool for academic endorsements. RESULTS: During the period of this study, there were 116 episodes regarding patient management, which were handled, in a timely fashion by using this application. In addition opinion of rotating residents in the section was sought regarding the efficacy of this method of communication. Overall majority of residents were satisfied with this mode of communication. CONCLUSIONS: This new method of communication is an effective method for clinical and academic endorsements. The method is cheap and quick and easy to operate.

Wannag, Ebba; Eriksson, Ann-Sofie; Larsson, Pål Gunnar (2010):

Attention-deficit hyperactivity disorder and nocturnal epileptiform activity in children with epilepsy admitted to a national epilepsy center.

In: *Epilepsy & Behavior* 18 (4), S. 445–449.

Abstract:

The aim of this study was to determine if there exists a relationship between attention-deficit hyperactivity disorder (ADHD) and the quantity of focal nocturnal epileptiform activity on the EEG (FNEA) measured as the percentage of epileptiform activity during non-REM sleep (spike index). This was accomplished with a prospective study of children aged 6–14 years consecutively admitted to our center. Of 362 patients, 44 (12.2%) had previously been diagnosed with ADHD. Twenty-four-hour ambulatory EEG recording and assessment of ADHD according to DSM-IV were performed in 46 children suspected of having ADHD. ADHD was diagnosed in 30. We could not find any correlation between the spike index in 8 children with FNEA and the severity of their ADHD symptoms. This study is underpowered and should be considered a pilot study. There is a need for further investigation of a possible causal effect of FNEA on ADHD symptoms in larger cohorts of patients with FNEA.

Ward, Jamie A.; Lukowicz, Paul; Troster, Gerhard; Starner, Thad E. (2006):

Activity recognition of assembly tasks using body-worn microphones and accelerometers.

In: *Pattern Analysis and Machine Intelligence, IEEE Transactions on* 28 (10), S. 1553–1567.

Abstract:

In order to provide relevant information to mobile users, such as workers engaging in the manual tasks of maintenance and assembly, a wearable computer requires information about the user's specific activities. This work focuses on the recognition of activities that are characterized by a hand motion and an accompanying sound. Suitable activities can be found in assembly and maintenance work. Here, we provide an initial exploration into the problem domain of continuous activity recognition using on-body sensing. We use a mock "wood workshop" assembly task to ground our investigation. We describe a method for the continuous recognition of activities (sawing, hammering, filing, drilling, grinding, sanding, opening a drawer, tightening a vise, and turning a screwdriver) using microphones and three-axis accelerometers mounted at two positions on the user's arms. Potentially "interesting" activities are segmented from continuous streams of data using an analysis of the sound intensity detected at the two different locations. Activity classification is then performed on these detected segments using linear discriminant analysis (LDA) on the sound channel and hidden Markov models (HMMs) on the acceleration data. Four different methods at classifier fusion are compared for improving these classifications. Using user-dependent training, we obtain continuous average recall and precision rates (for positive activities) of 78 percent and 74 percent, respectively. Using user-independent training (leave-one-out across five users), we obtain recall rates of 66 percent and precision rates of 63 percent. In isolation, these activities were recognized with accuracies of 98 percent, 87 percent, and 95 percent for the user-dependent, user-independent, and user-adapted cases, respectively

Warms, Catherine A.; Belza, Basia L.; Whitney, Joanne D. (2007):

Correlates of physical activity in adults with mobility limitations.

In: *Family & community health* 30, S. S5-S16.

Abstract:

This study identified the correlates of objectively and subjectively measured physical activity in adult wheelchair users. Fifty participants wore an activity monitor for a week and completed a questionnaire about factors associated with physical activity. Objectively measured activity correlated significantly with body mass index. Subjectively measured activity correlated significantly with age, stage of change, health, healthcare providers discussing exercise, and social support for exercise. Research on the effect of body mass index on activity in this population is needed. Intervention planners should plan programs that place emphasis on modifying the social environment (including healthcare providers) and removing attitudinal barriers.

Warner, Erica T.; Wolin, Kathleen Y.; Duncan, Dustin T.; Heil, Daniel P.; Askew, Sandy; Bennett, Gary G. (2012):

Differential accuracy of physical activity self-report by body mass index.

In: *American Journal of Health Behavior* 36 (2), S. 168–178. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-02829-003&site=ehost-live;wolink@wustl.edu.

Abstract:

Objectives: To examine whether agreement between self-reported and accelerometer-measured physical activity varies by BMI category in a low-income black sample. Methods: Participants completed a questionnaire and wore an accelerometer for 4-6 days. Using one- and 10-minute bouts, accelerometers measured light, moderate, and vigorous physical activity time. Results: Correlations varied by obesity (nonobese: one-minute r = 0.41; 10-minute r = 0.47; obese: one-minute r = 0.21; 10-minute r = 0 .14). Agreement was highest among nonobese persons (one-minute kappa = 0.48, 10-minute kappa = 0.023; obese: one-minute kappa = -0.024, 10-minute kappa = -0.020). Conclusions: We found compromised questionnaire performance among obese participants.

Variability of office, 24-hour ambulatory, and self-monitored blood pressure measurements.

In: *Br J Gen Pract* 60 (578), S. 675–680.

Abstract:

BACKGROUND:

The diagnosis of hypertension is difficult when faced with several different blood pressure measurements in an individual. Using the average of several office measurements is recommended, although considerable uncertainty remains. Twenty-four-hour ambulatory monitoring is often considered the gold standard, but self-monitoring of blood pressure has been proposed as a superior method.

AIM:

Determination of within-individual variability of blood pressure measured in the office, by ambulatory monitoring, and by a week of self-monitoring.

DESIGN OF STUDY:

Retrospective analysis of a clinical trial of 163 subjects.

METHOD:

Within-patient variability of office and ambulatory blood pressure was determined from measurements at 0 and 6 weeks. Subjects had performed self-monitoring of blood pressure twice each morning and evening, for at least 6 weeks; variability was determined from the means of week 1 and week 6.

RESULTS:

The within-individual coefficients of variation (CVs) for systolic blood pressure were: office, 8.6%; ambulatory, 5.5%; self, 4.2%. Equivalent values for diastolic blood pressure were 8.6%, 4.9%, and 3.9%. CVs tended to be lower with longer self-monitoring duration, and higher with longer intervals between self-monitoring.

CONCLUSION:

Office blood pressure is impractical for precise assessment, as 10-13 measurements are required to give the accuracy required for rational titration of antihypertensive drugs. Twenty-four-hour ambulatory monitoring is better than a single office measurement, but considerable uncertainty remains around the estimate. A week of self-monitoring appears to be the most accurate method of measuring blood pressure, but remains imperfect. Further research may identify superior self-monitoring schedules. Given the inherent accuracy in blood pressure measurement, the importance of considering overall cardiovascular risk is emphasised.

Warthen, Matthew W.; Tiffany, Stephen T. (2009):

Evaluation of cue reactivity in the natural environment of smokers using ecological momentary assessment.

In: *Experimental and Clinical Psychopharmacology* 17 (2), S. 70–77. DOI: 10.1037/a0015617.

Abstract:

The cue reactivity (CR) paradigm has been used extensively to assess smokers' craving responses to smoking-related stimuli. To date, nearly all CR research has been conducted in laboratory settings; there has been no experimental research of the impact of smoking cues on smokers' craving in their natural environment. The present research combined CR procedures with ecological momentary assessment (CREMA); the latter has been used successfully to monitor a variety of behaviors in real time using handheld personal digital assistants (PDAs). Participants were 43 daily, heavy smokers ages 18 and older. PDAs were sent home with participants over an 8-day CREMA period. PDAs were used to record each cigarette smoked and to administer daily CR trials. CR stimuli consisted of photographs and imagery scripts that were either smoking related or neutral. CR trials were also administered in the laboratory, by means of PDAs, at the beginning and end of the CREMA period. Results from CREMA trials indicated that smoking-related cues significantly increased craving, compared with neutral cues for both photographs and imagery scripts. This pattern was also observed in the laboratory-based trials. Findings indicate that CREMA is well suited for the investigation of cue-elicited craving under real-world conditions.

Wasielewska, Anna; Rudzinska, Monika; Tomaszewski, Tomasz; Banaszkiewicz, Krzysztof; Wojcik-Pedziwiatr, Magdalena; Dec-Cwiek, Malgorzata et al. (2013):

Tremor in neuropathies of different origin.

In: *Neurol Neurochir Pol* 47 (6), S. 525–533.

Abstract:

BACKGROUND AND PURPOSE: Tremor accompanies some poly-neuropathies, but its prevalence and its clinical and electrophysiological manifestations are not well known. The aim of the study was to assess the occurrence and characteristics of hand tremor in patients with polyneuropathy of different origins, as well as relations between the occurrence of tremors and

clinical and neurographic findings of polyneuropathy. MATERIAL AND METHODS: Eighty-nine patients diagnosed with polyneuropathy of known aetiology, and 50 age- and sex-matched healthy volunteers were included in the study. All subjects were interviewed regarding the occurrence of tremor. Tremor was assessed clinically and objectively using a triaxial accelerometer and electromyographic (EMG) recordings. A load test with a weight of 500 gamma was performed in order to differentiate between enhanced physiological tremor (EPT) and essential tremor-like (ET-L) tremor. RESULTS: Tremor was found in 59.5% of patients in clinical assessment and in 74% of patients in objective evaluation, significantly more often than in controls (12%). Tremor was detected in all types of polyneuropathy apart from paraproteinaemic IgM polyneuropathy. Tremor was postural (70%), but resting (51%) or kinetic (32%) tremor was also present. In the majority of cases, the severity of the tremor was mild. Essential tremor-like tremor prevailed in the study group. The occurrence of hand tremor was not related to the axonal or demyelinating type of polyneuropathy, nor to the conduction velocity or other electrophysiological findings of the investigated upper limb nerves. CONCLUSION: Tremor accompanies 60-70% of patients with polyneuropathy; it is mostly postural, ET-L type with mild severity, and unrelated to other typical clinical and electrophysiological findings of neuropathy.

Waters, Andrew J.; Li, Yisheng (2008):

Evaluating the utility of administering a reaction time task in an ecological momentary assessment study.

In: *Psychopharmacology* 197 (1), S. 25–35.

Abstract:

RATIONALE:

Cognitive processes underlying drug use have typically been assessed in laboratory settings. More detailed and ecologically valid data may be possible if assessments were conducted in an ecological momentary assessment (EMA) setting.

OBJECTIVES:

We evaluated the feasibility and utility of administering a reaction time task on a hand-held computer (personal digital assistant, PDA) in an EMA setting.

MATERIALS AND METHODS:

Twenty-two smokers and 22 non-smokers carried around the PDA for 1 week as they went about their daily lives. They were beeped at random times four times per day (random assessments, RAs). Participants were also instructed to press an "anxiety assessment" (AA) button on the PDA whenever they felt suddenly anxious. At each assessment (RA, AA), participants responded to items assessing subjective, pharmacological, and contextual variables, and subsequently completed a Stroop task (classic-Stroop, emotional-Stroop, or smoking-Stroop task).

RESULTS:

Participants responded to 81.2% of RAs, completed assessments in an average of 4.44 min, reported no interruptions on the majority of assessments (62.4%), and produced data with adequate reliability. Using generalized estimating equation (GEE) analyses, age was associated with the classic-Stroop effect, state anxiety was associated with the emotional-Stroop effect, and Fagerstrom Test for Nicotine Dependence scores were associated with the smoking-Stroop effect.

CONCLUSIONS:

The study provided evidence for the feasibility and utility of the approach.

Waters, Andrew J.; Marhe, Reshmi; Franken, Ingmar H. A. (2012):

Attentional bias to drug cues is elevated before and during temptations to use heroin and cocaine.

In: *Psychopharmacology* 219 (3), S. 909–921. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-01789-020&site=ehost-live;andrew.waters@usuhs.mil.

Abstract:

Rationale: Relapse is an important problem in substance dependence treatment. When drug users try to abstain from drug use, they often report strong temptations to use drugs. Temptation episodes have commonalities with relapse episodes, and assessment of temptation episodes may help to identify individuals at risk of relapse. Objectives: This study aims to examine affect and cognition prior to and during temptation episodes by administering self-report and implicit cognitive assessments on a handheld computer (PDA) using Ecological Momentary Assessment. Methods: Heroin-dependent patients (N = 68) attending a

drug detoxification unit completed up to four random assessments (RAs) per day on a PDA for 1 week. They also completed an assessment when they experienced a temptation to use drugs (temptation assessment; TA). Results: Participants completed 1,482 assessments (353 TAs, 1,129 RAs). The rate of TAs was maximal during the first 2 days. Participants reported higher levels of negative affect, anxiety, and difficulty concentrating, and more positive explicit attitudes to drugs, at TAs compared to RAs. In addition, they exhibited elevated attentional bias to drug cues (assessed using the modified Stroop task) at TAs compared to RAs. Implicit affective associations with drug cues (assessed using the Implicit Association Test) were not different at TAs compared to RAs. Attentional bias was elevated in the 1 h prior to the entry of a temptation episode. Conclusions: Elevated attentional bias may be a harbinger of temptation episodes. Interventions that target cognitions prior to or during temptation episodes may reduce the probability or severity of a temptation episode. Cognition and Craving During Smoking Cessation: An Ecological Momentary Assessment Study.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt108.

Abstract:

INTRODUCTION: Some studies using ecological momentary assessment (EMA) have revealed an association between craving for cigarettes and relapse. It is, therefore, important to understand the correlates of craving during smoking cessation. Attentional bias to smoking cues is a potential correlate of craving, but it has not previously been assessed using EMA during smoking cessation. METHODS: Smokers enrolled in a research smoking cessation study were offered the opportunity to take part in an EMA study. Volunteers carried around a personal digital assistant (PDA) for the first week of their quit attempt. They completed up to 4 random assessments (RAs) per day as well as assessments when they experienced a temptation to smoke and when they relapsed. Craving for cigarettes was assessed with a single item (1-7 scale). Attentional bias was assessed with a smoking Stroop task (a reaction time task) at every other assessment, as was self-reported attention to cigarettes. RESULTS: Data were available from 119 participants. Across 882 assessments, participants exhibited a significant smoking Stroop effect. Linear mixed models revealed a significant between-subject association between craving and the smoking Stroop effect. Individuals with higher levels of craving exhibited greater attentional bias. The within-subject association was not significant. Similar results were obtained for the relationship between self-reported attention to cigarettes and attentional bias. CONCLUSIONS: Attentional bias can be assessed in the natural environment using EMA during smoking cessation, and attentional bias is a correlate of craving during the early stages of a quit attempt

Watkins, K. L.; Regan, S. D.; Nguyen, N.; Businelle, M. S.; Kendzor, D. E.; Lam, C. et al. (2013):

Advancing Cessation Research by Integrating EMA and Geospatial Methodologies: Associations Between Tobacco Retail Outlets and Real-time Smoking Urges During a Quit Attempt.

In: *Nicotine Tob.Res* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt135.

Abstract:

INTRODUCTION: Residential tobacco retail outlet (TRO) density and proximity have been associated with smoking behaviors. More research is needed to understand the mechanisms underlying these relations and their potential relevance outside of the residential setting. This study integrates ecological momentary assessment (EMA) and geo-location tracking to explore real-time associations between exposure to TROs and smoking urges among 47 economically disadvantaged smokers in a cessation trial (59.6% female; 36.2% White). METHODS: EMA data were collected for 1 week postquit via smartphone, which recorded smoking urge strength </=4 random times daily along with real-time participant location data. For each assessment, the participants' proximity to the closest TRO and the density of TROs surrounding the participant were calculated. Linear mixed model regressions examined associations between TRO variables and smoking urges, and whether relations varied based on participants' distance from their home. Covariates included sociodemographics, prequit tobacco dependence, treatment group, and daily smoking status. RESULTS: Main effects were nonsignificant; however, the interaction between TRO proximity and distance from home was considered significant (p = .056). Specifically, closer proximity to TROs was associated with stronger smoking urges </=1 mile of home (p = .001) but not >1 mile from home (p = .307). Significant associations were attributable to assessments completed at participants' home addresses. All density analyses were nonsignificant. CONCLUSIONS: Technological challenges encountered in this study resulted in a significant amount of missing data, highlighting the preliminary nature of these findings, and limiting the inferences that can be drawn. However, results suggest that closer residential proximity to tobacco outlets may trigger stronger urges to smoke among economically disadvantaged smokers trying to quit, perhaps due to

enhanced cigarette availability and accessibility. Therefore, limiting tobacco sales in close proximity to residential areas may complement existing tobacco control efforts and facilitate cessation

Wearing, Jessica R.; Nollen, Nikki; Befort, Christie; Davis, Ann M.; Agemy, Carolina K. (2014):

iPhone App Adherence to Expert-Recommended Guidelines for Pediatric Obesity Prevention.

In: *Child Obes. DOI:* 10.1089/chi.2013.0084.

Abstract:

Abstract Background: Pediatric obesity is a serious and prevalent problem. Smartphone technology, which is becoming increasingly available to children of diverse backgrounds, presents a unique opportunity to instill healthy behaviors before the onset of obesity. Past studies have examined the use of smartphone applications as tools of health behavior modification for adults. The present study examines the content of children's exercise and nutrition smartphone apps. Method: Sixty-two iPhone apps were identified and coded by two independent raters for adherence to expert-recommended behaviors (e.g., five fruits/vegetables per day) and strategies (e.g., self-monitoring diet/physical activity) for the prevention of pediatric obesity. Results: App behavioral and strategy index scores were uniformly low. Apps were more likely to address expert-recommended behaviors for the prevention of pediatric obesity (93.5%), whereas few apps addressed recommended strategies (20.9%). The most common behaviors addressed included physical activity (53.2%) and fruit/vegetable consumption (48.3%). Other important behaviors (e.g., screen time [1.6%] and family meals together [1.6%]) were rarely addressed. Conclusions: Current children's diet and exercise apps could be improved with increased adherence to expert-recommended guidelines, especially expert-recommended strategies.

Webb, Alastair John Stewart; Rothwell, Peter Malcolm (2014):

Physiological correlates of beat-to-beat, ambulatory, and day-to-day home blood pressure variability after transient ischemic attack or minor stroke.

In: *Stroke* 45 (2), S. 533–538. DOI: 10.1161/STROKEAHA.113.003321.

Abstract:

BACKGROUND AND PURPOSE: Visit-to-visit and day-to-day variability in systolic blood pressure (SBP) are associated with an increased risk of stroke, more strongly than variability on 24-hour ambulatory BP monitoring, but underlying physiological mechanisms are unclear. We related potentially relevant physiological characteristics to beat-to-beat, ambulatory, and day-to-day BP variability to identify underlying mechanisms and potential therapeutic targets. METHODS: BP variability (coefficient of variation [CV]) on 1-month home BP monitoring (3 sitting readings, 3x daily), on 24-hour ambulatory BP monitoring, and on 5-minute beat-to-beat monitoring was related to BP reactivity (to mental arithmetic), arterial aging (aortic stiffness: carotid-femoral pulse wave velocity; aortic pulsatility), heart rate variability (CV of normal-to-normal R-R interval), and orthostatic responses. RESULTS: In 223 patients within 6 weeks of a transient ischemic attack or minor stroke, beat-to-beat and home SBP-CVs were associated with response to arithmetic (beat-to-beat odds ratio per SD=1.64; P<0.0001 and home BP monitoring, 1.41; P=0.025), aortic stiffness (1.84; P<0.0001 and 1.31; P=0.04), aortic pulsatility (1.98; P<0.0001 and 1.61; P<0.0001), and heart rate variability-CV of normal-to-normal R-R interval (1.34; P=0.03 and 1.35; P=0.03), independently of age, sex, and aortic BP. Orthostatic BP changes were associated only with SBP-CV on home BP monitoring (0.62; P=0.002). In contrast, no physiological measures were associated with within-day BP variability on awake ambulatory BP monitoring except response to mental arithmetic (1.40; P=0.01). CONCLUSIONS: Beat-to-beat and day-to-day SBP variability, but not variability on ambulatory BP monitoring, had similar physiological correlates, suggesting common underlying mechanisms and identifying potentially treatable targets that may be responsible for the relationship between SBP variability and stroke risk.

Webber, Larry S.; Catellier, Diane J.; Lytle, Leslie A.; Murray, David M.; Pratt, Charlotte A.; Young, Deborah R. et al. (2008):

Promoting physical activity in middle school girls: Trial of Activity for Adolescent Girls.

In: *Am J Prev Med* 34 (3), S. 173–184.

Abstract:

Background

Physical activity is important for weight control and good health; however, activity levels decline in the adolescent years, particularly in girls.

Design

Group randomized controlled trial

Setting/participants

Middle school girls with English-speaking skills and no conditions to prevent participation in physical activity in 36 schools in six geographically diverse areas of the United States. Random, cross-sectional samples were drawn within schools: 6th graders in 2003 (n=1721) and 8th graders in 2005 (n=3504) and 2006 (n=3502).

Intervention

A 2-year study-directed intervention (fall 2003 to spring 2005) targeted schools, community agencies, and girls to increase opportunities, support, and incentives for increased physical activity. Components included programs linking schools and community agencies, physical education, health education, and social marketing. A third-year intervention used school and community personnel to direct intervention activities.

Main outcome measures

The primary outcome, daily MET-weighted minutes of moderate-to-vigorous physical activity (MET-weighted MVPA), was assessed using accelerometry. Percent body fat was assessed using anthropometry.

Results

After the staff-directed intervention (pre-stated primary outcome), there were no differences (mean= −0.4, 95% CI= CI= −8.2 to 7.4) in adjusted MET-weighted MVPA between 8th-grade girls in schools assigned to intervention or control. Following the Program Champion–directed intervention, girls in intervention schools were more physically active than girls in control schools (mean difference 10.9 MET-weighted minutes of MVPA, 95% CI=0.52–21.2). This difference is about 1.6 minutes of daily MVPA or 80 kcal per week. There were no differences in fitness or percent body fat at either 8th-grade timepoint.

Conclusion

A school-based, community-linked intervention modestly improved physical activity in girls.

Webber, Sandra C.; Porter, Michelle M. (2009):

Monitoring mobility in older adults using global positioning system (GPS) watches and accelerometers: a feasibility study.

In: *J Aging Phys Act* 17 (4), S. 455–467.

Abstract:

This exploratory study examined the feasibility of using Garmin global positioning system (GPS) watches and ActiGraph accelerometers to monitor walking and other aspects of community mobility in older adults. After accuracy at slow walking speeds was initially determined, 20 older adults (74.4 +/- 4.2 yr) wore the devices for 1 day. Steps, distances, and speeds (on foot and in vehicle) were determined. GPS data acquisition varied from 43 min to over 12 hr, with 55% of participants having more than 8 hr between initial and final data-collection points. When GPS data were acquired without interruptions, detailed mobility information was obtained regarding the timing, distances covered, and speeds reached during trips away from home. Although GPS and accelerometry technology offer promise for monitoring community mobility patterns, new GPS solutions are required that allow for data collection over an extended period of time between indoor and outdoor environments.

Weber, Michael A.; White, William B.; Sica, Domenic; Bakris, George L.; Cao, Charlie; Roberts, Andrew; Kupfer, Stuart (2014):

Effects of combining azilsartan medoxomil with amlodipine in patients with stage 2 hypertension.

In: *Blood Press Monit* 19 (2), S. 90–97. DOI: 10.1097/MBP.0000000000000027.

Abstract:

OBJECTIVE: The aim of the study was to measure the effects on blood pressure (BP) of the angiotensin receptor blocker azilsartan medoxomil, in 40 and 80 mg doses, combined with 5 mg of the calcium channel blocker amlodipine and to compare these effects with placebo plus amlodipine 5 mg. METHODS: This was a randomized, controlled, double-blind study of 6 weeks' duration in 566 patients with stage 2 hypertension. The primary endpoint was 24-h systolic BP by ambulatory monitoring.

RESULTS: The mean age of the participants was 58 years; men and women were equally represented, and baseline 24-h BP (153-154/93 mmHg) and clinic BP (165-166/94-95 mmHg) were similar across the three treatment groups. After 6 weeks, 24-h BP decreased by 25/15 mmHg in both the azilsartan medoxomil/amlodipine 40/5 and 80/5 mg groups. These reductions were each greater than the 14/8 mmHg decrease with placebo plus amlodipine 5 mg (P</=0.001 for both comparisons). All treatments were well tolerated, and adverse events did not increase with the azilsartan medoxomil doses. Edema or fluid retention was less common in both combination groups (2.6 and 2.7%) than with placebo plus amlodipine (7.6%). CONCLUSION: Coadministration of azilsartan medoxomil with amlodipine was well tolerated and led to meaningful additional BP reductions compared with placebo plus amlodipine.

Webster, Gregory D.; Kirkpatrick, Lee A.; Nezlek, John B.; Smith, C. Veronica; Paddock, E. Layne (2007):

Different slopes for different folks: Self-esteem instability and gender as moderators of the relationship between self-esteem and attitudinal aggression.

In: *Self and Identity* 6 (1), S. 74–94.

Abstract:

The present research examined the relationships among self-esteem level, temporal self-esteem instability, gender, and self-reported aggression. Self-esteem level was negatively related to attitudinal aggression, although this relationship varied as a joint function of self-esteem instability and gender. It was strongest among men with unstable self-esteem and among women with stable self-esteem. Although self-esteem instability and narcissism (Study 3) were each positively related to behavioral aggression, the relationship between narcissism and attitudinal aggression varied as a function of self-esteem instability. The relationship between narcissism and attitudinal aggression was positive among people with stable self-esteem, but negative among people with unstable self-esteem, regardless of gender. The importance of considering gender, self-esteem instability, and narcissism in the self-esteem/aggression debate is discussed.

Weering, M. G. H.; Vollenbroek-Hutten, M. M. R.; Tönis, T. M.; Hermens, H. J. (2009):

Daily physical activities in chronic lower back pain patients assessed with accelerometry.

In: *Eur J Pain* 13 (6), S. 649–654.

Abstract:

BACKGROUND:

Normalization of activities in daily living is an important goal in rehabilitation treatment of chronic lower back pain (CLBP) patients. Clinicians indicate that CLBP patients often show deconditioning but also CLBP patients who seem to be too active are seen. The objective of the present cross-sectional study was to gain more insight into the daily activity pattern of CLBP patients compared to controls, using accelerometry.

METHODS:

Daily activities were assessed by measuring body movement with a tri-axial accelerometer that was worn for seven consecutive days during waking hours. Measurements were performed in the daily environment (in-doors and out-doors) of the participant. Differences between activity level, time of day and work status were tested.

RESULTS:

Data were obtained from 29 CLBP patients and 20 controls. Results show that the overall activity levels of patients (mean 0.75; SD 0.43) are not significantly different from those of controls (mean 0.71; SD 0.44). However, patients show significantly higher activity levels in the morning ($p<0.001$) and significantly lower activity levels in the evening ($p<0.01$) compared to controls. No significant differences in activity levels were found between leisure time and working days within either group; furthermore no significant differences in activity levels were found between patients with different work status.

CONCLUSION:

Overall activity levels do not differ significantly between CLBP patients and controls, but the distribution of activities over the day differs significantly.

Wegerer, M.; Blechert, J.; Kerschbaum, H.; Wilhelm, F. H. (2013):

Relationship between Fear Conditionability and Aversive Memories: Evidence from a Novel Conditioned-Intrusion Paradigm.

In: *PLoS.One.* 8 (11), S. e79025. DOI: 10.1371/journal.pone.0079025.

Abstract:

Intrusive memories - a hallmark symptom of posttraumatic stress disorder (PTSD) - are often triggered by stimuli possessing similarity with cues that predicted or accompanied the traumatic event. According to learning theories, intrusive memories can be seen as a conditioned response to trauma reminders. However, direct laboratory evidence for the link between fear conditionability and intrusive memories is missing. Furthermore, fear conditioning studies have predominantly relied on standardized aversive stimuli (e.g. electric stimulation) that bear little resemblance to typical traumatic events. To investigate the general relationship between fear conditionability and aversive memories, we tested 66 mentally healthy females in a novel conditioned-intrusion paradigm designed to model real-life traumatic experiences. The paradigm included a differential fear conditioning procedure with neutral sounds as conditioned stimuli and short violent film clips as unconditioned stimuli. Subsequent aversive memories were assessed through a memory triggering task (within 30 minutes, in the laboratory) and ambulatory assessment (involuntary aversive memories in the 2 days following the experiment). Skin conductance responses and subjective ratings demonstrated successful differential conditioning indicating that naturalistic aversive film stimuli can be used in a fear conditioning experiment. Furthermore, aversive memories were elicited in response to the conditioned stimuli during the memory triggering task and also occurred in the 2 days following the experiment. Importantly, participants who displayed higher conditionability showed more aversive memories during the memory triggering task and during ambulatory assessment. This suggests that fear conditioning constitutes an important source of persistent aversive memories. Implications for PTSD and its treatment are discussed

Beat-to-Beat, Reading-to-Reading, and Day-to-Day Blood Pressure Variability in Relation to Organ Damage in Untreated Chinese.

In: *Hypertension* 63 (4), S. 790–796. DOI: 10.1161/HYPERTENSIONAHA.113.02681.

Abstract:

Whether target organ damage is associated with blood pressure (BP) variability independent of level remains debated. We assessed these associations from 10-minute beat-to-beat, 24-hour ambulatory, and 7-day home BP recordings in 256 untreated subjects referred to a hypertension clinic. BP variability indices were variability independent of the mean, maximum-minimum difference, and average real variability. Effect sizes (standardized beta) were computed using multivariable regression models. In beat-to-beat recordings, left ventricular mass index (n=128) was not (P>/=0.18) associated with systolic BP but increased with all 3 systolic variability indices (+2.97-3.53 g/m(2); P<0.04); the urinary albumin-to-creatinine ratio increased (P</=0.03) with systolic BP (+1.14-1.17 mg/mmol) and maximum-minimum difference (+1.18 mg/mmol); and pulse wave velocity increased with systolic BP (+0.69 m/s; P<0.001). In 24-hour recordings, all 3 indices of organ damage increased (P<0.03) with systolic BP, whereas the associations with BP variability were nonsignificant (P>/=0.15) except for increases in pulse wave velocity (P<0.05) with variability independent of the mean (+0.16 m/s) and maximum-minimum difference (+0.17 m/s). In home recordings, the urinary albumin-to-creatinine ratio (+1.27-1.30 mg/mmol) and pulse wave velocity (+0.36-0.40 m/s) increased (P<0.05) with systolic BP, whereas all associations of target organ damage with the variability indices were nonsignificant (P>/=0.07). In conclusion, while accounting for BP level, associations of target organ damage with BP variability were readily detectable in beat-to-beat recordings, least noticeable in home recordings, with 24-hour ambulatory monitoring being informative only for pulse wave velocity.

Weikert, Madeline; Motl, Robert W.; Suh, Yoojin; McAuley, Edward; Wynn, Daniel (2010):

Accelerometry in persons with multiple sclerosis: measurement of physical activity or walking mobility?

In: *J Neurol Sci* 290 (1), S. 6–11.

Abstract:

Objective

Motion sensors such as accelerometers have been recognized as an ideal measure of physical activity in persons with MS. This study examined the hypothesis that accelerometer movement counts represent a measure of both physical activity and walking mobility in individuals with MS.

Methods

The sample included 269 individuals with a definite diagnosis of relapsing–remitting MS who completed the Godin Leisure-Time Exercise Questionnaire (GLTEQ), International Physical Activity Questionnaire (IPAQ), Multiple Sclerosis Walking Scale-12 (MSWS-12), Patient Determined Disease Steps (PDDS), and then wore an ActiGraph accelerometer for 7 days. The data were analyzed using bivariate correlation and confirmatory factor analysis.

Results

The results indicated that (a) the GLTEQ and IPAQ scores were strongly correlated and loaded significantly on a physical activity latent variable, (b) the MSWS-12 and PDDS scores strongly correlated and loaded significantly on a walking mobility latent variable, and (c) the accelerometer movement counts correlated similarly with the scores from the four self-report questionnaires and cross-loaded on both physical activity and walking mobility latent variables.

Conclusion

Our data suggest that accelerometers are measuring both physical activity and walking mobility in persons with MS, whereas self-report instruments are measuring either physical activity or walking mobility in this population.

School gardens and physical activity: A randomized controlled trial of low-income elementary schools.

In: *Prev Med* 69 Suppl 1, S. 27–33. DOI: 10.1016/j.ypmed.2014.10.012.

Abstract:

OBJECTIVE: This study examines effects of a school garden intervention on elementary school children's physical activity (PA). METHOD: Twelve schools in New York were randomly assigned to receive the school garden intervention (n=6) or to the waitlist control group that later received gardens (n=6). PA was measured by self-report survey (Girls Health Enrichment Multi-site Study Activity Questionnaire) (N=227) and accelerometry (N=124, 8 schools) at baseline (Fall 2011) and follow-up (Spring 2012, Fall 2012, Spring 2013). Direct observation (N=117, 4 schools) was employed to compare indoor (classroom) and outdoor (garden) PA. Analysis was by general linear mixed models. RESULTS: Survey data indicate garden intervention children's reports of usual sedentary activity decreased from pre-garden baseline to post-garden more than the control group children's (Delta=-.19, p=.001). Accelerometry data reveal that during the school day, children in the garden intervention showed a greater increase in percent of time spent in moderate and moderate-to-vigorous PA from baseline to follow-up than the control group children (Delta=+.58, p=.010; Delta=+1.0, p=.044). Direct observation within-group comparison of children at schools with gardens revealed that children move more and sit less during an outdoor garden-based lesson than during an indoor, classroom-based lesson. CONCLUSION: School gardens show some promise to promote children's PA. CLINICAL TRIALS REGISTRATION: clinicaltrials.gov # NCT02148315.

Biases in affective forecasting and recall in individuals with depression and anxiety symptoms.

In: *Pers.Soc.Psychol.Bull.* 38 (7), S. 895–906. DOI: 10.1177/0146167212447242.

Abstract:

The authors used experience sampling to investigate biases in affective forecasting and recall in individuals with varying levels of depression and anxiety symptoms. Participants who were higher in depression symptoms demonstrated stronger (more pessimistic) negative mood prediction biases, marginally stronger negative mood recall biases, and weaker (less optimistic) positive mood prediction and recall biases. Participants who were higher in anxiety symptoms demonstrated stronger negative mood prediction biases, but positive mood prediction biases that were on par with those who were lower in anxiety. Anxiety symptoms were not associated with mood recall biases. Neither depression symptoms nor anxiety symptoms were associated with bias in event prediction. Their findings fit well with the tripartite model of depression and anxiety. Results are also consistent with the conceptualization of anxiety as a "forward-looking" disorder, and with theories that emphasize the importance of pessimism and general negative information processing in depressive functioning

Wenze, Susan J.; Miller, Ivan W. (2010):

Use of ecological momentary assessment in mood disorders research.

In: *Clinical Psychology Review* 30 (6), S. 794–804.

Abstract:

Ecological momentary assessment (EMA) entails repeated, intensive sampling of respondents' current experiences while they are engaged in their typical daily routines, in their natural environments. In this article we discuss benefits of using EMA techniques in mood disorders research, provide an overview of the various specific EMA techniques that have been used with mood-disordered populations to date, and summarize the diverse range of research questions that EMA has been used to explore in this field. In addition, we evaluate the feasibility and acceptability of using EMA techniques with this population and suggest additional areas that might be fruitful to investigate, with a focus on the extension of EMA techniques into treatment research. Overall, data suggest that using EMA techniques in mood disorders research is feasible, generally acceptable, and highly promising. We conclude with a discussion of caveats, limitations, and ethical considerations.

Ambulatory assessment as a means of longitudinal phenotypes characterization in psychiatric disorders.

In: *Neuroscience Research*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-54627-001%26site%3dehost-live.

Abstract:

Ambulatory Assessment (AA) comprises the use of in-field methods to assess individuals' behavior, physiology, and the experience as they unfold in naturalistic settings. We propose that AA is favorable for the investigation of gene–environment interactions and for the search for endophenotypes, being able to assess the experienced environment and to track basic regulatory processes, such as stress reactivity, affective instability, and reward experience, which are potential common factors that underlie psychiatric disorders. In this article, we (a) first describe briefly the rationale of AA and summarize the key advantages of the approach, (b) highlight within-subject regulatory processes, such as stress reactivity, affective instability, and reward experience, (c) describe studies that used AA to examine genetic influences in psychiatric disorders, and (d) briefly review longitudinal studies that have investigated phenotypes of psychiatric disorders. The reported studies yielded promising, although sometimes inconclusive evidence for genetic effects on endophenotypes of psychiatric disorders. Moreover, most studies were twin or family studies, especially in stress-sensitivity research; thus, it is unclear which specific single nucleotide polymorphisms contribute to the endophenotypes of psychiatric disorders. We do hope that within-subject regulatory processes will enable us to clarify the fundamental psychological dimensions that cut across traditional disorders and link them to their genetic underpinnings. Multilevel modeling: Current and future applications in personality research.

In: *J Personality* 79 (1), S. 2–50.

Abstract:

Traditional statistical analyses can be compromised when data are collected from groups or multiple observations are collected from individuals. We present an introduction to multilevel models designed to address dependency in data. We review current use of multilevel modeling in 3 personality journals showing use concentrated in the 2 areas of experience sampling and longitudinal growth. Using an empirical example, we illustrate specification and interpretation of the results of series of models as predictor variables are introduced at Levels 1 and 2. Attention is given to possible trends and cycles in longitudinal data and to different forms of centering. We consider issues that may arise in estimation, model comparison, model evaluation, and data evaluation (outliers), highlighting similarities to and differences from standard regression approaches. Finally, we consider newer developments, including 3-level models, cross-classified models, nonstandard (limited) dependent variables, multilevel structural equation modeling, and nonlinear growth. Multilevel approaches both address traditional problems of dependency in data and provide personality researchers with the opportunity to ask new questions of their data.

Supporting research sites in resource-limited settings: challenges in implementing information technology infrastructure.

In: *J Acquir Immune Defic Syndr* 65 Suppl 1, S. S44-9. DOI: 10.1097/QAI.0000000000000039.

Abstract:

As information and communication technology infrastructure becomes more reliable, new methods of electronic data capture, data marts/data warehouses, and mobile computing provide platforms for rapid coordination of international research projects and multisite studies. However, despite the increasing availability of Internet connectivity and communication systems in remote regions of the world, there are still significant obstacles. Sites with poor infrastructure face serious challenges participating in modern clinical and basic research, particularly that relying on electronic data capture and Internet communication technologies. This report discusses our experiences in supporting research in resource-limited settings. We describe examples of the practical and ethical/regulatory challenges raised by the use of these newer technologies for data collection in multisite clinical studies.

Whalen, Carol K.; Henker, Barbara; Ishikawa, Sharon S.; Emmerson, Natasha A.; Swindle, Ralph; Johnston, Joseph A. (2010):

Atomoxetine versus stimulants in the community treatment of children with ADHD: an electronic diary study.

In: *J Atten Disord* 13 (4), S. 391–400. DOI: 10.1177/1087054708325118.

Abstract:

OBJECTIVE\r\nTo compare the morning and afternoon/evening functioning of children with ADHD treated in the community with either atomoxetine or long-acting stimulants and reported to be doing well.\r\nMETHOD\r\n109 8- to 12-year-olds and their mothers participated in one of three groups: stimulants (STIM, N = 26), atomoxetine (ATMX, N = 25), or comparison (COMP, N = 58). Mothers completed morning and evening electronic diaries installed on personal digital assistants throughout an entire week, rating the child's behaviors and moods as well as their own moods and perceptions.\r\nRESULTS\r\nThere was no evidence that ongoing pharmacotherapy fully normalized the behaviors of children with ADHD: Mothers in both ADHD groups reported higher rates of child inattention, hyperactivity/impulsivity, oppositionality, and negative affect and lower levels of parenting efficacy and positive affect than did COMP mothers. Although the behavioral profiles were generally comparable for the STIM and ATMX groups, there were indications of better functioning in the ATMX group during mornings only.\r\nCONCLUSION\r\nChildren treated in the community with either STIM or ATMX appear to have similar behavioral profiles, suggesting that medication decisions be guided by other factors such as comorbid disorders, child and parent preferences, and effects on nontargeted behaviors and moods.

Dietary self-monitoring, but not dietary quality, improves with use of smartphone app technology in an 8-week weight loss trial.

In: *J Nutr Educ Behav* 46 (5), S. 440–444. DOI: 10.1016/j.jneb.2014.04.291.

Abstract:

OBJECTIVE: Dietary self-monitoring is linked to improved weight loss success. Mobile technologies, such as smartphone applications (apps), might allow for improved dietary tracking adherence. The authors assessed the use of a popular smartphone app for dietary self-monitoring and weight loss by comparing it with traditional diet counseling and entry methods. METHODS: Diet tracking and weight loss were compared across participants during an 8-week weight loss trial. Participants tracked intake using 1 of 3 methods: the mobile app "Lose It!", the memo feature on a smartphone, or a traditional paper-and-pencil method. RESULTS: App users (n = 19) recorded dietary data more consistently compared with the paper-and-pencil group (n = 15; P = .042) but not the memo group (n = 13). All groups lost weight over the course of the study (P = .001), and no difference in weight loss was noted between groups. CONCLUSIONS AND IMPLICATIONS: Smartphone apps could represent a novel and feasible dietary self-monitoring method for individuals.

Where have they gone? Tracking movement patterns to document the process of situational exposure in agoraphobia.

In: *Professional Psychology: Research and Practice* 45 (3), S. 171–179. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-24102-003%26site%3dehost-live.

Abstract:

Therapists typically have limited information about how unaccompanied situational exposure is undertaken. To address this issue, we present a method of assessing movement patterns and concurrent arousal collected during situational exposure. We illustrate how this provides both objective and useful accounts of this important treatment component. In this case study, recordings of global positioning system-derived position and heart rate were obtained from a 47-year-old female patient suffering from panic disorder with agoraphobia who received treatment through an outpatient clinic. Ambulatory assessment of movement and accompanying physiology (heart rate) during situational exposure is described. Visualizations of positional and physiological data recorded during exposure sessions revealed (a) that the patient actually confronted feared environmental cues, (b) that she experienced elevated physiological arousal, and (c) good therapeutic compliance. These depictions were used to plan subsequent exposure sessions and we discuss how this information provided unique insights into the process of exposure. Assessment of movement patterns using commercially available technology can yield clinically relevant information about treatment progress. We conclude that this method could extend traditional self-report measures of agoraphobic avoidance. Future directions, such as the possibility of using movement information to refine follow-up assessment, and the limitations of this approach are discussed. Wichers, M. (2013):

The dynamic nature of depression: a new micro-level perspective of mental disorder that meets current challenges.

In: *Psychol.Med* (0033-2917 (Linking)), S. 1–12. DOI: 10.1017/S0033291713001979.

Abstract:

The examination of moment-to-moment, 'micro-level' patterns of experience and behaviour using experience sampling methodology has contributed to our understanding of the 'macro-level' development of full-blown symptoms and disorders. This paper argues that the micro-level perspective can be used to identify the smallest building blocks underlying the onset and course of mental ill-health. Psychopathology may be the result of the continuous dynamic interplay between micro-level moment-to-moment experiences and behavioural patterns over time. Reinforcing loops between momentary states may alter the course of mental health towards either a more or less healthy state. An example with observed data, from a population of individuals with depressive symptoms, supports the validity of a dynamic network model of psychopathology and shows that together and over time, this continuous interplay between momentary states may result in the cluster of symptoms we call major depressive disorder. This approach may help conceptualize the nature of mental disorders, and generate individualized insights useful for diagnosis and treatment in psychiatry

The catechol-O-methyl transferase Val158Met polymorphism and experience of reward in the flow of daily life.

In: *Neuropsychopharmacology : official publication of the American College of Neuropsychopharmacology* 33 (13), S. 3030–3036. DOI: 10.1038/sj.npp.1301520.

Abstract:

Genetic moderation of experience of reward in response to environmental stimuli is relevant for the study of many psychiatric disorders. Experience of reward, however, is difficult to capture, as it involves small fluctuations in affect in response to small events in the flow of daily life. This study examined a momentary assessment reward phenotype in relation to the catechol-O-methyl transferase (COMT) Val(158)Met polymorphism. A total of 351 participants from a twin study participated in an Experience Sampling Method procedure to collect daily life experiences concerning events, event appraisals, and affect. Reward experience was operationalized, as the effect of event appraisal on positive affect (PA). Associations between COMT Val(158)Met genotype and event appraisal on the one hand and PA on the other were examined using multilevel random regression analysis. Ability to experience reward increased with the number of 'Met' alleles of the subject, and this differential effect of genotype was

greater for events that were experienced as more pleasant. The effect size of genotypic moderation was quite large: subjects with the Val/Val genotype generated almost similar amounts of PA from a 'very pleasant event' as Met/Met subjects did from a 'bit pleasant event'. Genetic variation with functional impact on cortical dopamine tone has a strong influence on reward experience in the flow of daily life. Genetic moderation of ecological measures of reward experience is hypothesized to be of major relevance to the development of various behavioral disorders, including depression and addiction.

The dynamic interplay between negative and positive emotions in daily life predicts response to treatment in depression: a momentary assessment study.

In: *Br.J Clin.Psychol.* 51 (2), S. 206–222. DOI: 10.1111/j.2044-8260.2011.02021.x.

Abstract:

OBJECTIVES: Although the treatment of depressive illness aims to restore the imbalance between an excess of negative affect (NA) and a shortage of positive affect (PA), no study has examined how NA and PA may influence each other in depression. This study examines how NA and PA dynamically influence each other in depression and how this may impact on treatment response. DESIGN: Depressed help-seeking individuals participated in the Experience Sampling Method (ESM), which enables visualization of subtle dynamic alterations of momentary affective states over time. Thereafter, participants received a combination of antidepressant treatment and psychotherapy, and were followed up each month. METHODS: NA and PA were assessed during ESM at 10 random moments per day for 6 days. Depressive symptoms were assessed at baseline and at monthly intervals during treatment. RESULTS: Future response to treatment was associated with altered baseline NA-PA dynamics in individuals with previous depressive episodes. Their daily life boosts of PA were followed by a stronger suppression of NA over subsequent hours than in other depressed groups or controls. CONCLUSIONS: Subtle individual differences in daily life emotional dynamics predict future treatment outcome in depression

Wichers, Marieke; Myin-Germeys, Inez; Jacobs, Nele; Peeters, Frenk; Kenis, Gunter; Derom, Catherine et al. (2007):

Genetic risk of depression and stress-induced negative affect in daily life.

In: *The British Journal of Psychiatry* 191 (3), S. 218–223.

Abstract:

BACKGROUND:

A bias to develop negative affect in response to daily life stressors may be an important depression endophenotype, but remains difficult to assess.

AIMS:

To assess this mood bias endophenotype, uncontaminated by current mood, in the course of daily life.

METHOD:

The experience sampling method was used to collect multiple appraisals of daily life event-related stress and negative affect in 279 female twin pairs. Cross-twin, cross-trait associations between dailylife mood bias and DSM-IV depression were conducted.

RESULTS:

Probands whose co-twins were diagnosed with lifetime depression showed a stronger mood bias to stress than those with co-twins without such a diagnosis, independent of probands' current depressive symptoms and to a greater extent in monozygotic twins than in dizygotic twins.

CONCLUSIONS:

Genetic liability to depression is in part expressed as the tendency to display negative affect in response to minor stressors in daily life. This trait may represent a true depression endophenotype.

Wichers, M.; Peeters, F.; Geschwind, N.; Jacobs, N.; Simons, C. J. P.; Derom, Cathérine et al. (2010):

Unveiling patterns of affective responses in daily life may improve outcome prediction in depression: a momentary assessment study.

In: *J Affect Disord* 124 (1), S. 191–195.

Abstract:

Objective

Daily life affective responses are closely linked to vulnerability and resilience in depression. Prediction of future clinical course may be improved if information on daily life emotional response patterns is taken into account.

Method

Female subjects with a history of major depression (n = 83), recruited from a population twin register, participated in a longitudinal study using momentary assessment technology with 4 follow-up measurements. The effect of baseline daily life emotional response patterns (affect variability, stress-sensitivity and reward experience) on follow-up depressive symptomatology was examined.

Results

Both reward experience (B = −0.30, p = 0.001) and negative affect variability (B = 0.46, p = 0.001) predicted future negative affective symptoms independent of all other dynamic emotional patterns and conventional predictors.

Conclusion

Daily life information on dynamic emotional patterns adds to the prediction of future clinical course, independent of severity of symptoms and neuroticism score. Better prediction of course may improve decision-making regarding quantitative and qualitative aspects of treatment.

A time-lagged momentary assessment study on daily life physical activity and affect.

In: *Health Psychol*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-22910-001&site=ehost-live.

Abstract:

Objective: Novel study designs using within-subject methodology and frequent and prospective measurements are required to unravel direction of causality and dynamic processes of behavior over time. The current study examined the effects of physical activity on affective state. A primary and within-study replication sample was derived from twin pairs. Methods: Female twins (n = 504) participated in an experience sampling method study at baseline. Positive and negative affective changes were examined before and following daily life increases in physical activity. Neuroticism was measured at baseline and depressive symptoms were assessed at baseline and at each of four follow-up assessments. Diagnoses, derived by Structured Clinical Interview for Diagnostic and Statistical Manual for Mental Health–IV axis I disorders, (A. P. A., 1994) were obtained at baseline. Results: A significant increase in positive affect (PA) following the moment of increase in physical activity was replicated across both samples up to 180 min after physical activity. There was no effect of physical activity on negative affect (NA). Across the two samples, a history of fulfilling diagnostic criteria for depression at least once moderated the effect of physical activity on PA, in that the effect was lost more rapidly. Conclusions: The study supports a causal effect of physical activity on PA. However, people with past experience of clinical depression may benefit less from the PA-inducing effect of physical activity. These findings have implications for the use of physical exercise in clinical practice. (PsycINFO Database Record (c) 2011 APA, all rights reserved) (journal abstract)

Mechanisms of gene-environment interactions in depression: evidence that genes potentiate multiple sources of adversity.

In: *Psychological Medicine* 39 (7), S. 1077–1086. DOI: 10.1017/S0033291708004388.

Abstract:

BACKGROUND\r\nPrevious work suggests that daily life stress-sensitivity may be an intermediary phenotype associated with both genetic risk for depression and developmental stress exposures. In the current analysis we hypothesized that genetic risk for depression and three environmental exposures over the course of development [prenatal stress, childhood adversity and adult negative life events (NLEs)] combine synergistically to produce the phenotype of stress-sensitivity.\r\nMETHOD\r\nTwin pairs (n=279) participated in a momentary assessment study using the Experience Sampling Method (ESM), collecting appraisals of stress and negative affect (NA) in the flow of daily life. Prospective data on birthweight and gestational age, questionnaire data on childhood adversity and recent NLEs, and interview data on depression were used in the analyses. Daily life stress-sensitivity was modelled as the effect of ESM daily life stress appraisals on ESM NA.\r\nRESULTS\r\nAll three developmental stress exposures were moderated by genetic vulnerability, modelled as dizygotic (DZ) or monozygotic (MZ) co-twin depression status, in their effect on daily life stress-sensitivity. Effects were much stronger in participants with MZ co-twin depression and a little stronger in participants with DZ co-twin depression status, compared to those without co-twin depression. NLE main effects and NLE genetic moderation were reducible to birthweight and childhood adversity.\r\nCONCLUSIONS\r\nThe findings are consistent with the hypothesis that adult daily life stress-sensitivity is the result of sensitization processes initiated by developmental stress exposures. Genes associated with depression may act by accelerating the process of stress-induced sensitization.

Wichers, M.; Simons, C. J.; Kramer, I. M.; Hartmann, J. A.; Lothmann, C.; Myin-Germeys, I. et al. (2011):

Momentary assessment technology as a tool to help patients with depression help themselves.

In: *Acta Psychiatr.Scand.* 124 (4), S. 262–272. DOI: 10.1111/j.1600-0447.2011.01749.x.

Abstract:

OBJECTIVE: Given high relapse rates and residual symptoms in depression, new strategies to increase treatment effectiveness are required. A promising avenue is to investigate how electronic momentary assessment technology may contribute to clinical assessment and interventions in depression. METHOD: A literature search was conducted focusing on the potential contribution of momentary assessments to clinical applications in depression. RESULTS: Momentary assessments are able to reveal subtle, small but repetitive and relevant patterns of emotional expression that predict future course of depression. A momentary assessment tool may expose manageable pieces of daily life behaviour contributing to the depressive experience that patients can influence. The use of this explicit knowledge of daily life experience is understudied with regard to its contribution to diagnostic assessment, monitoring of treatment effects and feedback interventions in depressed patients. The clinical application of momentary assessments may stimulate a shift from passive consumption of treatment to an active role for patients in their recovery and increased patient ownership. CONCLUSION: The precise, prospective and fine-grained information that momentary assessment technology provides may contribute to clinical practice in various ways. Future studies should examine the clinical impact of its use and the feasibility of its implementation in mental health care

Wigman, J. T.; Collip, D.; Wichers, M.; Delespaul, P.; Derom, C.; Thiery, E. et al. (2013):

Altered Transfer of Momentary Mental States (ATOMS) as the Basic Unit of Psychosis Liability in Interaction with Environment and Emotions.

In: *PLoS One* 8 (2), S. e54653. DOI: 10.1371/journal.pone.0054653.

Abstract:

Psychotic disorders are thought to represent altered neural function. However, research has failed to map diagnostic categories to alterations in neural networks. It is proposed that the basic unit of psychotic psychopathology is the moment-to-moment expression of subtle anomalous experiences of subclinical psychosis, and particularly its tendency to persist from moment-to-moment in daily life, under the influence of familial, environmental, emotional and cognitive factors.In a general population twin sample (n = 579) and in a study of patients with psychotic disorder (n = 57), their non-psychotic siblings (n = 59) and unrelated controls (n = 75), the experience sampling paradigm (ESM; repetitive, random sampling of momentary mental states and context) was applied. We analysed, in a within-person prospective design, (i) transfer of momentary anomalous experience at time point () to time point () in daily life, and (ii) moderating effects of negative affect, positive affect, daily stressors, IQ and childhood trauma. Additionally, (iii) familial associations between persistence of momentary anomalous experience and psychotic symptomatology were investigated. Higher level of schizotypy in the twins (but not higher level of psychotic symptoms in patients) predicted more persistence of momentary anomalous experience in daily life, both within subjects and across relatives. Persistence of momentary anomalous experience was highest in patients, intermediate in their siblings and lowest in controls. In both studies, persistence of momentary anomalous experience was moderated by higher levels of negative affect, daily stressors and childhood trauma (only in twins), and by lower levels of positive affect. The study of alterations in the moment-to-moment transfer of subtle anomalous experience of psychosis, resulting in their persistence, helps to explain psychotic and emotional dysregulation tend to cluster in a single phenotype such as schizophrenia, and familial and environmental risks increase the risk of expression of psychosis from, first, subtle momentary anomalous experience to, second, observable clinical symptoms

Wilcox, T. K.; Chen, W. H.; Howard, K. A.; Wiklund, I.; Brooks, J.; Watkins, M. L. et al. (2013):

Item selection, reliability and validity of the Shortness of Breath with Daily Activities (SOBDA) questionnaire: a new outcome measure for evaluating dyspnea in chronic obstructive pulmonary disease.

In: *Health Qual.Life Outcomes.* 11 (1), S. 196. DOI: 10.1186/1477-7525-11-196.

Abstract:

BACKGROUND: Chronic obstructive pulmonary disease (COPD) is characterized by irreversible, progressive obstruction of lung airflow. Dyspnea (shortness of breath [SOB]) is the COPD symptom which most negatively impacts patients' daily activities. To assess how SOB affects daily activities, 37 items were drafted through focus group discussions and cognitive interviews with COPD patients to develop a patient-reported outcome instrument: the Shortness of Breath with Daily Activities questionnaire (SOBDA). Psychometric analysis was conducted to reduce the number of items and evaluate the measurement properties of the final SOBDA. METHODS: Prospective, observational study of 334 COPD patients, recruited from 24 pulmonology and internal medicine clinics in the United States. The 37-item SOBDA was administered to patients each evening for 28 days using an electronic diary. Patients answered every item and rated their level of SOB experienced that day during specific activities. Item selection was conducted by examining item characteristics, dimensionality, and Rasch model analysis results. The decision to delete an item was based on psychometric evidence, content validity, and expert clinical input. The final SOBDA instrument was evaluated for internal consistency, reproducibility, convergent validity, known-groups validity, and responsiveness. RESULTS: Twenty-four items from the 37-item pool were removed following the item selection process: nine items were removed due to high item-to-item correlations; five due to floor effects; three due to infrequent activity; one due to gender bias; two due to low factor loadings; three due to unordered response options; and one due to expert's discretion. Internal consistency and reproducibility of the final SOBDA were demonstrated by Cronbach Alpha = 0.87, and intra-class correlation coefficient = 0.91. Convergent validity was demonstrated by high correlation with the CRQ-SAS (0.60) and SGRQ-C (0.61). Known groups validity was demonstrated by significant difference between ratings of the mMRC and clinical global rating of severity. Evaluation of the ability to detect change was not performed owing to too few responders at the end of the study. CONCLUSIONS: Through the empirical item reduction process, 13 items were selected from the 37-item pool generated during qualitative development. The final 13-item SOBDA is a reliable and valid instrument for use in clinical trials

Wile, Daryl J.; Ranawaya, Ranjit; Kiss, Zelma H. T. (2014):

Smart watch accelerometry for analysis and diagnosis of tremor.

In: *J Neurosci Methods* 230, S. 1–4. DOI: 10.1016/j.jneumeth.2014.04.021.

Abstract:

BACKGROUND: Distinguishing the postural re-emergent tremor of Parkinson disease from essential tremor can be difficult clinically. Use of accelerometry to aid diagnosis is limited to laboratory settings. We sought to record and differentiate these tremors using a smart watch device in an outpatient clinic. NEW METHOD: 41 patients were enrolled. Recordings were made with a smart watch device on the predominantly affected hand (all patients), and simultaneously with an analog accelerometer (10 patients) with hands at rest and outstretched. Tremor peak frequency, peak power, and power of the first four harmonics was calculated and compared between the two devices. Mean power at the first four harmonics was calculated and used to classify tremor as parkinsonian or essential. Test characteristics were calculated to compare the device and clinical diagnoses. RESULTS: Mean harmonic peak power was both highly sensitive and specific for distinction of Parkinson disease postural tremor from essential tremor with an optimal threshold for our sample (sensitivity 90.9%, 95% CI 58.7-99.8%; specificity 100%, 95% CI 76.8-100%; Cohen's kappa=0.91, SE=0.08). COMPARISON WITH EXISTING METHODS: The smart watch and analog devices had nearly perfect concordance of peak frequency and proportional harmonic power. The smart watch recordings in clinic took 3-6 min. CONCLUSIONS: A smart watch device can provide accurate and diagnostically relevant information about postural tremor. Its portability and ease of use could help translate such techniques into routine clinic use or to the community.

Emotions beyond the laboratory: theoretical fundaments, study design, and analytic strategies for advanced ambulatory assessment.

In: *Biol Psychol* 84 (3), S. 552–569. DOI: 10.1016/j.biopsycho.2010.01.017.

Abstract:

Questionnaire and interview assessment can provide reliable data on attitudes and self-perceptions on emotion, and experimental laboratory assessment can examine functional relations between stimuli and reactions under controlled conditions. On the other hand, ambulatory assessment is less constrained and provides naturalistic data on emotion in daily life, with the potential to (1) assure external validity of laboratory findings, (2) provide normative data on prevalence, quality and intensity of real-life emotion and associated processes, (3) characterize previously unidentified emotional phenomena, and (4) model real-life stimuli for representative laboratory research design. Technological innovations now allow for detailed ambulatory study of emotion across domains of subjective experience, overt behavior and physiology. However, methodological challenges abound that may compromise attempts to characterize biobehavioral aspects of emotion in the real world. For example, emotional effects can be masked by social engagement, mental and physical workloads, as well as by food intake and circadian and quasi-random variation in metabolic activity. The complexity of data streams and multitude of factors that influence them require a high degree of context specification for meaningful data interpretation. We consider possible solutions to typical and often overlooked issues related to ambulatory emotion research, including aspects of study design decisions, recording devices and channels, electronic diary implementation, and data analysis.

Bridging the gap between the laboratory and the real world: Integrative ambulatory psychophysiology. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 210–234. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-012%26site%3dehost-live.

Abstract:

(from the chapter) In this chapter, shortly we introduce the scientific discipline of psychophysiology before we give an overview of psychophysiological assessment in real life. We then contrast the paradigms of ambulatory assessment and field experimentation with the very common laboratory experimentation. We consider the differential benefits of these approaches, as well as their unique pitfalls and difficulties, and argue for use of laboratory and field approaches in conjunction, as they are fundamentally complementary research approaches (Patry, 1982). We point out the necessity of (1) more frequent use of ambulatory approaches and (2) development of new, combined research strategies in order to gain data and insight from

different angles—strategies that are validated in the laboratory and close to daily life conditions at the same time (Fahrenberg, Myrtek, Pawlik, & Perrez, 2007). Finally, methods and instruments of ambulatory physiological measurement are presented. Difficulties of data collection and interpretation that are unique to each method are discussed, and possibilities to obviate them are presented. Conducting research in daily life: A historical review. In: Matthias R. Mehl und Tamlin S. Conner: Handbook of research methods for studying daily life.

Hg. v. Matthias R. Mehl und Tamlin S. Conner. New York, NY US: Guilford Press, S. 62–86. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-05165-004%26site%3dehost-live.

Abstract:

(from the chapter) Our aim in this chapter is to highlight the origins and important developments of major approaches for conducting research in daily life. Our focus is on different methods that have often been combined under the umbrella terms ecological momentary assessment (EMA; Stone & Shiffman, 1994; Stone, Shiffman, Atienza, & Nebeling, 2007) or ambulatory assessment (Fahrenberg, 1996a; Fahrenberg et al., 2007). Characteristic of these methods is that people's current experiences and behaviors are assessed repeatedly, in their natural environments, without or only with minimal latency. It would hardly be possible to give a comprehensive historical overview. Therefore, we have narrowed our focus on the development of three major approaches used to conduct research in daily life: (1) diaries and related methods to record everyday experiences and behaviors, (2) (psycho)physiological monitoring of heart activity, and (3) monitoring of physical activity and body movements. For these approaches, we have tried to capture technological beginnings, the circumstances under which they were first used, and factors that led to their further refinement. For more recent stages of research, we give selected examples or refer to literature reviews. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (chapter)

Willett, L. L.; Estrada, C. A.; Wall, T. C.; Coley, H. L.; Ngu, J.; Curry, W. et al. (2011):

Use of ecological momentary assessment to guide curricular change in graduate medical education.

In: *J Grad.Med.Educ.* 3 (2), S. 162–167. DOI: 10.4300/JGME-D-10-00165.1.

Abstract:

PURPOSE: To assess whether a novel evaluation tool could guide curricular change in an internal medicine residency program. METHOD: The authors developed an 8-item Ecological Momentary Assessment tool and collected daily evaluations from residents of the relative educational value of 3 differing ambulatory morning report formats (scale: 8 = best, 0 = worst). From the evaluations, they made a targeted curricular change and used the tool to assess its impact. RESULTS: Residents completed 1388 evaluation cards for 223 sessions over 32 months, with a response rate of 75.3%. At baseline, there was a decline in perceived educational value with advancing postgraduate (PGY) year for the overall mean score (PGY-1, 7.4; PGY-2, 7.2; PGY-3, 7.0; P < .01) and for percentage reporting greater than 2 new things learned (PGY-1, 77%; PGY-2, 66%; PGY-3, 50%; P < .001). The authors replaced the format of a lower scoring session with one of higher cognitive content to target upper-level residents. The new session's mean score improved (7.1 to 7.4; P = .03); the adjusted odds ratios before and after the change for percentage answering, "Yes, definitely" to "Area I need to improve" was 2.53 (95% confidence interval [CI], 1.45-4.42; P = .001) and to "Would recommend to others," it was 2.08 (95% CI, 1.12-3.89; P = .05). CONCLUSIONS: The Ecological Momentary Assessment tool successfully guided ambulatory morning report curricular changes and confirmed successful curricular impact. Ecological Momentary Assessment concepts of multiple, frequent, timely evaluations can be successfully applied in residency curriculum redesign

Use of ecological momentary assessment to determine which structural factors impact perceived teaching quality of attending rounds.

In: *J Grad.Med Educ* 4 (3), S. 322–328. DOI: 10.4300/JGME-D-11-00265.1.

Abstract:

INTRODUCTION: Providing high-quality teaching to residents during attending rounds is challenging. Reasons include structural factors that affect rounds, which are beyond the attending's teaching style and control. OBJECTIVE: To develop a new evaluation tool to identify the structural components of ward rounds that most affect teaching quality in an internal medicine (IM) residency program. METHODS: The authors developed a 10-item Ecological Momentary Assessment (EMA) tool and collected daily evaluations for 18 months from IM residents rotating on inpatient services. Residents ranked the quality of teaching on rounds that day, and questions related to their service (general medicine, medical intensive care unit, and subspecialty services), patient census, absenteeism of team members, call status, and number of teaching methods used by the attending. RESULTS: Residents completed 488 evaluation cards over 18 months. This found no association between perceived teaching quality and training level, team absenteeism, and call status. We observed differences by service ($P < .001$) and patient census ($P = .009$). After adjusting for type of service, census was no longer significant. Use of a larger variety of teaching methods was associated with higher perceived teaching quality, regardless of service or census (P for trend < .001). CONCLUSIONS: The EMA tool successfully identified that higher patient census was associated with lower perceived teaching quality, but the results were also influenced by the type of teaching service. We found that, regardless of census or teaching service, attendings can improve their teaching by diversifying the number of methods used in daily rounds

Analysis of critical incidents and shifting perspectives: transitions in illness careers among adolescents with ADHD.

In: *Qualitative health research* 19 (3), S. 352–365. DOI: 10.1177/1049732308329683.

Abstract:

Adolescence represents a developmental period during which the severity of mental health problems for children with attention deficit/hyperactivity disorder (ADHD) might change. It is a time when teens are consolidating their self-identity and possibly questioning the label of an ADHD diagnosis, treatment, and types of interventions. In this study we investigated the shared critical events related to help seeking reported by 8 teenagers with ADHD, their mothers, and their teachers and how the reported events and constructed shared focus on specific problems might explain teenagers' transitions in their illness careers. Data collected through a qualitative application of the experience sampling method illuminated diverse illness career transitions, including continuing treatment, transitioning from being treated to untreated or from being untreated to treated, and remaining untreated. Our findings support a model of shifting perspectives on illness and wellness among adolescents with ADHD, rather than a progression of adaptation to a chronic disorder.

Wilson, Sarah M.; Dedert, Eric A.; Dennis, Paul A.; Dennis, Michelle F.; Calhoun, Patrick S.; Kirby, Angela C.; Beckham, Jean C. (2014):

Do ethnicity and gender moderate the influence of posttraumatic stress disorder on time to smoking lapse?

In: *Addict Behav* 39 (7), S. 1163–1167. DOI: 10.1016/j.addbeh.2014.03.016.

Abstract:

BACKGROUND: Following a smoking cessation attempt, smokers with posttraumatic stress disorder (PTSD) experience smoking relapse at a higher and faster rate. Black ethnicity and female gender are also associated with lower success rates following smoking cessation. No study to date has prospectively examined how ethnicity and gender may moderate the effect of PTSD on smoking relapse. It was hypothesized that female gender and Black ethnicity would significantly predict early lapse after quitting; further, it was predicted that ethnicity and gender would moderate the effect of PTSD on relapse rate. METHODS: Smokers with PTSD (n=48) and without PTSD (n=56) completed ecological momentary assessment (EMA) the week after a quit date, and self-initiated EMA entries after smoking lapse. Smoking abstinence was biologically verified. The sample included Black (62%) and White (38%) participants, and was 50% female. Study hypotheses were tested with Cox proportional hazards regression modeling time to first smoking lapse. RESULTS: Study results confirmed the main hypothesis, with a significant PTSD x Ethnicity interaction emerging. The effect of PTSD on smoking relapse was significant for White participants but not for Black participants. No significant gender moderation was found. CONCLUSION: Taken together, study results support previous research, and suggest that the relationship between smoking and PTSD is stronger for White smokers than for minorities. This study has significant implications for research in smoking and mental disease, as well as for smoking cessation treatments for Black smokers.

Integrating Ecological Momentary Assessment and Functional Brain Imaging Methods: New Avenues for Studying and Treating Tobacco Dependence.

In: *Nicotine.Tob.Res.* (1462-2203 (Linking)). DOI: 10.1093/ntr/ntt129.

Abstract:

INTRODUCTION: Ecological momentary assessment (EMA) and related methods typically entail repeatedly and intensively sampling behavior as it occurs over time and under naturalistic conditions. Although the methodological features of EMA make it a highly valuable research technique in its own right, EMA can also be a potent counterpart to other approaches. One methodological partnership with substantial, yet largely untapped, potential for the study of tobacco dependence is the pairing of EMA with functional brain imaging. METHODS: The goal of this review is to outline the promise of this approach, with a focus on the combined use of EMA and functional magnetic resonance imaging (fMRI). Due to the unique and complementary strengths of each method, the merger of EMA and fMRI methods has the potential to advance the understanding of tobacco dependence in ways difficult or impossible to achieve through the use of either method in isolation. RESULTS: In addition to describing a conceptual basis for combining EMA with fMRI, we provide a preliminary empirical illustration of this integrative approach using data from an ongoing study. CONCLUSIONS: EMA and fMRI have independently yielded important findings regarding the nature and treatment of tobacco dependence. The integration of these powerful research methods, however, holds even greater potential for the field of tobacco research. In addition, recent advances are paving the way for the synergistic use of fMRI and EMA-based methods to develop innovative approaches to tobacco cessation

Winters, Meghan; Voss, Christine; Ashe, Maureen C.; Gutteridge, Kaitlyn; McKay, Heather; Sims-Gould, Joanie (2014):

Where do they go and how do they get there? Older adults' travel behaviour in a highly walkable environment.

In: *Soc Sci Med. DOI:* 10.1016/j.socscimed.2014.07.006.

Abstract:

Mobility-the ability to move about in one's neighbourhood and maintain independence-is essential for older adults' wellbeing. Neighbourhood environments support or hinder mobility especially as health declines and physical vulnerability increases with age. Linkages between mobility and planning and policy are key to designing age-friendly neighbourhoods with destinations that encourage older adults to get out and be physically active. We describe the mobility of older adults who live in a highly walkable neighbourhood. Specifically, we address the questions of 'where do older adults go?' (destinations) and 'how they get there?' (travel mode, physical activity). We recruited older adults (age 60+) who live in Vancouver's downtown core, an area acknowledged to be highly walkable (Walk Score(R): 94-97/100), and who leave their houses most days of the week. Participants (n = 184) recorded travel in diaries and wore an ActiGraph GT3X + accelerometer for 7 days during September to October 2012. We classified reported destinations according to the North American Industry Classification System, and analysed mobility [trip rates (overall and walking), steps, moderate to vigorous physical activity (MVPA)] and associations between travel and physical activity-related mobility measures. Key destinations were grocery stores (13.6% of trips), restaurants (7.2%), malls/marketplaces (5.5%), and others' homes (5.4%). Participants made 4.6 (std: 2.5) one-way trips/day, took 7910.1 (3871.1) steps/day, and accrued 39.2 (32.9) minutes/day of MVPA. Two-thirds of trips were by active modes (62.8% walk, 3.2% bike) and 22.4% were by car. Trip rates were significantly associated with physical activity outcomes. Older adults living in highly walkable neighbourhoods were very mobile and frequently used active transportation. Travel destinations signify the importance of nearby commercial and social opportunities, even in a highly walkable environment. The high rates of active travel and physical activity in a walkable neighbourhood suggest that when provided compelling destinations, community dwelling older adults walk more and may achieve health benefits through daily travel.

Withall, Janet; Stathi, Afroditi; Davis, Mark; Coulson, Jo; Thompson, Janice L.; Fox, Kenneth R. (2014):

Objective indicators of physical activity and sedentary time and associations with subjective well-being in adults aged 70 and over.

In: *Int J Environ Res Public Health* 11 (1), S. 643–656. DOI: 10.3390/ijerph110100643.

Abstract:

This study explored the associations of the volume and intensity of physical activity and the volume of sedentary time with subjective well-being in a diverse group of 228 older adults in the UK (111 female, mean age 78.2 years (SD 5.8)). Physical activity (PA) and sedentary behaviour were assessed by accelerometry deriving mean steps per day, mean moderate/vigorous PA

minutes per hour (MVPA min . h(-1)) and minutes of sedentary time per hour (ST min . h(-1)). Lower limb function was assessed by the Short Physical Performance Battery. Subjective well-being was assessed using the SF-12 health status scale, the Ageing Well Profile and the Satisfaction with Life Scale. Linear regressions were used to investigate associations between the independent variables which included physical activity (steps and MVPA), sedentary time, participant characteristics (gender, age, BMI, education, number of medical conditions), and lower limb function and dependent variables which included mental and physical well-being. Steps, MVPA and lower limb function were independently and moderately positively associated with perceived physical well-being but relationships with mental well-being variables were weak. No significant associations between sedentary behaviours and well-being were observed. The association between objectively evaluated physical activity and function and subjective evaluations of physical well-being suggest that improving perceptions of physical health and function may provide an important target for physical activity programmes. This in turn may drive further activity participation.

Witham, Miles D.; Donnan, Peter T.; Vadiveloo, Thenmalar; Sniehotta, Falko F.; Crombie, Iain K.; Feng, Zhiqiang; McMurdo, Marion E. T. (2014):

Association of day length and weather conditions with physical activity levels in older community dwelling people.

In: *PLoS One* 9 (1), S. e85331. DOI: 10.1371/journal.pone.0085331.

Abstract:

BACKGROUND: Weather is a potentially important determinant of physical activity. Little work has been done examining the relationship between weather and physical activity, and potential modifiers of any relationship in older people. We therefore examined the relationship between weather and physical activity in a cohort of older community-dwelling people. METHODS: We analysed prospectively collected cross-sectional activity data from community-dwelling people aged 65 and over in the Physical Activity Cohort Scotland. We correlated seven day triaxial accelerometry data with daily weather data (temperature, day length, sunshine, snow, rain), and a series of potential effect modifiers were tested in mixed models: environmental variables (urban vs rural dwelling, percentage of green space), psychological variables (anxiety, depression, perceived behavioural control), social variables (number of close contacts) and health status measured using the SF-36 questionnaire. RESULTS: 547 participants, mean age 78.5 years, were included in this analysis. Higher minimum daily temperature and longer day length were associated with higher activity levels; these associations remained robust to adjustment for other significant associates of activity: age, perceived behavioural control, number of social contacts and physical function. Of the potential effect modifier variables, only urban vs rural dwelling and the SF-36 measure of social functioning enhanced the association between day length and activity; no variable modified the association between minimum temperature and activity. CONCLUSIONS: In older community dwelling people, minimum temperature and day length were associated with objectively measured activity. There was little evidence for moderation of these associations through potentially modifiable health, environmental, social or psychological variables.

Witham, Miles D.; Ireland, Sheila; Houston, J. Graeme; Gandy, Stephen J.; Waugh, Shelley; MacDonald, Thomas M. et al. (2014):

Vitamin d therapy to reduce blood pressure and left ventricular hypertrophy in resistant hypertension: randomized, controlled trial.

In: *Hypertension* 63 (4), S. 706–712. DOI: 10.1161/HYPERTENSIONAHA.113.02177.

Abstract:

Low 25-hydroxyvitamin D levels are associated with higher prevalent blood pressure. We tested whether high-dose intermittent oral vitamin D therapy could reduce blood pressure and left ventricular mass in patients with hypertension resistant to conventional treatment. We conducted a parallel-group, double-blind, randomized placebo-controlled trial. Patients with supine office blood pressure >140/90 mm Hg on >/=3 antihypertensive agents received 100 000 U oral vitamin D3 or matching placebo every 2 months. Office and 24-hour ambulatory blood pressure, glucose, and cholesterol were measured at baseline, 2, 4, and 6 months; left ventricular mass index was measured by cardiac MRI on a subgroup at baseline and 6 months. The primary outcome was mean 24-hour ambulatory blood pressure at 6 months. A total of 68 participants were randomized, 34 in each group. Mean age was 63 (SD 11) years, mean baseline office blood pressure was 154/84 (13/10) mm Hg, and mean baseline 25-hydroxyvitamin D level was 42 (16) nmol/L. Treatment with vitamin D did not reduce 24-hour ambulatory blood pressure (adjusted treatment effects: systolic, +3 mm Hg; 95% confidence interval, -4 to +11; P=0.33; diastolic, -2 mm Hg; 95% confidence interval, -6 to +2; P=0.29); similar results were seen for office blood pressure. Left ventricular mass index was measured in a subgroup (n=25); no reduction was seen with vitamin D treatment (adjusted treatment effect, +4 g/m(2); 95% confidence interval, 0 to +7; P=0.04). There was no significant change in cholesterol or glucose levels. Thus, 6 months of intermittent, high-dose oral vitamin D3 did not reduce blood pressure or left ventricular mass in patients with resistant hypertension.

Witkiewitz, Katie; Desai, Sruti A.; Bowen, Sarah; Leigh, Barbara C.; Kirouac, Megan; Larimer, Mary E. (2014):

Development and evaluation of a mobile intervention for heavy drinking and smoking among college students.

In: *Psychol Addict Behav* 28 (3), S. 639–650. DOI: 10.1037/a0034747.

Abstract:

Nearly all college student smokers also drink alcohol, and smoking and heavy episodic drinking (HED) commonly co-occur. However, few studies have examined the factors that concurrently influence smoking and HED among college students and, to date, no interventions have been developed that target both HED and smoking in this population. The objective of the current study was to develop and evaluate a mobile feedback intervention that targets HED and smoking. Participants (N = 94) were non-treatment-seeking college students (Mage = 20.5 years, SD = 1.7) who engaged in at least a single HED episode in the past 2 weeks and reported concurrent smoking and drinking at least once a week. Participants were randomized to receive either the mobile intervention for 14 days, complete mobile assessments (without intervention) for 14 days, or complete minimal assessments (without intervention or mobile assessments). At a 1-month follow-up, compared with the minimal assessment condition, we observed significant reductions in the number of cigarettes per smoking day in both the mobile intervention (d = 0.55) and mobile assessment (d = 0.45) conditions. Among those randomized to the mobile intervention, receiving more modules of the intervention was significantly associated with a lower likelihood of any drinking during the 14-day assessment period and significant reductions in smoking at 1-month follow-up. The mobile intervention did not result in significant reductions in HED or concurrent smoking and drinking. Future research should continue to examine ways of using technology and the real-time environment to improve interventions for HED and smoking. (PsycINFO Database Record (c) 2014 APA, all rights reserved).

Wittmeier, Kristy Diane Marie; Mollard, Rebecca Christine; Kriellaars, Dean Johannes (2007):

Objective assessment of childhood adherence to Canadian physical activity guidelines in relation to body composition.

In: *Applied Physiology, Nutrition, and Metabolism* 32 (2), S. 217–224.

Abstract:

Low levels of childhood physical activity (PA) are a contributing factor to obesity. The objective of this study was to determine the adherence of children to PA guidelines in relation to body composition. Body fat (Slaughter equation) and body mass index (BMI) were determined during the school year (n = 251, ages 8-11 y). Daily energy expenditure (EE, kcal.kg-1.d-1) and activity time (AT, min.d-1) above moderate and vigorous intensity thresholds were assessed (accelerometry). Using EE criteria, 35.9% expended < 3.0 kcal.kg-1.d-1, 27.9% expended between 3.0 and 5.9 kcal.kg-1.d-1, 13.5% expended between 6.0 and 7.9 kcal.kg-1.d-1, and 22.9% expended >or= 8.0 kcal.kg-1.d-1. Using AT criteria, 52.2% accumulated < 30.0 min, 31.1% accumulated 30.0-59.9 min, 12.7% accumulated 60.0-89.9 min, and 4.0% accumulated >or=90.0 min of AT. The EE corresponding to accumulation of AT > 90 min was 14.8 kcal.kg-1.d-1. The AT corresponding to >or= 8 kcal.kg-1.d-1 was 73.0 min. Inverse relationships were observed between EE and body fat (p = 0.0004), BMI (p = 0.002), mass (p = 0.008), and fat mass index (FMI) (p = 0.001), as well as between AT and body fat (p = 0.001), BMI (p = 0.008), mass (p = 0.017), and FMI (p = 0.002). Controlling for BMI, FMI was inversely related to EE (p = 0.049) and AT (p = 0.039). Fat-free mass index and AT were positively related (p = 0.038). Physical activity had beneficial effects on body composition for children independent of BMI. The relationship between AT and daily EE guidelines was rationalized (60 min.d-1 with 8 kcal.kg-1.d-1) and demonstrated association with acceptable body composition. The 60 min.d-1 of moderate activity may be a more suitable initial target than 90 min.d-1, as so few children met the upper tiers of PA guidelines.

Altered Cardiovascular Rhythmicity in Children Born Small for Gestational Age.

In: *Hypertension* (0194-911X (Linking)). DOI: 10.1161/HYPERTENSIONAHA.112.196949.

Abstract:

Low birth weight is frequently associated with a disproportionately high incidence of cardiovascular disease, diabetes mellitus, and kidney disease in adulthood. Epidemiological studies have identified an inverse association between low birth weight or being small for gestational age and hypertension in adulthood. We hypothesized that children born with low birth weight might have altered circadian and ultradian cardiovascular rhythmicity independent of the prevailing blood pressure level. Twenty-four-hour ambulatory blood pressure and heart rate rhythmicity was prospectively evaluated by Fourier analysis in a cohort of healthy children born with low birth weight and compared with normative pediatric data. Seventy-five children born small for gestational

age (mean age, 8.1+/-2.2 years) and 139 controls matched for age and sex were investigated. In addition to increased 24-hour, daytime, and especially nighttime blood pressure levels (P<0.05), children born small for gestational age exhibited blunted circadian (24-hour) and ultradian (12-, 8-, and 6-hour) blood pressure rhythmicity (P<0.05). In a multivariate analysis including children born with low birth weight and controls, being born with low birth weight independently influenced ultradian blood pressure rhythmicity, whereas in a multivariate analysis including children born with low birth weight only, circadian and ultradian rhythms were independently influenced by catch-up growth, gestational age, and blood pressure level. This study demonstrates blunted circadian and ultradian cardiovascular rhythmicity in prepubertal children born small for gestational age, independent from the presence of arterial hypertension. Circadian and ultradian rhythms may be sensitive indicators for detecting subtle early abnormalities of cardiovascular regulation

Cortisol Responses to Naturalistic and Laboratory Stress in Student Teachers: Comparison with a Non-stress Control Day.

In: *Stress Health* (1532-3005 (Linking)). DOI: 10.1002/smi.2439.

Abstract:

Ambulatory assessments of hypothalamus-pituitary-adrenal axis responses to acute natural stressors yield evidence on stress regulation with high ecological validity. Sampling of salivary cortisol is a standard technique in this field. In 21 healthy student teachers, we assessed cortisol responses to a demonstration lesson. On a control day, sampling was repeated at analogous times. Additionally, the cortisol awakening response (CAR) was assessed on both days. Participants were also exposed to a laboratory stressor, the Trier Social Stress Test, and rated their individual levels of chronic work stress. In pre-to-post-stress assessment, cortisol levels declined after the lesson. However, post-stress cortisol levels were significantly higher compared with those on the control day. Also, the Trier Social Stress Test yielded higher cortisol responses when using the control day as reference baseline. Associations between the CAR and chronic stress measures were observed solely on the control day. There were no significant associations between cortisol responses to the natural and laboratory stressors. Our results indicate that a control day might be an important complement in laboratory but especially in ambulatory stress research. Furthermore, associations between chronic stress measures and the CAR might be obscured by acute stress exposure. Finally, responses to the laboratory stressor do not seem to mirror natural stress responses. Copyright (c) 2012 John Wiley & Sons, Ltd

Personality-based clusters in bulimia nervosa: differences in clinical variables and ecological momentary assessment.

In: *Journal of Personality Disorders* 21 (3), S. 340–357.

Abstract:

The present study examined whether personality-based subgroups of bulimic individuals differed in eating disorder behavior, comorbid psychopathology, treatment history, and momentary assessments of mood and behavior. Participants completed an Ecological Momentary Assessment (EMA) protocol for a period of 2 weeks. Latent profile analysis on the Dimensional Assessment of Personality Pathology revealed 3 groupings of bulimic participants: Interpersonal-emotional, Stimulus seeking-hostile, and Low personality pathology. The personality-based groups differed in histories of mood, anxiety, substance use disorders, features of borderline personality disorder, treatment history, and several momentary measures. These findings suggest that personality variation within the bulimia nervosa diagnostic construct may be associated with meaningful conceptual and clinical differences, including daily experiences in the natural environment.

Examining convergence of retrospective and ecological momentary assessment measures of negative affect and eating disorder behaviors.

In: *Int J Eat Disord*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-37436-001%26site%3dehost-live.

Abstract:

ABSTRACT Objective Data gathered via retrospective forms of assessment are subject to various recall biases. Ecological momentary assessment (EMA) is an alternative approach involving repeated momentary assessments within a participant's natural environment, thus reducing recall biases and improving ecological validity. EMA has been used in numerous prior studies examining various constructs of theoretical relevance to eating disorders. Method This investigation includes data from three previously published studies with distinct clinical samples: (a) women with anorexia nervosa (N = 118), (b) women with bulimia nervosa (N = 133), and (c) obese men and women (N = 50; 9 with current binge eating disorder). Each study assessed negative affective states and eating disorder behaviors using traditional retrospective assessments and EMA. Spearman rho correlations were used to evaluate the concordance of retrospective versus EMA measures of affective and/or behavioral constructs in each sample. Bland–Altman plots were also used to further evaluate concordance in the assessment of eating disorder behaviors. Results There was moderate to strong concordance for the measures of negative affective states across all three studies. Moderate to strong concordance was also found for the measures of binge eating and exercise frequency. The strongest evidence of concordance across measurement approaches was found for purging behaviors. Discussion Overall, these preliminary findings support the convergence of retrospective and EMA assessments of both negative affective states and various eating disorder behaviors. Given the advantages and disadvantages associated with each of these assessment approaches, the specific questions being studied in future empirical studies should inform decisions regarding selection of the most appropriate method. © 2014 Wiley Periodicals, Inc. Wonderlich, Stephen A.; Rosenfeldt, Steven; Crosby, Ross D.; Mitchell, James E.; Engel, Scott G.; Smyth, Joshua; Miltenberger, Raymond (2007):

The effects of childhood trauma on daily mood lability and comorbid psychopathology in bulimia nervosa.

In: *Journal of Traumatic Stress* 20 (1), S. 77–87.

Abstract:

A study of bulimic women examined the relationship between histories of childhood trauma and psychiatric disorders, as well as daily measures of mood and behavior. One hundred twenty-three women with bulimia nervosa were assessed with interviews and completed an Ecological Momentary Assessment (EMA) protocol in which they carried a palmtop computer for 2 weeks. Sexual abuse was associated with a history of mood and anxiety disorders, and emotional abuse with eating disorder psychopathology. In the EMA assessment, sexual abuse was associated with daily purging frequency and self-destructive behavior. Emotional abuse was associated with average daily mood and mood lability. These findings support the idea that child maltreatment may be associated with various aspects of bulimia-related psychopathology.

Woodiwiss, Angela J.; Molebatsi, Nomonde; Maseko, Muzi J.; Libhaber, Elena; Libhaber, Carlos; Majane, Olebogeng H. I. et al. (2009):

Nurse-recorded auscultatory blood pressure at a single visit predicts target organ changes as well as ambulatory blood pressure.

In: *J Hypertens* 27 (2), S. 287–297. DOI: 10.1097/HJH.0b013e328317a78f.

Abstract:

AIM\r\nTo determine whether high-quality nurse-recorded auscultatory blood pressure (BP) values obtained at a single visit predict cardiovascular target organ changes as closely as ambulatory BP measurements.\r\nMETHODS\r\nIn a randomly selected population sample (n = 458, 21% receiving antihypertensive treatment; approximately 40% hypertensive), we compared high-quality single visit nurse-recorded auscultatory BP values to same-day 24-h ambulatory BP in their ability to predict multiple target organ changes [left ventricular mass index (LVMI), left ventricle (LV) mean wall thickness (MWT), early-to-late transmitral velocity ratios (E/A), (echocardiography); log of urinary albumin-to-creatinine ratios (log ACR) (24-h urine samples); large artery dysfunction [carotid-femoral pulse wave velocity (PWV) and central augmentation index (AIc) (applanation tonometry)].\r\nRESULTS\r\nNurse-recorded systolic BP (SBP) measurements obtained at a single visit were as closely associated with LVMI (r = 0.44), LV MWT (r = 0.44), E/A (r = -0.55), log ACR (r = 0.20), PWV (r = 0.62) and AIc (r = 0.41) (P < 0.0001 for all relations) as was 24-h SBP (LVMI; r = 0.33, LV MWT; r = 0.37, E/A; r = -0.35, log ACR; r = 0.24, PWV; r = 0.41, and AIc; r = 0.18, P < 0.001 for all relations) and either day or night SBP. On multivariate regression analysis with both nurse-recorded SBP and 24-h SBP in the same model, nurse-recorded SBP was independently associated with LVMI (P = 0.006), LV MWT (P = 0.03), E/A (P < 0.02), PWV (P < 0.0001) and AIc (P = 0.0002), and 24-h SBP was independently and positively associated with log ACR (P < 0.005), and PWV (P = 0.01).\r\nCONCLUSION\r\nOne or more, high-quality single visit nurse-recorded auscultatory BP

measurements may be equally as effective as ambulatory BP in predicting target organ damage in a population sample of African ancestry.

Estimating heart rate and RSA from the mattress-recorded kinetocardiogram.

In: *Psychophysiology* 44 (4), S. 635–638.

Abstract:

This article describes a method for extracting heart rate (HR) and respiratory sinus arrhythmia (RSA) from the kinetocardiogram (KCG) recorded from accelerometers embedded in a mattress topper. Validation has been performed via comparison with simultaneously recorded ECG. All-night estimates of HR and RSA magnitude derived from both methods were highly correlated. KCG-derived estimates of HR were slightly lower, and those of RSA magnitude higher, than those derived from ECG. These biases are consistent with the need to constrain KCG estimation to periods free of body movement. Mattress actigraphy represents a zero-burden method of obtaining intensive longitudinal indices of cardiac status.

Impact of Stress Reduction Interventions on Hostility and Ambulatory Systolic Blood Pressure in African American Adolescents.

In: *J Black.Psychol.* 37 (2), S. 210–233. DOI: 10.1177/0095798410380203.

Abstract:

This study examined the impact of breathing awareness meditation (BAM), life skills (LS) training, and health education (HE) interventions on self-reported hostility and 24-hour ambulatory blood pressure (ABP) in 121 African American (AA) ninth graders at increased risk for development of essential hypertension. They were randomly assigned to BAM, LS, or HE and engaged in intervention sessions during health class for 3 months. Before, after, and 3 months following intervention cessation, self-reported hostility and 24-hour ABP were measured. Results indicated that between pre- and postintervention, BAM participants displayed significant reductions in self-reported hostility and 24-hour systolic ABP. Reductions in hostility were significantly related to reductions in 24-hour systolic ABP. Between postintervention and follow-up, participants receiving LS showed a significant reduction in hostility but not in 24-hour ABP. Significant changes were not found for the HE group in 24-hour ABP or self-reported hostility, but these change scores were significantly correlated. The implications of the findings are discussed with regard to behavioral stress reduction programs for the physical and emotional health of AAs

Dysregulation of the behavioral activation system in remitted bipolar I disorder.

In: *Journal of Abnormal Psychology* 117 (4), S. 838–848. DOI: 10.1037/a0013598.

Abstract:

The current study tests a prediction of the behavioral activation system (BAS) dysregulation theory of bipolar disorder, namely that following high levels of reward or frustration, individuals with bipolar disorder will take longer than will healthy controls to recover to baseline levels of BAS activity. Eighty individuals (40 with bipolar I disorder, currently euthymic; 40 with no history of affective disorder) completed a daily diary over a 28 day period. No differences were found between the 2 groups in terms of the relation among levels of reward or frustration experienced, magnitude of initial response, or time taken to recover. However, examination of the relation between number of previous episodes and time to recover revealed that history of mania was associated with prolonged activation following reward, whereas history of both mania and depression were associated with prolonged recovery following frustration. The findings do not support an association between lifetime diagnosis of bipolar disorder and slow recovery of BAS activity. Nevertheless, they offer tentative support for an association between number of previous episodes and slow recovery of BAS activity.

A new approach for assessing sleep duration and postures from ambulatory accelerometry.

In: *PLoS One* 7 (10), S. e48089. DOI: 10.1371/journal.pone.0048089.

Abstract:

Interest in the effects of sleeping behavior on health and performance is continuously increasing-both in research and with the general public. Ecologically valid investigations of this research topic necessitate the measurement of sleep within people's natural living contexts. We present evidence that a new approach for ambulatory accelerometry data offers a convenient, reliable, and valid measurement of both people's sleeping duration and quality in their natural environment. Ninety-two participants (14-83 years) wore acceleration sensors on the sternum and right thigh while spending the night in their natural environment and following their normal routine. Physical activity, body posture, and change in body posture during the night were classified using a newly developed classification algorithm based on angular changes of body axes. The duration of supine posture and objective indicators of sleep quality showed convergent validity with self-reports of sleep duration and quality as well as external validity regarding expected age differences. The algorithms for classifying sleep postures and posture changes very reliably distinguished postures with 99.7% accuracy. We conclude that the new algorithm based on body posture classification using ambulatory accelerometry data offers a feasible and ecologically valid approach to monitor sleeping behavior in sizable and heterogeneous samples at home

Can’t Get It Out of My Head: Age Differences in Affective Responsiveness Vary With Preoccupation and Elapsed Time After Daily Hassles.

In: *Emotion*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-41985-001%26site%3dehost-live.

Abstract:

To better understand age differences in negative affective responses to daily hassles, the current study investigated how responses may depend on how much time has elapsed after the hassle and how much one still thinks about the hassle. In an experience-sampling approach with mobile phones, 397 participants aged 12 to 88 years reported their momentary activating (e.g., angry) and deactivating (e.g., disappointed) negative affect and occurrences of hassles, on average 55 times over 3 weeks. On measurement occasions when a hassle had occurred, participants also reported how long ago it occurred and how much they were currently preoccupied with thoughts about the hassle. Multilevel modeling results showed that, compared with more recent hassles, people across the entire age-range of the sample reported lower activating, yet higher deactivating, negative affect when hassles occurred a longer time ago. Age differences only emerged in situations when individuals were still preoccupied with a past hassle. In these situations, deactivating negative affect was higher with stronger preoccupation and more elapsed time after the hassles; these effects were more pronounced with older age. Activating negative affect was higher the more people reported being preoccupied with the hassle and this effect was also more pronounced with age. The results foster an understanding of age differences in negative affective responses to daily hassles by considering preoccupation with hassles and investigating activating and deactivating negative affect separately. We discuss under which circumstances affective responsiveness and age differences therein are more or less pronounced. (PsycINFO Database Record (c) 2014 APA, all rights reserved). Wrzus, Cornelia; Wagner, Gert G.; Riediger, Michaela (2014):

Feeling good when sleeping in? Day-to-day associations between sleep duration and affective well-being differ from youth to old age.

In: *Emotion* 14 (3), S. 624–628. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-04653-001%26site%3dehost-live.

Abstract:

The current study investigated how night-to-night variations in sleep duration relate to affective well-being the next morning as well as how the relationship varies for people of different ages. Using an Experience Sampling approach, 397 participants aged 12 to 88 years reported their sleep duration and their momentary affect on 9 mornings, on average. Associations between sleep

duration during the previous night and morning affect differed depending on the participants' age. For adolescents, for example, affective well-being in the morning was worse the shorter participants had slept the previous night. For adults aged over 20 years, however, affective well-being was worse following nights with shorter or longer than average sleep duration. This effect was more pronounced the older the participants were. The findings demonstrate that the importance of sleep duration for daily affective well-being is better understood when considering the age of the sleeper. In adults, but not adolescents, not only sleeping less but also sleeping more than one's average can be associated with lower affective well-being. Fine particulate matter, temperature, and lung function in healthy adults: Findings from the HVNR study.

In: *Chemosphere. DOI:* 10.1016/j.chemosphere.2014.01.032.

Abstract:

Both ambient particulate air pollution and temperature alterations have been associated with adverse human health effects, but the interactive effect of ambient particulate and temperature on human health remains uncertain. The present study investigated the effects of ambient particulate matter with an aerodynamic diameter2.5mum (PM2.5) and temperature on human lung function simultaneously in a panel of 21 healthy university students from the Healthy Volunteer Natural Relocation (HVNR) study in the context of suburban/urban air pollution in Beijing, China. Each study subject used an electronic diary meter to record peak expiratory flow (PEF) and forced expiratory volume in 1s (FEV1) twice a day for 6months in three periods before and after relocating from a suburban area to an urban area with changing ambient PM2.5 and temperature levels in Beijing. Hourly-averaged environmental data were obtained from central air-monitoring sites. Exposure effects were estimated using generalized linear mixed models controlling for potential confounders. Study subjects provided 6494 daily measurements on PEF and 6460 daily measurements on FEV1 over the study. PM2.5 was associated with reductions in evening PEF and morning/evening FEV1 whereas temperature was associated with reductions in morning PEF. The estimated PM2.5 effects on evening PEF and morning/evening FEV1 in the presence of high temperature were generally stronger than those in the presence of low temperature, and the estimated temperature effects on morning/evening PEF and morning FEV1 in the presence of high PM2.5 were also generally stronger than those in the presence of low PM2.5. For example, there were a 2.47% (95% confidence interval: -4.24, -0.69) reduction and a 0.78% (95% confidence interval: -1.59, 0.03) reduction in evening PEF associated with an interquartile range increase (78.7mug/m3) in PM2.5 at 4-d moving average in the presence of high temperature (21.6 degrees C) and low temperature (<21.6 degrees C), respectively. Our findings suggest that ambient particulate and temperature may interact synergistically to cause adverse respiratory health effects.

An innovative smartphone-based otorhinoendoscope and its application in mobile health and teleotolaryngology.

In: *J Med Internet Res* 16 (3), S. e71. DOI: 10.2196/jmir.2959.

Abstract:

BACKGROUND: The traditional otorhinoendoscope is widely used in the diagnosis of a variety of ear and nose diseases, but only one doctor can use it at a time. It is also very difficult to share observations from one doctor with another doctor. With advances in electronic health technology, the extended potential application of smartphones to support medical practice or mobile health has grown steadily. OBJECTIVE: The first phase of the study discussed how smartphones may be used for otorhinoscopic imaging and image management via an innovative adaptor. The second phase of the study was to evaluate the diagnostic capability of the smartphone-based otorhinoendoscope, as compared to the traditional otorhinoendoscope, and its application in mobile health and teleotolaryngology. METHODS: We designed a unique adaptor to connect the otorhinoendoscope and smartphone in order to perform smartphone-based otorhinoendoscopy. The main aim was to transform the smartphone into an otorhinoendoscope. We devised a method that would allow us to use the smartphone's camera to capture otorhinoscopic images. Using a freely available Web-based real-time communication application platform and the 3G (or WIFI) network, the smartphone-based otorhinoendoscope could synchronize the smartphone-based otorhinoscopic image with smartphones, tablet PCs, computer notebooks, or personal computers. RESULTS: We investigated the feasibility of telemedicine using a smartphone, tablet PC, and computer notebook. Six types of clinical otorhinoscopic images were acquired via the smartphone-based otorhinoendoscope from six patients, which were examined in this study. Three teleconsultants (doctors A, B, and C) reviewed the six types of clinical otorhinoscopic images and made a telediagnosis. When compared to the face-to-face diagnosis, which was made in-person via a traditional otorhinoendoscope, the three teleconsultants obtained scores of a correct primary telediagnosis 83% (5/6), 100% (6/6), and 100% (6/6) of the time, respectively. When the clinical data were provided, the

three teleconsultants obtained a correct secondary telediagnosis score of 100% (6/6), 100% (6/6), and 100% (6/6) of the time, respectively. CONCLUSIONS: The use of previously available technologies in the absence of any additional expensive devices could significantly increase the quality of diagnostics while lowering extraneous costs. Furthermore, this could also increase the connectivity between most isolated family doctors and remote referral centers.

Wuerzner, G.; Bochud, M.; Zweiacker, C.; Tremblay, S.; Pruijm, M.; Burnier, M. (2013):

Step Count is Associated With Lower Nighttime Systolic Blood Pressure and Increased Dipping.

In: *Am J Hypertens* 26 (4), S. 527–534. DOI: 10.1093/ajh/hps094.

Abstract:

BACKGROUND Higher nighttime blood pressure (BP) and the loss of nocturnal dipping of BP are associated with an increased risk for cardiovascular events. However, the determinants of the loss of nocturnal BP dipping are only beginning to be understood. We investigated whether different indicators of physical activity were associated with the loss of nocturnal dipping of BP. METHODS We conducted a cross-sectional study of 103 patients referred for 24-hour ambulatory monitoring of BP. We measured these patients' step count (SC), active energy expenditure (AEE), and total energy expenditure simultaneously, using actigraphs. RESULTS In our study population of 103 patients, most of whom were hypertensive, SC and AEE were associated with nighttime systolic BP in univariate (SC, r = -0.28, P < 0.01; AEE, r = -0.20, P = 0.046) and multivariate linear regression analyses (SC, coefficient beta = -5.37, P < 0.001; AEE, coefficient beta = -0.24, P < 0.01). Step count was associated with both systolic (r = 0.23, P = 0.018) and diastolic (r = 0.20, P = 0.045) BP dipping. Nighttime systolic BP decreased progressively across the categories of sedentary, moderately active, and active participants (125mm Hg, 116mm Hg, 112mm Hg, respectively; P = 0.002). The degree of BP dipping of BP increased progressively across the same three categories of activity (respectively 8.9%, 14.6%, and 18.6%, P = 0.002, for systolic BP and respectively 12.8%, 18.1%, and 22.2%, P = 0.006, for diastolic BP). CONCLUSIONS Step count is continuously associated with nighttime systolic BP and with the degree of BP dipping independently of 24-hour mean BP. The combined use of an actigraph for measuring indicators of physical activity and a device for 24-hour measurement of ambulatory BP may help identify patients at increased risk for cardiovascular events in whom increased physical activity toward higher target levels may be recommended

Wundersitz, Daniel W. T.; Netto, Kevin J.; Aisbett, Brad; Gastin, Paul B. (2013):

Validity of an upper-body-mounted accelerometer to measure peak vertical and resultant force during running and change-of-direction tasks.

In: *Sports Biomech* 12 (4), S. 403–412.

Abstract:

This study assessed the validity of a tri-axial accelerometer worn on the upper body to estimate peak forces during running and change-of-direction tasks. Seventeen participants completed four different running and change-of-direction tasks (0 degrees, 45 degrees, 90 degrees, and 180 degrees; five trials per condition). Peak crania-caudal and resultant acceleration was converted to force and compared against peak force plate ground reaction force (GRF) in two formats (raw and smoothed). The resultant smoothed (10 Hz) and crania-caudal raw (except 180 degrees) accelerometer values were not significantly different to resultant and vertical GRF for all running and change-of-direction tasks, respectively. Resultant accelerometer measures showed no to strong significant correlations (r = 0.00-0.76) and moderate to large measurement errors (coefficient of variation [CV] = 11.7-23.9%). Crania-caudal accelerometer measures showed small to moderate correlations (r = -0.26 to 0.39) and moderate to large measurement errors (CV = 15.0-20.6%). Accelerometers, within integrated micro-technology tracking devices and worn on the upper body, can provide a relative measure of peak impact force experienced during running and two change-of-direction tasks (45 degrees and 90 degrees) provided that resultant smoothed values are used.

Xia, Y.; Cheung, V.; Garcia, E.; Ding, H.; Karunaithi, M. (2011):

Development of an automated physical activity classification application for mobile phones.

In: *Stud.Health Technol.Inform.* 168 (0926-9630 (Linking)), S. 188–194. Online verfügbar unter PM:21893928.

Abstract:

BACKGROUND: Physical activity classification is an objective approach to assess levels of physical activity, and indicates an individual's degree of functional ability. It is significant for a number of the disciplines, such as behavioural sciences, physiotherapy, etc. Accelerometry is found to be a practical and low cost method for activity classification that could provide an objective and efficient measurement of people's daily activities. METHODS: This paper utilises a mobile phone with a built-in tri-axial accelerometer sensor to automatically classify normal physical activities. A rule-based activity classification model, which can recognise 4 common daily activities (lying, walking, sitting, and standing) and 6 transitions between postural orientations, is introduced here. In this model, three types of statuses (walking/ transition, lying, and sitting/standing) are first classified based on the kinetic energy and upright angle. Transitions are then separated from walking and assigned to the corresponding type using upright angle algorithm. To evaluate the performance of this developed application, a trial is designed with 8 healthy adult subjects, who are required to perform a 6-minute activity routine with an iPhone fixed at the waist position. RESULTS: Based on the evaluation result, our application measures the length of time of each activity accurately and the achieved sensitivity of each activity classification exceeds 90% while the achieved specificity exceeds 96%. Meanwhile, regarding the transition identification, the sensitivities are high in stand-to-sit (80%) and low in sit-to-stand (56%)

Urinary albumin excretion, blood pressure changes and hypertension incidence in the community: effect modification by kidney function.

In: *Nephrol Dial Transplant. DOI:* 10.1093/ndt/gfu057.

Abstract:

BACKGROUND: Both increased albuminuria and reduced kidney function may predict blood pressure (BP) progression in the community, while they exacerbate each other's effects. We investigated associations and interactions between these two risk factors, BP changes and hypertension incidence in community-dwelling elderly men. METHODS: Observational study from the Uppsala Longitudinal Study of Adult Men, which included 1051 men (all aged 71 years) with assessments on urinary albumin excretion rate (UAER), 24-hour ambulatory BP monitoring (ABPM) and cystatin-C estimated glomerular filtration rate (eGFR). Of these, 574 men attended re-examination after 6 years, and ABPM measurements were again recorded to assess blood pressure changes and hypertension incidence. RESULTS: UAER was found to be associated with ABPM measurements both at baseline and longitudinally. In longitudinal analysis, there were significant interactions between UAER and kidney function in its association with the changes of systolic BP, mean arterial pressure and pulse pressure. After stratification for renal function state, UAER independently predicted BP changes only in those who had eGFR <60 mL/min/1.73 m2. At re-examination, 71 new cases of hypertension were recorded. In multivariable logistic models, similar interactions were observed on hypertension incidence: UAER was an independent predictor of incident hypertension only in those with reduced renal function. These associations were evident also in the subpopulation of non-diabetics and in participants with normal range UAER (<20 microg/min). CONCLUSIONS: In community-dwelling elderly men, UAER associates with BP progression and hypertension incidence, even within the normal range. Concurrent reduction of renal function modifies and exacerbates these associations.

Actigraphic Motor Activity in Mild Cognitive Impairment Patients Carrying Out Short Functional Activity Tasks: Comparison between Mild Cognitive Impairment with and without Depressive Symptoms.

In: *J Alzheimers Dis. DOI:* 10.3233/JAD-131691.

Abstract:

Background: Individuals with mild cognitive impairment (MCI) may exhibit changes in motor activity in conducting their activities of daily living. Depression, one of the most frequent neuropsychiatric symptoms, might affect motor activity in MCI. Objective: To assess motor activity in MCI subjects carrying out short functional activity tasks using ambulatory actigraphy. Secondly, we sought to investigate the influence of depressive symptoms on motor activity. Methods: 20 MCI and 14 healthy subjects carried out a 30-minute standardized scenario while wearing a chest actigraph. The protocol consisted of directed activities (execution of motor tasks), semi-directed activities (execution of Instrumental Activities of Daily Living, IADL), and undirected 'free' activities. Several common assessment scales (GDS, MADRS, and NPI) were used to diagnose depression. Results: MCI subjects had significantly reduced mean motor activity while carrying out directed and semi-directed activities, compared to healthy control subjects. No difference was found in motor activity between MCI subjects with or without depression. Conclusion: Actigraphic measurement of motor activity during the evaluation of IADLs and motor tasks is a potential objective tool in detecting early changes in MCI. Depressive symptoms seem not to be associated with motor activity in MCI subjects.

Yalachkov, Yavor; Kaiser, Jochen; Naumer, Marcus J. (2012):

Functional neuroimaging studies in addiction: Multisensory drug stimuli and neural cue reactivity.

In: *Neuroscience and Biobehavioral Reviews* 36 (2), S. 825–835. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2012-02186-007&site=ehost-live;Yalachkov@med.uni-frankfurt.de.

Abstract:

Neuroimaging studies on cue reactivity have substantially contributed to the understanding of addiction. In the majority of studies drug cues were presented in the visual modality. However, exposure to conditioned cues in real life occurs often simultaneously in more than one sensory modality. Therefore, multisensory cues should elicit cue reactivity more consistently than unisensory stimuli and increase the ecological validity and the reliability of brain activation measurements. This review includes the data from 44 whole-brain functional neuroimaging studies with a total of 1168 subjects (812 patients and 356 controls). Correlations between neural cue reactivity and clinical covariates such as craving have been reported significantly more often for multisensory than unisensory cues in the motor cortex, insula and posterior cingulate cortex. Thus, multisensory drug cues are particularly effective in revealing brain–behavior relationships in neurocircuits of addiction responsible for motivation, craving awareness and self-related processing. Yamaguchi, Yoshitaka; Wada, Manabu; Sato, Hidenori; Nagasawa, Hikaru; Koyama, Shingo; Takahashi, Yoshimi et al. (2014):

Impact of Ambulatory Blood Pressure Variability on Cerebral Small Vessel Disease Progression and Cognitive Decline in Community-Based Elderly Japanese.

In: *Am J Hypertens. DOI:* 10.1093/ajh/hpu045.

Abstract:

BACKGROUND: Recent epidemiological studies reported a relationship between 24-hour ambulatory blood pressure (ABP) variability and cardiovascular events. However, the impact of ABP variability on small vessel disease (SVD) progression or cognitive decline in the elderly has seldom been investigated in community-based longitudinal studies. METHODS: Subjects (n = 210) underwent ABP monitoring, brain magnetic resonance imaging (MRI), and cognitive testing at baseline and 4 years later. ABP variability was quantified by the SD, weighted SD, coefficient of variation (CV), and average real variability (ARV). ABP variability parameters were divided into 2 groups by median values. RESULTS: Multivariable logistic regression analyses showed that higher systolic CV, diastolic weighted SD, and diastolic CV were significant predictors of SVD progression (P = 0.02, 0.03, and 0.02, respectively). In subjects with SVD on the first MRI, higher systolic and diastolic ARV also predicted progression (P = 0.04 and 0.03, respectively). Higher quartiles of systolic weighted SD and CV had higher incidences of SVD progression (P trend = 0.03 and 0.03, respectively, Cochran-Armitage test), and higher quartiles of systolic ARV had higher incidences of SVD progression in subjects with SVD on the first MRI (P trend = 0.03). Higher systolic ARV was an independent predictor of cognitive decline (P < 0.01), and higher tertiles of systolic ARV had higher incidences of cognitive decline (P trend = 0.02). CONCLUSIONS: This community-based longitudinal study found that increased ABP variability was associated with SVD progression, particularly in individuals with SVD at baseline. Higher systolic ARV predicted SVD progression and cognitive decline.

The relationships among sleep efficiency, pulmonary functions, and quality of life in patients with asthma.

In: *Int J Gen Med* 7, S. 505–512. DOI: 10.2147/IJGM.S72713.

Abstract:

BACKGROUND: Sleep disturbance is commonly observed in patients with asthma, especially in those with poorly controlled asthma. Evaluating sleep quality to achieve good control of asthma is important since nocturnal asthmatic symptoms such as cough, wheezing, and chest tightness may disturb sleep. Actigraphy is an objective, ambulatory monitoring method for tracking a patient's sleep and wake activities and for assessing sleep quality, as reflected by total sleep time, sleep efficiency, duration of awakening after sleep onset (WASO), and sleep onset latency. PATIENTS AND METHODS: Fifty patients with asthma were enrolled in this study. Sleep quality was assessed employing wristwatch-type actigraphy (Actiwatch 2). The level of asthma control was assessed by the Asthma Control Questionnaire (ACQ), and asthma-related quality of life was assessed by the Asthma Quality of Life Questionnaire (AQLQ). The parameters for sleep quality were compared using ACQ scores, AQLQ scores, and pulmonary function test results. RESULTS: The total sleep time was 387.2 minutes, WASO was 55.8 minutes, sleep efficiency was

87.01%, sleep onset latency was 8.17 minutes, and the average ACQ was 0.36. Neither sleep efficiency nor WASO correlated with respiratory functions, ACQ scores, or AQLQ scores. CONCLUSION: Sleep-related parameters assessed by actigraphy in well-controlled asthma do not correlate with pulmonary functions, the asthma control level, or daytime quality of life. Sleep quality should be evaluated independently when asthma is well-controlled.

A new device to estimate VO2 during incline walking by accelerometry and barometry.

In: *Med Sci Sports Exerc* 41 (12), S. 2213–2219. DOI: 10.1249/MSS.0b013e3181a9c452.

Abstract:

PURPOSE\r\nTo examine whether the biased estimation of oxygen consumption rate (VO2, mL x kg(-1) x min(-1)) by accelerometry during incline walking can be improved by the addition of altitude changes as measured by barometry.\r\nMETHODS\r\nWe measured VO2 by respiratory gas analysis and vector magnitude (VM, G) from triaxial accelerations in 42 healthy people (mean +/- SD age = 63 +/- 7 yr) during graded walking on a treadmill while the incline was varied from -15% to +15%. They walked at subjectively slow, moderate, and fast speeds on level and uphill inclines and, in addition to these, at their fastest speed at 0% incline. They then walked at approximately 3, 4, and 5 km x h(-1) on downhill inclines for 3 min each. We determined a regression equation to estimate VO2 from VM and theoretical vertical upward (Hu, m x min(-1)) and downward speeds (Hd, m x min(-1)) for the last 1 min of each trial. To validate the precision of the equation, we measured VM and altitude changes with a portable device equipped with a triaxial accelerometer and a barometer in 11 of the 42 subjects walking on an outdoor hill and compared the estimated VO2 with the value simultaneously measured by respiratory gas analysis.\r\nRESULTS\r\nVO2 above resting was estimated from VO2 = 0.044 VM + 1.365 Hu + 0.553 Hd (r = 0.93, P < 0.001) and the estimated V O2(y) was almost identical to the measured VO2(x) (y = 0.97x, r = 0.88, P < 0.001) with a mean difference of -0.20 +/- 3.47 (mean +/- SD) by Bland-Altman analysis in the range of 2.0-33.0 mL x kg(-1) x min(-1).\r\nCONCLUSIONS\r\nVO2 during walking on various inclines can be precisely estimated by using the device equipped with a triaxial accelerometer and a barometer.

Epidemiological characteristics and clinical features of black African subject's resistant hypertension.

In: *Ann Cardiol Angeiol (Paris). DOI:* 10.1016/j.ancard.2014.01.002.

Abstract:

INTRODUCTION: Few studies in sub-Saharan Africa were interested in resistant hypertension. The objectives of this study were to determine the frequency of resistant hypertension in hypertensive black African population, and to describe its clinical and therapeutic features. PATIENTS AND METHODS: From May 1, 2010 to May 31, 2012, we included consecutively hypertensive followed in two hospitals in the city of Ouagadougou, under antihypertensive treatment at optimum dose and observant. Patients whose blood pressure was uncontrolled despite a triple antihypertensive therapy at the optimal dose including a diuretic associated with dietary measures have received ambulatory blood pressure monitoring. Following this examination, patients whose blood pressure was >/=135/85mmHg during the day and/or >/=120/70mmHg at night were considered resistant hypertension. We investigated the cardiovascular risk factors as well as target organ damages. We combined spironolactone 50mg in treatment when absence of contra-indication appreciated the evolution of blood pressure under this treatment. The measurement of plasma renin activity was not performed. Statistical analysis was performed using SPSS Version 17 for Windows. RESULTS: We included 692 patients with 14.6% of resistant hypertension. The average age of patients was 54.8+/-11.1years in the general population, 56.5+/-11.8years in the subgroup of non-resistant hypertension and 64.2+/-5.4years in the subgroup of resistant hypertension. The symptoms were represented by headache (11.9%), dizziness (9.9%) and chest pain (8.9%). Modifiable cardiovascular risk factors were dominated by dyslipidemia, diabetes and obesity/overweight. These risk factors were significantly more frequent in the subgroup of resistant hypertension. The global cardiovascular risk was high in 24.9% of cases in the general population, 22.5% in the subgroup of non-resistant hypertension and 38.6% in the subgroup of resistant hypertension. The target organ damages were significantly more frequent in the same subgroup of resistant hypertension. After addition of spironolactone, 21.8% of resistant hypertensive patients were controlled. CONCLUSION: This study shows that resistant hypertension is common in black Africans. It is mostly subjects of the sixth decade, with limited economic income and living in rural areas. In the absence of contra-indication, spironolactone contributed to decrease the morbidity of this pathology.

Yan, Iris Renfei; Poon, Carmen Chung Yan; Zhang, Yuan-Ting (2009):

Evaluation scale to assess the accuracy of cuff-less blood pressure measuring devices.

In: *Blood Press Monit* 14 (6), S. 257–267. DOI: 10.1097/MBP.0b013e328330aea8.

Abstract:

OBJECTIVE\r\nThe call for early detection of hypertension and cardiac events creates a heavy demand for devices that can be used for blood pressure (BP) monitoring at home and in ambulatory settings. An emerging type of BP monitors without an occluding cuff has drawn great attentions for this application because it is comfortable and capable of providing continuous readings. For the development the cuff-less devices, it is crucial for the clinicians and engineers to joint efforts in establishing an evaluation standard.\r\nMETHODS\r\nThis study attempts to contribute to its initiation in two ways. First, a new distribution model for measurement differences between the test device and the reference was proposed. We verified the model using evaluation results from 40 devices, of which 80% of the American Association for the Advancement of Medical Instrumentation and British Hypertension Society reporting results were in agreement, as compared with 50%, if the original normal model was used. We further tested a cuff-less device on 85 patients for 999 datasets and found that the differences between the proposed distribution and that of the device were nonsignificant for systolic BP measurements (Kolmogorov-Smirnov = 0.036, P = 0.15). Second, some evaluation scales were studied for their capability to assess the accuracy of cuff-less devices. For mean absolute difference, a map was developed to relate it with the criteria of American Association for the Advancement of Medical Instrumentation, British Hypertension Society, and European Society of Hypertension protocols, on the basis of the proposed distribution model; for mean absolute percentage difference, it is prominent in evaluating devices that have measurement errors often increasing with BP, which is an issue has not been fully explored in existing standards.\r\nCONCLUSION\r\nThis study focused on the statistical aspect of establishing standard to assess the accuracy of cuff-less BP measuring devices. The results of our study on the validation reports of various cuff-based devices and an experimental study on a cuff-less device showed that the t4 distribution is better than the normal distribution in portraying the underlying error distribution of both kinds of devices. Moreover, based on both the theoretical and experimental studies, mean absolute difference or mean absolute percentage difference is recommended as continuous scale to assess the accuracy of cuff-less devices for their own distinctive advantages.

Development of a wearable motion detector for telemonitoring and real-time identification of physical activity.

In: *Telemed J E Health* 15 (1), S. 62–72. DOI: 10.1089/tmj.2008.0060.

Abstract:

Characteristics of physical activity are indicative of one's mobility level, latent chronic diseases, and aging process. Current research has been oriented to provide quantitative assessment of physical activity with ambulatory monitoring approaches. This study presents the design of a portable microprocessor-based accelerometry measuring device to implement real-time physical activity identification. An algorithm was developed to process real-time tri-axial acceleration signals produced by human movement to identify targeted still postures, postural transitions, and dynamic movements. Fall detection was also featured in this algorithm to meet the increasing needs of elderly care in free-living environments. High identification accuracy was obtained in performance evaluation. This device is technically viable for telemonitoring and real-time identification of physical activity, while providing sufficient information to evaluate a person's activity of daily living and her/his status of physical mobility. Limitations regarding real-time processing and implementation of the system for telemonitoring in the home environment were also observed.

Real-Time Gait Cycle Parameter Recognition Using a Wearable Accelerometry System.

In: *Sensors.(Basel)* 11 (8), S. 7314–7326. DOI: 10.3390/s110807314.

Abstract:

This paper presents the development of a wearable accelerometry system for real-time gait cycle parameter recognition. Using a tri-axial accelerometer, the wearable motion detector is a single waist-mounted device to measure trunk accelerations during walking. Several gait cycle parameters, including cadence, step regularity, stride regularity and step symmetry can be estimated in real-time by using autocorrelation procedure. For validation purposes, five Parkinson's disease (PD) patients and five young healthy adults were recruited in an experiment. The gait cycle parameters among the two subject groups of different mobility can be quantified and distinguished by the system. Practical considerations and limitations for implementing the autocorrelation procedure in such a real-time system are also discussed. This study can be extended to the future attempts in real-time

detection of disabling gaits, such as festinating or freezing of gait in PD patients. Ambulatory rehabilitation, gait assessment and personal telecare for people with gait disorders are also possible applications

Nocturnal blood pressure and cardiovascular disease: a review of recent advances.

In: *Hypertens.Res.* (0916-9636 (Linking)). DOI: 10.1038/hr.2012.26.

Abstract:

The accurate measurement, prediction and treatment of high blood pressure (BP) are essential issues in the management of hypertension. Ambulatory blood pressure monitoring (ABPM) has been shown to be superior to clinic BP measurements as ABPM can provide the following important information: (i) the mean BP levels, (ii) the diurnal variation in BP and (iii) the short-term BP variability. Among these parameters, there is increasing evidence that the mean nocturnal BP level is the most sensitive predictor of cardiovascular morbidity and mortality. Furthermore, several studies have shown that less nocturnal BP dipping, defined as less nocturnal BP decline relative to daytime BP, or a high night-day BP ratio was associated with poor prognosis irrespective of the 24-hour BP levels. These findings can be interpreted in at least two ways: namely, high nocturnal BP or less nocturnal BP dipping might be not only a potent risk factor for cardiovascular disease (CVD), but also a marker of pre-existing or concurrent diseases that can lead to nocturnal BP elevation. In this review, we consider the clinical utility of ABPM and in particular focus on the nocturnal BP levels or nocturnal BP dipping as a potent risk factor for CVD. In addition, the clinical management of high nocturnal BP and blunted nocturnal BP dipping with antihypertensive medications is discussed.Hypertension Research advance online publication, 1 March 2012; doi:10.1038/hr.2012.26

Yeh, V. M.; McCarthy, D. E.; Baker, T. B. (2012):

An Ecological Momentary Assessment Analysis of Prequit Markers for Smoking-Cessation Failure.

In: *Exp.Clin.Psychopharmacol.* (1064-1297 (Linking)). DOI: 10.1037/a0029725.

Abstract:

This study aimed to identify correlates of smoking-cessation failure, a failure to establish abstinence during a quit-smoking attempt. Identifying risk factors for early failure could facilitate the development of tailored interventions to promote cessation. The current study used existing ecological momentary assessment (EMA) data to investigate the extent to which prequit craving, negative affect, and recent smoking were associated with cessation failure in 374 smokers (189, 50.5% female). Subjects were prompted to complete 4-7 real-time reports of craving, negative affect, and recent smoking daily in the four days prior to quitting. Multilevel models of craving and negative affect (mean level, growth, volatility, and association with smoking) were estimated. Results indicated that recent smoking was associated with significantly lower craving among smokers who failed to quit than those who achieved a full day of cessation, but this held only among smokers who reduced smoking by at least 10% in the days preceding the quit attempt. Smokers who failed to quit on the quit day also experienced slower increases in negative affect in the days preceding the quit attempt than did initial abstainers, but delayed quitters and delayed cessation failures did not differ in negative-affect trajectories. These results suggest that successful abstainers and cessation failures can be differentiated by specific dimensions of prequit craving and negative-affect experiences, but the effects hold only in certain circumstances. Impacts of suppression on emotional responses and performance outcomes: An experience-sampling study in younger and older workers.

In: *The Journals of Gerontology: Series B: Psychological Sciences and Social Sciences* 67B (6), S. 666–676. DOI: 10.1037/t06463-000;

Abstract:

Objectives: Past studies have demonstrated that older adults used less emotional suppression to regulate their emotions than did younger adults, but the effectiveness of using this emotion regulatory strategy on psychosocial well-being across age remains largely unexplored. The present study adopted an experience-sampling method to examine whether the impacts of momentary employment of emotional suppression on momentary positive and negative emotions and job performance would be different by age. Method: Eighty-seven Chinese insurance workers, aged between 18 and 61 years, participated in a 5-day

sampling study. Their affective responses at work, momentary task performance, and sales productivity were recorded. Results: Results showed that older workers' greater use of suppression at work was associated with lower intensity of negative emotions, whereas such association was not found among younger workers. Moreover, greater use of suppression over the sampling period was significantly predictive of sales productivity of older workers, but such a positive association was not shown in younger workers. Discussion: These findings reveal that the use of suppression at work may be more effective for older workers than for younger workers. Positive Effect of Social Work--Related Values on Work Outcomes: The Moderating Role of Age and Work Situation.

In: *J.Gerontol.B Psychol.Sci.Soc.Sci.* (1079-5014 (Linking)). DOI: 10.1093/geronb/gbt094.

Abstract:

Objectives. This study investigated the effect of social work-related values on job performance through job satisfaction and tested whether age and work situation would moderate such associations.Methods. This study consists of two parts: Part 1 is a cross-sectional survey among 299 Chinese clerical employees aged 19-60 years and Part 2 is a 14-day experience sampling study in a subsample of Part 1 (N = 67).Results and Discussion. Part 1 revealed that age moderated the effect of social work-related values on job performance through job satisfaction, with a stronger positive effect in older workers than in younger workers. Part 2 demonstrated that the moderating effect of age shown in Part 1 also varied across work situations. In particular, holding momentary social work-related values was beneficial to the task performance of older workers, and the effect was significantly stronger when they were in social situations than in nonsocial situations, whereas the effect remained weak among younger workers regardless of work context. Moreover, the moderating effect of age could be accounted for by future time perspective. This study supports socioemotional selectivity theory that goal orientation shifts toward the emphasis of interpersonal closeness when one perceives future time as increasingly limited

Oscillometric 24-h ambulatory blood pressure reference values in Hong Kong Chinese children and adolescents.

In: *J Hypertens* 32 (3), S. 606–619. DOI: 10.1097/HJH.0000000000000062.

Abstract:

OBJECTIVES: We aimed to establish community-based normal reference values of 24-h ambulatory blood pressure monitoring (ABPM) for Chinese children and adolescents. Furthermore, we investigated how excluding overweight children affects BP percentiles and compared them with German references. METHODS: In this territory-wide cross-sectional prospective cohort

study, 1445 Hong Kong Chinese children and adolescents aged 8-17 years with body height between 119 and 185 cm were recruited. Their ABPM assessment was performed using validated arm oscillometric recorders (A&D TM-2430) and complied with American Heart Association's recommendations. The reference tables were constructed using the LMS method to normalize skewed distribution of ABP data to sex and age or height. RESULTS: The ambulatory BP was higher among boys and the difference between boys and girls progressively widened with age. An increasing trend in daytime and night-time SBP and DBP with age and height was observed in both sexes. The age-specific and sex-specific 95th percentiles from nonoverweight children (n=1147; 79%) were lower than the whole cohort by up to 2.5 and 1 mmHg for SBP and DBP, respectively. In comparison, our overall and nonoverweight reference standards were generally higher than corresponding German references. CONCLUSION: The study provides ambulatory BP standards for Chinese children, with sex-related age-specific and height-specific percentiles. Further longitudinal studies are required for investigating its clinical utility in Chinese.

Yogarajah, M.; Powell, H. W. R.; Heaney, D.; Smith, S. J. M.; Duncan, J. S.; Sisodiya, S. M. (2009):

Long term monitoring in refractory epilepsy: the Gowers Unit experience.

In: *Journal of neurology, neurosurgery, and psychiatry* 80 (3), S. 305–310. DOI: 10.1136/jnnp.2008.144634.

Abstract:

INTRODUCTION\r\nGuidelines from the National Institute for Health and Clinical Excellence (NICE) and the International League Against Epilepsy recommend long term EEG monitoring (LTM) in patients for whom seizure or syndrome type is unclear, and in patients for whom it is proving difficult to differentiate between epilepsy and non-epileptic attack disorder (NEAD). The purpose of this study was to evaluate this recommended use of LTM in the setting of an epilepsy tertiary referral unit.\r\nMETHODS\r\nThis study reviewed the case notes of all admissions to the Sir William Gowers Unit at the National Society for Epilepsy in the years 2004 and 2005. A record was made of the type, duration and result of all LTM performed both prior to and during the admission. Pre- and post-admission diagnoses were compared, and patients were divided according to whether LTM had resulted in a change in diagnosis, refinement in diagnosis or no change in diagnosis. The distinction between change and a refinement in the diagnosis was made on the basis of whether or not this alteration resulted in a change in management.\r\nRESULTS\r\n612 patients were admitted during 2004 and 2005, 230 of whom were referred for diagnostic clarification. Of these, LTM was primarily responsible for a change in diagnosis in 133 (58%) and a refinement of diagnosis in 29 (13%). In 65 (29%) patients the diagnosis remained the same after LTM. In those patients in whom there was a change in diagnosis, the most common change was in distinguishing epilepsy from NEAD in 73 (55%) and in distinguishing between focal and generalised epilepsy in 47 (35%). LTM was particularly helpful in differentiating frontal lobe seizures from generalised seizures and non-epileptic attacks. Inpatient ambulatory EEG proved as effective as video telemetry in helping to distinguish between NEAD, focal and generalised epilepsy.\r\nDISCUSSION\r\nThe study revealed that LTM led to an alteration in the diagnosis of 71% of patients referred to a tertiary centre for diagnostic clarification of possible epilepsy. Although LTM is relatively expensive, time consuming and of limited availability, this needs to be balanced against the considerable financial and social cost of misdiagnosed and uncontrolled seizures. This service evaluation supports the use of performing LTM (either video or ambulatory) in a specialist setting in patients who present diagnostic difficulty.

Development of a first-responder dispatch system using a smartphone.

In: *J Telemed Telecare* 20 (2), S. 75–81. DOI: 10.1177/1357633X14524152.

Abstract:

We constructed a prototype community first responder (CFR) dispatch system. The system sends incident information, including a map, to the chosen CFR's mobile phone. We tested it in a simulation of 30 out-of-hospital cardiac arrest incidents which had occurred in the town of Motegi during the previous year. Thirty off-duty firefighters acted as CFRs and were sent to the same locations. The mean response time (from the CFR receiving dispatch information to arrival at the scene) was 3 min 37s faster than the actual response time in the corresponding historical control, i.e. the response time was reduced by 36% ($P < 0.01$). The median travel distance of the CFRs was 3.4 km and there was a positive correlation between response time and travel distance. The study showed that interactive communication between dispatcher and CFR was important for effective operation and that CFRs could reach an OHCA patient before the Emergency Medical Service arrives.

Yoon, Youngzoon; Cho, Jung H.; Yoon, Gilwon (2009):

Non-constrained blood pressure monitoring using ECG and PPG for personal healthcare.

In: *J Med Syst* 33 (4), S. 261–266.

Abstract:

Blood pressure (BP) is one of the important vital signs that need to be monitored for personal healthcare. Arterial blood pressure (BP) was estimated from pulse transit time (PTT) and PPG waveform. PTT is a time interval between an R-wave of electrocardiography (ECG) and a photoplethysmography (PPG) signal. This method does not require an aircuff and only a minimal inconvenience of attaching electrodes and LED/photo detector sensors on a subject. PTT computed between the ECG R-wave and the maximum first derivative PPG was strongly correlated with systolic blood pressure (SBP) (R = −0.712) compared with other PTT values, and the diastolic time proved to be appropriate for estimation diastolic blood pressure (DBP) (R = −0.764). The percent errors of SBP using the individual regression line (4–11%) were lower than those using the regression line obtained from all five subjects (9–14%). On the other hand, the DBP estimation did not show much difference between the individual regression (4–10%) and total regression line (6–10%). Our developed device had a total size of 7 × 13.5 cm and was operated by single 3-V battery. Biosignals can be measured for 72 h continuously without external interruptions. Through a serial network communication, an external personal computer can monitor measured waveforms in real time. Our proposed method can be used for non-constrained, thus continuous BP monitoring for the purpose of personal healthcare.

A real-time assessment of the effect of exercise in chronic fatigue syndrome.

In: *Physiol Behav* 92 (5), S. 963–968.

Abstract:

Patients with chronic fatigue syndrome (CFS) report substantial symptom worsening after exercise. However, the time course over which this develops has not been explored. Therefore, the objective of this study was to investigate the influence of exercise on subjective symptoms and on cognitive function in CFS patients in natural settings using a computerized ecological momentary assessment method, which allowed us to track the effects of exercise within and across days. Subjects were 9 female patients with CFS and 9 healthy women. A watch-type computer was used to collect real-time data on physical and psychological symptoms and cognitive function for 1week before and 2weeks after a maximal exercise test. For each variable, we investigated temporal changes after exercise using multilevel modeling. Following exercise, physical symptoms did get worse but not until a five-day delay in CFS patients. Despite this, there was no difference in the temporal pattern of changes in psychological symptoms or in cognitive function after exercise between CFS patients and controls. In conclusion, physical symptoms worsened after several days delay in patients with CFS following exercise while psychological symptoms or cognitive function did not change after exercise.

Yoshiuchi, Kazuhiro; Yamamoto, Yoshiharu; Akabayashi, Akira (2008):

Application of ecological momentary assessment in stress-related diseases.

In: *BioPsychoSocial Medicine* 2 (1), S. 13.

Abstract:

Many physical diseases have been reported to be associated with psychosocial factors. In these diseases, assessment relies mainly on subjective symptoms in natural settings. Therefore, it is important to assess symptoms and/or relationships between psychosocial factors and symptoms in natural settings. Symptoms are usually assessed by self-report when patients visit their doctors. However, self-report by recall has an intrinsic problem; "recall bias". Recently, ecological momentary assessment (EMA) has been proposed as a reliable method to assess and record events and subjective symptoms as well as physiological and behavioral variables in natural settings. Although EMA is a useful method to assess stress-related diseases, it has not been fully acknowledged, especially by clinicians. Therefore, the present brief review introduces the application and future direction of EMA for the assessment and intervention for stress-related diseases.

Peer Reviewed: Patterns of Physical Activity Among Overweight and Obese Adults.

In: *Preventing chronic disease* 6 (3).

Abstract:

Introduction

Little is known about patterns of physical activity in overweight and obese adults, although they are at high risk for chronic disease and can benefit from physical activity. We describe patterns of moderate-to-vigorous physical activity (MVPA) and MVPA in bouts of 10 minutes or longer in overweight and obese adults.

Methods

Overweight and obese participants (n = 1,648) who were screened for the multicenter Weight Loss Maintenance Trial wore RT3 accelerometers for at least 3 weekdays and 1 weekend day. We determined minutes spent in moderate physical activity, vigorous physical activity, and MVPA overall, by weekday vs weekend, and by time of day. We also measured bouts of at least 10 minutes of sustained MVPA.

Results

Participants were active for an average of 15.8 minutes per day. Among those who engaged in bouts of MVPA, the average bout was 33.3 minutes long. Participants who were younger than 50 years, male, non-African American, or overweight were more active than were those who were older than 50, female, African American, or obese. Participants were more active on weekends than on weekdays and in the morning than in the afternoon or evening. Only 2% of participants were active for 60 or more minutes per day.

Conclusion

We found differences in physical activity patterns by demographic characteristics, day, and time of day. Weekend mornings may be an opportune time to promote additional physical activity.

Young, K. P.; Lavender, J. M.; Wonderlich, S. A.; Crosby, R. D.; Engel, S. G.; Mitchell, J. E. et al. (2012):

Moderators of post-binge eating negative emotion in eating disorders.

In: *J Psychiatr.Res* (0022-3956 (Linking)). DOI: 10.1016/j.jpsychires.2012.11.012.

Abstract:

The purpose of this study was to test the impact of two variables on post-binge eating negative emotion in a combined sample of women with anorexia nervosa (AN; n = 47) and bulimia nervosa (BN; n = 121). Participants completed two weeks of an ecological momentary assessment protocol during which they provided multiple daily ratings of overall negative affect and guilt and reported eating disorder behaviors including binge eating and self-induced vomiting. The results indicate that both overall negative affect and guilt exhibited a statistically significantly decrease in the hour immediately following binge eating episodes. The decrease in guilt, but not overall negative affect, was moderated by eating disorder diagnosis and the tendency to engage in self-induced vomiting. Specifically, individuals with BN reported a greater reduction in guilt than those with AN, and individuals who did not typically engage in self-induced vomiting reported more decreases in guilt than those who typically engaged in self-induced vomiting. This study extends the existing literature on the relationship between negative affect and eating disorder behaviors, suggesting guilt as a potentially relevant facet of negative affect in the maintenance of binge eating. In addition, the findings indicate that two individual differences, eating disorder diagnosis and self-induced vomiting, may influence the trajectory of guilt following binge eating episodes

Young, K. P.; Lavender, J. M.; Steffen, K.; Wonderlich, S. A.; Engel, S. G.; Mitchell, J. E. et al. (2013):

Restrictive eating behaviors are a nonweight-based marker of severity in anorexia nervosa.

In: *Int.J Eat.Disord.* (0276-3478 (Linking)). DOI: 10.1002/eat.22163.

Abstract:

OBJECTIVE: The purpose of this study was to compare the type and frequency of restrictive eating behaviors across the two subtypes of anorexia nervosa (AN; restricting [ANr] and binge eating/purging [ANbp]) using ecological momentary assessment (EMA) and to determine whether subtype differences in restrictive eating behaviors were attributable to severity of the disorder or the frequency of binge eating. METHOD: Participants (N = 118) were women at least 18 years of age with full (n = 59) or

subthreshold (n = 59) AN who participated in a two week (EMA) protocol. RESULTS: General estimating equations revealed that individuals with ANbp generally reported more frequent restrictive eating behaviors than individuals with ANr. These differences were mostly accounted for by greater severity of eating psychopathology, indicating that the presence and frequency of restrictive eating behaviors in AN may be nonweight-based markers of severity. Binge eating frequency did not account for these findings. DISCUSSION: The present findings are especially interesting in light of the weight-based severity rating in the DSM-5. Young, Kyle P.; Lavender, Jason M.; Crosby, Ross D.; Wonderlich, Stephen A.; Engel, Scott G.; Mitchell, James E. et al. (2014):

Bidirectional associations between binge eating and restriction in anorexia nervosa. An ecological momentary assessment study.

In: *Appetite* 83C, S. 69–74. DOI: 10.1016/j.appet.2014.08.014.

Abstract:

This study examined the association between restrictive eating behaviors and binge eating in anorexia nervosa (AN) using data collected in the natural environment. Women (N = 118) with DSM-IV full or subthreshold AN reported eating disorder behaviors, including binge eating episodes, going >/= 8 waking hours without eating, and skipping meals, during 2 weeks of ecological momentary assessment (EMA). Time-lagged generalized estimating equations tested the following hypotheses: 1) dietary restriction would predict binge eating while controlling for binge eating the previous day; 2) binge eating would predict restriction the subsequent day while controlling for restriction the previous day. After controlling for relevant covariates, the hypotheses were not supported; however, there appeared to be a cumulative effect of repeatedly going 8 consecutive hours without eating (i.e. fasting) on the risk of binge eating among individuals who recently engaged in binge eating. In addition, skipping meals was associated with a lower risk of same day binge eating. The relationship between binge eating and dietary restriction appears to be complex and may vary by type of restrictive eating behavior. Future research should aim to further clarify the nature of the interaction of binge eating and restrictive eating among individuals with AN in order to effectively eliminate these behaviors in treatment.

A smartphone application of alcohol resilience treatment for behavioral self-control training.

In: *Conf.Proc.IEEE Eng Med Biol.Soc.* 2012 (1557-170X (Linking)), S. 1976–1979. DOI: 10.1109/EMBC.2012.6346343.

Abstract:

High relapse rate is one of the most prominent problems in addiction treatment. Alcohol Resilience Treatment (ART), an alcohol addiction therapy, is based on Cue Exposure Treatment, which has shown promising results in preliminary studies. ART aims at optimizing the core area of relapse prevention, and intends to improve patients' capability to withstand craving of alcohol. This method emphasizes the interplay of resilience and resourcefulness. It contains 6 sessions with different topics according to the stage of treatment circuit, and each session consists of 6 steps. Due to the purity and structure of the treatment rationale, it is realistic, reasonable and manageable to transform the method into a smartphone application. An ART app in Android system and an accessory of bilateral tactile stimulation were developed and will be used in a study with behavioral self-control training. This paper presents the design and realization of the smartphone based ART application. The design of a pilot study, which is to examine the benefits of a smartphone application providing behavioral self-control training, is also reported in this paper

Analysis of Heart Rate Variability in Masked Hypertension.

In: *Cell Biochem Biophys. DOI:* 10.1007/s12013-014-9882-y.

Abstract:

To investigate heart rate variability (HRV) in patients with masked hypertension (MH), participants were classified based on clinic and 24-h ambulatory blood-pressure monitoring: essential hypertension (EH, n = 40; MH, n = 36) and normotension (NT, n = 48). The HRV parameters were observed using a 24-h Holter monitor. Compared with NT controls, the parameters of HRV (SDNN, SDANN, SDNN Index, RMSSD, HF) and parameters in EH and MH patients had significantly decreased. No statistically

significant difference in the HRV parameters was found between the EH and MH groups. The changes in HRV parameters show cardiac autonomic nerve dysfunction in patients with MH.

Application of cross-sectional time series modeling for the prediction of energy expenditure from heart rate and accelerometry.

In: *Journal of Applied Physiology* 104 (6), S. 1665–1673.

Abstract:

Accurate estimation of energy expenditure (EE) in children and adolescents is required for a better understanding of physiological, behavioral, and environmental factors affecting energy balance. Cross-sectional time series (CSTS) models, which account for correlation structure of repeated observations on the same individual, may be advantageous for prediction of EE. CSTS models for prediction of minute-by-minute EE and, hence, total EE (TEE) from heart rate (HR), physical activity (PA) measured by accelerometry, and observable subject variables were developed in 109 children and adolescents by use of Actiheart and 24-h room respiration calorimetry. CSTS models based on HR, PA, time-invariant covariates, and interactions were developed. These dynamic models involve lagged and lead values of HR and lagged values of PA for better description of the series of minute-by-minute EE. CSTS models with random intercepts and random slopes were investigated. For comparison, likelihood ratio tests were used. Log likelihood increased substantially when random slopes for HR and PA were added. The population-specific model uses HR and 1- and 2-min lagged and lead values of HR, HR(2), and PA and 1- and 2-min lagged values of PA, PA(2), age, age(2), sex, weight, height, minimum HR, sitting HR, HR x height, HR x weight, HR x age, PA x weight, and PA x sex interactions ($P < 0.001$). Prediction error for TEE was 0.9 +/- 10.3% (mean +/- SD). Errors were not correlated with age, weight, height, or body mass index. CSTS modeling provides a useful predictive model for EE and, hence, TEE in children and adolescents on the basis of HR and PA and other observable explanatory subject characteristics of age, sex, weight, and height.

Zakeri, Issa F.; Adolph, Anne L.; Puyau, Maurice R.; Vohra, Firoz A.; Butte, Nancy F. (2010):

Multivariate adaptive regression splines models for the prediction of energy expenditure in children and adolescents.

In: *Journal of applied physiology (Bethesda, Md. : 1985)* 108 (1), S. 128–136. DOI: 10.1152/japplphysiol.00729.2009.

Abstract:

Advanced mathematical models have the potential to capture the complex metabolic and physiological processes that result in heat production or energy expenditure (EE). Multivariate adaptive regression splines (MARS) is a nonparametric method that estimates complex nonlinear relationships by a series of spline functions of the independent predictors. The specific aim of this study is to construct MARS models based on heart rate (HR) and accelerometer counts (AC) to accurately predict EE, and hence 24-h total EE (TEE), in children and adolescents. Secondarily, MARS models will be developed to predict awake EE, sleep EE, and activity EE also from HR and AC. MARS models were developed in 109 and validated in 61 normal-weight and overweight children (ages 5-18 yr) against the criterion method of 24-h room respiration calorimetry. Actiheart monitor was used to measure HR and AC. MARS models were based on linear combinations of 23-28 basis functions that use subject characteristics (age, sex, weight, height, minimal HR, and sitting HR), HR and AC, 1- and 2-min lag and lead values of HR and AC, and appropriate interaction terms. For the 24-h, awake, sleep, and activity EE models, mean percent errors were -2.5 +/- 7.5, -2.6 +/- 7.8, -0.3 +/- 8.9, and -11.9 +/- 17.9%, and root mean square error values were 168, 138, 40, and 122 kcal, respectively, in the validation cohort. Bland-Altman plots indicated that the predicted values were in good agreement with the observed TEE, and that there was no bias with increasing TEE. Prediction errors for 24-h TEE were not statistically associated with age, sex, weight, height, or body mass index. MARS models developed for the prediction of EE from HR monitoring and accelerometry were demonstrated to be valid in an independent cohort of children and adolescents, but require further validation in independent, free-living populations.

Zakeri, I. F.; Adolph, A. L.; Puyau, M. R.; Vohra, F. A.; Butte, N. F. (2013):

Cross-sectional time series and multivariate adaptive regression splines models using accelerometry and heart rate predict energy expenditure of preschoolers.

In: *J Nutr* 143 (1), S. 114–122. DOI: 10.3945/jn.112.168542.

Abstract:

Prediction equations of energy expenditure (EE) using accelerometers and miniaturized heart rate (HR) monitors have been developed in older children and adults but not in preschool-aged children. Because the relationships between accelerometer counts (ACs), HR, and EE are confounded by growth and maturation, age-specific EE prediction equations are required. We used advanced technology (fast-response room calorimetry, Actiheart and Actigraph accelerometers, and miniaturized HR monitors) and sophisticated mathematical modeling [cross-sectional time series (CSTS) and multivariate adaptive regression splines (MARS)] to develop models for the prediction of minute-by-minute EE in 69 preschool-aged children. CSTS and MARS models were developed by using participant characteristics (gender, age, weight, height), Actiheart (HR+AC_x) or ActiGraph parameters (AC_x, AC_y, AC_z, steps, posture) [x, y, and z represent the directional axes of the accelerometers], and their significant 1- and 2-min lag and lead values, and significant interactions. Relative to EE measured by calorimetry, mean percentage errors predicting awake EE (-1.1 +/- 8.7%, 0.3 +/- 6.9%, and -0.2 +/- 6.9%) with CSTS models were slightly higher than with MARS models (-0.7 +/- 6.0%, 0.3 +/- 4.8%, and -0.6 +/- 4.6%) for Actiheart, ActiGraph, and ActiGraph+HR devices, respectively. Predicted awake EE values were within +/-10% for 81-87% of individuals for CSTS models and for 91-98% of individuals for MARS models. Concordance correlation coefficients were 0.936, 0.931, and 0.943 for CSTS EE models and 0.946, 0.948, and 0.940 for MARS EE models for Actiheart, ActiGraph, and ActiGraph+HR devices, respectively. CSTS and MARS models should prove useful in capturing the complex dynamics of EE and movement that are characteristic of preschool-aged children

Zaki, Landon F.; Coifman, Karin G.; Rafaeli, Eshkol; Berenson, Kathy R.; Downey, Geraldine (2013):

Emotion differentiation as a protective factor against nonsuicidal self-injury in borderline personality disorder.

In: *Behav Ther* 44 (3), S. 529–540. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-22014-008%26site%3dehost-live;landon.fuhrman@gmail.com.

Abstract:

Evidence that nonsuicidal self-injury (NSSI) serves a maladaptive emotion regulation function in borderline personality disorder (BPD) has drawn attention to processes that may increase risk for NSSI by exacerbating negative emotion, such as rumination. However, more adaptive forms of emotion processing, including differentiating broad emotional experiences into nuanced emotion categories, might serve as a protective factor against NSSI. Using an experience-sampling diary, the present study tested whether differentiation of negative emotion was associated with lower frequency of NSSI acts and urges in 38 individuals with BPD who reported histories of NSSI. Participants completed a dispositional measure of rumination and a 21-day experience-sampling diary, which yielded an index of negative emotion differentiation and frequency of NSSI acts and urges. A significant rumination by negative emotion differentiation interaction revealed that rumination predicted higher rates of NSSI acts and urges in participants with difficulty differentiating their negative emotions. The results extend research on emotion differentiation into the clinical literature and provide empirical support for clinical theories that suggest emotion identification and labeling underlie strategies for adaptive self-regulation and decreased NSSI risk in BPD. Assessment of blood pressure control in hypertensive stroke survivors: an ambulatory blood pressure monitoring study.

In: *Blood Press Monit* 11 (5), S. 235–241.

Abstract:

Background: We compared the sensitivity of office blood pressure and ambulatory blood pressure monitoring recordings in evaluating the effectiveness of antihypertensive treatment and identified factors related to inadequate blood pressure control among hypertensive stroke survivors.

Methods: Office blood pressure and ambulatory blood pressure monitoring measurements were performed at 120±30 days after ictus in 187 first-ever consecutive hypertensive stroke survivors who were receiving blood pressure-lowering medications according to international guidelines. Handicap was assessed by the modified Rankin Scale. Blood pressure was regarded as controlled if office and daytime ambulatory systolic and diastolic blood pressure values were <140/90 and <135/85 mmHg, respectively. Patients were subclassified according to the degree of their nocturnal systolic blood pressure fall [(mean daytime values−mean night-time values)100/mean daytime values] as dippers (≥10%), nondippers (≥0% and< 10%) and reverse dippers (<0%).

Results: Effective blood pressure control was documented in significantly (P<0.001) fewer patients using ambulatory blood pressure monitoring (32.1%) than those using office recordings (43.3%), whereas in 16% of the study population a masked lack of per-treatment blood pressure control (elevated ambulatory blood pressure in the presence of normal office blood pressure levels) was identified. The distribution of dipping patterns differed significantly (P=0.01) between controlled hypertensive individuals (normal office and ambulatory measurements) and patients with isolated ambulatory hypertension (dippers: 31.3 vs. 10.0%; nondippers:56.9 vs. 53.3%; reverse dippers: 11.8 vs. 36.7%). Logistic regression analysis revealed diabetes mellitus and functional independency (modified Rankin Scale score <2) as independent predictors of inadequate blood pressure control.

Conclusion: Ambulatory blood pressure monitoring detects a substantial number of treated hypertensive stroke survivors with a masked lack of per-treatment blood pressure control, who present a higher prevalence of abnormal circadian blood pressure patterns (reverse dipping). Diabetes mellitus and poststroke functional independency are the main factors contributing to inadequate blood pressure control.

Zanobetti, Antonella; Stone, Peter H.; Speizer, Frank E.; Schwartz, Joel D.; Coull, Brent A.; Suh, Helen H. et al. (2009):

T-wave alternans, air pollution and traffic in high-risk subjects.

In: *The American journal of cardiology* 104 (5), S. 665–670. DOI: 10.1016/j.amjcard.2009.04.046.

Abstract:

Particulate pollution has been linked to risk for cardiac death; possible mechanisms include pollution-related increases in cardiac electrical instability. T-wave alternans (TWA) is a marker of cardiac electrical instability measured as differences in the magnitude between adjacent T waves. In a repeated-measures study of 48 patients aged 43 to 75 years, associations of ambient and home indoor particulate pollution, including black carbon (BC) and reports of traffic exposure, with changes in 0.5-hourly maximum TWA (TWA-MAX), measured by 24-hour Holter electrocardiographic monitoring, were investigated. Each patient was observed up to 4 times within 1 year after percutaneous intervention for myocardial infarction, acute coronary syndromes without infarction, or stable coronary artery disease, for a total of 5,830 0.5-hour observations. Diary data for each 0.5-hour period defined whether a patient was home or not home, or in traffic. Increases in TWA-MAX were independently associated with the previous 2-hour mean ambient BC (2.1%, 95% confidence interval 0.9% to 3.3%) and with being in traffic in the previous 2 hours (6.1%, 95% confidence interval 3.4% to 8.8%). When subjects were home, indoor home BC effects were largest and most precise; when subjects were away from home, ambient central site BC effects were strongest. Increases in pollution increased the odds of TWA-MAX > or =75th percentile (odds ratio 1.4, 95% confidence interval 1.2 to 1.6 for a 1 microg/m(3) increase in 6-hour mean BC). In conclusion, after hospitalization for coronary artery disease, being in traffic and short-term ambient or indoor BC exposure increased TWA, a marker of cardiac electrical instability.

Zanstra, Ydwine Jieldouw; Johnston, Derek William (2011):

Cardiovascular reactivity in real life settings: Measurement, mechanisms and meaning.

In: *Biol Psychol* 86 (2), S. 98–105.

Abstract:

Cardiovascular reactivity to stress is most commonly studied in the laboratory. Laboratory stressors may have limited ecological validity due to the many constraints, operating in controlled environments. This paper will focus on paradigms that involve the measurement of cardiovascular reactions to stress in real life using ambulatory monitors. Probably the most commonly used paradigm in this field is to measure the response to a specific real life stressor, such as sitting an exam or public speaking. A more general approach has been to derive a measure of CV variability testing the hypothesis that more reactive participants will have more variable heart rate or blood pressure. Alternatively, self-reports of the participants' perceived stress, emotion or demands may be linked to simultaneously collected ambulatory measures of cardiovascular parameters.

This paper examines the following four questions: (1) What is the form and what are the determinants of stress-induced CV reactivity in real life? (2) What are the psychophysiological processes underlying heart rate and blood pressure reactivity in real life? (3) Does CV reactivity determined in the laboratory predict CV reactivity in real life? (4) Are ambulatory cardiovascular measures predictive of cardiovascular disease?

It is concluded that the hemodynamic processes that underlie the blood pressure response can reliably be measured in real life and the psychophysiological relationships seen in the laboratory have been obtained in real life as well. Studies examining the effects of specific real life stressors show that responses obtained in real life are often larger than those obtained in the laboratory. Subjective ratings of stress, emotion and cognitive determinants of real life stress (e.g. demand, reward and control) also relate to real life CV responses. Surprisingly, ambulatory studies on real life cardiovascular reactivity to stress as a predictor of cardiovascular disease are rare. Measuring the CV response to stress in real life may provide a better measure of the stress-related process that are hypothesized to cause disease than is possible in the laboratory. In addressing these questions, below we review the studies that we believe are representative of the field. Therefore, this review is not comprehensive.

Dear Mr Chocolate: Constructing a typology of contextualized chocolate consumption experiences through qualitative diary research.

In: *Qualitative market research: An international Journal* 14 (1), S. 55–82.

Abstract:

Purpose

– This paper aims to advance theory-building in the area of food consumption research, by exploring how consumers experience chocolate consumption in different contexts and by viewing these inductive findings in the light of the relevant existing body of knowledge.

Design/methodology/approach

– A qualitative study is conducted on a non-student sample of Italian consumers. The qualitative diary research technique is used as it is particularly suitable to capturing sensations, feelings, thoughts, and behaviours related to various chocolate consumption contexts. Content analytical and interpretive principles are followed in the production of the study findings.

Findings

– Chocolate generates rich and complex consumption experiences as a function of various contextual forces. Seven main contextual chocolate consumption categories are identified: context of physiological need, context of sensorial gratification, context of memories and nostalgia, context of escapism, context of materialism, context of chocoholism, and context of interpersonal and self-gifts. On the basis of these chocolate consumption categories and ideas from past consumer behaviour research, four more general contextualized chocolate consumption experience types are extracted: chocolate consumption experience as medicine, as mind manoeuvring, as regression and as ritual enhancement.

Originality/value

– Past research has not explored how different chocolate consumption contexts shape and define these experiences, even though contextual variation in food consumption experiences is recognized as important. The nuances of chocolate consumption in various contexts are explored to the unprecedented depth, a conceptually novel typology of contextualized chocolate consumption experiences is presented, the field of application of self-congruity theory is expanded and the profiles of chocolate consumer segments identified by past research are enriched.

Zawadzki, M. J.; Smyth, J. M.; Merritt, M. M.; Gerin, W. (2013):

Absorption in Self-Selected Activities Is Associated With Lower Ambulatory Blood Pressure but Not for High Trait Ruminators.

In: *Am J Hypertens* (0895-7061 (Linking)). DOI: 10.1093/ajh/hpt118.

Abstract:

BACKGROUND: A range of nonpharmacological interventions (e.g., meditation) have positive effects on blood pressure (BP) but tend to have poor adherence. These interventions may lower BP partly by absorbing and directing attention away from one's negative thoughts. We hypothesized that recurring self-selected activities (SSAs) that are attentionally absorbing may similarly lower BP. We examined the effect of reported engagement in SSAs during the previous month prior to participation on ambulatory BP (ABP) and whether those prone to rumination were less likely to show these effects. METHODS: Participants (n = 38) reported engagement in SSAs and how absorbing they were, responded to trait rumination and perceived stress questionnaires, wore an ABP monitor for 24 hours, and at each ABP measurement answered electronic diary questions assessing activity levels, affect, social interactions, and caffeine and tobacco use. RESULTS: Regression analyses tested whether the reported absorption of SSAs, trait rumination, and their interaction predicted daytime and nighttime systolic and diastolic ABP. Greater absorption predicted lower daytime and nighttime ABP (bs = -18.83 to -8.79; Ps < .05), but this relationship was moderated by trait rumination (bs = 3.72 to 9.97; Ps < .05). Follow-up analyses revealed that absorption was unrelated to ABP for those with high trait rumination but that more absorption predicted lower ABP for those less prone to rumination. CONCLUSIONS: Our results suggest that regular engagement in absorbing SSAs is related to lower ABP. These findings have implications for the development of nonpharmacological interventions and suggest SSAs may serve as an adjuvant intervention strategy to lower BP

Zdziechowska, Krystyna; Czy++Ak, Izabela; Murawiec, S. +.; Prot, Katarzyna (2012):

Characteristics of subjects with self reported history of psychosis who were interested in self-assessment of their functional status via online e-diaries.

In: *Archives of Psychiatry and Psychotherapy* 14 (4), S. 31–36. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-01920-004%26site%3dehost-live;murawiec@ipin.edu.pl.

Abstract:

Aim: To identify a profile of subjects with psychotic symptoms who were interested in self–monitoring of their functional status via an online electronic diary (e-diary). Method: The TacyJakJa.pl website was promoted by means of a standard online advertising and positioning methods together with limited traditional advertising activities (an article in press, a radio broadcast). Physicians were not involved in recruitment process. Registered users of the website were offered a simple and convenient self-assessment tool to monitor their functional status in the form of e-diary. E-diaries were designed by psychiatrists for the purpose of self-assessment of mental state, everyday activities, therapy and treatment tolerability, in a registered users group. Results: Over 18 months 450 individuals registered in the after psychotic crisis section of the website. Answering question of how did they found out about the website 86% of users pointed internet as the source of information, 8% – friends , 4% – their physician, 2% – the press. 70% of users, as they reported, were diagnosed with schizophrenia and paranoid disorders, 82% of them were hospitalized due to their condition. The group of users consisted mainly of people in their thirties, who completed their secondary education. 70% of them did not have paid job; majority of them were single (57% of women and as much as 77% of men; $p < 0.0001$). Despite significant life independence of users, as well as their understanding of the necessity of treatment (97% of registered users received outpatient psychiatric treatment), depressive mood was observed in the group. At registration the WHO-5 Well-being scale was completed by 239 subjects; and as much as 76% of them achieved total score below 13 ($Chi2(239.1) = 65$, $p < 0.0001$), what indicates depressive mood and higher risk for developing clinical depression. There were no statistically significant differences between results of men and women. Conclusions: Self-monitoring of functional status via e-diary generated a great deal of interest among younger users with psychotic experiences who received outpatient treatment, mostly singles, often with depressive mood. Self-assessment via e-diaries proved to be manageable and worthwhile. E-diary users were interested in active participation in their treatments, however without being encouraged by their physician, they discontinued regular self-assessment after several entries. Still, they visited other sections that the website, such as: ask a doctor corner, medical library, photo contests section, online chat rooms, and discussion forum they kept in touch, chatted and talked also with persons with no psychic disorders, who registered on the website. Zeitzer, J. M.; David, R.; Friedman, L.; Mulin, E.; Garcia, R.; Wang, J. et al. (2012):

Phenotyping Apathy in Individuals With Alzheimer Disease Using Functional Principal Component Analysis.

In: *Am.J.Geriatr.Psychiatry* (1064-7481 (Linking)). DOI: 10.1097/JGP.0b013e318248779d.

Abstract:

OBJECTIVES:: To determine if there is a specific pattern of gross motor activity associated with apathy in individuals with Alzheimer disease (AD). DESIGN:: Examination of ad libitum 24-hour ambulatory gross motor activity patterns. SETTING:: Community-dwelling, outpatient. PARTICIPANTS:: Ninety-two individuals with AD, 35 of whom had apathy. MEASUREMENTS:: Wrist actigraphy data were collected and examined using functional principal component analysis (fPCA). RESULTS:: Individuals with apathy have a different pattern of gross motor activity than those without apathy (first fPCA component, $p < 0.0001$, $t = 5.73$, $df = 90$, t test) such that there is a pronounced decline in early afternoon activity in those with apathy. This change in activity is independent of depression ($p = 0.68$, $F[1, 89] = 0.05$, analysis of variance). The decline in activity is consistent with an increase in napping. Those with apathy also have an early wake and bedtime (second fPCA component, $t = 2.53$, $df = 90$, $p < 0.05$, t test). CONCLUSIONS:: There is a signature activity pattern in individuals with apathy and AD that is distinct from those without apathy and those with depression. Actigraphy may be a useful adjunctive measurement in the clinical diagnosis of apathy in the context of AD

Zenk, Shannon N.; Horoi, Irina; McDonald, Ashley; Corte, Colleen; Riley, Barth; Odoms-Young, Angela M. (2014):

Ecological momentary assessment of environmental and personal factors and snack food intake in African American women.

In: *Appetite. DOI:* 10.1016/j.appet.2014.09.008.

Abstract:

This study examined contributions of environmental and personal factors (specifically, food availability and expense, daily hassles, self-efficacy, positive and negative affect) to within-person and between-person variations in snack food intake in 100 African American women. Participants were signaled at random five times daily for seven days to complete a survey on a study-provided smartphone. Women reported consuming snack foods at 35.2% of signals. Easier food availability accounting for one's usual level was associated with higher snack food intake. Being near outlets that predominately sell snacks (e.g., convenience stores), while accounting for one's usual proximity to them, was associated with higher snack food intake. Accounting for one's usual daily hassle level, we found that on days with more frequent daily hassles snack food intake was higher. The positive association between within-person daily hassles frequency and snack food intake was stronger when foods were easily available. Public and private policies to curb ubiquitous food availability and mobile health interventions that take into account time-varying influences on food choices and provide real-time assistance in dealing with easy food availability and coping with stressors may be beneficial in improving African American women's day to day food choices.

Zettl, U. K.; Bauer-Steinhusen, U.; Glaser, T.; Hechenbichler, K.; Limmroth, V. (2013):

Evaluation of an electronic diary for improvement of adherence to interferon beta-1b in patients with multiple sclerosis: design and baseline results of an observational cohort study.

In: *BMC Neurol* 13 (1), S. 117. DOI: 10.1186/1471-2377-13-117.

Abstract:

BACKGROUND: Multiple sclerosis is a chronic, incurable, demyelinating disease that requires long-term treatment. Rates of non-adherence to prescribed therapy of up to 50% have been reported for chronic diseases. Strategies to improve treatment adherence are therefore of the utmost importance. This study will evaluate the effect of using electronic and paper diaries on treatment adherence to interferon beta-1b in patients with a first clinical isolated syndrome (CIS) or relapsing-remitting multiple sclerosis (RRMS). Here we report on the study design and results of baseline assessments. METHODS: Patients were recruited into a prospective national multicenter cohort study for an observational period of 2 years. At the start of the study, patients opted to use a digital (DiD) or paper diary (PD) to document self-administered injections of interferon beta-1b. Adherence to treatment will be assessed on the dropout rate at the end of the observation period and on the regularity of injections every other day at 6-month intervals. Patient-related health outcomes will also be evaluated. RESULTS: 700 patients with a mean age of 38.3 (SD 10.3) years and a mean duration of disease since diagnosis of 3.6 (SD 5.9) years were enrolled. 383 patients opted for the digital diary, 192 of which included an injection reminder. Significantly more male than female patients opted for the DiD. Only gender was identified as a factor influencing the decision for DiD or PD. Based on rating scales, a significantly higher proportion of women had depressive comorbidities at baseline. CONCLUSIONS: Demographic characteristics of the two cohorts were similar at baseline. More women chose a paper diary, and more had depression at baseline. These imbalances will be addressed in the analysis of the study as possible confounders influencing long-term treatment adherence in the digital and paper diary cohorts.Trial RegistrationClinicalTrials.gov Identifier: NCT00902135

Zhang, Wenwen; Cadilhac, Dominique A.; Churilov, Leonid; Donnan, Geoffrey A.; O'Callaghan, Christopher; Dewey, Helen M. (2014):

Does abnormal circadian blood pressure pattern really matter in patients with transient ischemic attack or minor stroke?

In: *Stroke* 45 (3), S. 865–867. DOI: 10.1161/STROKEAHA.113.004058.

Abstract:

BACKGROUND AND PURPOSE: Patients with stroke are more likely to have impaired autonomic nervous function and abnormal circadian blood pressure (BP) patterns. It remains unclear whether circadian BP patterns in patients with transient ischemic attack or minor stroke (National Institutes of Health Stroke Scale </=3) differ from those in the normal population. METHODS: Participants were assessed using a 24-hour ambulatory BP monitor and a short-term measurement of heart rate variability. RESULTS: There were 76 patients (mean age, 67.2 years; 57.9% men; and 61.8% transient ischemic attack) and 82 controls (65.6 years; 54.9% men). A history of hypertension was more prevalent in patients (72.4%; controls 48.8%). Circadian BP patterns were distributed similarly among patients and controls, and heart rate variability was also consistent between patients and controls. CONCLUSIONS: In contrast to previous findings among patients with acute stroke, patients with transient ischemic attack or minor stroke had similar BP patterns and autonomic nervous system function, when compared with controls.

Zhang, Melvyn Wb; Ho, Cyrus Sh; Fang, Pan; Lu, Yanxia; Ho, Roger Cm (2014):

Usage of social media and smartphone application in assessment of physical and psychological well-being of individuals in times of a major air pollution crisis.

In: *JMIR Mhealth Uhealth* 2 (1), S. e16. DOI: 10.2196/mhealth.2827.

Abstract:

BACKGROUND: Crisis situations bring about many challenges to researchers, public institutions, and governments in collecting data and conducting research in affected individuals. Recent developments in Web-based and smartphone technologies have offered government and nongovernment organizations a new system to disseminate and acquire information. However, research into this area is still lacking. The current study focuses largely on how new social networking websites and, in particular, smartphone technologies could have helped in the acquisition of crucial research data from the general population during the recent 2013 Southeast Asian Haze. This crisis lasted only for 1 week, and is unlike other crisis where there are large-scale consequential after-effects. OBJECTIVE: To determine whether respondents will make use of Internet, social media, and smartphone technologies to provide feedback regarding their physical and psychological wellbeing during a crisis, and if so, will these new mechanisms be as effective as conventional, technological, Internet-based website technologies. METHODS: A Web-based database and a smartphone application were developed. Participants were recruited by snowball sampling. The participants were recruited either via a self-sponsored Facebook post featuring a direct link to the questionnaire on physical and psychological wellbeing and also a smartphone Web-based application; or via dissemination of the questionnaire link by emails, directed to the same group of participants. Information pertaining to physical and psychological wellbeing was collated. RESULTS: A total of 298 respondents took part in the survey. Most of them were between the ages of 20 to 29 years and had a university education. More individuals preferred the option of accessing and providing feedback to a survey on physical and psychological wellbeing via direct access to a Web-based questionnaire. Statistical analysis showed that demographic variables like age, gender, and educational levels did not influence the mechanism of access. In addition, the participants reported a mean number of 4.03 physical symptoms (SD 2.6). The total Impact of Event Scale-Revised (IES-R) score was 18.47 (SD 11.69), which indicated that the study population did experience psychological stress but not post-traumatic stress disorder. The perceived dangerous Pollutant Standards Index (PSI) level and the number of physical symptoms were associated with higher IES-R Score ($P<.05$). CONCLUSIONS: This is one of the first few studies demonstrating the use of Internet in data collection during an air-pollution crisis. Our results demonstrated that the newer technological modalities have the potential to acquire data, similar to that of conventional technologies. Demographic variables did not influence the mechanism of usage. In addition, our findings also suggested that there are acute physical and psychological impacts on the population from an air-pollution crisis.

Enabling Psychiatrists to be Mobile Phone App Developers: Insights Into App Development Methodologies.

In: *JMIR Mhealth Uhealth* 2 (4), S. e53. DOI: 10.2196/mhealth.3425.

Abstract:

BACKGROUND: The use of mobile phones, and specifically smartphones, in the last decade has become more and more prevalent. The latest mobile phones are equipped with comprehensive features that can be used in health care, such as providing rapid access to up-to-date evidence-based information, provision of instant communications, and improvements in organization. The estimated number of health care apps for mobile phones is increasing tremendously, but previous research has highlighted the lack of critical appraisal of new apps. This lack of appraisal of apps has largely been due to the lack of clinicians with technical knowledge of how to create an evidence-based app. OBJECTIVE: We discuss two freely available methodologies for developing Web-based mobile phone apps: a website builder and an app builder. With these, users can program not just a Web-based app, but also integrate multimedia features within their app, without needing to know any programming language. METHODS: We present techniques for creating a mobile Web-based app using two well-established online mobile app websites. We illustrate how to integrate text-based content within the app, as well as integration of interactive videos and rich site summary (RSS) feed information. We will also briefly discuss how to integrate a simple questionnaire survey into the mobile-based app. A questionnaire survey was administered to students to collate their perceptions towards the app. RESULTS: These two methodologies for developing apps have been used to convert an online electronic psychiatry textbook into two Web-based mobile phone apps for medical students rotating through psychiatry in Singapore. Since the inception of our mobile Web-based app, a total of 21,991 unique users have used the mobile app and online portal provided by WordPress, and another 717 users have accessed the app via a Web-based link. The user perspective survey results (n=185) showed that a high proportion of students valued the textbook and objective structured clinical examination videos featured in the app. A high proportion of students concurred that a self-designed mobile phone app would be helpful for psychiatry education. CONCLUSIONS: These methodologies can enable busy clinicians to develop simple mobile Web-based apps for academic, educational, and research purposes, without any prior knowledge of programming. This will be beneficial for both clinicians and users at large, as there will then be more evidence-based mobile phone apps, or at least apps that have been appraised by a clinician.

Smartphone versus pen-and-paper data collection of infant feeding practices in rural China.

In: *J Med Internet Res* 14 (5), S. 156–167. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2012-32279-011%26site%3dehost-live;summyzh@yahoo.com.cn.

Abstract:

Background: Maternal, Newborn, and Child Health (MNCH) household survey data are collected mainly with pen-and-paper. Smartphone data collection may have advantages over pen-and-paper, but little evidence exists on how they compare. Objective: To compare smartphone data collection versus the use of pen-and-paper for infant feeding practices of the MNCH household survey. We compared the two data collection methods for differences in data quality (data recording, data entry, open-ended answers, and interrater reliability), time consumption, costs, interviewers' perceptions, and problems encountered. Methods: We recruited mothers of infants aged 0 to 23 months in four village clinics in Zhaozhou Township, Zhao County, Hebei Province, China. We randomly assigned mothers to a smartphone or a pen-and-paper questionnaire group. A pair of interviewers simultaneously questioned mothers on infant feeding practices, each using the same method (either smartphone or pen-and-paper). Results: We enrolled 120 mothers, and all completed the study. Data recording errors were prevented in the smartphone questionnaire. In the 120 pen-and-paper questionnaires (60 mothers), we found 192 data recording errors in 55 questionnaires. There was no significant difference in recording variation between the groups for the questionnaire pairs (P = .32) or variables (P = .45). The smartphone questionnaires were automatically uploaded and no data entry errors occurred. We found that even after double data entry of the pen-and-paper questionnaires, 65.0% (78/120) of the questionnaires did not match and needed to be checked. The mean duration of an interview was 10.22 (SD 2.17) minutes for the smartphone method and 10.83 (SD 2.94) minutes for the pen-and-paper method, which was not significantly different between the methods (P = .19). The mean costs per questionnaire were higher for the smartphone questionnaire (-€143, equal to US $23 at the exchange rate on April 24, 2012) than for the pen-and-paper questionnaire (-€83, equal to US $13). The smartphone method was acceptable to interviewers, and after a pilot test we encountered only minor problems (eg, the system halted for a few seconds or it shut off), which did not result in data loss. Conclusions: This is the first study showing that smartphones can be successfully used for household data collection on infant feeding in rural China. Using smartphones for data collection, compared with pen-and-paper, eliminated data recording and entry errors, had similar interrater reliability, and took an equal amount of time per interview. While the costs for the smartphone method were higher than the pen-and-paper method in our small-scale survey, the costs for both methods would be similar for a large-scale survey. Smartphone data collection should be further evaluated for other surveys and on a larger scale to deliver maximum benefits in China and elsewhere. Zhao, Xiaoyi; Sun, Zhichao; Ruan, Yanping; Yan, Jianhua; Mukherjee, Bhramar; Yang, Fumo et al. (2014):

Personal Black Carbon Exposure Influences Ambulatory Blood Pressure: Air Pollution and Cardiometabolic Disease (AIRCMD-China) Study.

In: *Hypertension* 63 (4), S. 871–877. DOI: 10.1161/HYPERTENSIONAHA.113.02588.

Abstract:

Few prospective studies have assessed the blood pressure effect of extremely high air pollution encountered in Asia's megacities. The objective of this study was to evaluate the association between combustion-related air pollution with ambulatory blood pressure and autonomic function. During February to July 2012, personal black carbon was determined for 5 consecutive days using microaethalometers in patients with metabolic syndrome in Beijing, China. Simultaneous ambient fine particulate matter concentration was obtained from the Beijing Municipal Environmental Monitoring Center and the US Embassy. Twenty-four-hour ambulatory blood pressure and heart rate variability were measured from day 4. Arterial stiffness and endothelial function were obtained at the end of day 5. For statistical analysis, we used generalized additive mixed models for repeated outcomes and generalized linear models for single/summary outcomes. Mean (SD) of personal black carbon and fine particulate matter during 24 hours was 4.66 (2.89) and 64.2 (36.9) mug/m(3). Exposure to high levels of black carbon in the preceding hours was associated significantly with adverse cardiovascular responses. A unit increase in personal black carbon during the previous 10 hours was associated with an increase in systolic blood pressure of 0.53 mm Hg and diastolic blood pressure of 0.37 mm Hg (95% confidence interval, 0.17-0.89 and 0.10-0.65 mm Hg, respectively), a percentage change in low frequency to high frequency ratio of 5.11 and mean interbeat interval of -0.06 (95% confidence interval, 0.62-9.60 and -0.11 to -0.01, respectively). These findings highlight the public health effect of air pollution and the importance of reducing air pollution.

Zheng, Kai; Padman, Rema; Johnson, Michael P.; Diamond, Herbert S. (2009):

An interface-driven analysis of user interactions with an electronic health records system.

In: *Journal of the American Medical Informatics Association : JAMIA* 16 (2), S. 228–237. DOI: 10.1197/jamia.M2852.

Abstract:

OBJECTIVES\r\nThis study sought to investigate user interactions with an electronic health records (EHR) system by uncovering hidden navigational patterns in the EHR usage data automatically recorded as clinicians navigated through the system's software user interface (UI) to perform different clinical tasks.\r\nDESIGN\r\nA homegrown EHR was adapted to allow real-time capture of comprehensive UI interaction events. These events, constituting time-stamped event sequences, were used to replay how the EHR was used in actual patient care settings. The study site is an ambulatory primary care clinic at an urban teaching hospital. Internal medicine residents were the primary EHR users.\r\nMEASUREMENTS\r\nComputer-recorded event sequences reflecting the order in which different EHR features were sequentially accessed.\r\nMETHODS\r\nWe apply sequential pattern analysis (SPA) and a first-order Markov chain model to uncover recurring UI navigational patterns.\r\nRESULTS\r\nOf 17 main EHR features provided in the system, SPA identified 3 bundled features: \"Assessment and Plan\" and \"Diagnosis,\" \"Order\" and \"Medication,\" and \"Order\" and \"Laboratory Test.\" Clinicians often accessed these paired features in a bundle together in a continuous sequence. The Markov chain analysis revealed a global navigational pathway, suggesting an overall sequential order of EHR feature accesses. \"History of Present Illness\" followed by \"Social History\" and then \"Assessment and Plan\" was identified as an example of such global navigational pathways commonly traversed by the EHR users.\r\nCONCLUSION\r\nUsers showed consistent UI navigational patterns, some of which were not anticipated by system designers or the clinic management. Awareness of such unanticipated patterns may help identify undesirable user behavior as well as reengineering opportunities for improving the system's usability.

Zheng, Huan; Xie, Xiaoyun; Xie, Nanzi; Xu, Huifeng; Huang, Junling; Luo, Ming (2014):

Sphingomyelin levels in nondipper and dipper hypertensive patients.

In: *Exp Ther Med* 7 (3), S. 599–603. DOI: 10.3892/etm.2013.1455.

Abstract:

A number of studies have focused on the association between sphingomyelin (SM) levels and atherosclerosis, however, there are few data concerning the correlation of SM with nondipper hypertension. The present study aimed to investigate the correlation between plasma SM levels and nondipper status in patients with hypertension. A total of 200 hypertensive patients were enrolled and divided into two groups according to their ambulatory blood pressure monitoring (AMBP) results: Dipper group (84 patients) and nondipper group (116 patients). All patients were subjected to transthoracic echocardiography examination and laboratory tests. No statistically significant difference was observed between the two groups in terms of basic clinical characteristics. However, the plasma SM levels in the dipper group were significantly lower than those of the nondipper group (41.9+/-17.5 vs. 96.4+/-14.3 mg/dl, P=0.003). The left ventricular mass index (LVMI) was higher in the nondipper patients than in the dipper patients and the diastolic function parameters in the nondipper patients were less favorable. Correlation analysis showed that the SM level was negatively correlated with the magnitude of systolic blood pressure (SBP) fall at night (r=-0.42, P<0.01) and diastolic blood pressure (DBP) fall at night (r=-0.31, P<0.01). The nondipper status had contributory effects on hypertensive concentric hypertrophy and diastolic function impairment. In addition, the plasma SM level was associated with a nondipper pattern of hypertension.

Zhou, Sophia H.; Helfenbein, Eric D.; Lindauer, James M.; Gregg, Richard E.; Feild, Dirk Q. (2009):

Philips QT interval measurement algorithms for diagnostic, ambulatory, and patient monitoring ECG applications.

In: *Annals of noninvasive electrocardiology : the official journal of the International Society for Holter and Noninvasive Electrocardiology, Inc* 14 Suppl 1, S. S3-8. DOI: 10.1111/j.1542-474X.2008.00258.x.

Abstract:

BACKGROUND\r\nCommonly used techniques for QT measurement that identify T wave end using amplitude thresholds or the tangent method are sensitive to baseline drift and to variations of terminal T wave shape. Such QT measurement techniques commonly underestimate or overestimate the \"true\" QT interval.\r\nMETHODS\r\nTo find the end of the T wave, the new Philips QT interval measurement algorithms use the distance from an ancillary line drawn from the peak of the T wave to a point beyond the expected inflection point at the end of the T wave. We have adapted and optimized modifications of this basic approach for use in three different ECG application areas: resting diagnostic, ambulatory Holter, and in-hospital patient monitoring. The Philips DXL resting diagnostic algorithm uses an alpha-trimming technique and a measure of central tendency

to determine the median QT value of eight most reliable leads. In ambulatory Holter ECG analysis, generally only two or three channels are available. QT is measured on a root-mean-square vector magnitude signal. Finally, QT measurement in the real time in-hospital application is among the most challenging areas of QT measurement. The Philips real time QT interval measurement algorithm employs features from both Philips DXL 12-lead and ambulatory Holter QT algorithms with further enhancements.\r\nRESULTS\r\nThe diagnostic 12-lead algorithm has been tested against the gold standard measurement database established by the CSE group with results surpassing the industrial ECG measurement accuracy standards. Holter and monitoring algorithm performance data on the PhysioNet QT database were shown to be similar to the manual measurements by two cardiologists.\r\nCONCLUSION\r\nThe three variations of the QT measurement algorithm we developed are suitable for diagnostic 12-lead, Holter, and patient monitoring applications.

Zhou, J.; Liu, C.; Shan, P.; Zhou, Y.; Xu, E.; Ji, Y. (2012):

Prevalence and distinguishing features of masked hypertension in type 2 diabetic patients.

In: *J Diabetes Complications* (1056-8727 (Linking)). DOI: 10.1016/j.jdiacomp.2012.07.003.

Abstract:

OBJECTIVE: The prevalence and clinical features of masked hypertension (MH) in type 2 diabetes mellitus patients (T(2)DM) were investigated to define clinical indices which may aid diagnosis and treatment. METHODS: Clinical blood pressure (CBP) and ambulatory blood pressure (ABP) were measured in 856 T(2)DM patients to differentiate normotensive (NT), essential hypertensive (EH), and MH. Waist circumference (WC), abdominal circumference (AC), body mass index (BMI), waist to height ratio (WHtR), fasting blood glucose (FBG), and glycated hemoglobin levels were measured and compared between BP groups. RESULTS: In total, 359 patients had normal CBP, of which 13.37% were diagnosed with MH based on established criteria. Males had significantly higher rates of MH (15.30%) than females (11.36%) (P=0.036). The MH detection rate increased with age and T(2)DM duration. There were no significant differences in BMI, WC or WHtR between total MH and EH groups. MH females, however, had lower BMIs than female EH females (P=0.023). Smoking, alcohol, and familial EH history were lower in MH than EH patients (smoking, P=0.029; alcohol ,P=0.001; and EH history, P=0.000), while BMI (male, P=0.037, female, P=0.015), WC (male, P=0.012, female, P=0.021), WHtR (P=0.011), smoking (P=0.016), and alcohol consumption (P=0.000) were higher in MH than NT patients. BMI, WHtR, 6-15year disease course of diabetes, smoking and alcoholism were independent risk factors of T(2)DM complicated with MH. The dipper BP circadian pattern was significantly lower in MH than NT patients (P=0.001). The non-dipper pattern was lower in MH than EH (P=0.018) but higher than in NT (P=0.000). CONCLUSIONS: A significant fraction of T(2)DM patients were diagnosed with MH. Clinical presentation also contrasted sharply from EH, MH is a specific blood pressure status that may severely damage target organs in T(2)DM

Zhu, Zheng; Chen, Peijie; Zhuang, Jie (2013):

Intensity classification accuracy of accelerometer-measured physical activities in Chinese children and youth.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S4-11.

Abstract:

PURPOSE: Many ActiGraph accelerometer cutoff points and equations have been developed to classify children and youth's physical activity (PA) into different intensity levels. Using a sample from the Chinese City Children and Youth Physical Activity Study, this study was to develop new ActiGraph cutoff points for moderate-to-vigorous physical activity (MVPA) and vigorous physical activity (VPA) for Chinese children and youth and to compare the classification accuracy to that of a set of existing cutoff points. METHOD: A total of 367 Chinese children and youth (179 boys, 188 girls, ages 9-17 years old) had their resting metabolic rate measured and completed six 5-min treadmill walking/running tests (tested at different speeds: 3 km x h(-1), 4 km x h(-1), 5 km x h(-1), 6 km x h(-1), 7 km x h(-1), and 8 km x h(-1)), one unit of the 3rd broadcast gymnastics (Version 3, Xi-Wang-Feng-Fan and Wu-Dong-Qing-Chun), and 2 sets of table tennis exercises (continuous attack and multiple balls). Participants wore 1 ActiGraph GT3X accelerometer on their right hip during each test, and their oxygen consumption and heart rate (HR) were measured using Cosmed K4b2 and Polar HR transmitter. The participants were randomly divided into a calibration group (n = 331, 90%) and a cross-validation group (n = 36, 10%). Using the receiver-operating characteristic curve, the data from the calibration group were used to determine the cutoff points for MVPA and VPA. Using the data from the cross-validation group, classification accuracy of different cutoff points was evaluated through kappa statistics, sensitivity, and specificity. RESULTS: A set of new cutoff points of counts per minute (CPM) was generated using the calibration data, and these cutoff points were proven to be more accurate compared with those developed in previous studies. CONCLUSION: When using ActiGraph accelerometers to measure the Chinese children and youth's PA, we recommended using the cutoff points of CPM > or = 2,800 to define MVPA and CPM > or = 4,000 for VPA.

Zhu, Zheng; Chen, Peijie; Zhuang, Jie (2013):

Predicting Chinese children and youth's energy expenditure using ActiGraph accelerometers: a calibration and cross-validation study.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S56-63.

Abstract:

PURPOSE: The purpose of this study was to develop and cross-validate an equation based on ActiGraph accelerometer GT3X output to predict children and youth's energy expenditure (EE) of physical activity (PA). METHOD: Participants were 367 Chinese children and youth (179 boys and 188 girls, aged 9 to 17 years old) who wore 1 ActiGraph GT3X accelerometer on their right hip during the following tests/activities: resting metabolic rate (RMR), six 5-min treadmill walk/runs (tested at different speeds: 3 km x h(-1), 4 km x h(-1), 5 km x h(-1), 6 km x h(-1), 7 km x h(-1), and 8 km x h(-1)), 1 broadcast gymnastics, and 2 table-tennis exercises. Participants' oxygen consumption was measured using Cosmed K4b(2). The participants were randomly divided into a calibration group (n = 331, 90%) and a cross-validation group (n = 36, 10%). The calibration group's data were used to determine the relationship between EE and triaxial vector magnitude counts (VM) using the Pearson correlation and to derive the equation using a stepwise multiple regression. In the cross-validation group, differences between measured and predicted EE were evaluated using pairwise t tests. RESULTS: VM activity counts had a moderately high correlation with EE (r = .758, p < .01). An EE prediction equation was developed: EE (kcal x min(-1)) = 0.00083 x VM + 0.073 x weight-2.01 (R2 = .72, SEE = 1.45 kcal x min(-1)). According to the cross-validation study results, this equation could predict the EE within the range of known accuracy (i.e., about 20% error). CONCLUSIONS: An equation based on ActiGraph accelerometer VM activity counts was derived to predict EE of PA in Chinese children and youth within the range of known accuracy.

Zhuang, Jie; Chen, Peijie; Wang, Chao; Huang, Liang; Zhu, Zheng; Zhang, Wenjie; Fan, Xiang (2013):

Characteristics of missing physical activity data in children and youth.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S41-7.

Abstract:

PURPOSE: The purpose of this study was to investigate the characteristics of missing physical activity (PA) data of children and youth. METHOD: PA data from the Chinese City Children and Youth Physical Activity Study (N = 2,758; 1,438 boys and 1,320 girls; aged 9-17 years old) were used for the study. After the data were sorted by the weekday (WD) and recording day (RD), the missing ratio (MR) was calculated by gender, age, and body mass index (BMI). Chi-square tests were used to determine the effect of WD and RD on missing data. The joint impact (WD x RD) on the MR, as well as their interactions with age, gender, and BMI, were also analyzed. RESULTS: Out of a total of 19,306 records, 5,400 (28.0%) were missing. The total MR significantly differed by WD and RD. There were more missing data during weekend days than during WDs, with the highest being on Sunday (36.2%). Older youth (aged 15-17 years old) had more missing data than did the 9- to 11-year-old group and 12- to 14-year-old group. In terms of RD, the 7th day had the most total missing data (36.0%), and again, older youth (15-17 years old) had more missing data than did the other 2 age groups. Gender and BMI had no impact on missing data by WD or RD. When the joint effect of WD and RD was examined, it was found that providing the measurement devices on Thursday and collecting data from Friday onward resulted in the lowest amount of missing data (18.5%). CONCLUSION: This study examined missing data characteristics with different sorting orders, which may help design more effective measures to prevent missing data in future PA measurement using accelerometers.

Zhuang, Jie; Chen, Peijie; Wang, Chao; Jin, Jing; Zhu, Zheng; Zhang, Wenjie (2013):

Recovering physical activity missing data measured by accelerometers: a comparison of individual and group-centered recovery methods.

In: *Res Q Exerc Sport* 84 Suppl 2, S. S48-55.

Abstract:

PURPOSE: The purpose of this study was to determine which method, individual information-centered (IIC) or group information-centered (GIC), is more efficient in recovering missing physical activity (PA) data. METHOD: A total of 2,758 Chinese children and youth aged 9 to 17 years old (1,438 boys and 1,320 girls) wore ActiGraph GT3X/GT3X+ accelerometers for 7 consecutive days. Those with no missing data (n = 900) were used to form a nonmissing sample, which, based on a semisimulation approach, was used to create a missing data set to evaluate a set of recovery methods, including 2 IIC and 22 GIC methods. Root mean square difference (RMSD), mean signed difference, and paired t test were used to determine the effectiveness of the recovery methods. RESULTS: The smallest RMSD values, which represent the most accurate recovery, were found with: (a) GIC-Expectation-maximization (GIC-EM) regardless of gender and by age (113,957.64); (b) GIC-EM regardless of

gender and age (114,367.88); (c) GIC-EM regardless of age and by gender (114,697.06); (d) GIC-EM by gender and age (116,178.34); and (e) IIC averaging of remaining days (125,851.23). CONCLUSION: To recover 7-day PA accelerometer-determined activity missing data, we recommend using the GIC-EM and IIC approaches.

Zhuo, Shang; Wen, Wang; Li-Yuan, Ma; Shu-Yu, Wang; Yi-Xin, Wang (2009):

Home blood pressure measurement in prehypertension and untreated hypertension: comparison with ambulatory blood pressure monitoring and office blood pressure.

In: *Blood Press Monit* 14 (6), S. 245–250. DOI: 10.1097/MBP.0b013e328332fd25.

Abstract:

OBJECTIVES\r\n(i) To explore blood pressure (BP) baseline characteristics in prehypertension (PH) and untreated essential hypertension (HT), and (ii) to evaluate whether simple home blood pressure (HBP) measurement can provide more reliable BP information than office blood pressure (OBP) in PH and untreated essential HT, and (iii) to investigate whether HBP measurement can also satisfactorily screen out masked hypertension (MH) and white-coat hypertension (WCH) by comparing with ambulatory blood pressure (ABP) monitoring.\r\nMETHODS\r\nWe recruited 122 Beijing community volunteers. According to OBP measurement, they were divided into three groups, including PH group (n=51), stage 1 HT group (HT-1, n=51) and stage 2 HT group (HT-2, n=20). We calculated average OBP, HBP, and ABP, detection rate of MH, WCH, and nondipper status percentage in each group.\r\nRESULTS\r\nNondipper status percentage of PH, HT-1, and HT-2 was 54.9, 45.1, and 75%, respectively. Except for diastolic blood pressure difference between HBP and ABP, the others did not reach statistical significance. ABP correlated more strongly with HBP than OBP. Detection rate of MH in PH participants by HBP and ABP was 49.0 and 52.9% (P=0.56), respectively, and MH diagnostic agreement between ABP and HBP was moderate (kappa=0.53, 95% confidence interval: 0.30-0.76). Detection rate of WCH in stage 1 HT participants by HBP and ABP was 9.8 and 11.8% (P=0. 65), respectively, and WCH diagnostic agreement between ABP and HBP was moderate (kappa=0.49, 95% confidence interval: 0.10-0.87).\r\nCONCLUSION\r\nNondipper status percentage was higher in PH and untreated HT, and detection rate of MH in PH participants was also higher. The simple HBP measurement can provide more reliable and actual BP information and may be a feasibility of screening out MH and WCH for the clinical practice.

Zielke, Desiree Joy (2014):

Ecological momentary assessment versus traditional retrospective self-reports as predictors of health-relevant outcomes.

In: *Dissertation Abstracts International: Section B: The Sciences and Engineering* 74 (7-B(E)). Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-99020-413%26site%3dehost-live.

Abstract:

Ecological momentary assessment (EMA) has been asserted by proponents of the technique as being superior to standard paper-and-pencil measurements in terms of the reliability and validity of the information obtained; however, this claim has not yet been fully evaluated in the literature. Accordingly, the purpose of this study was to evaluate one aspect of this assertion by comparing the utility of EMA and retrospective measures of depressive symptoms in predicting health-relevant biological and behavioral outcomes. It was hypothesized that (1) the EMA measure will have better predictive utility when examining objective sleep quality (a biological outcome), and that (2) the retrospective measure will have better predictive utility when examining blood donation intention (a behavioral outcome). Ninety-six undergraduate females participated in this 2-week study. Depressive symptoms were measured momentarily and retrospectively using the Center for Epidemiological Studies-Depression Scale (CES-D). The biological outcome was assessed by actigraphy, whereas the behavioral outcome was measured via a self-report questionnaire. Unfortunately, it was not possible to fully test these hypotheses due to the failure to observe relationships between the predictor variables and the outcomes. The reported results, although limited, did not provide support for the hypotheses. Supplemental analyses revealed a moderate to high amount of shared variance between the EMA and retrospective measures, a similar extent of random error in both measures, and potentially a greater degree of systematic error in the retrospective measure. Due to the paucity of literature examining the claim of superior reliability and validity of EMA versus retrospective measures, as well as the failure of the current study to evaluate this assertion sufficiently, it appears that this claim remains unfounded. Therefore, suggestions for future research are provided. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

Ubiquitous human computing.

In: *Philosophical Transactions of the Royal Society of London A: Mathematical, Physical and Engineering Sciences* 366 (1881), S. 3813–3821.

Abstract:

Ubiquitous computing means network connectivity everywhere, linking devices and systems as small as a drawing pin and as large as a worldwide product distribution chain. What could happen when people are so readily networked? This paper explores issues arising from two possible emerging models of ubiquitous human computing: fungible networked brainpower and collective personal vital sign monitoring.

Ecological momentary assessment of bulimia nervosa: Does dietary restriction predict binge eating?

In: *Behav Res Ther* 49 (10), S. 714–717. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx?direct=true&db=psyh&AN=2011-20201-015&site=ehost-live;swonderlich@nrifargo.com.

Abstract:

The purpose of this study was to examine the relationship between caloric restriction (CR) and binge eating (BE) using ecological momentary assessment (EMA). Participants included 133 women with bulimia nervosa (BN) who completed an EMA protocol for 2 weeks. Logistic regression analyses tested whether CR increased the probability of BE episodes. The results revealed that the odds of BE increased on the day that restriction occurred as well as on the following day. In addition, both restriction and BE on one day predicted the likelihood of BE the subsequent day, but restriction for two days prior to the episode failed to add additional information for predicting BE. These findings support the cognitive behavioral therapy (CBT) model of BN, suggesting that self-reported dietary restriction is predictive of subsequent BE episodes, and that reducing dietary restriction in treatment may lead to improvements in bulimic symptoms. Does being well-off make us happier? Problems of measurement.

In: *Journal of Happiness Studies* 14 (3), S. 795–815. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2013-22230-006%26site%3dehost-live;zuzanek@uwaterloo.ca.

Abstract:

The article uses General Social Survey data (GSS) collected by Statistics Canada from 1986 to 2005 and experience sampling data (ESM) collected in 1985 and 2003 at the University of Waterloo to examine relationships between economic growth, household income, and subjective sense of well-being. The article puts to a test two propositions made by Easterlin (Nations and households in economic growth: Essays in Honor of Moses Abramovitz. Academic Press, New York, NY,1974), namely that personal and household incomes correlate positively with subjective well-being, but this does not apply to the relationship between subjective well-being and societal economic growth. Analyses of GSS data reported in this article support Easterlin's findings. They show that higher household incomes correlate positively with respondents' retrospective assessments of life satisfaction, but economic growth has not been accompanied by a corresponding rise of subjective wellbeing. Analyses of ESM data suggest that when relationships between household income and subjective well-being are measured by "experiential" measures (Csikszentmihalyi and Larson in J Nerv Ment Dis 175: 526–537, 1987), these relationships are not statistically significant and subjective valuations of well-being taper off at the top of the income pyramid. Of happiness and of despair, is there a measure? Time use and subjective well-being.

In: *Journal of Happiness Studies*. Online verfügbar unter http://www.redi-bw.de/db/ebsco.php/search.ebscohost.com/login.aspx%3fdirect%3dtrue%26db%3dpsyh%26AN%3d2014-24488-001%26site%3dehost-live.

Abstract:

Data from the 1975 U.S. time use survey, Canadian time use surveys (GSS) conducted from 1986 to 2010, and experience sampling surveys (ESM) conducted in 1985 and 2003 at the University of Waterloo (Canada) are used to examine well-being effects of time use. Indicators of subjective well-being (SWB) under investigation include: (a) generalised enjoyment ratings of selected daily activities; (b) reporting of the single most enjoyed activity performed on the time diary day; (c) affect ratings of daily activities recorded in ESM surveys at the time of their occurrence; (d) correlations between time use and levels of respondents' perceived happiness and life satisfaction, and (e) relationships between frequency of participation in different groups of daily activities and respondents' cumulative affect ratings during a survey week (ESM 1985, 2003). An argument is made that attempts to delineate indices of SWB as multiples of activity enjoyment ratings and their duration encounter considerable measurement and conceptual difficulties. It is suggested that prolonged exposure to highly enjoyed daily activities does not always foretell higher levels of cumulative subjective well-being, which is associated with balanced use of time rather than increased participation in individual activities.
